The structure of this paper is as follows. The next section presents the main types of quality certifications and some aggregate data of their adoption in Chile and other countries in the region. Section 3 reviews theoretical arguments and some empirical evidence on how standards may contribute to international trade in IT services. Subsequently, the role of standards in the Chilean IT sector is explored through a semi-structured questionnaire, which was sent to all 110 members of the Chilean Association of IT services firms (ACTI). The final section concludes and provides suggestions for future research.

2 Quality certifications and their use in Chile and neighbouring countries

There are different types of QCs that IT producers can adopt to improve the quality and excellence of their services and products. Standardization (normalization) and certification were first developed in manufacturing and agriculture, but

¹⁴³ IT services include computer equipment consulting, computer programme editing; computer programme consulting; computer programme supply; data processing; maintenance and repair work for office machinery; accounting and information; and activities related to databases and the online distribution of electronic contents (IMF Balance of Payments Manual, Fifth Edition).

have spread to the IT services industry over the past two decades. Standardization refers to a process by which the service features are reflected in a document also known as “Standard”. Certification relates to the result of a process in which an independent certification entity examines the conformity of a service according to the requirements of the standard. Its approval means that the production process and final product of IT services meet a minimum quality level (Castagnino, 2006).

Standards are developed within specific countries and at the international level. As this study focuses on the role of standards in exports, the focus is on those requirements used by multiple countries. For the IT services industry, specific international certifications exist that apply to any organization independent of its size.

One of the most widespread families of standards and guidelines for the quality of management systems within the IT services industry is the norm 9000 of the International Organization for Standardization (ISO). It has been adopted by over 90 countries worldwide (UNCTAD, 2012). The ISO 9001 has a multisectoral character and it is applied in companies engaged in service design, production or use. Within the ISO norms, there are also specific standards for IT services which deal with specific requirements not covered by the general rules. Examples are ISO 27001 for information security, ISO 20000 for IT service management, and ISO 22301 for business continuity.

Other common international quality standards are CMMI and ITIL.¹⁴⁴ The Capability Maturity Model Integration (CMMI) was created in 2007 by the Software Engineering Institute of Carnegie Mellon University in cooperation with the US government. This maturity model integrated internal processes of service providers of the US government in order to improve their quality. This reference model contains a set of practices aimed at improving the software process maturity and other areas of an organization’s information technologies. This model considers the improvement of IT processes as a gradual process, and defines five levels of maturity. For its part, the ITIL model, or IT Infrastructure Library Information, emerged in the 1980s in the Office of Government Commerce (OGC) in the United Kingdom. The ITIL comprises standardized processes for planning, delivery and support of IT services. In its latest version (ITILv3 2011), standards are structured in five areas, which cover the entire life cycle of IT management services. Each area presents guidelines on the design, transition, operation and continual service improvement.

The aforementioned models have several commonalities but also differences. For example, the ITIL and CMMI models have a similar philosophy of continuous improvement of IT services focused on improving conditions of people, processes and products as well as in process maturity. CMMI and ISO 9001 models have the same principles and approach to quality management process of continuous improvement and process management. Companies often implement CMMI and ISO 9001 as complements. Table 1 compares the three models in terms of goals, advantages and disadvantages.

Within the region, Chile is one of most advanced countries with regard to the adoption of these QCs. For example, in this country 230 ISO 9001 certificates per 1 million population were issued in 2012, compared to 220 in Uruguay, 212 in Colombia, 161 in Argentina, 131 in Brazil and 47 in Mexico (2012 ISO Survey, www.iso.org/iso/iso-survey). With regard to CMMI, Chile had 0.6 firms per 1 million population with this certification in 2012, compared to 0.4 in Mexico, 0.2 in Argentina and Colombia, and 0.1 in Brazil (<https://sas.cmmiinstitute.com/pars/pars.aspx>).

In addition to these general statistics, some surveys have been carried out by software and other IT services business associations in the region. In Argentina, the Chamber of Software companies and IT services (CESSI), with approximately 600 member companies, conducts a survey every semester to assess the development of the IT sector. The March 2014 version of the survey was answered by 89 companies, of which 48% export (CESSI, 2014). Three quarters of the respondents informed they had adopted both international and local QCs. In particular, 69% of the respondents had ISO 9001, 13% had ISO90003, 9% had CMMI and 3% had ISO 27000. Several firms have adopted multiple QCs. Their adoption has been promoted by a software law, which provides tax benefits to companies if they are certified. Another stimulus was the support by a European Union SME program called AL-INVEST, involving micro, small and medium enterprises in Greater Buenos Aires. The National Institute of Industrial Technology (INTI) also promotes the adoption of national QCs.

¹⁴⁴ For more information, see Framework Information Technology Infrastructure Library (www.itil-officialsite.com/aboutitil/whatisitil.aspx) and Capability Maturity Model Integration, <http://cmmiinstitute.com/>.

Table 1. Comparison of CMMI, ISO 9001 and ITIL.

	CMMI	ISO 9.001	ITIL
Focus of organizations	Organizations developing software-based systems	Suppliers of any type of product or service	Providers of IT services
Objectives	Provide best practices for software development, systems, products, integrated processes, and acquisition.	Requirements for the establishment of a quality system.	Framework for organizing the processes of IT service provision.
Pros	Designed specifically for IT industry; provides guidelines for improvement through processes throughout the organization; compatible with other standards such as ISO and ITIL; model with continuous improvement	Recognized internationally; required in both private and public sphere; applicable to organizations of various industries and sizes; not specific for IT industry, but has specific IT standards (ISO 27001, ISO 20000)	Well established and internationally recognized for IT service management; Maps entire life cycle of IT service; supports the ISO standard 20000
Cons	Complex and demanding model that is costly to implement; requires highly trained staff to manage the system.	Not a standard specified for IT organizations; costly to implement, allows creation of slow processes and future needs for staff	There is no certification oriented organizations; exclusive focus on IT services

Source: UNCTAD (2012).

In Colombia, an evaluation of the IT sector was conducted by the Colombian Federation of Software Industry and Information Technology in 2012 (Fedesoft, 2012). A questionnaire was sent to 5,512 enterprises of which 1,120 companies responded. Of all companies surveyed, 162 had some type of certification. Half of this group had ISO 9001 certification and 12% CMMI certification.

In Uruguay, the 2009 annual survey of the Uruguayan Chamber of Information Technology (Cuti), with 300 member companies, shows that 20% of companies have some type of certification or it is in the process of obtaining one. Regarding those which have certification, 52% has ISO 9001 certification, 19% has CMMI certification, 8% has ITIL and the remaining 21% has other certification. Of those companies that are in the process of certification, 52% were preparing for ISO 9001, 7% for CMMI and the remaining 41% for other QCs. In this country, the Inter-American Development Bank (IDB) helps small companies with export potential to obtain QCs.

3 Theories and evidence on the role of QCs in exports

Many studies have assessed how QCs may enhance the performance and exports of goods producers, but those on the IT services industry are mostly limited to the case of India. This section reviews both the theoretical arguments and empirical evidence on this issue.

The causal relationship between QCs, on the one hand, and firm performance and exports, on the other, runs both ways. This dual relationship can be described by three theories: signaling theory, process efficiency theory, and institutional theory (Gopal and Gao, 2009). All three contribute to explain why a firm wants to obtain a QC and what potential benefits it receives from certification. In particular, they show how a firm's performance, approximated by average costs and exports, influences its decision to adopt QCs. Moreover, they show how the adoption of QCs in turn may affect average costs and exports.

The signaling theory emphasizes the role of information asymmetries between buyers and sellers, which is particularly important as IT services are intangible. Buyers have insufficient information to judge the quality of sellers, in particular in offshore destinations. Also, sellers lack instruments to demonstrate their capabilities to clients. In this context, a third-party providing a QC can give a signal of capability that distinguishes a firm from its competitors. If a signal is to separate high-capability from low-capability producers, its cost of adopting a QC should be low enough for the former to acquire the signal and high enough to prevent the latter from doing so. Typical indicators of high-capability sellers are low average costs and high exports. Once the QC is adopted, demand and exports are expected to increase. However, average costs will not change significantly, as QCs are only granted to firms that already performed well.

The process efficiency theory states that firms want to acquire QCs to optimize and standardize processes, improve service and product quality, and worker productivity. The motivation to obtain QCs depends on expected future benefits arising from improved internal firm efficiency. Therefore, the higher average operating cost, the higher the willingness to obtain certification. Once a QC is obtained, it is expected that the average cost will fall and worker productivity increase. According to this theory, there will be no direct effect on sales and exports from certification. However, there may be indirect benefits, as better management will improve the use of scarce resources to increase revenues.

From the viewpoint of institutional theory, firms adopt QCs to gain legitimacy in their home market and abroad. This is a demand-side argument. The more firms are exposed to the norms of export markets, the more likely they are to adopt processes or norms that are considered legitimate. According to this theory, a firm's cost performance does not matter for the decision to adopt a QC, as institutional norms prevail for all firms in a market. Once a QC is adopted, the institutional argument foresees no improvement in sales and exports. This is because the adoption of a QC is seen as a necessary condition for a business to compete in a market, but not a determinant for sales as these depend on a firm's resources and technology. The average cost of adopting a QC is expected to be higher for young firms than old ones, as the former face fewer institutional constraints and can more easily adapt their organization. The above theories are summarized in Figure 1.

The empirical evidence for the three outlined theories and corresponding hypotheses is mostly supportive (Gopal and Gao, 2009). This evidence is drawn not only from studies on IT services firms, but also on firms in other services sectors and manufacturing. Moreover, Gopal and Gao (2009) also tested the hypotheses using data on 220 large and export-intensive software firms in India for the period 1997 to 2002 in relationship to the CMM certification. Their results show that firms with lower costs are more likely to require CMM, which is consistent with the signaling theory but against the efficiency theory. Another result is that firms that export more adopt more quickly CMM, confirming the signaling and institutional arguments. Once the QC is obtained, the authors find a strong positive impact on exports, being consistent with the signaling argument but not with the efficiency and institutional hypotheses. The effect on exports is strongest in the first year after the QC adoption, but fades afterwards. Two surprising results are: i) there seems to be no difference between early and late adopters with respect to average costs and exports, and ii) the adoption of CMM does not affect the average cost of early or late adopters, maybe because the analysis does not consider quality improvements. In short, QCs mostly represents a signal of a better quality of the seller, with most benefits arising from sales rather than cost reductions.

Figure 1. Theoretical relationships between CMM, average costs and exports.

Source: Gopal, A.; Guodong, G. (2009): Certification in the Indian Offshore IT Services Industry. *Manufacturing & Service Operations Management*. Vol. 11, No. 3, Summer, pp. 471–492.

Other studies also confirm some of the above hypotheses. Using 1996-1997 revenue and employment data for a sample of 95 export-oriented Indian software firms, Arora and Asundi (1999) indicate that the main advantage of the adoption of ISO 9001 certification is to show to foreign customers that software processes are defined and documented. In turn, this allows these companies to get better and more profitable contracts. However, to the extent a larger share of firms gets certified, the potential of the signal diminishes. On the basis of a questionnaire responded by 424 Indian software

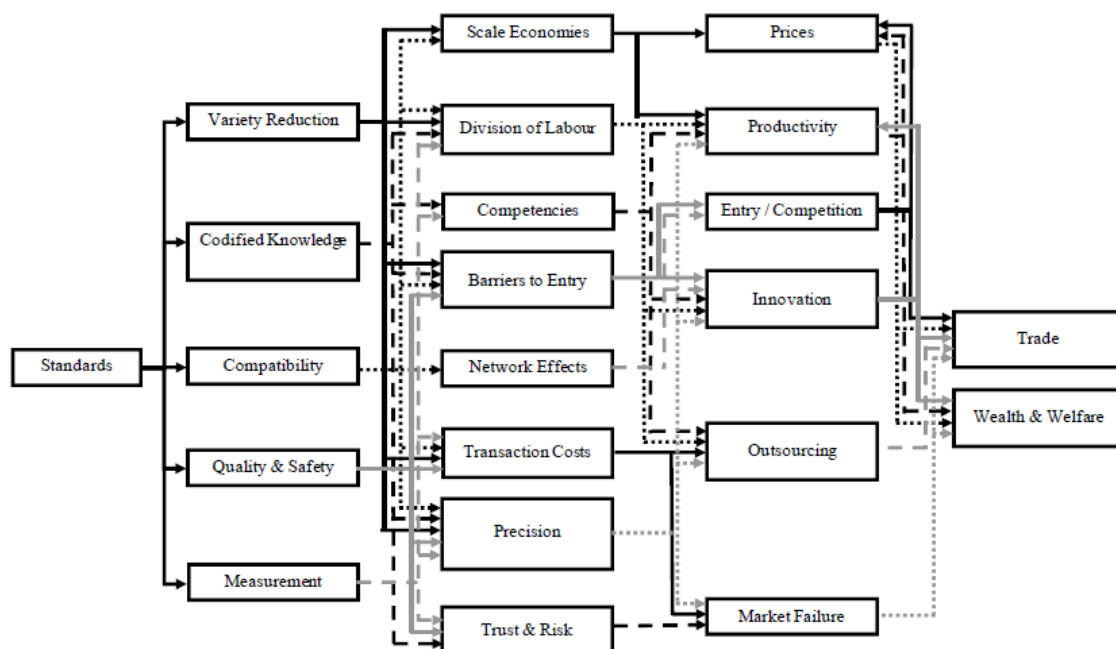

firms, Ankur and Gupta (2011) confirm the above process and efficiency hypothesis. Firms that adopted CMM or ISO 9000 certifications show better operating and human resource performance, and higher productivity than non-certified firms.

In a study on how certification can promote Spain's software industry, the National Institute of Information Technology (2008) interviewed small companies on their reasons to implement a QC. For them, certification is mainly motivated by the desire to reduce costs (73%), improve client satisfaction (52%) and satisfy customer requirements (49%). The main benefits after implementation are better service quality (48%), higher sales (47%) and increased competitiveness (38%). In the case of large companies, the main motivations for QCs are the satisfaction of customer requirements, standardization of processes and marketing abroad (signaling). The most common QCs are CMMI for large and medium sized enterprises and ISO 9001 for all companies.

Beyond the software and IT services industry, many studies have been carried out on the impact of QCs on trade. Clougherty and Grajek (2013) assess the impact of the diffusion of ISO 9000 on trade between 91 countries from 1999 to 2005. Their evidence supports the signaling hypothesis, as high certification levels in trading partner countries reduces information asymmetries and allows for a better organization of vertical relations in bilateral trade relationships. Also, the competitiveness of exporting countries improves with the adoption of ISO 9000. Another interesting finding is that exports of developing nations which lag behind in the adoption of the QC to developed countries where this QC is widespread are dampened.

In a literature review on standards and goods trade, Swann (2010) shows eight linkages between the two (see Figure 2). First, standards reduce the variety of goods being traded, which in turn cuts transaction costs. Examples are pallets and container sizes. Second, standards reduce transactions costs and promote the division of labor, outsourcing and off-shoring. Third, standards are a carrier of codified knowledge, which is similar to the signaling argument above. Examples given above are ISO 9000, which is the most adopted standard world-wide. Fourth, good institutions can promote trade as they have larger informational and conformity capacities. Fifth, standards promote network effects and innovation, as is the case for example in information and communication technologies. Sixth, standards may promote a more accurate measurement of intermediate inputs and other products, which in turn also favors innovation. Seven, standards may raise the quality of products, but also may increase the cost of compliance and therefore constitute a trade barrier. Finally, standards promote trust and therefore reduce transaction costs and promote trade.

The same author also reviews the empirical evidence on the links between standards and trade. Most of the reviewed econometric results show a positive relationship between international standards, exports and imports. However, studies show both positive and negative relationships between national standards and trade, which show that national barriers may constitute a trade barrier.

* 'competencies' encompass institutions, innovation- and productivity-relevant knowledge, and vision
 ** 'barriers to entry' include compliance costs
 *** 'precision' includes uniformity and consistency

Figure 2. Theoretical links between standards, trade, wealth and welfare.

Source: G. P. Swann, (2010): International Standards and Trade: A Review of the Empirical Literature. OECD Trade Policy Working Papers, No. 97. Paris: OECD Publishing.

To sum up, certification is a tool to enhance a firm’s competitiveness in the global market. In this way, a QC provides a guarantee of an internationally recognized and independent entity, with the quality requirements defined in its parameters. This certification allows the development of exports with higher value added and ensuring a better quality service; which undoubtedly raises customer satisfaction, and increases long-term buyer-seller relationships.

4 The questionnaire and results

As detailed data on the adoption of QCs and performance measures of IT services producers are lacking in Chile, which makes an econometric assessment impossible, a special survey was conducted instead for the purpose of this paper. This survey’s goal is to get an impression on how many firms have adopted QCs, what are their motivations for doing so, and what are the (potential) benefits.

4.1 Design of the questionnaire and target group

A sample list of questions was prepared in light of the aforementioned literature survey. These were sent to two companies and two academics to assess their relevance, clarity, and un-ambiguity. This ensures the relevance of the questionnaire. The questionnaire is qualitative and consists mainly of closed questions with the option to add comments as a way to collect additional information (see the Annex).

In turn, the questionnaire was sent by e-mail to all 110 member companies of the Chilean Association of IT services firms (ACTI). This is the main business association in the IT sector in Chile, including companies producing hardware, software, training, hosting, systems integration and Internet services.¹⁴⁵ The distribution of the questionnaire was followed up with on average 4 phone calls and three email reminders.¹⁴⁶ In total 42 firms responded the questionnaire, which is a response rate of 38%. The information obtained from the questionnaires was synthesized and analyzed. The companies that responded can be grouped into 3 sizes defined in terms of their annual sales in 2012 (see Table 2): 21% of businesses are small, 45% medium and 33% large companies.

Table 2. Sales of companies that answered the questionnaire, 2012.

Size	Lower Limit (US\$)	Upper Limit (US\$)	# of firms that replied questionnaire
Small	100,000	1,033,000	9
Medium	1,033,001	4, 132,590	19
Large	4, 132,590	and more	14
Total			42

Source: Authors’ calculations based on firm size classification of Chile’s Internal Revenue Service (SII) and answers to the questionnaire.

4.2 Outcomes

Two thirds of the sample companies export IT services, whereas one third only sells to the domestic market. As expected, proportionally fewer small firms export than those selling to the local market. Within the group of firms that export, 14% are small companies, 50% are medium-sized companies and 36% are large companies. Regarding to the number of years the company is exporting, this study finds that 29% of companies began exporting less than two years ago, 25% exported between the last two to four years and 46% exported continuously for more than four years. Only 8% of companies that export since more than four years are small businesses, 31% are medium-sized companies, while 62% are large companies. With respect to the export revenues, two thirds of companies informed these revenues are less than 20% of total revenues. Another 27% said that their export revenues represent between 21% and 80% of their income. Only about 7% of companies pointed out that more than 80% of their revenues come from exports.

More than half (55%) of all export destinations of IT services are concentrated in South America, followed by North America (23%) and Central America (17%). The American continent accounts for about 95% of total of exports, while Asia and Europe account for the remaining 5%. Within South America, the main destination markets are Peru, Colombia, and Brazil, followed by Argentina (Figure 3). Companies often export to more than 1 market.

¹⁴⁵ Another small business association in the Chilean IT sector is Gechs, which includes mainly small firms (www.gechs.cl)

¹⁴⁶ The authors would like to thank ACTI and their members for their collaboration in this survey.

Figure 3. Chilean IT services firms: Destination countries of IT exports, 2012 (Percentage of all firms in survey).

Source: Authors' calculations based on answers to the questionnaire.

The majority (79%) of respondents mentioned they focus on Latin America for the expansion of their exports in the next couple of years. It turns out "nearshoring" is the main business model of Chilean IT service producers. In this context, Peru and Colombia seem to have the largest potential, due to factors such as geographical proximity, cultural and linguistic similarity, and time zone. Other important factors that may explain the preference for the Peruvian and Colombian market is the similarity of these countries in terms of export and production specialization (minerals, retail) and economic development model. This "like-mindedness" was recognised by the signature of the Pacific Alliance in 2011, which also includes Mexico. Its aim is to create an area of deep economic integration and to move gradually toward the free circulation of goods, services, capital and persons.

With regard to the obtained QCs in the IT industry, 69% of the sample has some kind of international QC. With 31%, the ISO 9001 is the main standard. This was followed by CMMI (at different levels) (21% of all firms), ITIL (12%) and PMP (10%). The adoption of security of information certification ISO 27001 is only 7% (Figure 4).

Almost 85% of companies that export since more than 4 years has at least one QC (independent of the size of the company), suggesting a relationship between presence in international markets and certification.

Figure 4. Chilean IT services firms: Adoption rate of Quality Certification, 2012 (Percentage of all firms in survey).

Source: Authors' calculations based on answers to the questionnaire.

As expected, the degree of certification increases with the size of firms. Many small businesses prioritize certified products and platforms (such as Microsoft, Linux, Unix, etc.) and few adopt QCs, in part due to their high cost. Several medium and large companies have implemented internationally recognised QCs. For example, 55% of the CMMI certified companies are medium sized, while the ITIL model is present in 40% of medium sized companies and 60% in large companies.

The majority of firms plan to increase their level and number of QCs. For example, over 40% of small businesses contemplate or show interest in the ISO 9001 standard in the short or-medium term and 22% in the CMMI standard. These outcomes are consistent with the importance that entrepreneurs give to each of these certifications. The first preference is ISO 9001 with 16%, followed by CMMI with 14% and ITIL with 13%. It is important to mention CMMI and ITIL require a high degree of commitment considering the voluminous financial and human resources needed for their implementation.

One of the central questions of the questionnaire with regard to the hypothesis of this paper is the motivation for the adoption of QCs. Almost half (44%) of all companies reported the improvement and standardization of processes as one of the main motivations for obtaining these certifications, followed by the desire to increase the participation in the local market with 32% and increase the participation in the overseas markets with 24%. These answers seem to reject the hypothesis that the main motivation for adopting QCs are “export driven”. However, they seem to be in line with the alternative hypothesis of QCs being primarily motivated by the efficiency argument.

Most companies that currently do not export adopt QCs mainly to improve their processes and to expand sales in the local market. Some motivations by domestic market oriented companies to adopt a QC include i) reduce entry barriers to new domestic markets, and ii) compete better with other firms and adapt to the requirements of the bidding procedures of the government and some customers. Other firms mentioned that certification is "... a way to demonstrate the quality of our processes and the delivery of services to our customers and business partners," as well as "the generation of prestige in the market and therefore more competitiveness."

The main attributable benefit from obtaining a QC is an increase in sales. Other benefits are an increase in exports, a reduction of delivery times of projects, and cost reductions. In additional comments, the companies point to an increase in the service quality and customer satisfaction, market differentiation and recognition. Some firms noted that "the standardization process speeds up the learning process and saves time in business processes"; All above are key factors for the management of a company, which are in line with the reasons given for obtaining a certification. This shows the positive expectations of business towards quality certification when starting the process (Figure 5).

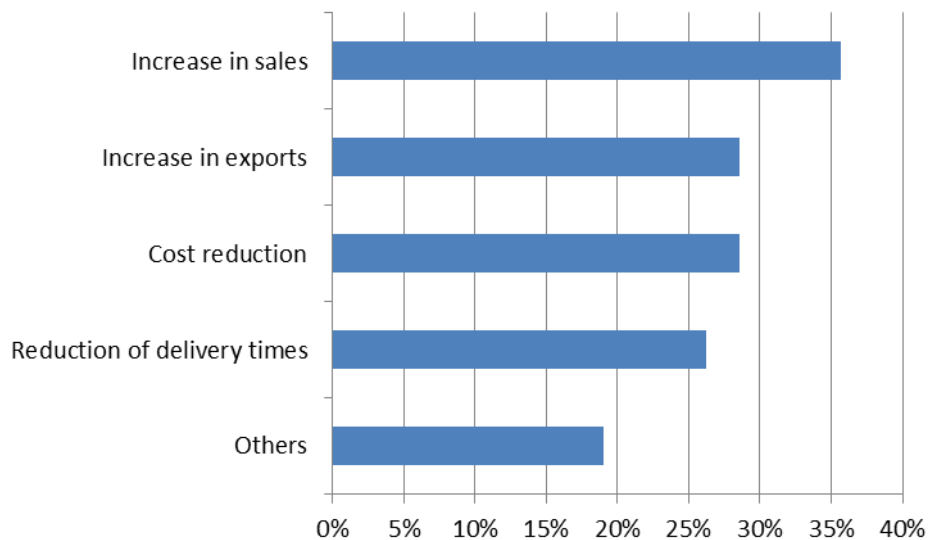

Figure 5. Attributable benefits from obtaining a quality certification (Percentage of all firms in survey).

Source: Authors' calculations based on answers to the questionnaire.

The survey outcomes show that 58% of companies agree that the lack of quality certification has limited their international expansion. Several companies would like to export to Asia, Europe or the United States, but their lack of adequate QCs limit their participation in bids of the private and public sector, as well as possibilities to sell services to (multinational) companies abroad. The remaining 42% of companies, which feel that the lack of QCs does not constrain their growth, mainly export to Latin American countries or sell to the local market. They argue that QCs are not an exclusive requirement to export to the region, but are aware that at some point in the near future this may change.

A striking outcome of the survey is the lack of knowledge of two-thirds of all companies about the required (or desired) quality certifications in the countries where companies want to export. Within this group, 60% are currently selling their services abroad.

There are several obstacles to obtain a QC. One third of all firms mention the limited time available to invest in a certification process, insufficient human resources (25%) and lack of credit (29%). Only 8% claim ignorance of the benefits of certification, as the main obstacle to obtain certification (Figure 6).

Figure 6. Main obstacles to begin a certification process (Percentage of all firms in survey).

Source: Authors' calculations based on answers to the questionnaire.

Public support to obtain a QC is very low. Almost 80% of companies said they had not received support or incentives for certification. The remainder (21%) acknowledged to have had some kind of support. In 2003, CORFO (a public-sector organization dedicated to promoting entrepreneurship, innovation and growth in Chile), through its development program (PROFO) supported 25 companies to obtain ISO 9001 and CMMI certification. In collaboration with ACTI, another public initiative started in 2012 to promote the adoption of CMMI.

5 Final considerations

The results of the survey show a high presence of some kind of quality certification within Chilean IT service producers and exporters. The most common standard is ISO 9001, because the costs, human resources and time required for the implementation of other QCs are much higher. In the case of small IT services firms, the low presence of QCs are due to their almost prohibitive costs. For this reason, they focus their efforts on the adoption of products platforms.

The answers to the questionnaire seem to reject the main hypothesis of this paper stating that the main motivation to adopt QCs are "export driven", meaning the reduction of information asymmetries between the seller and foreign buyer with regard to the seller's capabilities. Almost half (44%) of all companies reported the improvement and standardization of processes as one of the main motivations for obtaining these certifications, followed by the desire to increase the participation in the local market (32%) and increase the participation in the overseas markets (24%). In sum, the results seem to be in line with the alternative hypothesis of QCs being primarily motivated by the efficiency argument.

Other elements that seem to confirm the rejection of the main hypothesis is the little knowledge about the most important quality certifications in countries where companies want to export. Furthermore, it was observed that the share of exports revenue in total sales is low still relatively low overall.

Regarding the benefits that companies obtain with QCs, most firms agree they help to increase sales. Other benefits are a reduction in service delivery times, the improvement and standardization of processes, and cost reductions of projects. Overall, firms seem to be satisfied with the results obtained from QCs.

On the basis of the literature review and results of the survey, the following recommendations can be made to develop future analysis and policies in the area of QCs in the IT services sector. These findings are intended to better understand the benefits and obstacles of QCs in boosting exports of IT services in Latin America and define types of policies that may promote these goals:

- Incorporate questions on the use of QCs in the annual services survey of the national statistics institute of Chile or surveys on innovation.
- Conduct econometric studies on the links between QCs, exports and firm performance using firm level data, in collaboration with the IT service firms' organizations ACTI and Gechs.

- Investigate causes of the lack of awareness among IT services producers of the importance of QCs in export markets, and implement policies that may support the adoption of market relevant QCs. An example is tax reduction of the costs incurred to implement certain QCs in Argentina and Brazil.
- Develop a guide on the requirements and steps of a certification process.
- Promote partnerships between IT service companies that are already certified and those wishing to become certified.
- Establish a database in the export promotion agency PROCHILE with information on the most appropriate or valued certification in the different countries firms want to export to.

Internationalization, Integration, and Innovation in Multinational Enterprises in Mexico: Services versus Manufacturing

Redi Gomis, Jorge Carillo

Comprehensive discussion of multinational corporations and their impact on the development of the host country revealed a significant difference between services and manufacturing (Dunnig, 2008). Furthermore, a greater integration in both sectors is occurring, stressing the increasing importance of vertical linkages and inter-sectoral knowledge exchanges between these interrelated branches of the economy (Castellacci, 2008).

The goal of this paper is to document the type of participation by manufacture and services MNCs in the global value chain in Mexico. We compare the “Three I” (internationalization, integration and innovation) in this two sectors based on a face-to-face survey with HR managers. The survey is statistically representative of MNCs located in Mexico.

The hypothesis is that in Mexico, manufacture multinationals have specialized in the efficiency-seeking strategy through exports, while services are focus on domestic market-seeking strategy. It is expected that manufacturing companies maintain a better position both in the global value chain and its impacts on employment due to their global networks, from service MNCs whose primary investment strategy is the domestic market. In other words, higher internationalization, integration and innovation are expected in the manufacture sector as well as better employment conditions. Results shows that these sectors are more hybrid that we expected.

¿Are global enterprises the most socially inclusive? In other words, are the most internationalized companies better integrated into their respective value chains and are the most innovative those that offer better working conditions to their employees? Based on what a significant part of the fundamental literature suggests on the subject, one might be mostly inclined to suppose so, especially regarding manufacturing companies that are presumably more innovative and inclusive than services companies. In reality, however, this is more a provisional judgment than a conclusive one. The empirical evidence is ambiguous enough as to prevent that axiomatic conclusions be established in this respect. Therefore, it constitutes a matter still under discussion and a debate within which this paper seeks to be inserted.

This paper has two main objectives. First, it explores the relationship between economic and social progress. To this end, the behavior of the labor and employment status in multinational enterprises (MNEs) in Mexico is analyzed, according to different levels of internationalization, integration into global value chains, and innovation. It is an empirical analysis based on a 2008-2009 survey of MNEs operating in Mexico conducted by El Colegio de la Frontera (COLEF) (College of the Northern Border).

Exporting global companies are generally associated with the idea that they are more innovative and competitive and, derived from this, have better job performance. Thus, many multinational manufacturing companies are considered to fall into this classification, as opposed to services MNEs, which traditionally focus on the domestic (Mexican) market. Therefore, considering the variables of internationalization, integration into global value chains, and innovation, there is usually a tendency to attribute high scores in these three dimensions to manufacturing MNEs (partly composed of world-class maquiladoras). By contrast, in the case of services companies, the inclination is to identify them with the lowest levels in these dimensions, particularly because of their domestic market orientation. This relationship will be explored through a comparative analysis of companies in these sectors, in order to examine if indeed services MNEs have the possibilities and opportunities that they are supposedly attributed. The second objective of the work consists specifically of this.

The structure of this paper is as follows. After presenting the work objectives in this introduction, the following four sections will present: (1) a discussion of the literature about the impacts of globalization on the labor characteristics of MNEs; (2) methodological issues related to the analysis that will be conducted, especially those associated with the nature of the data, as well as the analytical strategies to be followed; (3) proper analysis of the data from the results of the analysis techniques applied; and, finally, (4) some brief conclusions.

Theoretical and Conceptual Discussion

Although it is quite a commonly used idea, the fact cannot be ignored that it really is difficult to overstate the importance of multinational enterprises in today's economy—both in the developed and relatively less developed countries—taking into account the extent and power of their impact in that arena. Within this same logic, for example, both Dicken (1998) and Sklair (2001) argue that multinational enterprises are the institutions that have influenced more than any other, the globalization process that for several decades has been generated around the world.

One of the main features that has distinguished this process has been the rapid expansion of foreign direct investment (FDI) flows to developing countries, a display largely led by the worldwide reorganization of production networks, precisely of multinational enterprises. In Mexico, for example, FDI has flowed steadily and in significant volumes. Although in 2012 it experienced a significant drop in its investment flows, during the previous ten years, FDI remained relatively steady with an annual average of about 23 billion (CEPAL, 2013:34).

It is perhaps for this reason that in recent years, accompanying these transformations, the debate has been widening and deepening regarding the role-played by FDI through MNEs in the economic, social, and political dynamics of the host countries. This has been a heated debate in the ideological and political arenas. Although logically more nuanced than in these two spheres, the same controversy has also been present in the academic field, facing the arguments of those who are inclined to ponder all the benefits of multinational companies from those who more likely tend to emphasize their disadvantages. Both stances were masterfully summarized by Moran (2000) in the taxonomy of rival models—"benign" and "malign"—of the effects of direct foreign investment on development.

One of the representative effects of FDI is what Lee (2013) calls "the trap of middle-income countries." This is shown in full force when developing countries face an economic slowdown by remaining halfway between low-income exporters and their low technological level, which does not allow them to compete with developed economies. Therefore, following Rodrik (2008), it can be said that in any case it would be better to maintain economic growth on par with technological growth rather than economic growth without support in technological capabilities.

To avoid falling into the "trap of middle-income countries"—or to get out of it if already inside—Lee and Lim (2001) argue three proposals: (1) newly arrived companies should continue with research and development (R&D) activities using already established companies as examples; (2) if applicable, each company should omit certain stages in the R&D pathway that do not benefit it in order to save time; and (3) already established companies should explore their own path to technological development.

In any case, it is important to note that there is certain consensus among specialists with regard to the role that MNEs can play in relation to the transfer of knowledge, the dissemination of best practices, the establishment of standards, and, particularly, technological capacity building (Lee, 2013; Nelson, 2008; Lundvall, 2004). From current discussions, however, the central interest of this work's objectives is related to the impact of MNE activities on the labor market because, as Lundan and Dunning (2008) point out, "almost all actions of multinational enterprises or their subsidiaries tend to directly or indirectly impact the level, quality, growth, stability, and motivation of the labor force" (p. 414). This becomes important in developing countries because, historically, the technological transformation has taken place in the core countries of the world system and in the leading multinational enterprises from the different productive sectors (Pérez, 2008).

Perhaps the most important idea deduced from all these debates about divergent impacts of MNE activities on developing countries is that there is evidence supporting one stance as much as the other. That is, no stance constitutes an unfounded point of view that should be challenged a priori. In fact, the phenomenon of the activity of multinational enterprises is varied in its effects, which may be due to: (a) the diversity of situations in which MNEs operate; and (b) that MNEs, rather than a univocal reality, constitute themselves a heterogeneous reality.

One aspect that has gotten more attention is the relationship between export specialization and job creation. In this field, the debate in recent years has focused on knowing whether exporting firms would be more productive and create more and better employment opportunities and wages. Several empirical studies have found that companies that develop internationalization processes have higher levels of productivity than companies that only produce for domestic markets (Tumini, 2011). This author initially refers to the pioneering research of Bernard and Jensen (1995), who analyze the differences between exporting and non-exporting firms. Their purpose was to understand the role that exports play in the structure and dynamics of productivity, employment, and wages. Both authors found that exporting companies show better performance characteristics than non-exporting companies, and present higher levels of productivity, higher growth rates, and higher wages. Although in general the evidence shows a positive relationship between exports and employment, the differentials found regarding the enterprises geared toward the domestic market are not so clear, nor homogeneous.

A similar debate has emerged regarding innovations, an element that enterprises, academia, and government confer high prominence as a development factor. Innovation is not detached from the regional context. Laursen, Masciarelli, and Prencipe (2012) found that social capital that is geographically connected affects the innovative capacity of enterprises. Regional social interaction helps build innovation through the interaction of actors in a region and through the effects of support from trusteeships. In other words, innovation ecosystems are an important matter. Thus, companies that are located in regions characterized by a high level of structural social capital show a higher propensity to innovate. Institutions that serve as local learning centers, universities, research centers, and laboratories, as well as

access to foreign knowledge bases, mainly represented by MNEs, are recognized as the critical success factors in increasing technological capabilities (Lee, 2013).

Innovation does not seem to be linked, as one might think, to social inclusion. Empirical evidence does not show binding actions between these two concepts, but it does in relation to employment. Although the relationship between innovation and employment is highly complex (Pianta, 2006), in general, and according to Tumini (2011), current empirical evidence tends to consider that innovations have an overall positive impact on employment: with regard to non-innovative firms, the most innovative—not only in products but also in processes—tend to be the fastest growing and, therefore, also the ones that expand their employment more.

While not objecting to this idea, García, Rodríguez, and Jaumandreu (2002) complicate, in general, this same relationship between innovation and employment. According to these authors, innovation—basically that of processes—could displace employment, causing its decrease. Although parallel, in turn, and also as a result of this innovation, favorable conditions could be created to generously compensate such displacement. Thus, the significant reduction in marginal costs from innovation processes could easily be transferred to the price of the product. This would expand its demand and, thus, generate a compensatory effect on employment previously suppressed as a consequence of innovation. At the same time, however, these authors emphasize that the role of compensatory mechanisms may be blocked and, in some cases, even completely blocked (García, Rodríguez, and Jaumandreu, 2002: p 117.). The latter would directly hurt employment, not wages themselves; in any event, its negative effects would be temporary, since they would tend to be positive in the long run.

Nature of Data: Analysis and Sample Unit

The nature of the data establishes both limits and possibilities for exploration and analyses. Knowing the characteristics of the information used thus allows a clearer notion with regard to its limitations.

The information that will serve as a primary source for this work originated in a survey of a sample of 171 multinational firms in Mexico—in a universe of 922—carried out between late 2008 and early 2009. The survey took place within the framework of a research project developed in COLEF, with the objective of studying the organizational structure, innovation, and employment practices of MNEs in Mexico. This project, in turn, closely followed the guidelines established by Intrepid,¹⁴⁷ an international network of independent researchers that seeks to consolidate, with input from all participating national groups, a reliable and relatively homogeneous database that allows the production of comparable high-quality analyses of employment policies and practices of multinational enterprises around the world.

The target population of the research is from the operational definition adopted by mutual agreement of the Intrepid group participants. According to this definition, the firms that shall be considered multinational are those that participate in the economy of at least one other country besides Mexico, and have at least 500 total employees, but a minimum of 100 employees in the country where the survey originates.

Due to its methodological implications, one restriction should be more specifically defined. It derives from the adopted operational definition, according to which the *firm* is considered as the sole and total analysis unit. It means—and this is what should first be understood—that all survey questions are addressed to the head of the organization in human resources, not to subordinate or lower-level business units. The notion of firm, in this case, refers to the enterprise's *corporate* structure in Mexico. Thus, for example, while a multinational corporation may have several plants or production units within Mexican territory—with intense activity and dependencies on each other, or relatively isolated and disconnected from each other—according to the definition presented, only one of them, the most important among all, would be part of the sample universe. The information thereby collected would correspond to the conglomerate as a whole and not to each of the separate units that would shape it.

A specification such as this one logically has advantages and disadvantages. Among the most important advantages—besides ensuring the alluded comparability within Intrepid's global database—the following three would be found: (a) prevents duplication, since the information of each firm is collected only once, ultimately providing more consistent conclusions about the processes and phenomena to be analyzed; (b) allows the incorporation of Mexican companies, which are often excluded from studies of multinationals, under the wrong consideration that the latter are only those subject to foreign investment; and (c) do not completely exclude relatively smaller MNEs, because although it is true that the definition includes a minimum of employees—500 globally and 100 for Mexico—it is much more inclusive than sources such as *Revista Expansión*, for example, which incorporates only the 500 largest among its kind.¹⁴⁸

Among the most obvious disadvantages, three stand out: (a) definitely, smaller multinationals would also be lost, in case there were some that because of their size would not be able to reach the minimum number of employees

¹⁴⁷ Intrepid is the acronym for “Investigation of Transnational Employment Practices: An International Database.” This network's participants are researchers from nine countries: England, Ireland, Spain, Canada, Mexico, Argentina, Norway, Finland, and Australia. Its members meet approximately every year with the intent to exchange information and outline long-term research strategies, emphasizing comparative studies.

¹⁴⁸ *Revista Expansión* is a biweekly Mexican publication that focuses on issues of economic, financial, and business interests. It is owned by Time Warner. It annually presents, in a special issue, the list in order of the 500 most important enterprises in Mexico.

established by the rule, either at the global or national level; (b) the difficulties to expeditiously find corporations within an ocean of thousands of enterprises with foreign capital registered in Mexico as independent and autonomous company names, although in many instances they really are not; and (c) the loss of the significant heterogeneity that exists within many firms, particularly those that have a more complex organization and multiple units.

The recounting and final identification process of corporations—under the conceptual approach that interested us and from which appropriate criteria for sample selection can be established—was arduous and rigorous. Several strategies were followed.¹⁴⁹ The achievement of the proposed goal implied overall great efforts and major time investment. Even so, the result was satisfactory, since it ultimately allowed the completion of a robust and reliable database of multinational enterprises.

Nonetheless, there are limitations related to the information that was collected and stored in the database that should be noted. One is that, while attempts were made at all times to have a random selection of cases sufficiently representative, there were difficulties in the response rate of the enterprises, which gradually modified these initial selections both quantitatively and qualitatively. The reluctance of MNEs to agree to answer the questionnaire was derived from the simultaneous effect of three situations: (a) the global economic crisis that started precisely in 2008 and worsened in 2009; (b) the growing public insecurity in several states of the Mexican Republic; and (c) the epidemic of the A-H1N1 influenza virus. Another limitation is that, conditioned by the aforementioned, not one multinational company from the primary sector could be interviewed, so its representation was missing from the database. It is difficult to determine how these limitations may affect the validity of the conclusions, but it can be presumed that they will somehow diminish their strength and their power of generalization.

Methodological Strategy

In the first exercise to be developed, “the labor and employment conditions or status” will be considered a dependent variable. The behavior of this variable would be assumed, in this case, to be subject to the influence of the remaining aspects of the company considered earlier in this paper that, in turn, are the independent variables of the model: “degree of internationalization,” “integration into global value chains,” and “innovative capacity.”

The four variables were conceived, at first, as indices obtained from a set of conceptually related indicators whose value would be established by simply adding them. However, both for the convenience of simplicity in the data analysis as well as for the requirements of the technique planned to be used, in all cases their ranges were finally established in only two values (e.g., upper-lower, plus-minus, major-minor, etc.). The average of each index in each of the variables is the cutoff or separation point between these two values, depending on whether it is lower or higher than that average value. Table 1 shows a summary of the variables (indices) considered and, for each, the survey indicators that were used to create them and their related dichotomous values. As can be seen, in the process, a large set of variables was reduced to just four, allowing for more manageable analyses.

Table 1. Variables, Indicators, and Values.

Variables	Indicators	Values
Labor and employment status or condition	<ul style="list-style-type: none"> • Employment dynamics • Employment of college students/graduates • Salary • Level of representation 	<ul style="list-style-type: none"> • Inferior labor environment • Superior labor environment
Innovative capacity	<ul style="list-style-type: none"> • Employment in Research and Development (R&D) • Ties with universities to develop R&D • Search for government support to develop R&D • Existence of reverse innovation 	<ul style="list-style-type: none"> • Less noticeable capacity • More noticeable capacity
Degree of internationalization	<ul style="list-style-type: none"> • Exports • International assignments • Adaptive strategy 	<ul style="list-style-type: none"> • Less internationalized • More internationalized

¹⁴⁹ In an earlier study, published by the *Frontera Norte* journal, we detailed some of the intricacies of the laborious process followed then. It can be consulted in Vol. 23, No. 46, July-December 2011, pp. 35-59.

Variables	Indicators	Values
Level of integration into the global value chain (GVC)	<ul style="list-style-type: none"> • Incorporation of innovations within the GVC, but outside of Mexico • Existence of specific mandates • Trade insertion within the GVC • Degree of independence in decisions 	<ul style="list-style-type: none"> • Lower integration • Higher integration

Source: Authors, 2014.

The relationships among these four variables will be explored from a logistic regression in the particular case of the surveyed MNEs in Mexico. As is known, this is a nonlinear statistical technique that aims to determine the weight of the predictor or independent variables on the probability of occurrence or not of a supposedly dependent event on the variables. In the specific case at hand, this event would be: (a) the existence of some employment and labor conditions above the index average; or (b) its counterpart in the dichotomy, that is, that the employment and labor conditions are below that average value. It should be made clear that the aim is not to conduct an exhaustive study that explains the causal determinants of the labor and employment environment in MNEs in Mexico, since this would far exceed the scope of this work. Rather, it is to estimate with greater precision, both the extent and degree of influence that other factors examined have on the occurrence of the resulting events.

The relationships that are to be explored among the described variables could also be perfectly achieved through other simpler procedures, such as the analysis of contingency tables. However, although it is more complex, there are two advantages of logistic regression itself that make it superior to others and thus more suitable for purposes of the research. One is that the analyses are less biased, to the extent that the effect of each variable is isolated and controlled in the process by the remaining variables that are part of the model. This determines that the results are logically more reliable. The other advantage is that the odds ratios provide the weight with which each of the variables considered affect the outcome; this allows them to be ranked according to the strength of their effect. All this takes place, of course, without completely losing sight that all models are only approximations, as fully accounted in the famous line by George Box, often quoted: “Essentially, all models are wrong, but some are useful” (Box, 1987: 424).

The comparison between sectors followed a similar path. Likewise, a logistic regression was applied, considering the same independent variables as in the previous model, but considering the sector as a dependent variable. The essential idea here is to see how different the manufacturing and services sectors are with regard to this group of factors. Once this point is clarified, whether the employment and labor status has differences in one or the other is ultimately determined.

Analyses of Results

In accordance with the two objectives presented at the beginning, and in correspondence with the methodological strategy subsequently presented, the empirical results of the data used will be analyzed in this section.

Employment Dynamics: Internationalization, Integration, and Innovation

Table 2 shows the logistic regression results related to employment status in MNEs in Mexico (shown in SPSS statistical program output format). As this table shows, the “superior employment and labor status” value of the dependent variable was chosen as the *reference value*. This means that, in general, the model compares the probability of occurrence of the other outcome—“inferior employment and labor status”—in relation to the reference one. It is known as the *comparison value* because of this. The data in each of the columns have a particular meaning within the model, some of which will be explained in detail as the reader proceeds through the document in the review of information.

Table 2. Multinomial Logistic Regression (Employment Status) Parameter Estimates (SPSS Program).

Reference Category: Superior Labor and Employment Status		B	Std. Error	Wald	df	Sig.	Exp (B)	95% Confidence Interval for Exp (B)	
								Lower Bound	Upper Bound
Inferior Labor and Employment Status	Intercept	0.34	0.11	10.11	1	.001			
	Highest innovative capacity	-0.38	0.16	5.36	1	.021	0.68	0.50	0.94
	Greater internationalization	1.73	0.18	95.12	1	.000	5.63	3.98	7.96
	Integration into the highest GVC	-0.68	0.15	20.86	1	.000	0.51	0.38	0.68

Source: Survey of Multinational Corporations, COLEF-CONACYT Project #55108, “Firmas Multinacionales en México: un estudio sobre la estructura organizacional, la innovación y las prácticas de empleo” (Multinational Firms in Mexico: A Study of the Organizational Structure, Innovation, and Employment Practices), 2008-2009.

Following the logic of interpretation of the technique used (see UCLA: Statistical Consulting Group), and based on the findings shown in the table, the following is a list of the main ideas that can be drawn from it:

1. The column titled “Sig.” captures whether the findings are statistically significant or not. In all cases, it shows that the value of this parameter was less than 0.05, which would suggest a confidence level greater than 95%. As a result, it can be assumed that all independent variables considered in the model have such an influence on the dependent variable that it can be classified as important, at least in statistical terms.
2. What is the meaning of the influence noted in the independent variables on the dependent one? In what direction is the relationship between the former and the latter established? The column titled “B” defines the regression coefficients that establish the change that should take place in the dependent variable with the changes that have occurred in each of the independent ones, assuming that the others remain constant. The positive or negative sign of the coefficient indicates whether the result will favor the reference value or that of comparison. That is, if it is positive, it shows that the dependent variable has a *direct* relation to the comparison value and *inverse* with that of reference. Conversely, if it is negative, it shows that the direct relation is to the reference value and inverse to the comparison value. Thus, since the *intercept* is positive, it would most generally be expected that the probability that enterprises exhibit an inferior labor and employment status is higher than the probability that they stand out for their superior labor and employment status. The same applies specifically to the “degree of internationalization” independent variable. In this case, the regression coefficient is also positive, indicating that when the internationalization of the company is greater, its labor and employment status is lower. Exactly the opposite occurs in relation to the “innovative capacity” and “integration into the global value chain” independent variables with regard to the direction in which the relationship occurs. When the value of the regression coefficient is negative in both cases, this means that when both the innovative capacity of the company, as well as the degree of integration into their respective chains are higher, then it is more likely that the result is preferably that of a superior labor and employment status, compared to the opposite result.
3. What is the strength of each of these relationships? Which variables have greater influence on the outcome and on which is that influence less? The odds ratios of the coefficients—shown in the column titled “Exp (B)”—help to clarify these questions. If the regression coefficients, previously analyzed, indicated in which group—comparison or reference—it is more likely to fall, the odds ratios, in turn, reveal the scope and strength of that probability. Considering the aforementioned, it can be seen that, of the three independent variables, the “degree of internationalization” is the one that more powerfully influences the dependent variable. Translating the table results, then, it can be said that it is 5.63 times more likely that, as the degree of internationalization of the company increases, working conditions and employment status will worsen rather than improve. While the other two independent variables were also statistically significant, as seen, their impact on the result is not as intense as in the case of the previous variable. Given that there is an inverse relationship between them—keeping in mind that *B* is a negative sign—and based on the odds ratios, it can be said that as the innovative capacity and its integration into the global value chain increase, it is 0.68 and 0.51 times more likely, respectively, that working conditions and employment status in the company will improve rather than worsen.

In summary, one may say that the magnitude and quality of employment, as well as other working conditions, hold some degree of dependence regarding the processes related to innovation, internationalization, and integration of enterprises into global value chains. However, while the innovative capacity and the integration processes into the chains favor the improvement of those aspects related to employment, the strength of their influence is not as intense.

Conversely, the weight of internationalization is more noticeable, but intervening in the opposite direction, as this factor contributes more to the deterioration of conditions related to employment.

The Sector in Action: Manufacturing versus Services

As characteristics or qualities peculiar to enterprises, both the processes of internationalization and integration into value chains, as well as innovative developments, continue to be attributed, at a level of representation, more to manufacturing than to services. This is quite a widespread idea whose origin and persistence would be better understood if the following considerations were taken into account: (a) first, because of the fact that products have usually been privileged when one thinks about innovation. Product innovation, for example, was the dominant factor in the early stages of the conceptualization of innovation; (b) second, because many of the services traditionally have required a direct interaction with the end user, which would demand the presence of the company that provides the services in the consumer market (Álvarez and González, 2009). Hence, it has even been suggested that the objective of direct foreign investment in the area of services has historically been the search for markets (UNTAD, 2004); (c) third, and final, because likewise many of the services, due to their intangible nature, are indivisible and therefore cannot be fragmented into discrete phases. In many cases, this leads to investments becoming independent subsidiaries—as already stated—aimed at conquering local markets and, therefore, generally less integrated into international value chains (UNTAD, 2004). Moreover, as technology in manufacturing in certain sectors progressed considerably (think successful production models such as Fordism and lean production), services had lower technological development. This changed radically with the arrival of the Internet, information technology and telecommunications, and development of semiconductors.

How accurate are these three considerations? To conceive innovation—taken here as an economic function, according to the classical meaning conferred by Schumpeter (1978)—as a result only relative to the product, is a highly restrictive consideration. It is widely accepted that, in addition to the product, innovations can also aim at different business processes, which in this case are also service companies and legitimate carriers of innovations. Moreover, the most innovative companies currently are the service ones. Suffice is to recall that Steve Jobs did not invent the telephone, Howard Schultz did not create coffee, and Mark Zuckerberg did not found the Internet or online databases, but they were able to find new ways to use the phone, serve coffee, and use social networks. Thus, “they transformed their markets” (*Revista Expansión*, March, 2014).

It is not so simple, however, to neutralize those factors that are related to the other two considerations presented earlier; that is, the alleged impediment of services to become international because of the need for face-to-face interaction with the end user, and the alleged indivisibility of activities that comprise it. Recent decades have witnessed a rapid phenomenon of internationalization and fragmentation of services led largely by the extraordinary advances in information technology and communications. The problem is, though, that there are still barriers that would be limiting the global expansion of all or parts of the services.

With the development of so-called new technologies, various contents have been gradually digitized with the potential to be stored and/or sent anywhere in the world within seconds. Books, songs, movies, among others, would be examples of these recent innovations. Relative to the interest of this work, this has two important direct consequences. One is that services have been added continually with the ability to become marketable across borders. The other important consequence is that production of many services could be fragmented to unimagined limits just recently, thereby giving rise to various forms of outsourcing services internationally. The term “offshoring” that came into vogue a few years ago clearly outlines this phenomenon. In some cases, it presumes outsourcing some part of the service, such as the diagnosis of a medical examination or review of a book. In others, the full service is international, including customer service through call centers, or remote monitoring of facilities through electronic means. The speed and depth with which these changes occurred resulted in some considering this as a *revolution* in transit (UNTAD, 2004; Blinder, 2006).

Not all services, however, have the necessary characteristics to become candidates to participate fully in these processes. Legal services, for example, which require local knowledge of specific codes, can be one of them. There may also be technological and idiosyncratic limitations, among others. The important idea here, based on what has been analyzed, is that at least some services MNEs in Mexico should supposedly be prevented from developing internationalization strategies and integrating naturally into international value chains, which would be reflected in the characteristics shown by all.

This leads to the center of interest of this section. Based on the above, one would expect in theory, as an advanced hypothesis, that manufacturing MNEs operating in Mexico have more developed processes of internationalization and integration into their respective chains than services MNEs. But one might ask whether it is really so. How different are the companies that belong to the two sectors in these and other related aspects? Does one or the other truly “produce” different labor and employment conditions?

With the idea of exploring these issues, another logistic regression was performed. Similarly to the previous model, the same independent variables were used in this one. But in this case, and differently, the sector was the dependent variable. The intention is to assess how deeply manufacturing MNEs are related to the services MNEs. In other words, which of the two sectors is more given to developing processes of internationalization and integration into productive chains, and which has a higher innovative capacity. Table 3 shows the results for this new regression. The “services”

value of the “activity sector” dependent variable was taken as a category or reference value, while “manufacturing” is the comparison value.

*Table 3. Multinomial Logistic Regression (Activity Sector)
Parameter Estimates (SPSS Program).*

Reference Category: Activity Sector: <i>Services</i>		<i>B</i>	Std. Error	Wald	df	Sig.	Exp (<i>B</i>)	95% Confidence Interval for Exp (<i>B</i>)	
								Lower Bound	Upper Bound
Activity Sector: <i>Manufacturing</i>	<i>Intercept</i>	0.02	0.11	0.03	1	.087			
	Highest innovative capacity	0.50	0.18	7.51	1	0.01	1.65	1.15	2.37
	Greater internationalization	2.35	0.24	94.00	1	0.00	10.48	6.52	16.85
	Integration into the highest GVC	0.19	0.16	1.46	1	0.23	1.21	0.89	1.65

Source: Survey of Multinational Corporations, COLEF-CONACYT Project #55108, “Firmas Multinacionales en México: un estudio sobre la estructura organizacional, la innovación y las prácticas de empleo” (Multinational Firms in Mexico: A Study of the Organizational Structure, Innovation, and Employment Practices), 2008-2009.

Following similar analysis patterns, the main ideas can be listed as follows:

1. The most obvious idea is given by the intercept. The low value of the regression coefficient (0.02) and the Wald test statistic (0.03), together with a p-value (0.87) much higher than 0.05, are indicating that, most generally, the two sectors are very similar in terms of the variables examined, although not completely homogeneous. There are differences, obviously, as will be seen immediately, but they would not be extreme.
2. Of the independent variables, not all were statistically significant in this model. The p-value of the “degree of integration into the chain” variable is 0.23 (see column titled Sig), a value above 0.5, which rejects the hypothesis that they are statistically and importantly interlinked, so it will no longer be considered in the following points. The other two independent variables, “degree of internationalization” and “innovative capacity,” were significant.
3. The relationship that these two significant variables have with the comparison value, that is, manufacturing, is straightforward, since all coefficients are positive (column titled “B”). This means that, if internationalization and innovative capacity were to grow, it is more likely that, in a general sense, it is a manufacturing company rather than a services one.
4. The strength of this probability is unequal, being much more intense in the “degree of internationalization” variable than in the “innovative capacity” one. If the first is increased, it is 10.48 times more likely that the change occurs in a manufacturing company. If the considered growth refers to the second variable, then the probability that it is a manufacturing company is only 1.65 times more relative to it being a services one.

Summarizing these three points, it can be said that the levels of integration into value chains are similar in both types of enterprises, and they are not a reliable parameter to tell them apart. While the innovative capacity is a more common feature among manufacturing enterprises, it is not much more than in the services ones. Another situation is what happens with internationalization. In Mexico, manufacturing companies are much more internationalized than those of services. The global trend noted previously does not yet seem to have reached transnational service companies operating in Mexico. In general, when considering these three variables, there does not seem to be major differences between the two sectors, except the degree of internationalization.

Table 4 shows the intersection of the two dependent variables of the two logistic regression models presented: employment status and sector.

Table 4. Labor and Employment Status in MNEs, by Main Activity Sector.

Employment Status	Sector	
	Manufacturing	Services
Inferior labor environment	63.5%	52.9%
Superior labor environment	36.5%	47.1%
Total	100%	100%

Source: Survey of Multinational Corporations, COLEF-CONACYT Project #55108, “Firmas Multinacionales en México: un estudio sobre la estructura organizacional, la innovación y las prácticas de empleo” (Multinational Firms in Mexico: A Study of the Organizational Structure, Innovation, and Employment Practices), 2008-2009.

As expected, although it is most common to find below average employment statuses in both types of enterprises, nonetheless, services enterprises show a slightly higher profile than manufacturing ones regarding job characteristics that have been considered in this work.

Conclusion

Considering the results of the analyses conducted based on the survey data, some ideas can be derived, more like preliminary inferences, logically subject to further intense studies, than as final conclusions.

1. While the magnitude and quality of employment enjoy a slightly higher situation in the most innovative and integrated companies, the reality is that neither the strength of the innovative capacity nor the degree of consistency of the integration of companies into their respective chains seem to have a *transcendent* effect on the considered dimensions of employment.
2. This is not the case, however, of the degree of internationalization. This was a particularly influential element, although with an impact that could be considered negative. The job performance tended to be lower among MNEs with higher levels of internationalization.
3. It was also this same factor the only truly discriminant one of the sector. In terms of innovative capacity and degree of integration, manufacturing and services do not differ categorically. But they do depending on the degree of internationalization, manufacturing MNEs leading in this dimension over services MNEs. The degree of internationalization would thus be—considering the issues in the previous point—the key factor to explain why employment status is slightly higher in services MNEs than in manufacturing MNEs. The word “slightly” should be emphasized because actually no substantive differences are noted between the sectors regarding the magnitude and quality of employment.

Some of these ideas do not work in favor of the existing general representations regarding the relationships among these variables. When it comes to establishing differences relative to job characteristics, it does not seem to matter much if the company is more or less innovative, let alone how much it is integrated into global value chains. Nor does it seem to matter much if the MNE conducts its economic activity in manufacturing or services. What is most common is that the employment status is below average in all these cases. Other ideas are even carried out in reverse. Not only do the findings not show any support for the notion that the export capacity—and, in general, the degree of internationalization—favors employment conditions, but the results contradict this principle.

Are the MNEs located in Mexico so different in these aspects from those operating in other countries? By contrasting the results presented with the existing literature, it could be intuited that, precisely, that is the reality, at least to some extent, which would eventually allow the pursuit of a line of research in this direction. But that assessment is only, of course, at the level of conjecture. No statement in this regard could be conclusive since, as was already stated, none of these results is definitive. Issues relating to the data and the analyses themselves could be contributing to limiting the range of the conclusions. Nonetheless, the results are sufficiently suggestive as to stimulate debate on the subject and encourage more in-depth research on these same issues in future studies.

Le rôle de la veille stratégique dans l'agilité du processus d'innovation. Application au champ non médical en milieu hospitalier, le cas "Assiette Durable"

Sid Ahmed Gozim¹, Marie-Christine Monnoyer²

¹Université d'Aix Marseille, ²Université Toulouse 1 Capitole/IAE

Si le processus de l'innovation de service a fait l'objet de travaux importants au cours des 20 dernières années, le lien entre veille concurrentielle et stratégique avec la construction de l'innovation a été moins analysé. Cette communication, se propose de confronter un modèle représentatif de ce lien avec une étude de cas réalisée dans le secteur hospitalier sur une innovation non médicale. Celle-ci confirme l'existence d'un lien fort entre veille et innovation, avant et pendant le processus de construction de l'innovation, pour une grande variété d'acteurs impliqués dans le processus, quel que soit leur niveau de responsabilité.

If researchers have investigated the service innovation process for the last twenty years, one cannot say the same about the link between strategic and competitive watch, and the innovation process. We will focus our attention on this link. In this paper, we will analyse a case study (non medical innovation in the hospital sector) through our model. It confirms how many people with various responsibilities are involved in the innovation process, and search for information, data and knowledge to participate.

1 Introduction

Le développement de la réflexion sur le management des activités de service s'est accompagné en parallèle d'une interrogation sur la nature et les modalités de l'innovation dans ces activités. Le modèle de Booz, Allen & Hamilton, construit pour analyser l'innovation dans les activités manufacturières a servi de base de réflexion pour la conception de plusieurs modèles destinés aux services : Shostack (1984) ; Donnelly, Berry & Thompson (1985) ; Bowers (1985, 1987 & 1989) ; Scheuing, Johnson & Gaida (1986) ; Anderson & Pennington (1992) ; Palmer & Cole (1995) ; Edvardson & Olsson (1996), Lovelock & Lapert (1999) Toutefois ces modèles apparaissent fragiles dans leur phase amont, c'est à dire la génération des idées et leur sélection, (Jallat, 2000). Des blocages apparaissent également dans la réalisation du processus d'innovation et semblent avoir plusieurs causes qui affectent là encore l'amont de la procédure, telles les différences d'appréciation entre les individus ou sous-groupes de l'entreprise par rapport à la validité du projet en cours, les hypothèses émises, les méthodes employées, les critères utilisés pour la validation de l'innovation (De Coninck, 1998). Toutefois, c'est davantage l'analyse de la partie aval de la mise en œuvre du processus d'innovation qui va intéresser les chercheurs, d'autant que le développement des TIC ouvre des opportunités à la transformation des processus de production des services qui affecte souvent la partie « visible » du modèle de servuction (Eiglier & Langeard, 1987).

L'émergence de l'idée dans l'étude du processus d'innovation de service nous a semblé mériter des analyses complémentaires. En effet, les travaux de Lesca et son équipe (2006) ont mis en évidence les effets positifs de la veille anticipative sur l'identification des phénomènes intéressants, comme celle de phénomènes potentiellement dangereux en termes de développement de nouveaux produits ou services. La veille qui consiste à identifier des discontinuités ou des ruptures et qui pourraient être sources de menaces ou d'opportunités (exploration de l'environnement) peut par exemple alimenter très en amont des démarches d'anticipation, d'innovation et de créativité. De même les travaux de Simon mettent en exergue, dès 1960, les effets de la veille sur le processus de décision stratégique via la phase d'intelligence de l'environnement.

Dans cette communication qui reprend une partie des travaux de thèse de S.A Gozim, nous avons centré notre réflexion sur les innovations non médicales dans le secteur hospitalier. Ce secteur d'activité a en effet été très précisément investigué (Djellal et Gallouj, 2004, 2007) parce que les innovations de processus qu'il suscite combine une réflexion technologique plus ou moins visible par le destinataire du service et un nouveau concept auquel le destinataire peut être sensible. Il présente enfin des caractères similaires à ceux que l'on peut trouver, de façon plus parcellaire, dans des secteurs aussi différents que l'assurance, l'hôtellerie, la restauration....

Dès lors notre question de recherche portera sur la complémentarité entre veille stratégique et processus d'innovation et sera centrée sur la définition des fonctions essentielles d'un dispositif de veille stratégique, pouvant s'articuler dans un tout cohérent et complémentaire à un processus d'innovation applicable aux services.

Figure 1. Graphe 1. Les rouages de la complémentarité de la veille stratégique au processus d'innovation.

Etabli par SA Gozim à partir des travaux de Lesca

Dans une première partie, nous nous appuyerons sur les travaux relatifs à l'innovation de services et à la veille stratégique pour construire un modèle mettant en relation veille et process d'innovation. Dans une seconde partie nous confronterons ce modèle à une étude de cas réalisée dans le champ des services hospitaliers non médicaux.

2 De la veille à l'innovation de services

2.1 Le processus d'innovation dans les services: modèles par étape

Un certain nombre d'auteurs spécialisés dans le champ du management des services (Jougoux, 1993 ; Everaere, 1997a ; Durieux, 2000a ; Flipo, 2001 et Abramovici & Bancel-Charensol, 2002, etc.), et plus particulièrement celui du marketing des services (Shostack, 1984 ; Eiglier & Langeard, 1987 ; Scheuing & Johnson, 1989 ; Jallat, 1992 & 1994 et Lovelock & Lapert, 1999, etc.) ont consacré des investigations aux aspects spécifiques de l'innovation. La plupart ont insisté sur le fait que les processus connus pour les biens matériels nouveaux devaient être revus pour tenir compte des caractéristiques des services et de l'organisation des entreprises du tertiaire. Aussi, l'immatérialité des services doit être en quelque sorte surcompensée par la rationalité et le formalisme de l'approche. La méthode proposée consiste en l'identification d'un certain nombre d'étapes variables selon les auteurs.

Pour illustrer ce courant de recherche, nous avons choisi le modèle de Scheuing & Johnson (1989) dont la complétude n'est pas synonyme de complexité dans l'application.

Ce processus comprend quinze (15) étapes détaillées, que l'on peut aussi regrouper en quatre (4) grandes phases, reproduites dans le tableau ci-dessous :

Table 1. Modèle normatif de processus de développement d'un service nouveau (adapté de Scheuing & Johnson, 1989, vol.3, n°2, pp. 25-35).

Phases	Étapes détaillées
La direction à donner I	1. Objectifs et stratégie, cadre de la formulation du nouveau service. 2. Génération d'idées. 3. Tri des idées.
La conception du service nouveau II	4. développement du concept. 5. test de concept. 6. Analyse du potentiel des ventes. 7. Autorisation du projet de lancement.
La validation opérationnelle III	8. Conception de la servuction et test. 9. Mise en œuvre de la servuction et test. 10. Conception du plan marketing. 11. Formation du personnel.

Phases	Étapes détaillées
Le lancement du service nouveau. IV	12. Test du service et première expérimentation. 13. Test marketing. 14. Lancement en vraie grandeur. 15. Evaluation post-lancement.

La réalisation des deux premières phases du processus décrit, que nous avons qualifiées de „direction à donner“ et „conception d’un nouveau service“ font l’objet de remarques dans la pratique (Jallat 1992 & 2000) :

- Peu de procédures systématiques de génération d’idées sont mises en place.
- Le processus d’innovation est souvent initié par des facteurs internes.
- Le personnel au contact est le principal perceuteur des faiblesses du processus productif existant
- L’impact potentiellement défavorable du lancement d’un nouveau service sur les services existants est largement relayé par les salariés de l’entreprise.

En l’absence d’une concurrence pressante, le processus d’innovation trouve essentiellement sa dynamique créative dans celle des salariés de l’entreprise, en fonction de la liberté d’expression accordée. Si la pratique de la servuction conduit à se focaliser sur la relation et les échanges informationnels entre le personnel en contact et le client (Djellal F. & Gallouj F, 1999), limiter la collecte d’informations et le regard sur la pertinence du service actuel n’apparaît donc pas sans danger, en particulier dans des structures très hiérarchisées.

Mais l’analyse du processus de la prestation de services hospitaliers et des innovations correspondantes réalisée par l’équipe de l’université de Lille permet d’enrichir notre réflexion, dans ce contexte particulier. En effet, l’impact de la prégnance des tutelles sur les organisations prestataires ne peut être sous-estimée quant à ses effets sur la dynamique d’innovation née des interactions entre agents prestataires et client usager.

Figure 2. Pentagone des services hospitaliers
Source : Djellal F., Gallouj C. & Gallouj F., (2002).

Les travaux de l’équipe concernée nous permettent aussi d’affiner l’analyse des relations entre les acteurs de l’innovation dans ce secteur.

2.2 Les relations entre acteurs au sein du processus d’innovation dans les services hospitaliers

S’appuyant sur la représentation lancastérienne élargie du produit ou du service F.Gallouj (2002) et Gallouj et al,(2004) rendent compte des nombreuses caractéristiques du service obtenues (Y), par la mobilisation de compétences (C), de matériel, (M), de méthodologies (K), de relations (R).

Table 3. Décomposition fonctionnelle du produit ou de la prestation hospitalière.

Prestations de services élémentaires	Compétences	Support du service, opérations ou fonctions correspondantes et technologies associées				Caractéristiques ou fonctions (« externes ») d'usage finales ou de services

Source : DJELLAL F., GALLOUJ C., GALLOUJ F. & GALLOUJ K., (2004), L'hôpital innovateur : de l'innovation médicale à l'innovation de service, Masson, Paris, p. 77.

Chaque case du tableau ci-dessus peut constituer un gisement d'innovation à l'hôpital. D'autre part, certaines cases peuvent être ajoutées et d'autres supprimées, permettant ainsi d'accroître ou de réduire le périmètre du « produit hospitalier » et le champ de prospection de l'innovation. De la sorte, cette grille peut être utilisée à la fois comme instrument d'audit de l'existant et de prospective, puisqu'il devient possible de mettre en évidence un certain nombre d'axes ou de logiques d'innovation hospitalière.

2.3 De la veille au processus d'innovation dans les services hospitaliers

A partir des années 60 le rôle d'une surveillance de l'environnement de l'entreprise sur la qualité de la prise de décision comme sur la dynamique de l'innovation est souligné par des chercheurs comme Simon (déjà cité), Aguilar (1967) et Lesca (1986). Qu'elle soit passive ou active. (Martinet & Ribault, 1989) la veille permet d'explorer l'environnement et de décoder les signaux dont il est porteur. Elle soutient alors l'activité, le métier et les processus clés de l'organisation, la prise de décision des managers et la réalisation d'une stratégie délibérée ou émergente. Son but ultime est de construire un avantage concurrentiel, de contribuer à la création de valeur ou de se protéger contre d'éventuelles menaces, et finalement de pérenniser une activité ou une organisation.

Le choix du secteur d'activité (services hospitaliers) nous conduit à proposer un modèle qui s'appuie à la fois sur les travaux et le modèle de Lesca (exploration de l'environnement et étapes du processus de veille), les travaux de Simon (intelligence de l'environnement) et l'analyse du processus d'innovation de l'équipe Gallouj présenté précédemment (facteurs impliqués et structuration du processus).

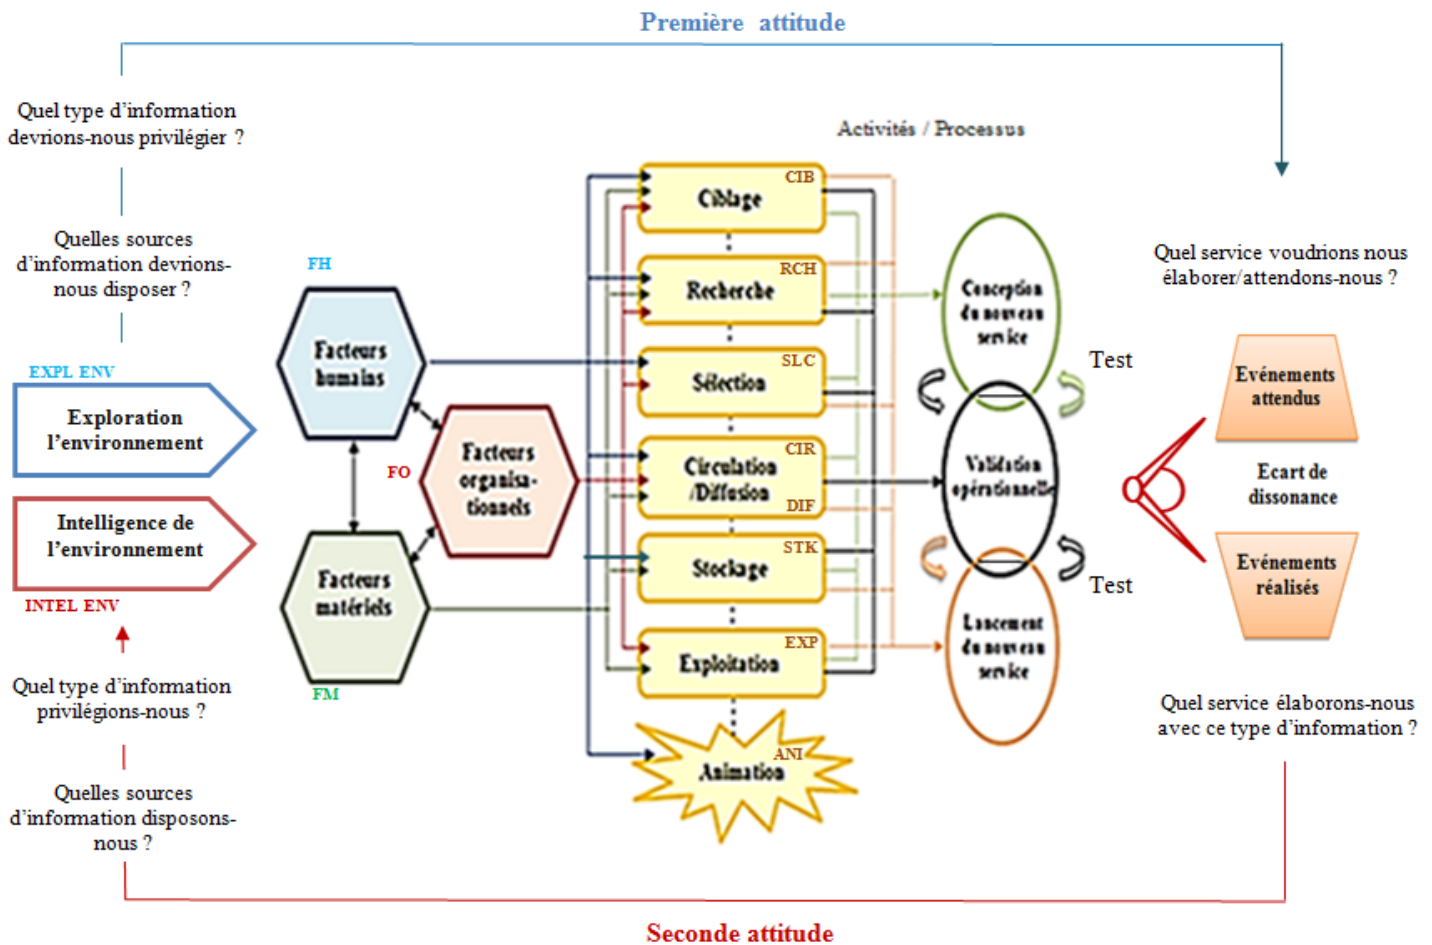

Figure 3. Modèle d'intégration de la veille dans le processus d'innovation de services.
 Source Thèse de Sid Ahmed Gozim à paraître.

Nous confronterons dans la seconde partie de cette communication ce modèle à une étude de cas réalisée dans une structure hospitalière.

3 Le modèle au crible du cas « assiette durable »

3.1 Le choix méthodologique

Le choix d'une méthode qualitative s'appuyant sur l'analyse de plusieurs cas nous a paru justifié par Charreire et Durieux (1999) qui rappellent l'intérêt de cette méthode lorsque l'objectif de la recherche est « de créer de nouvelles articulations théoriques entre des concepts et d'intégrer de nouveaux concepts dans un champs théorique donné ». Ici l'objectif est de comprendre et d'analyser le processus d'innovation quant à son déclenchement et son développement en fonction d'une éventuelle attitude à prêter attention à l'environnement, cette attitude étant considérée elle-même comme un processus organisationnel.

Bien que la méthode des cas ait été longtemps critiquée pour son manque de rigueur, sa faible capacité de généralisation scientifique, elle se révèle très adaptée et justifiée pour l'exploration des caractéristiques complexes des phénomènes sociaux, lorsque les théories actuelles n'offrent qu'une vision partielle, ou pour générer de nouvelles conceptions théoriques (Eisenhardt, 1989 ; Yin, 1994 ; David, 2004).

Pour représenter les articulations entre la veille stratégique et l'innovation en milieu hospitalier, il était nécessaire d'observer plusieurs contextes, compte tenu de la richesse des activités périphériques. L'étude de cas multiples a semblé plus appropriée. Dans le cadre de cette communication, une seule, pourtant, sera présentée, choisie au sein des 4 qui sont analysées dans le cadre du travail doctoral et ont permis d'étudier des logiques de métiers, des domaines de compétence hétérogènes des processus d'innovation permettant d'envisager l'identification de régularités et différences dans les pratiques. L'ensemble du travail doctoral ayant mis en évidence les contraintes fortes des structures publiques (sur lesquelles nous reviendrons ultérieurement, quant à la démarche d'innovation, nous avons choisi ici de présenter une des études de cas effectuées dans une clinique privée (SA) de la région toulousaine (France). Le point d'observation de cette étude est la direction technique, informatique et logistique, meneur du processus d'innovation étudié. Une analyse de contenu a été effectuée à partir des entretiens semi directifs réalisés auprès de 13 personnes, en

utilisant le logiciel Modalisa qui permet de « faire émerger des codes dits principaux dénommés nœuds puis d'organiser les données sous forme d'arbre hiérarchique ou de réseau conceptuel » (Bournois et al.,2002, p 77)

3.2 Le cas assiette durable

L'arrivée de la nouvelle direction de la clinique marque l'engagement dans une démarche active en termes de développement durable, qu'elle veut construire autour de 3 piliers : qualité de l'environnement, efficacité économique, équité sociale. « La restauration fait partie des soins » sera une phrase que nous entendrons tout au long des entretiens, et positionne ainsi les objectifs de l'innovation étudiée dans la stratégie de l'entreprise. L'environnement économique se caractérise au moment du lancement de la réflexion par une baisse de l'activité des médecins, une concurrence accrue d'autres établissements de santé, et la baisse du niveau de prise en charge des soins par la sécurité sociale française. Par ailleurs, l'ensemble des enquêtes de sortie des patients met en évidence l'importance accordée aux activités connexes au médical et plus particulièrement l'hôtellerie et la restauration.

3.2.1 La direction à donner

Pour la diabétologue que nous avons interrogée, membre du conseil d'administration de la clinique P, présidente du CLAN (comité de liaison de l'alimentation et de la nutrition) et de l'association « *Diabète Ensemble* », tout a commencé par un ouvrage qui a pour titre : « *Tous gros demain ? : 40 ans de mensonges, 10 kilos de surpoids* » du chercheur et agronome Pierre Weill¹⁵⁰. Celle-ci a tenu à faire partager la vision de l'auteur à ses plus proches collaborateurs, ainsi qu'à sa hiérarchie, en prêtant l'ouvrage au président directeur général de la clinique, au directeur de l'établissement ainsi qu'au directeur technique, informatique et logistique, sans oublier les diététiciennes dont elle en a la charge. L'auteur a été invité à animer une conférence, basée sur son nouvel ouvrage intitulé : « *Mon assiette, ma santé, ma planète* », qui à l'époque n'était pas encore commercialisé. Les idées de l'auteur, qualifiées de révolutionnaires, suscitent une réflexion approfondie, une participation au salon Dietecom¹⁵¹, des contacts avec les responsables de SIIN (Scientific Institute for intelligent Nutrition) ainsi qu'avec l'association et le label Bleu-Blanc-Cœur¹⁵².

Figure 4. Emergence de l'idée de la refonte des menus.

Interrogés : 13 / Répondants : 13., Pourcentages calculés sur la base des répondants

Source : Etabli par l'auteur

L'approche choisie requiert une prise en compte de la préparation du repas dans son ensemble. Une analyse complète du processus de restauration est dès lors été effectuée afin d'en faire un véritable axe de différenciation pour la clinique. Dès lors, les composantes suivantes du processus sont analysées : approvisionnements et logistique, transformation et le contenu de la prestation, service au client. La rénovation antérieure (5 ans plus tôt des installations de cuisine) et la décision prise à l'époque de maintenir *in situ* la fabrication des repas, facilitent la mise en place du processus d'innovation.

¹⁵⁰ Weill P. travaille depuis quinze (15) ans sur le lien entre modes de production agricole et santé. Il a signé de nombreux articles scientifiques sur le sujet.

¹⁵¹ Le 1^{er} salon de la nutrition destiné aux professionnels de la santé.

¹⁵² Label du ministère de la santé français relatif à la qualité nutritionnelle.

3.2.2 La conception du nouveau service

Une « *commission menu* », est créée, dont le but est le recueil des besoins informationnels de l'ensemble des professionnels de la clinique considérés comme impactés par cette innovation. Elle comprend un membre du CLAN¹⁵³, des médecins de différentes spécialités, des chefs cuisiniers et une personne chargée des menus, des diététiciennes, des aides soignants, une gouvernante, un membre du service qualité, un informaticien. Ce groupe de travail pluridisciplinaire rédige un cahier des charges, définissant les règles à utiliser pour constituer une nouvelle carte.

La gestion d'une carte sous entend la gestion des cycles (nombre, saisonnalité, durée), les caractères des menus déjeuner et dîner (composantes du menu normal, définition des déclinaisons et / ou des régimes), la définition des petits déjeuners et collations (composantes de base, définition des déclinaisons et / ou des régimes). Elle doit aussi intégrer les cartes de remplacement, la gestion de la présentation et le traitement des odeurs, dans le respect de l'équilibre économique.

Parallèlement à cette commission, les diététiciennes ont en charge la confection d'un plan alimentaire, et les chefs ont la responsabilité d'élaborer une liste des produits disponibles et de leurs coûts. Les conclusions sont transmises à la commission pour que, le cas échéant, elle puisse émettre des avis.

Un second groupe de travail restreint est alors constitué, faisant étroitement collaborer les chefs cuisiniers avec les diététiciennes pour construire les menus, les agrémenter, les écrire dissolvant ainsi le manque habituel de communication et les cloisonnements latéraux habituels les deux (2) services.

La validation des menus par la commission clôt le processus. Chaque membre de la commission doit valider le fait que les nouveaux menus soient conformes aux exigences de son activité et de ses responsabilités (diètes, équilibre des repas, satisfaction des patients, coûts...). Le service auprès du patient doit être optimisé, ainsi que le processus de fonctionnement de la chaîne « *approvisionnement - commande - préparation - livraison* ».

Les nombreuses déclinaisons du menu normal liées aux besoins spécifiques des patients supposaient l'intégration de ceux-ci sur des tablettes utilisables par les hôtelières et l'adjonction d'une documentation permettant à ces personnes de répondre en cas d'interrogation du patient.

Au cours de ce processus de conception, la clinique signe un partenariat avec un maraicher local, l'ESAT (établissement de service et d'aide par le travail), grâce à l'un des responsables de la cuisine qui connaissait personnellement cette structure, en a référé à sa hiérarchie qui a estimé que la qualité des produits frais se ferait sentir sur le plan gustatif et aurait un impact positif sur la santé du patient. La commission s'est fait accompagner par le C2DS pour vérifier que la dimension durable était bien prise en considération tout au long du processus (achats, consommation d'énergie, d'eau, traitement des déchets...).

La durée de cette phase a paru longue aux membres de l'équipe projet qui ont considéré ne pas avoir suffisamment de temps, du fait de leurs autres activités, pour effectuer les recherches nécessaires, contacter les patients et intégrer les observations et critiques émises par les membres de la commission. Par ailleurs, les différences de sensibilité entre diététiciens et chefs cuisiniers (équilibre alimentaire versus processus de fabrication), ou entre l'hôtelière intégrée à la commission et les patients ont rendu les échanges difficiles, en particulier avec l'avancée du projet et la fatigue correspondante.

¹⁵³ Le CLAN est un organe technique, collégial, spécifique créé pour une durée indéterminée. Il participe à la définition et à la mise en œuvre de la démarche d'amélioration de la qualité de l'ensemble de la prestation alimentation - nutrition au sein de la clinique.

Figure 5. Les acteurs impliqués - Cas « Assiette durable ».

3.2.3 Lancement du nouveau service

La mise en place du nouveau service a conduit à réviser à plusieurs reprises les caractéristiques des repas qui étaient proposés tant aux patients qu'au self service de la clinique. Si un plat ne passait pas ou était jugé trop lourd, l'hôtière transmettait l'information aux diététiciennes et au chef de projet. Le chef cuisinier s'est rendu souvent auprès des patients pour recueillir une information qu'il trouvait trop parcellaire.

Une fois la proposition des menus été /hiver réalisée, une prolongation du projet a abouti à celle des menus automne/printemps dans le même souci du respect de l'ensemble des contraintes « développement durable ».

Pour diffuser l'information et motiver l'ensemble du personnel et particulièrement ceux qui n'étaient pas représentés dans la commission projet, le service communication (facturation, pharmacie...). Une chaîne télévision restauration a été ajoutée à la chaîne institutionnelle avec l'annonce du menu du jour, de ses déclinaisons et caractéristiques, des articles dans le journal de la clinique ont été publiés avec diffusion d'interviews des patients.... Des soirées ont été organisées avec le personnel médical pour expliquer les choix. Pourtant la communication est jugée insuffisante par un grand nombre de répondants.

3.3 Le modèle et la pratique

3.3.1 Les différentes formes de l'innovation étudiée

La perception de l'innovation par les patients et le personnel de la clinique est rendue visible par l'évolution des menus (saisonnalité, régionalisation, diversité). En affirmant „la restauration fait partie des soins“, la direction de la clinique choisissait de modifier le positionnement de la restauration vis à vis tant du personnel médical que des patients. L'intégration de choix de plats et d'un renouvellement de la vaisselle utilisée apportait aussi une dimension « plaisir » susceptible d'exercer une influence sur la psychologie du patient. Enfin, en élargissant l'utilisation des menus à la restauration du personnel, la direction affichait l'intégration d'une dimension développement durable dans le quotidien des acteurs de la clinique. Nous pouvons donc parler d'une innovation de service.

Derrière cette innovation transparaissent aussi des innovations organisationnelles. La diète des malades n'est plus considérée comme une contrainte qui affecte l'organisation des repas, mais comme une information qui enrichit le processus de construction du service de restauration.

- Le diététicien n'intervient plus en aval du chef cuisinier mais en partenariat avec lui. Le responsable des achats est intégré à ce binôme car susceptible de proposer des produits ou des producteurs compétitifs dans l'instant ou dans le temps.

- Le choix de l'utilisation plus importante de produits frais supposait une modification importante de la logistique nécessaire au traitement des matières premières consommables (contrôle à réception, stockage, refroidissement).
- les fonctions de l'hôtière ne se limitent plus à la vérification de l'adéquation repas-destinataire, elle doit proposer, en fonction de la diète du patient, les plats proposés avant leur réalisation. Si le contact fait partie de l'évolution visible du service, la collecte de l'information et son transfert vers la cuisine constitue une innovation organisationnelle, d'autant qu'elle se traduit par une transmission sous forme numérique.

Les innovations organisationnelles dans leur dimension technologique, humaine et partenariale s'ajoutent donc à l'innovation servicielle apparente.

Figure 6. Changements produits ou éléments de nouveauté significatifs engendrés par la refonte des menus.

3.3.2 Les différentes compétences et supports utilisés

La grille d'analyse de l'innovation de service proposée par l'équipe de Lille (Djellal et al.,2004) permet de mettre en valeur les différentes fonctions utilisées et la variété des compétences nécessaires pour réaliser l'innovation étudiée.

Table 3. Le projet « Assiette Durable » dans la grille d'analyse de l'innovation.

Prestations de services élémentaires	Compétences	Support du service, opérations ou fonctions correspondantes et technologies associées				Caractéristiques ou fonctions (« externes ») d'usage finales ou de services
		M Opérations « matérielles » (+ sciences et technologies correspondantes)	I Opérations « informationnelles » (+ sciences et technologies correspondantes)	K Opérations « méthodologiques » (+ sciences et technologies correspondantes)	R Opérations de service en contact relationnelles (+ sciences et technologies correspondantes)	
Médecine, soins						
Hôtellerie- Lingerie- Diététique.						
Maintenance						
Accueil, réception						
Transport						
Gestion, administration						
Restauration						
Crèche						
Buanderie						
Loisir						
Commerce						
Funéraire						
Nettoyage, traitement des déchets						
Etc.						

Le concept d'élargissement vertical et horizontal des acteurs du projet (tels que définis par l'équipe de Lille) appliqué à l'innovation étudiée met l'accent sur leurs besoins informationnels.

Figure 7. Elargissement vertical et horizontal des acteurs du projet « Assiette Durable ».

3.3.3 Les sources et formes de veille.

L'orientation de la direction de la clinique vers une politique de développement durable, s'est appuyée, sur une exploration de l'environnement concurrentiel et une évolution des attentes de la clientèle. Exploration dont le caractère actif n'est pas certain, puisque la sensibilité aux problèmes environnementaux en général est largement présente dans les medias. Pourtant elle apparaît suffisamment partagée par l'équipe de direction pour qu'elle soit réceptive à la proposition de réflexion lancée par la diabétologue, membre du conseil d'administration.

La politique de veille menée alors par la diabétologue prend un caractère très actif et même proactif par ses actions de « lobbying », auprès des autres membres du conseil d'administration, et de nombreux médecins et diététiciens.

Pour que l'idée de révision des formes de la restauration prenne corps, il apparaît nécessaire à la diabétologue et sans doute à la direction de s'appuyer sur un médiateur, l'auteur des ouvrages sur la nutrition, pour que les acteurs de la clinique, puissent envisager leur rôle dans un projet innovant. Il s'agit en effet de nourrir leur propre discipline et responsabilité de cette réflexion sur la nutrition. Nous pouvons évoquer une intelligence de l'environnement qui vient compléter la démarche d'exploration de l'environnement.

A partir de la mise en place du processus de construction de l'innovation (commission pluridisciplinaire et commission des menus), le processus de veille est porté par de nombreux membres de ces commissions (veille concurrentielle, veille logistique, para médicale...), voir leurs adjoint ou collègues travaillant dans leur service. Nombreux seront les acteurs qui se plaindront de ne pouvoir mener cette veille avec le sérieux nécessaire. Des retours permanents seront effectués devant les commissions ad hoc qui conduiront à un élargissement du projet initial. Ils permettront aux animateurs des commissions et au responsable du projet de valider son opérationnalité et de le lancer.

4 Conclusion

En proposant de passer une étude de cas au crible d'un modèle d'analyse du rôle de la veille sur le processus d'innovation d'un service, nous prenons évidemment un risque, puisque celle-ci ne peut être jugée représentative de toutes les situations d'innovation, même si nous nous limitons aux services non médicaux dans le domaine hospitalier. Toutefois, celle-ci et les autres menées dans le cadre d'un travail doctoral, fait apparaître les modalités de l'émergence d'une idée, dans une structure de production complexe, et les apports des différentes formes de veille pour chaque acteur qu'il se sente concerné et impliqué dans le projet ou qu'on lui demande de s'impliquer.

Si le dynamisme de la structure, du conseil d'administration aux équipes productives transparait dans ce cas, les freins et les réticences ne manquent pas dans cette structure privée, en particulier après la première phase d'enthousiasme.

Les autres études de cas réalisées dans le travail doctoral ont permis de faire apparaître l'influence de la structure juridique sur le processus d'innovation et la mise en place de la veille. Elles seront présentées dans le travail final.

Non-profit service providers and social innovation for liveable and fair cities. Empirical evidence from Italian case studies

Angelamaria Groppi¹, Paolo Nardi², Paola Garrone¹

¹Politecnico di Milano, ²Università Bocconi;

Recent European social policies have highlighted the importance of social innovation as a tool to improve urban livability, in particular during the last decades of economic crisis, collapsing Welfare State and emergence of new social demands. While the Keynesian urban planning has shown great limits of economic sustainability, neoliberalism has introduced new risks of splintering urbanism: emergence of premium networked spaces, commodification of public services and financialization of local infrastructure (Graham; Marvin, 2001). Local community interests on social, cultural and environmental issues are often overwhelmed by economic development per se (Perkins, 2010). On the contrary, an increasing emphasis has been spread on community and its initiatives both in the governance of urban public spaces and in the delivery of public services (Swyngedouw, 2005). Civil society initiatives, actually, show a relevant capacity of social innovation linked to a deeper knowledge of community needs, enhancing transparency and information flows, stimulation of original solutions and, finally, a stronger motivation in (voluntary) workers (Bovaird, 2007). A set of Italian case studies of civil society activities have been chosen from the main sectors which mostly affect the livability of a city: health, education, housing, local mobility, environment, sport and cultural facilities. Founders and managers have been interviewed and reports, where available, have been collected and analyzed. The analysis aims at identifying the attitude of these organizations to social innovation, the origin and the main characteristics of this attitude and, finally, the impact on urban livability.

1 Background

“Can neighbourhoods save the city?”: this is the question Moulaert et al. (2010) moved from studying third sector initiatives and urban livability. In fact, beyond the dichotomy public-private for profit, studies on civil society initiatives have more and more underlined the importance of third sector in order to face the challenges of unlivability in cities based on both social exclusion and urban individualization.

Because of their great opportunities, cities have been experiencing since last century a huge enlargement of their dimension and an increase of population; by 2030, 60% of world population will live in cities (McKinsey, 2013). A similar trend can be seen in Italian cities, where, during the last 15 years, the percentage of people living there is more than 30%, in particular around the “metropolitan regions” of Milan, Rome, Naples and Turin. While the growth of cities increase the opportunities for citizens, it is the same urban economic development which gives a boost to many disadvantages which have often justified the concept of “unliveable city”, namely economic, social and environmental barriers: inequality, lack of security, poor common spaces, decrease of green areas, traffic, pollution, deployment of natural resources (water, energy), reduction of biodiversity and ecosystems (Colding; Barthel, 2013; Gerometta et al., 2005).

In this tension between opportunities and risks of urban life, livability can be introduced as a condition concerning equity, social inclusion and living quality. Hankins and Power (2009) have underlined how livability is something beyond quality, stressing the importance of the “community” factor. Howley et al. (2009), on this very point, state that only a stronger involvement by community seems to have a positive impact on the perception of livability in citizens. The concept of urban livability has received in last years many different definitions. According to Timmer and Seymour (2005), livability concerns three main pillars: accessibility, equity and participation. In particular, they underline that ‘[t]he quality of life experienced by citizens living in a city is tied to their ability to access infrastructure (transportation, communication, water, and sanitation); food; clean air; affordable housing; meaningful employment; and green space and parks. The differential access of people within a city to the infrastructure and amenities highlights questions of equity. The livability of a city is also determined by the access that its residents have to participate in decision-making to meet their needs’ (2005: 2). To the extent of this paper, this definition seems the one which better fits the aim to relate livability with quality of time-and-space dimensions in urban daily life. Urban livability, henceforth, relies on a strong connection between physical infrastructure, connecting people to place, and social infrastructure, connecting people to people (Grimm, 2011).

As Bovaird and Loeffler underline, Not so long ago—it was only the 1980s—public services were essentially seen as activities which professionals did to, or for, members of the public to achieve results ‘in the public interest’. Much has changed since then. We now believe that public services should be designed to bring about ‘outcomes’, not just ‘results’, and that these outcomes should, in large measure, correspond to those which

service users and citizens see as valuable, not simply those which are valued by politicians, service managers and professionals. From being a kind of ‘marketeting’ heresy in the 1980s, such views are now largely shared across most stakeholders involved in public services. This has, indeed, been a kind of revolution—‘public services for the public’. (2012, 1120-1121).

Thus, scholars have hugely debate on what ‘make[s] urban living enjoyable’ (Dumbaugh 2005, 283). Last century has showed two different (antithetic) theoretical approaches, also in urban planning: keynesianism versus neoliberalism. On one hand, Keynesianism has shown great limits of economic sustainability (Weisbrod, 1998); on the other hand, Bovaird (2007) points out two other elements: governance drivers, in terms of decline in governance capacity by bureaucracy, and logistical drivers, because of the need of a too high requested degree of flexibility in planning and provision of services. While the Keynesian urban planning has shown these limits, neoliberalism has introduced new risks of splintering urbanism: emergence of premium networked spaces, commodification of public services and financialization of local infrastructure (gated communities) (Graham; Marvin, 2001). Local community interests on social, cultural and environmental issues have been often overwhelmed by economic development per se (Perkins, 2010), even depoliticized (Swyngedouw, 2009) , with severe distortions in urban life (Pestoff, 2006).

Thus, according to several scholars, a “third-way” approach based on third sector initiatives can be seen as a positive opportunity for increasing urban livability. In section 2 some studies on the role of civil society initiatives in urban living have been collected and analyzed in order to show the relationship with urban livability, the intrinsic aspect of social innovation these initiatives have, and the concrete sector where they have got a successful impact. Section 3 illustrates research strategy and the adopted methodology. Main results and a consequent reflection on the concept of co-production follow in sections 4 and 5. Some conclusions and policy implications are suggested in section 6.

2 Third sector and livability: key issues in scholars’ debate

To what extent can third sector initiatives positively affect urban livability? Weisbrod (1998) argues that in wealthy societies urban needs related to mobility, green areas, housing, amenities, become very differentiated and are subject to very fast changes. In such a condition it is very hard for local government to identify exactly people (new) needs and provide them adequate services. Besides, as mentioned above, for profit initiatives often generates in the management of common-pool resources severe failures related to over-exploitation (and depletion) of resources and spaces, problems of market power and, finally, social exclusion. Third sector initiatives, on the contrary, show a good attitude to identify and radically understand citizens’ needs, catch new emergences, introduce new services or new processes in providing them, without neglecting quality.

Scholars from those streams of literature related to co-production, polycentricity, inverse infrastructure (Egyedi et al., 2010) and subsidiarity in local economies and planning, converge on these points above mentioned. Polycentricity, as developed by Vincent and Elinor Ostrom, defines a model where people and their aggregations can - or should - have an active role in both managing commons and even promoting policies. Local community, henceforth, can exactly identify their needs related to urban “times and spaces”: as Somerville (2005) argued, ‘those who are most dependent on the services are those who value them most highly, it follows that they should have the greatest say in how those services are run’. Public or private for profit intervention, according to this approach, should follow and integrate civil society initiatives. An interesting contribution on this point comes from Evans (2002), although focused on liveable cities in developing countries: case studies show how the presence of “translocal actors”, namely non profit organizations, associations, neighbourhoods, encourages and strengthens local initiatives based on the social capital of the same communities; public agencies, in such a context, operates as allies.

In conclusion, the management of urban “times and spaces” is the key issue which have a decisive impact on the level of urban liveability: besides Keynesian and Neoliberal approaches, polycentrism models based on the involvement of civil society seems to show a more effective impact on citizens’ life. Other two main topics from literature, related to the development of this paper, are relevant: the structural attitude to social innovation in third sector initiatives as keystone for their success (section 2.1); which are the sectors or urban life where civil society has shown a positive impact (section 2.2).

2.1 The importance of social innovation in civil society initiatives

Most of scholars put the attitude of civil society initiatives towards urban livability in relationship with the intrinsic social innovation generated within their activities. As Moulaert et al. (2010) state, social innovation signifies satisfaction of specific needs owing to collective initiative, which is typical for those actions which are neighbourhood or small community-rooted, and which stimulate, at the same time, the process of involvement. Thus, why have the third sector initiatives got this attitude to social innovation? A brief excursus on social innovation and its relation with third sector has been here suggested. Since last decade, social innovation has been recognized as a key factor in a broad range of EU policies: ‘social innovation ranges across a wide area of community policies from new models of childcare to web-based social networks; from the care of the elderly to climate change. It is commonly understood as a new policy and management stream field that cuts across traditional domains encompassing notions of novelty harnessed to the active involvement of citizens aiming to address current social challenges’, as stated in Bonifacio (2014). More

precisely, the European Commission relates social innovation to the development of new forms of organisation and interactions to respond to social issues, addressing:

- ‘Social demands that are traditionally not addressed by the market or existing institutions and are directed towards vulnerable groups in society. Approach 1
- Societal challenges in which the boundary between ‘social’ and ‘economic’ blurs, and which are directed towards society as a whole. Approach 2
- The need to reform society in the direction of a more participative arena where empowerment and learning are sources and outcomes of well-being. Approach 3.’ (2011 : 43).

Similarly, Gerometta et al. identifies social innovation ‘with three core dimensions: the satisfaction of human needs (content dimension); changes in social relations especially with regard to governance (process dimension); and an increase in the socio-political capability and access to resources (empowerment dimension)’ (2005 : 2007), which are common in third sector initiatives, their processes, products and services and their impact on local governance.

On this topic, Brandsen and Pestoff (2009) openly stress how civil society initiatives positively affect urban livability owing to social innovation. In particular, they underline two main effects of civil society initiatives: democratization and innovation. These two elements are strictly connected: innovation implies the attitude to provide services for both neglected and new needs emerging in the community, involving the same community in the process (co-production, co-design), generating a stronger democratization; this process usually has an impact in the relationship with public sector and private for profit companies, so that Fyfe, citing Jessop (2002) and his neo-communitarianism paradigm, can state that ‘rather than lying “between” market and state, as Jessop suggests, the third sector is more accurately conceptualised as lying within a triangular “tension field”, the cornerstones of which are the state, the market and the informal sector, with “the characteristics of the landscapes of organisations in the third sector”’ (2005).

2.2 Urban life and third sector: examples of concrete actions

The previous sections offered a synthetic overview on scholars’ contribution about why civil society initiatives can positively affect urban livability, owing to their attitude to innovation. It is interesting to introduce in this section which are the boundaries of civil society intervention in urban life: to what extent, in fact, can third sector affect effectively urban life? Can civil society initiatives influence only few aspects of urban life? Studies on third sector initiatives, starting with Elinor Ostrom’s seminal research on co-production and governance of the commons (1990; 1996), have nowadays provided interesting evidence on the positive output, outcome and social impact of their activities in a wide spectrum of urban life. According with more recent studies, this relationship between third sector and livability is going to increase, as stated by Pestoff:

The third sector is poised to play a leading role in major public sector innovations in the twenty-first century. It can enhance, facilitate, and even promote greater citizen participation in the determination, provision, and governance of public services through the co-production of such services (2012, 1104).

However, while the positive impact of third sector in health and education sectors has been deeply analyzed, new evidence is emerging from research in other sectors (OECD, 2011), not only in developed but also in developing countries (Joshi and Moore, 2004): ‘Civil society has been a neglected partner in urban regimes; its role in shaping the entrepreneurial activities of cities needs far greater understanding’ (Pincetl 2003: 998).

Self-help groups and social support networks are a clear example of direct impact by civil society on urban livability (Bovaird, 2007), but these are only few examples of this attitude. For instance, a wide range of examples come from the above mentioned contribution of Moulaert et al. (2005). Mori, focusing on so called community-cooperatives, an example of third sector initiative, underlines they can provide ‘a variety of personal and recreational services to residents in small neighbourhoods, like running village shops, pubs, cafes and restaurants, community centres, etc., or promoting child care, outdoor pursuits, sports, refurbishment of buildings’ (2014, 338), even utilities, i.e. energy communities (Walker, 2008).

Social housing and co-housing have been deeply analyzed (Mullins; Pawson, 2010) as a field of action for non profit organizations and in particular social enterprises, namely cooperatives, ‘with high levels of volunteering and collective engagement’ (Brandsen; Helderma, 2012) in a sector usually characterized by strong individualism.

Green infrastructure (Pincetl and Gearin, 2005) or urban green commons (Colding; Barthel, 2013), including parks and amenities, have been stressed as positive examples of environmental non profits’ involvement as partners of local governance institutions in planning, management, even fund raising (Brownlow, 2006 ; Perkins, 2010 ; Zukin, 1995 ; Pincetl, 2003). Pincetl underlines how non profits have ‘slimmer staffs, lower salaries than their state counterparts, and do not require the same rates of return as do their business counterparts’ (2003: 994).

Community centres, play areas and sports facilities are another interesting field of urban life where non profits began to provide positive examples of direct involvement in the management of these urban infrastructure (Boivard, 2007), which have drifted away to privately-owned costly areas (Donaggio and Zorzi, 2011). The same risk occurs in urban regeneration, concerning abandoned buildings and places, which represent a great opportunity for third sector involvement (Pares, et al., 2012; Perkins, 2010): ‘a lot of the existing reuse experiences in this field can be thus seen as

occasions for increasing social (and not only environmental) sustainability', according to Cottino and Zeppetella (2009: 7).

In conclusion, many case studies show the positive involvement of non profits in sectors affecting urban livability (beyond health and education), the quality of their services (Weisbrod, 1998) and their innovation (Osborne, 1998, 2010).

Nevertheless, some critics have been raised up, including that 'the development of participatory governance networks is dialectically related to policy outcomes and to prior structural elements like the position of the neighbourhoods within the urban system or the availability and characteristics of the local social capital' (Pares et al., 2012). Furthermore, 'the determinants of such abilities have not been clarified yet' (Mariani and Cavenago, 2013: 1012-1013).

This paper aims at offering a new contribution on this topic, exposing and analyzing some case studies from the Italian urban context.

3 Research Strategy and Methodology

As discussed in the previous sections, from one side, big cities are expected to play a fundamental role in the economic development of countries, as they represent nodes of knowledge, competencies, resources in a fertile network linking all the world's centres. However, livability (declined in terms of accessibility, equity, participation, and sustainability for all the city's dwellers, including elderly, children, disabled people, poor and families in general), represents a critical issue, from the other side. This is true in particular in the present situation, even exacerbated by the persistent financial crisis, further characterized by an increasing social complexity and social vulnerability. We refer for instance to issues like: increasing housing prices leading to problems of affordability; the changing demographic structure (increasing elderly and proportion of immigrants on the overall population), rising youth unemployment and consolidated trend towards temporary work and short-term contracts; changing family relations (single parent with small children and persistent reconciliation issues); fragility of social or family relations, and so on. In the face of these new needs and complexities, only relying on the traditional State response appears to be inadequate. Professional rigidities and self-seeking behaviour commonly found in public sector organizations, along with lasting austerity policies, make Public Administrations (PA) unable to effectively face these new challenges. By contrast, Third Sector (TS) could play a positive role in that, thanks to specific recognized peculiarities. In short, their claimed flexibility and adaptability, a deep knowledge of their client groups' needs and expectations, a focus on results rather than on structural and procedural matters, typical of traditional public sector organizations, and close proximity to the service users, make TS organizations well-placed to provide new innovative ways of providing services (Kelly, 2007). By and large, TS organizations are expected to promote active citizenship and voluntarism, to address social cohesion, to help to reduce social exclusion through civil renewal, or, in other words, to improve livability. To this purpose, specific capacities of third sector organisations are largely acknowledged: i. community integration; ii. giving the respective groups a voice; iii. pioneering innovations in service provision that address groups, situations and/or needs neglected by States and markets; iv. their complementary role in enhancing the qualities of established public services (Pestoff and Brandsen, 2009). Overall, these features are expected to increase cities' livability. However, it is not true that these benefits always occur and that involving the third sector is always good: the empirical research on the impact of TS organizations on the cities livability is still poor and lacks a deep understanding of the micro-dynamics that explains TS behaviour and effects. In other words, if TS organizations are potentially well-equipped to intercept new needs and expectations, it is not clear whether and how they effectively succeed in improving the cities livability in practice. Furthermore, in case of a positive evidence, it is not clear what makes TS organizations able to deliver such good effects.

In the light of the previous discussion, we then formulate the following two research questions.

1. May TS organizations improve cities' livability?
2. What are the qualifying factors that characterize the positive TS organizations' *modus operandi*?

In particular, we rely upon the evidence that in a city there are many subjects, each one with a specific knowledge of new rising problems. We believe that a knowledge advantage allows people and associations to design and offer an answer adequate to the needs of the urban community. This intervention is not substitute of the PA, but it is complementary: in other words, besides Public Administrations and for-profit activities, we see associations of people and families, social enterprises, cooperatives ... which recognize problems, new or neglected, and find an original answer on a local scale. Hence, we want to provide evidence to the effectiveness and relevance of some of these initiatives, sometime at small-scale, but determinant for many people and families, with spillovers over the entire city.

It has to be noted that in this paper we do not consider essential welfare services and deliberately exclude educations and health sectors. We specifically deal with sectors that affect the normal life of families, struggling with common problems, made more severe in big cities¹⁵⁴: housing, mobility, environment, and leisure, which can be thought as setting the typical day of a family.

The TS potential and the underlying mechanism of TS to improve the cities' livability has been studied basing on case study methodology. This kind of qualitative descriptive research has been considered adequate to the objectives of

¹⁵⁴ Cities with more than 250.000 inhabitants.

our paper for several reasons. It allowed us to go in depth to capture peculiarities of various TS initiatives, to highlight their potential impact on the cities livability, to identify some specific effects of their activity, to find out some common specific factors which could explain the related benefits on the dwellers' quality of life, despite the extreme diversity of analyzed case studies.

We selected a set of 19 Italian case studies, basing our choice on the following criteria: the initiatives belong to TS; are distributed across Italy; differ from origin and ideals; are located in big cities, provide services in one of the four considered sectors, are known as best practices on the base of either public documents or recommendations from experts of the respective sector. Case studies had been carried out through a protocol which included an interview to representatives (executives, volunteers, sometime directly one of the founders, in addition also users) in the organization venue, based on a semi-structured questionnaire organized in sections (general information, governance and management, description of provided services and users; origin and motivation, time development, method, relationship with Public Administrations and other private subjects). This information, along with other public documentation (from website, blogs, media, and official documents and reports) was meant to identify distinctive aspects. The sample of the selected case studies is shown in Table 1. Four initiatives refer to Housing, three to Mobility, six to Environment, six to Leisure. Nine are located in Milan and two in Turin (Northern Italy); one in Bologna (North-Centre Italy); one in Rome (Centre Italy); two in Catania, two in Naples, one in Bari and one in Palermo (Southern Italy).

Table 1 Case-studies: sector, city, provided service.

Sector	Case-study	City	Provided service
Housing	<i>Pompeo Leoni</i>	<i>Milan</i>	<i>Social housing for students and other categories of users</i>
	<i>Zoia</i>	<i>Milan</i>	<i>Social housing</i>

3.1 Case studies description

The initiatives belonging to the Housing sector are relatively homogeneous. Pompeo Leoni is an example of good quality apartments offered at moderate rent to various type of users: university students, young families, single parents with children, and elderly people, in the idea to promote an effective integration between people from Milan and outside, and of different age. In the Zoia case the residences (high energy efficiency certified) had been built on a plot belonging to the Municipality of Milan, granted through a tender offer. The tender announcement required a mix of different uses: purchase at a price agreed upon with the concession, and rent at different level of prices (social and

agreed upon). Many additional common services have been provided (janitor, vegetable gardens, childcare centre, community centre for elderly people, daycare for children, bicycle workshop, laundry), in order to support the integration of the miscellaneous community as a whole. Camplus d'Aragona located in Catania (Sicily) is a historical building refurbished, which is not simply a student residence, but also is active in supporting students during the university studies, organizing cultural initiatives open to all the city. Villaggio Barona has been developed at a greater size, arriving to represent a true neighborhood in Milan suburbs. Along with the social housing main service, through the urban regeneration of a disused brown-field site (belonging to a private charitable Foundation) new facilities have been built open to the whole neighborhood (park, nursery school, community centre, auditorium, library) and many welfare-related activities have been promoted.

By contrast, the cases for the Mobility are rather differentiated. As far as Pedibus is concerned, it is not only the organization for accompanying school kids on the way home-school, thanks to volunteers, but it involves other education activities in terms of sustainable mobility, neighborhood history, road safety, orienteering, ... Car sharing Italia was the first initiative of car sharing in Milan, promoted by some members of an Italian environmental association. Only after three years, the Municipality of Milan followed, starting an analogue initiative. Amicobus is a service, based only upon volunteers, for transporting elderly and sick people to hospital, public offices, post offices. The service is not limited to the transport (as it would be the taxi service), but the "driver" physically accompanies and assists the user and wait for him/her until the end of the visit/procedure.

Among the six initiatives in the Environment sector, there are four related to parks and vegetable gardens and two to urban spaces. Boscoincittà has been represented a pioneering experience to create a real wood in the city, as a new park in an area previously cultivated to maize and corn crops. Nowadays, Boscoincittà has been hosting many activities: summer centres, team-building courses for companies, urban vegetable gardens, botanical techniques and collecting/preserving seeds, environmental education for school kids, sports... Orti urbani Garbatella is the initiative promoted by some members of an Italian environmental association aimed at creating and managing vegetable gardens, as a first nucleus of a future park, to be made in a dismissed area, against a previous different decision of Rome Municipality. Sentieri della Collina torinese is an initiative promoted by an Italian hiking association aimed at restoring, opening again, maintaining, and valuing old historical and cultural foot trails on the hills surrounding Turin, accessible directly on foot from the city centre, with no need of using the car to reach them. In Ceglie del Campo, a Bari cooperative has created urban vegetable gardens to involve disabled people as producers of vegetables, sold with success to close shops. Finally, Friarielli Ribelli is an informal group of girls and boys who have promoted the cleaning and reclamation of urban spaces (piazzas) in Naples, planting also trees in some cases. Each initiative is preceded by an awareness campaign on web to stimulate neighbourhood's interest, to involve volunteers, and to maintain continuity in the care of Piazzas. In a similar way, Piazza Santa Maria Ausiliatrice in Catania is an urban space recovered by a spontaneous committee of neighborhoods, tired of its decline. Dwellers have dealt with fund-raising and organized festivals to return the Piazza to the town. Nowadays, the Catania Municipality has formally granted to the Committee, through a tender offer, the regular maintenance and some new investments for improving the Piazza furniture.

As far as the six cases in the Leisure sector, two refer to help in learning initiatives addressed to school students, both based on volunteers. The first case, Portofranco, developed in Milan, is aimed at supporting high school students through a series of services: one-to-one support in specific subjects, tutoring, counseling point, but also conferences and other cultural and recreational events, which make Portofranco a true community centre for adolescents. Parsifal cooperative gives support to junior high school students, signaled as dropping out school, in a really problematic neighborhood in Palermo suburbs. Parsifal volunteers follow kids not only in the learning but also in the educational path and in taking up a career path after the diploma. Three initiatives (Centro sportivo Colombo, AD Polisportiva Europa, Polisportiva Pontevecchia) refer to sport activities addressed to young people, based mainly on volunteers, aimed all at making affordable to many people and families practicing sports. The core service (training in sports) is accompanied by events that make such facilities meeting and supporting points. Finally, Aperti per voi makes it possible to open to public (both tourists and city dwellers) artistic buildings (historical palazzos, churches, stately mansions, ...), otherwise not available for visits because of lack of public resources. The initiative is totally based on enthusiastic volunteers, which welcome and accompany visitors.

Overall, the 19 case studies present some common aspects. As for the ownership is concerned, cooperative, foundation and not-for profit association are found. The organization is very lean, if compared to the number of users. This fact is due to the essential contribution of many volunteers, prompted and endorsed by these initiatives. In addition, this peculiar characteristic makes it the service free for users in many of them. In most cases the service provided can be considered innovative at all, whereas in few cases (i.e., Pedibus, Carsharing Italia, Friarielli Ribelli) the service is inspired from experiences activated in other Italian cities or abroad, even whether adapted to the specific context. Most initiatives have been recent, only five started before 2000. Anyway, all the initiatives had been able to demonstrate their validity both in the offered service and in the adopted approach. This fact is even confirmed not only by many public acknowledgments and formal grants, but also by the capacity of replica in other Italian cities (for instance, Portofranco and Aperti per voi), in addition to the simple evidence of the increasing number of served users for all the examined cases.

4 Main results

4.1 Impact on cities livability and effects on residents and families

In general, livability is defined as “quality of life” as experienced by all the residents within a city or region, however the qualities of a livable city are not univocally defined. In this paper, livability encompasses an array of different issues that are underpinned by a common set of guiding principles: accessibility/affordability, equity, participation, and sustainability. This definition is sufficiently general and completed, and fully in line, for example, with the announcement made in the Europe 2020 Report, which set for our continent a development over than smart (in terms of knowledge and innovation development), also sustainable and inclusive. Within this context, we found that all these initiatives have been proven a positive impact on the cities livability, as they have contributed to improve one of more aspects of livability (affirmative answer to the first research question). More in detail, the affordability principle has been the core element in all the housing initiatives, but it is also incidental to each service provided free of charge (i.e., Amicobus, Portofranco, Parsifal, Aperti per voi, etc). By and large, accessibility can be refer to time and space made more adequate to families needs, constrained by the fast and overcrowded urban life style. Accordingly to this more general interpretation, accessibility means also additional urban spaces made accessible to all the community, like suburban green land taken away either from the state of neglect (Boscoincittà), or from the excessive property speculation (Garbatella); possibility to access artistic buildings and historical paths, otherwise closed or not longer walkable (Aperti per voi and Sentieri della collina torinese); flexibility in the opening hours (aware choice of continuous hours from morning to evening in case of Aperti per voi); practicable paths for weak users (Pedibus, for the safety of pedestrian ways for children, and Sentieri della collina torinese for walking tours suitable not only for expert hikers). In other words, it is about initiatives though really for everybody, which extend the traditional offer of services. Equity is similarly found in all the analyzed experiences, as the solidarity is intrinsically pursued in all the 19 cases. Villaggio Barona is exemplary in that sense: the inclusion of marginalized and weak people and the integration of normality along with disadvantage is the pivot of the life and the organization of the community. Also Orti sociali urbani a Ceglie del Campo is explicitly aimed at the work placement and integration of mental disabled people. More in general, equity can be refer to the integration of a broad spectrum of subjects: among different generations (Portofranco, Sentieri della Collina torinese, Boscoincittà, Pompeo Leoni), among different cultures and nationalities (Portofranco, Villaggio Barona), neighbourhoods and social classes (Orti urbani La Garbatella, Parsifal, S.Maria Ausiliatrice, Friarielli Ribelli), in addition to weaker and disadvantaged people, like elderly and children, unemployed, disabled and sick people (Sentieri della Collina torinese, Amicobus, Pedibus, Orti urbani Garbatella, Villaggio Barona, Orti di Ceglie del Campo). These two elements are aimed at building a city really inclusive, able to attenuate the unavoidable tensions and potential conflicts, and to transform and tunnel the multiple diversities in constructive energy and positive interests. As far as the third aspect, participation, is concerned, the involvement of users and more in general of residents is, in some cases, the logic outcome of the ownership pattern chosen for these initiatives (i.e. cooperative of users like Pompeo Leoni and Zoia). In other cases, they were born as associations of single residents either with a common ideal (environmental protection, solidarity, attention for the community) as in Orti urbani La Garbatella, Car Sharing Italia, Sentieri della Collina torinese, Pedibus, Villaggio Barona, Portofranco, Parsifal, Orti di Ceglie del Campo Aperti per voi, Friarielli Ribelli, Piazza S.Maria Ausiliatrice cases, or with a shared need (Arca, AD Polisportiva Europa, Polisportiva Pontevicchio). The involvement and the relationships between founders, volunteers, users is a natural consequence. Sometime participation comes from the explicit will to adopt a participated design, to favour a deeper social acceptance, minimizing mistrust and prejudices, focusing on the community needs and expectations (Villaggio Barona, Zoia). Finally, even sustainability can be found in many of these experiences, as the protection of the rare environmental resources, in particular in urban spaces, with the aim to conserve landscape and making available to residents and families new green areas, equipped and usable, is the fundamental reason of all the cases in the Environment sector (Boscoincittà, Orti urbani La Garbatella e Ceglie del Campo, Sentieri della Collina torinese). In addition, it can be detected also a tentative to educate people and Public Administration about an attentive management and respect of the environment and of common spaces (Friarielli Ribelli, S.Maria Ausiliatrice). Of course, sustainability is the main reason for pursuing initiatives like Pedibus and Car sharing Italia, but also Zoia and Villaggio Barona have paid attention to it (for example, parks instead of buildings, or energy efficiency certification).

In the light of the received literature (Section 2), we were able to identify some common effects of the analyzed cases, despite their heterogeneity. By accident, it has to be noted that this heterogeneity was an explicit criterion to select our sample, in order to generalize results to a greater extent. In particular, we believe that the added value of these initiatives are attributable to four dimensions:

- Ability to design and provide innovative services
- Increase in the social capital of cities, through the educations of users and the creation of relationship networks
- Improving the quality of common spaces, with in most cases an additional beauty donated to cities
- The solidarity, in terms of qualified services provided not to clubs, but to large segments of residents, including weaker people and groups.

First of all, we detected in all the analyzed cases the ability to provide innovative services: TS initiatives seem to be able to intercept either new or previously neglected needs and to design an original answer. In detail, they behave as

antennas towards the other subjects in the city, signalling to Public Administrations new needs and expectations thanks to their closeness to people, families and community. Examples are Polisportiva Pontevecchio, that in 1957, when PA priorities were building houses, hospitals, schools, highways, etc, identified leisure as a neglected need of residents, satisfied neither by PA nor by expensive and exclusive for-profit initiatives. Even Amicobus has intercepted an unanswerable and innovative mobility demand: the need to accompany and assist elderly people up to clinics or bureaucratic help desk. In turn, the difficulty to find respectable apartments at affordable prices for university students residing out of town (need satisfied neither by council housing nor by market with its high prices) stimulate the answer by La Ringhiera. Strong novelty elements can be found also in Collegio Camplus d'Aragona (inclusion of education and training activities, cultural seminars, in addition to traditional student residence), in Sentieri della Collina Torinese (historical paths rediscovered and restored to city), Boscoincittà (innovative idea to create a wood as an urban park in a previously cultivated land), just as examples. In other cases, the initiatives do not represent first experiences in absolute terms, as they borrow ideas from outside, but the originality stems in the ability to introduce and successfully adapt such practices in the own urban context (i.e., Car sharing Italia, Friarielli Ribelli, Orti urbani Garbatella, Orti sociali urbani a Ceglie del Campo).

As far as social capital is concerned, we identified in all the initiatives a strong relationship-wise dimension, declined in terms of ability to involve people, to attract volunteers, to generate social networks of trust and support. Just as an example, in Portofranco, students (often from immigrant families) working together with volunteers (university students or tutors) has favoured the creation of rapports among teenagers and their families, among retired teachers and young students. Moreover, one of the key factors in the school recovery is that users perceive the free support given by volunteers. Even in Aperti per voi, it may be identified the attachment from volunteers to the involved sites: more than an adoption, a true identification with the sites; the volunteers become the first promoters of their territory and of architectural and artistic goods. Sometime social capital generates from the integration of different subjects in a well-balanced equilibrium. This is the case, for instance, in Orti urbani Garbatella, where the management of vegetable gardens is committed to a variety of users (unemployed, elderly people, school kids, ..), which has encouraged a spontaneous sociality among users and families, with events open to the whole neighbourhood. Analogue tentative to favour an integration among different users may be seen in both Pompeo Leoni and Zoia housing cases. Again, the ability to involve city dwellers in the participation to cleaning and maintenance of urban spaces and piazzas, as in Friarielli Ribelli and Piazza Santa Maria Ausiliatrice. In short, all these initiatives have resulted to educate users to a greater responsibility towards urban common goods and to stimulate a deep attachment to the community.

As far as the quality, we detected a strong attention not only to the quality of service, but also to the quality and beauty of facilities, despite the economic vulnerability of such organizations. Camplus D'Aragona refurbished an old historical building and stimulated analogue works in close buildings in the street. Public acknowledgments had been received by Zoia, Boscoincittà, Friarielli Ribelli, and Centro Colombo, for the quality of project, the attention paid to sustainability and energy efficiency, the care in the maintenance of green areas, the provision of green furniture, the promotion of urban renewal and sanitation. Aperti per voi, a part from the opening of artistic buildings, has started to promote these sites by organizing cultural events, concerts, including it in holidays packages. We may conclude that the relationship between providers and users allows, despite budget constraints, an attention to quality of spaces outstanding. In comparison, for profit subjects are sometime characterized by efficiency but less quality, or high quality set aside only for few high income people.

Finally, we found that such initiatives tend to be open to the whole community, being the service not restricted to specific segments. In this sense, Villaggio Barona is emblematic, as it was explicitly designed to include and integrate disabled and vulnerable people in a open community where "normality" coexists with disadvantage (different kind of residences, services, facilities are in the neighbourhood). However, solidarity can be identified either in the mission (as in Amicobus, Parsifal, Portofranco, Orti sociali di Ceglie del Campo) or indirectly in the attention towards weaker categories of potential users (for instance the distribution of student grants in Pompeo Leoni, Campus D'Aragona, AD Polisportiva Europa).

4.2 Distinctive method and characteristics of processes

The case studies analyzed present of course different origin, scope, sector, method, as they often were born and operate in non conventional contexts, adopt innovative methods, give an answer specific to the needs and characteristics of the local community demand, rarely adopt pre-packaged models. However, in our various sample, we were able to identify some common elements (second research question), that we believe crucial in improving livability:

- Specialization of the offer
- Flexibility in the service provision from one side, freedom and responsibility on the part of users from the other side
- Donated labour, in terms of both volunteers involvement and additional commitment from operators.

In detail, these initiatives tend to keep a specific focus on the original goal and initial mission. They can extend the choice of offer, but only through correlated services which integrate and improve the initial mission. Just as examples, the sport initiatives, that have differentiated during the years the sport activities; Portofranco, that, a part from the simply help in learning, has now added other services: tutoring, orienteering, counselling, but also organization of

cultural events and conferences, excursions, etc. Even Boscoincittà enriches the park by co-operating with schools, firms, and families in the organization of courses, working experiences, summer centres for children etc.

The second element refers to the freedom in enjoying the service and the responsibility requested to users. In Portofranco, users decide how often attend the centre and are requested to personally book their lessons on the specific matters. In a similar way, disabled people, who have worked at Orti sociali urbani a Ceglie del Campo, can rely on a personal job scheduling, tailored on their specific needs.

Finally, we found the ability to involve volunteers and to encourage donated labour from operators, beyond their actual tasks.

In particular, Pedibus, Amicobus, Orti urbani Garbatella, Sentieri della Collina torinese, Friarielli ribelli, Piazza S.ta Maria Ausiliatrice, Portofranco, Aperti per voi, Centro sportivo Colombo, Polisportiva Pontevicchio mainly rely on volunteers contribution for their service provision, while in the other initiatives we detected a strong propension to donated labour expressed in many ways (for instance, in Orti sociali urbani a Ceglie del Campo, operators are used to accompanying home the involved disabled people, etc.). In some cases, the contribution of volunteers allows a cost saving in the management and maintenance of facilities (i.e., Villaggio Barona and Boscoincittà). Amicobus may provide a better service at a smaller price than taxi offer.

Of course, we are aware that these results should be confirmed by extending the sample of case studies and adopting a quantitative research method. In addition, it would be interesting carry out analogue research in other countries, with the aim of comparing for instance the influence of institutional and social context on the success or failure of such initiatives performed by TS. Furthermore, we would like to better deepen issues like the time development, the economic sustainability in the long run, the survival rate, the ability to diffuse the innovative practices in other realities. The role of Public Administration in fostering such positive initiatives finally is worth being better understood. We postpone it to future research.

5 From co-production to subsidiarity

What emerged in the previous sections has pointed out how these initiative, if managed by a single citizen, could not stand; on the contrary, the aggregation around formal or informal associations or social enterprises not only strengthens the single initiative but also becomes a multiplier of social innovation. On one side, these initiatives let city to have back some public spaces which becomes “piazza”, physical infrastructure for social infrastructure. On the other side they strengthen new networks in a fragmented and individual society, a real positive impact for a livable city. Direct consequence of these two aspects is an increasing attitude to respect (1) themselves as a person notwithstanding any problem or disease, (2) the neighbours, notwithstanding any difference, (3) common-pool resources, which become something citizens feel as a shared property and treats properly. These outcomes can be considered as dimensions of social capital: this is the beginning of a virtuous circle where the increasing social capital encourage new initiatives by citizens to improve even more urban livability; as a positive consequence, social capital will keep increasing.

This is the reason why all the third sector initiatives above mentioned cannot be reduced to simple co-production: co-production, in fact, can be a dimension characterizing also gated communities. In these civil society activities, on the contrary, there is not any boundary or limit to the outcome; furthermore, the creation of social capital is inclusive by definition. Thus, while co-production defines a methodology, and polycentricity implies a structure of governance, both do not completely represent the narrative represented in these case studies. The dimension of solidarity, in terms of inclusion of all the citizens, is indeed a constant element of every single case study. They are real examples of subsidiarity, an approach where people is prompt to help each other, not just waiting for a top-down public intervention but exposing themselves and involving those who receive the service.

6 Conclusions and policy implications

Third sector initiatives above mentioned and analyzed are characterized by an important focus on their aims (specialized supply). Nevertheless, it is focusing on their aims strictly related to people needs, that the same initiatives develop new services and new processes in order to satisfy demand (flexible provision). This tension between their focus on a specialized supply and their flexible provision is made possible owing to their highly committed staff, including volunteers, who show increasing levels of donated labour. This attitude has been defined as an important dimension of social innovation (in services and processes), joint to a safeguard of quality services. This important contribution to livability is not exclusive for a gated community, but it is, in most cases, an opportunity for the whole city and its inhabitants (solidarity): re-qualified common spaces, new social ties among people, education to the beauty for all citizens, inclusive solidarity, are impacts shareable in common.

The aim of this paper is not to point out the end of the State or local governments; to some extent the authors of this paper only partially agree with the concept of “governance beyond the state” by Swyngedouw (2005, 1992). On the contrary, urban governance needs a polycentric approach where the role of third sector is recognized not as a mere provider, but a co-producer and co-policy maker in tight connection (Dente et al., 2005) with other public and private institutions at local level, where even conflicts and different interests can emerge and bring to a solution for the welfare and the livability of cities (HABITAT, 2001). What is the role of State in such a context? The answer to this question concerns the policy implications related to this study. The concept of Enabling State, developed in the stream of the

Network Public Management and Collaborative Networks (Balducci et al., 2011; Agranoff; McGuire, 1998, 2003; McGuire, 2006), is quite a fitting definition. In the scientific debate on urban governance during last decade, a key issue has been the more and more diversified demand of specified and not standardized services. Local public actors and State as well are not able to provide adequate services with adequate timing: this is the reason why the State, according to the “deregulation” stream, gives room to other actors, with two often consequences: either it disappears letting the invisible hand to do the job (with bad results sometimes) or it pretends third sector to do even more work than it should do by the same economic and political conditions. It cannot work: the State should not abdicate its role, but it should distinguish those services where third sector initiatives can be just substitutive from those where third sector provision is merely addictive. In both cases, State is required to modify its intervention from exclusively provider to enabler. It implies two main aspects.

First of all, the State should, in fact, make third sector able to provide those services people need: as the case studies show, when a service is required and the State cannot provide it, society often intervenes and co-produces it. However, as Osborne et al. point out (2008), the public policy framework can help third sector by, for example, simplifying State bureaucracy, recognizing economic and financial support, promoting and encouraging both local rooting and openness to international innovations of these initiatives (Cottino; Zeppetella, 2009). A second aspect of this paradigm shift towards the Enabling State is a more radical change of mind: citizens are not “passive” actors, on the contrary they can play an active role in identifying a fragmented demand, planning an innovative and wide range of services, producing and providing them, giving an immediate feed-back and, finally, improving the service.

Besides, but for further research, not every third sector initiative is worth of public enabling: on this very point it clearly emerges, including from this study, the need for an adequate system of evaluation of third sector activity, in particular the metric, the object of evaluation, the method.

The leverage effect of coordination on interaction work Pareto effects on the design of productivity conformation in social services¹⁵⁵

Joachim Hafkesbrink, Janina Evers

Rhein-Ruhr Institut für angewandte Systeminnovation, Duisburg

Instead of an abstract

A man dripping sweat stands in a wood and saws and saws and saws... Then another man comes around and asks: "Tell me, why don't you grind the saw? You would be much faster!" The first one responds: "THEREFOR I have no time!" (Source: www.pflegeboard.de)

1 Introduction: Four hypotheses to the coordination work and interaction work in social services

Social service work (e.g. caring, psychosocial care) is knowledge work in the form of individual-related and interactive creation of value. Employees in social services for example have to have a comprehensive knowledge and correspondingly professional, methodical, social and personal competences. This also includes the actual implementation of care activities among other tasks like in areas of nursing anamnesis, treatment diagnosis, care planning, care evaluation, procurement of health promotional measures, psychosocial care, as well as the documentation and organization of care. Social service work is 'high-touch work', connected with close and often also incriminating junctions to clients and their relatives. There is a large responsibility: in each individual case employees have to make decisions with immense consequences which impact on participants and other affected people. The dialogue about problems in the job situation is rightly pointed to multitudinous sources of impact (cf. Becke et al. 2013)¹⁵⁶ - for example time pressure, elevated communication tempo, high complexity of working task and of work intensification etc. The length of time spent in social service work decreases as a result of dissatisfaction (cf. Klein and Gaugisch 2005, Bass 2005, Heinze 2011).

Hypothesis 1: Because of the interaction work with clients social services are hardly standardized: "The interaction work is a central condition for the success of the proposal; but it merely is terminally standardized, heavily characterized and therefore connected with a high level of unpredictability. Hence it results from the uno-actu principle also to a certain resistance to rationalizing" (Hartmann 2011, p.77). The efficiency e.g. of a care process among others is dependent on local parameters (logistics, autonomic structural quality of the clients' rooms), and the clients' competence to cooperation (ability and willingness) in the interaction process. Professional routines which specially refer to nursing management (e.g. expert standards of the German Network for Quality Development in Nursing (DNQP) quality testing guidelines of the MDK, cf. MDK 2007) have therefore to be on an individual basis with the result that they have to be attuned to the client's behaviour.

Because of the limited opportunities for standardization and rationalization and also the limited possibility to use technical equipment (lever to help etc.), even social services are afflicted with Baumol's cost disease (cf. Baumol and Bowen, 1966). This means then that increasing incomes in this sector are not or are not enough to compensate for corresponding productivity. The result is a low-pay sector, where people often just work because they are strongly intrinsically motivated, and have other professional ethics than commercial employees (cf. Kumbruck and Senghaas-Knobloch 2006). A result of this dilemma is the development of an extended productivity concept (cf. Evers et al. 2013) and a further professionalization of the coordination work in care adapted to the Pareto principle: "with 20% investment in coordination work attaining 80% more time for effective nursing" (cf. www.pflegeboard.de). This 80/20 hypothesis for social services is investigated in a department of nursing management in an empirical context on the basis of an organizational development project.

Hypothesis 2: In the new research on productivity in social services (cf. Hafkesbrink 2013) it is unclear at present which coordinative and interactive actions should count as value-adding and which ones as transaction costs (TC). Actually in this context, TC are defined as those costs which arise in the establishment and preservation of productive (interactive) value creation. Hence this includes search costs, negotiation costs, control costs to establish and maintain the employment system, organizational costs to establish and maintain the performance, and ongoing costs to pay for the handling, adaptation and control of all internal and external organized transactions (cf. Hafkesbrink 2009, p.94; Hafkesbrink 2013). Particularly, the normative issue as to which of these portions of costs are manifested as a desirable use of resources (for example the direct interaction with clients, the direct arranged coordination of the interactive performance), and which ones involve undesirable waste of resources (requesting or subsequent work concerning the

¹⁵⁵ A modified version of this paper is published in Becke, Guido and Bleses, Peter (2014): *Interaktion und Koordination*. Wiesbaden: Springer VS. Translation by the authors.

¹⁵⁶ Translation of German quotes by the authors.

suboptimal coordination e.g. of committals, documentations or concerning balloting of clients, employees, relatives, doctors etc.) are unresolved.

The answers to these questions are not only necessary for the definition of a new concept of productivity in social service, as an expedient of the Baumol's cost disease, but also essential for the orientation of measures to improve the productivity of social services (cf. Evers et al. 2013, Evers et al. 2013a, Hafkesbrink et al. 2011). The central question in this context is, whether implemented design measures are able to strengthen the direct productivity (added-value), related-added value or if they strengthen the transaction costs and with this lower added-value processes.

TC can be generally characterized as the costs of coordination of economic performance. The term was coined by Oliver E. Williamson, in order to allow a comparative analysis of alternative institutions or governance structures between market and hierarchies (Williamson 1979). The basic idea is that markets and organizations (hierarchy) create very different transaction conditions for economic operators (cf. Wieland 1998, p.16ff.). The market mainly uses prices (for commodities or services) as a tool for behaviour coordination. Organizations use specific organizational rules or principles, such as different arrangements of working environment, working hours, communication flows, organizational culture, interaction with clients, involvement of clients in the process of service delivery, qualification of personnel, internal and external co-operation, with the aim to position the service best on the market. TC can make these different institutional arrangements calculable and thus transparent (cf. Hafkesbrink 2013). In this sense changes in these institutional arrangements within the meaning of interventions, such as in the context of organizational development processes will have an impact on current operational value and transaction costs for the creation of the service.

Even Richter and Furubotn (1996, p.45) have suspected that, in the knowledge economy, pure TC in the sense of Oliver Williamson (1979) can account for up to 60% of net national product. Own preliminary research in the field of knowledge-intensive media services (cf. Hafkesbrink 2009) and also in the field of social services (Hafkesbrink and Evers 2013) suggests even higher values.

Our hypothesis in this context is: due to the limited standardization in the interactive part of the social service (e.g. time corridors in basic care¹⁵⁷), there is here no further rationalization potential. Nevertheless, in the on-stage area (see Fig. 3) and in the back-stage area as well as in support processes there is untapped potential for rationalization, where further time savings seem possible through effective coordination work. These time savings might then lead to an increase of interaction work. For social services it is relevant to uncover ineffective uses of resources and avoid them. In the present paper we want to emphasize this with an empirical analysis of a social service provider.

Hypothesis 3: Routinization and professionalization as an expression of individual and organizational learning do not only apply to the interactive part of a social service. According to special conditions (e.g. structural quality of the care organization and opportunities for participation of the client) this establishes an optimal value of time availability for basic care services, e.g. for interacting with clients during washing, brushing teeth, getting dressed, etc. This form of routinization and professionalization concerns the individual level between employees and clients. Here the potential for rationalization and productivity improvement is -as already mentioned- very limited.

However, in the coordination work an even greater potential for rationalization apparently occurs. This arises from an effective interaction between individual and organizational learning and - so our thesis goes- which at the same time opens up more space for the needed interaction and empathic work with clients (care, attention, etc.). We argue here, following the 'substitution principle of organization' (cf. Gutenberg 1983), that there is an optimum between balancing improvisation, occasionally regulation and permanent general rules (routines), with which the success of organizational arrangements is maximized (see Fig. 1).

¹⁵⁷ "Guidelines for the assessment of long-term care in accord with the XI. Book of the Social Code" (Bri)

Figure 1. Substitution principle of organization, according to Gutenberg (1983, s. 293) (source: <http://www.bankstudent.de/downloads4/bwl-o3.htm>).

At the optimum point, there is a so-called 'organizational balance', which equally considers the requirements for stability (organization) and flexibility (improvisation). This leads to the current organizational and innovation research, where this organizational equilibrium is discussed under the theme of "ambidexterity" (organizational ambidexterity) (cf. Hafkesbrink et al. 2013). Thus, especially those companies survive permanently on the market that are able to balance resource exploitation and resource exploration (cf. Wollersheim 2010, p. 3). "Thus, exploitation is regularly associated with efficiency-oriented and thus experienced use of resources, while under the term exploration all aspects are subsumed in which a certain capacity for change is reflected that appears essential for the renewal of resources" (ibid., p.7). Considering the specific characteristics of a knowledge-intensive interactive social service such as care, it is immediately clear that a balancing of general and occasional rules and improvisation is necessary.

We now believe that – based on the considered context of balancing coordination and social interaction work- a genuine potential for rationalization in the substitution principle according to the Pareto principle can be realized (80–20 rule of good coordination work). Here it is essential to have an interplay of individual and organizational learning and unlearning, so this potential can be lifted.

Organizational learning, that is the explication of implicit knowledge from the individual level to the level of the organization and its compression to (general) organizational routines, should therefore be pursued as long as the marginal product of routine is not zero. Applied to the practice of coordination work in care services: if I invest in outpatient care in the route planning, then I should do this only as long as the travel times of outpatient care are in fact optimized. A further investment in route planning through intelligent linear or non-linear programming and software is then often not economical because, based on situational conditions (traffic problems), time management in logistics cannot be further improved.

The same applies to organizational unlearning: in certain situations general organizational rules obviously fail, because they lead to an over-organization. The result is that the company is not customizable, can no longer ensure efficient resource utilization with existing resources and cannot develop new resources. A lot of care facilities are mired in exactly this dilemma. Because of socio-demographic changes and the increase of dementia, the demand for social services will significantly change in the future. Dementia sufferers or e.g. psycho-socially impaired people get older, and need extensive help from a combination of care and support services. Palliative care will increase; working in collaborative networks will place new demands on the social service organizations. Sometimes there are organizational and bureaucratic rules that constrict the flexibility of institutions to develop new services (e.g. boundaries in the compatibility between different funding schemes according to the Social Code Book for care and other social services, or the much-lamented documentation requirements). In part, these are general, unbalanced and occasional rules (e.g. frequency of meetings with staff operations planning), but also a mismatch between formal and informal organization (lack of trust culture and appreciation in relation to formal rules) that affect the quality of work in nursing. These have to be organizationally unlearned - if they do not meet a compliance event -, so that there is more time and thus more money for an efficient and effective use of resources. Against this background, our empirical investigation shows how investments in work and cooperation design pay off in a meaningful and desirable use of resources in the interaction work.

Hypothesis 4: Added to this is an aspect which plays an important role in the development of organizations: Following the growth and crisis model of Greiner (cf. Greiner 1998, Greiner 1972) a company goes through certain phases in which growth and crises become detached. This has to do with the fact that in the growth of an organization, states of under- and over-organization repeatedly become detached, depending on the age and size of the organization. Depending on the pressure to innovate from the outside, the company needs organizational learning and unlearning,

form routines, reconsider established routines and create new routines. For very small companies without comprehensive organizational arrangements, work processes are more "chaotic", as communication runs informally, and creativity is important. Leadership is informally by the founders, based on a transformational leadership pattern and enthusiasm. As soon as the company grows and new employees are required, the demand for formal structures arises. The foreseeable crisis of leadership is evident when the founders establish professional management, e.g. a new person in management is added. The company is growing with formal rules that are reaching out as long as it does not come to an autonomy crisis, that is, where individuals can no longer cope individual functions alone. Here new structures and organizational arrangements are needed to perform complex tasks to delegate in a hierarchy. The company is growing via the principle of delegation, and reaches its growth limit with a lack of control. The division of tasks between management and the Head of Department has to be redefined etc. Further growth can be made possible in the subsequent phase only by extensive coordination and thus an increase of formal organizational rules. The structure of cooperation, and the communication within the company, is formally designed in essential parts, which end with progressive growth in a bureaucracy crisis, i.e. the optimum between general and case by case rules in fig. 1 is long exceeded, and the bureaucracy inhibits further growth. In this phase, the company needs a new structure and, moreover, a new culture, more teamwork, and more collaboration, also with partners in the corporate field. Here growth frequently can be achieved only via such external partnerships.

Obviously in this context there are different types or tasks of coordination work at different stages with which the growth path can be managed. In any case, it is to be expected that with such an organizational learning process at least sequential phases of incremental improvement of existing resources alternate with exploitation phases of normatively desirable innovation, i.e. the discovery and implementation of new resource uses. The latter includes innovative work to produce new routines for new activities in the field of social services.

In the present paper our thesis is the following: in a young organization the coordination effort is still relatively high, as it is in the process of organizational innovation, and there is not yet a sophisticated and proven routine in work and service development process. Coordination work in this phase is innovation work; routines have to be formed with appropriate expenditure of organizational experiments. Experiential learning based on the formed routines is not possible in a short period of time. In the transition from innovation to routinization, coordination work can be relieved by general economic organizational rules. The effort for coordination work then describes a declining course for the improvement of existing routines.

This thesis is developed here based on the costs of coordination in the establishment and growth phases of a social service company.

2 Theoretical background

2.1 Coordination and interaction work from the perspective of the institutional economics

First we want to develop a - for our purposes - manageable definition for the terms 'coordination' and 'interaction work'. For this we use concepts from institutional economics' and transaction cost theory.

In the institutional economics (cf. Williamson 2000) the terms "institutional environment", "governance" and the micro level of the involved actors ("individuals") play a major role for the coordination of economic benefits:

1. The institutional framework reflects political, social, juridical and economic principles, value systems, i.e. formal and informal rules, in which economic exchange acts are involved.
2. For "governance", the entirety of institutional arrangements in the sense of coordination, monitoring and enforcement systems for controlling the interactions of economic agents is designated. As "corporate governance" it communicates between the institutional framework and individuals in the economy.
3. Individuals (business entities) with their specific expectations of behaviour and properties are the key players of acts of exchange. They operate under the impact of the emerging governance structures and are socially embedded in them.

Companies are now constantly looking for "governance" forms with which they can minimize transaction and added-value costs. The implementation of these forms of governance, i.e. their establishment, development, continuous adaptation and innovative reconfiguration – can be equated as regards to content with management and coordination work, when combined with various tasks:

1. Coordination work represents the hub between the institutional frameworks and (social) acts of exchange e.g. by implementing compliance requirements for economic activity (e.g. approval of a nursing home) from the control system translated into the necessary skills for the provision of services, i.e. human and material conditions of the institution (keyword "structural quality"). In the language of institutional economics, it is about the 'transfer of property rights'. To use an example from the field of social services, it is a property right to exercise a mobile ambulatory care services among others transmitted towards SGB V and SGB XI. Coordination work also deals with the one-time or ongoing transfer of property rights in markets, such as in the form of initiation activities for cooperation with external third service providers e.g. in the context of establishment of neighbourhood concepts in the healthcare industry or their management and monitoring (e.g.

contract control). Costs which arise in the transfer of such property rights in the context of coordination work are referred to as "*transaction costs in the strict sense*" (cf. fig. 2).

2. Coordination work also focuses on the transfer of property rights inside the organization, e.g. via the development of frameworks for workflow management and process control; via role assignments in the employment system; via the establishment and monitoring of communication systems; via the development of quality assurance systems, etc. Costs which arise in the context of such coordination work are also referred as "*organizational costs*" (cf. fig. 2).

Coordination work can be generally defined as an activity of the transfer of property rights on markets or from the control system and of property rights within companies. The costs involved are referred as "transaction costs in the broad sense", as Fig. 2 shows.

Institution	Market	Companies	
Cost definition	Costs that depend on the transfer of property rights on markets	Costs that depend on the transfer of rights of disposals in companies	Costs that depend directly or indirectly on the production of goods or services
Costs in the new institutional economics	Transaction costs in the strict sense	Organizational costs	Production costs
	Transaction costs in the wide sense		
	Overall cost		
Costs in the neoclassic economics	unconsidered	Only production costs	

Figure 2. Terms and cost demarcation according to the transaction cost theory (source: Möller 2002, p.108).

The demarcation of the terms in this way defines coordination work from interaction work accomplished with the institutional economy and the transaction cost theory: thereafter, as interaction work can be referred to as the direct or indirect activities for the production of a social service via the Uno-actu principle (see fig. 2).

For a more precise definition of interaction work, it is necessary to identify the process types in the provision of services in order to differentiate particular indirect activities with regard to their relationship to value creation. Taking into account the terms in figure 3, interaction within the meaning of productive, directly adding value service activities (i.e., the physical interaction with clients such as caring or counselling) can be separated from coordination work within the meaning of related added -value "On-stage processes" (i.e., visible activities without physical contact with customers, such as coordination of customer affairs with other external contractors). And also to separate these activities from "backstage processes" below the visibility line (i.e., preparatory activities for the provision of customer interaction such as internal team meetings) and support processes (i.e. basic compliance, organizational and training processes) (see fig. 3).

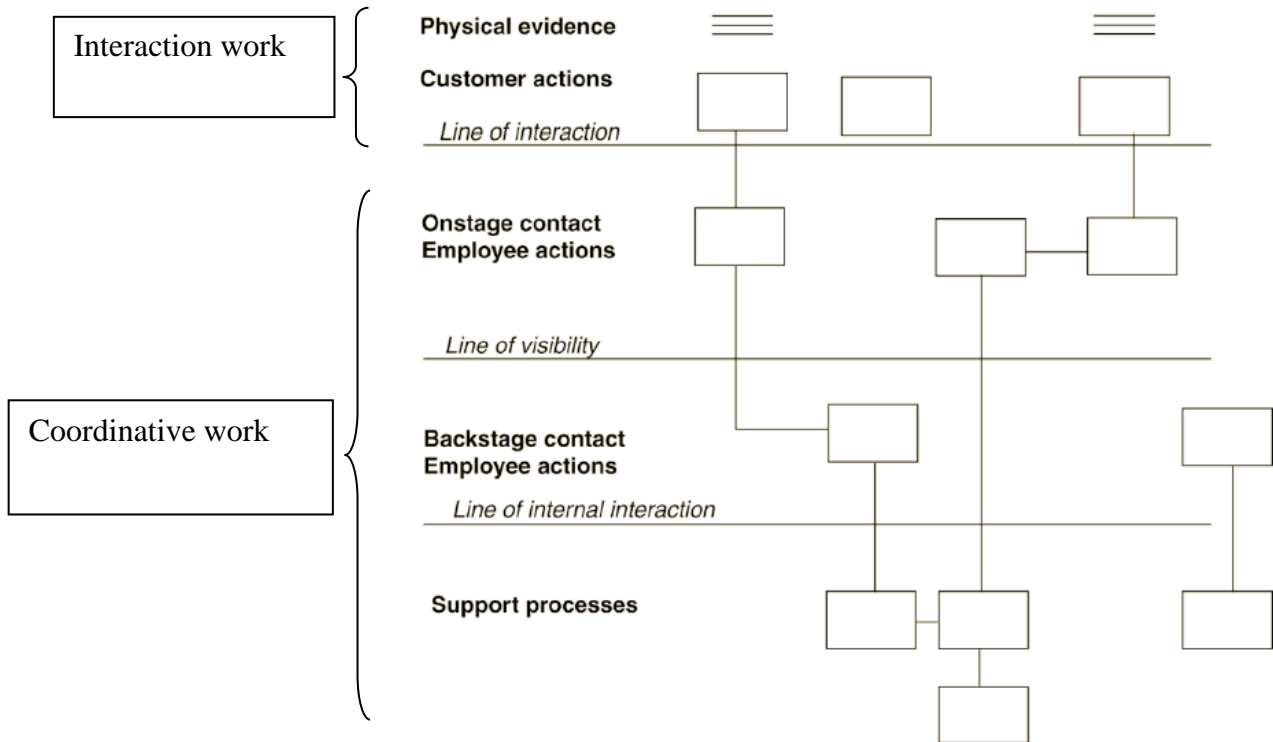

Figure 3. distribution of the types of processes in the field of interactive services (source: *Service Blueprint Components*; <http://www4.ncsu.edu/~hp/MMW-Lecture4.pdf>, varied).

The question remains as to which of these processes are directly value-adding, which are indirectly value-adding, and which are not value-adding and thus are supportive work. Basically one could follow the principle: "everything that the client pays for is directly value-adding". This applies to social services, such as to the performance catalogues of care fund (for primary care) and the benefits groups of health insurance (for the technical care). Thus, for an out-patient care service the travel costs would also be part of the basic care as a billable activity: however, there is no interaction but only coordination work. What is certainly needed for the empirical study is a classification of coordination and interaction work (cf. chap. 2.2.). Finally, the question is to discuss which forms of coordination and interaction work represent a sensible use of resources, and what forms an undesirable waste of resources. Interaction work is initially not suspected to be a waste of resources, because one just generated at all a billable service by these interactive service activities. A non-efficient resource consumption in the interaction work, however, is to assume for those cases where the service provider does not fulfil the interaction routine (yet) in the specifically time. This is if the coordination work (incorrectly or inadequate preparation of the interactive performance) was not effective or the client denied or restricts his involvement in the service process. Coordination work can be divided into planned and unplanned work considering the aspects of resource use / waste of resources. Planned coordination work would then lead to a first approximation to transaction costs for planned use of resources, and unplanned coordination work to transaction costs for unplanned waste of resources (see in more detail the following section 2.2.).

2.2 The Pareto Principle and the leverage effect of coordination on interaction work

2.2.1 How to distinguish between organizational, production and transaction costs of organizational development projects

With regard to hypotheses 1 and 2 (Pareto Principle or 80/20 principle), it is important for further considerations to differentiate between the costs of an intervention (investment organization costs), production and ongoing transaction costs (see, Hafkesbrink 2010).

Thus we define *organizational investment costs* in the context of an intervention all those costs that are incurred once for an operational reorganization project, i.e. costs for the planning of intervention, for external consultancy, for surveys in the company, for the valued proportion of time for employees included in the measures, etc. Basically, these costs are to be equated with so-called "project costs of intervention" connected with the question: "How much money does a company need to invest in order to implement the planned intervention in the organizational structure in the context of a time-limited project?". Therefore, investment costs would show up as "quasi-depreciation" in the organization costs. Thus, in the transaction cost approach, one would distribute the investment-related costs for the planning, development and implementation of intervention measures (cost of project) to the duration of the project in

the form of a pro rata depreciation and charge it as "organizational costs". In addition to these one-time investment-related costs, there are ongoing organizational development costs (OD-costs) as soon as an intervention is aimed at a continuous organizational learning process. Here the recurrent transaction costs of coordinating such OD projects, and the possible costs of external change agents and internal capacities of employment, would be part of the OD project group.

On the other side is the expected benefit. From the intervention in the organizational structure or in the process organization, different beneficial effects are expected which reflect in part as changes in the quality of service delivery and / or in the quantity of resources, which have short-, medium- or long-term effects. The benefit of the measures as initially described, can mean an improvement of qualitative "soft" factors (e.g., performance, motivation); an improvement of products and service quality; and a reduction of the costs of service provision or a change in the transaction costs. Concerning the latter, it is of interest to know its extent and at what time the investment into the organization leads to a payback, i.e. the current organization may cost less and / or allow more space for the desired interaction to work with clients. The empirical case can be mathematically expressed as follows:

$$t = \frac{\text{Investment in the Organization (initial outlay)}}{\text{Average return flow (per year)}}$$

Formula 1. Payback period.

The focus is on the question at which time does the initial outlay (investment in the organization) over the average return per year refinances (e.g. in the form of saved transaction costs). One aim could be to minimize such transaction costs, which represent an undesirable waste of resources, such as unplanned coordination processes, organizational inefficiencies, etc. A second aim could be to design interaction work more efficiently, i.e. the desired coordination work. Both aims lead back to the discussion on the question of the use and waste of resources. The accuracy of the ratio of added-value costs and necessary transaction costs in the field of social services has already been established, is shown in first approaches (cf. Hafkesbrink, 2013). Perhaps one may think of the "organization" as a function of system coordination as an engine up to a certain speed (under "normal load") which has a reasonable fuel consumption. However, under constant overload it consumes exponentially more resources. This image from the everyday experience of many motorists will provide a basis to generate a better understanding of the relationship of the transaction to added-value costs.

The modification of organizational structures and the re-engineering of work processes in this context often establish the need to make work more efficient and reduce costs. However it usually remains uncertain whether transaction- or added-value costs are meant. Anyway, it becomes apparent that organizational processes that are unbalanced, non-transparent, time-critical and uncoordinated and are in a constant state of overload, rather generate high - "negative" (undesired) - transaction costs, optimized organizational structures and processes, vice versa, lead to a reduction of added value- and transaction costs. In this sense, "efficient organization forms" along with a "double dividend" are connected in that they also improve the working conditions for the performance and health of employees, as well as improve the quality of work and results through the creation of scopes with regard to the ratio of value added to output costs (Hafkesbrink 2009). The leverage in this regard is reasonable: by reducing unintended transaction costs via optimized organizational design in favour of a relief in the direct value added costs. At the same time, relatively optimized organizational design offers the option of reducing unintended transaction costs in favour of more flexibility and innovation.

Organizational development projects, from the perspective of institutional economics, thus focus on the design of specific institutional arrangements (design of corporate governance) with the aim to reduce the adverse transaction costs as much as possible, and, at the same time, to produce a double dividend in terms of good quality employees' work.

A distinction is made in this context for the empirical part of the following cost categories:

Added-value costs = cost of interaction work, i.e. all costs that are connected to a direct value-added progress in the service process ("transformation cost" for the interactive core process, that is all activities to increase customer participation, all visible interactive care activities).

Related added-value = costs of coordination work that directly support the core process (e.g. planning, directions, preparatory activities at the client) and are essential for efficient use of resources (on-stage processes).

Transaction costs for Support-/Backstage processes = cost of coordination work that arise in connection with the preparation and quality assurance of organizational performance processes, and sustainably supports the interactive core processes (e.g. development of integrated service concepts, documentation and accounting tasks).

Planned coordination costs = costs of coordination work in on-stage-, backstage- and support processes that are necessary and planned for interactive performance, and the necessary use of resources.

Unplanned coordination costs = costs of coordination work in on-stage-, backstage- and support processes that are unnecessary and unplanned for the interactive services.

Empirically, the question is, through which intervention measures a maximum leverage of coordination on interaction work can be generated in the sense of the Pareto principle, with the aim of reducing the unplanned waste of

resources in favour of the planned use of resources to support effective coordination and efficient interaction work, and at the same time produce good quality work and services.

2.2.2 Framework, indicators and survey methodology for the empirical investigation

The reliable detection of effects of intervention measures in OD projects on cost and benefit factors is scientifically sophisticated as a result of various cause-effect relationships and multifactorial influences. In practice this is done with the help of appropriate qualitative and quantitative indicators, that reflect at least the major part of the decision situation. For our empirical examples, the framework and the indicators used, and the survey methodology, are outlined in order to assess the validity of the results presented here.

Empirical framework: In this paper two empirical cases of intervention measures will be presented in the field of social service agencies:

1. A social service organization that exists for many years, that faces the task of merging various decentralized residences in the area of psycho-social care with different organizational cultures developed over many years.
2. A social service organization which developed as an outsourcing project of a residential care facility that offers outpatient social services (such as counselling seniors) and begins to professionalize their services and organization.

In both cases the relation of coordinative and interaction work is of interest. The focus is on the question of which coordinative work leads to "positive" leverage effects on interaction work? That is, which specific design of coordination work can be developed and implemented that is likely to provide more (cost) efficiency and effectiveness for the interaction work in the sense of "Pareto-leverage"? Does the routinization of coordination work in this context lead to time benefits for interactive activities with clients?

Under (cost) efficiency ("doing things right"), we understand the ratio of output to input (see formula 2), expressed as a cost factor, thus being a more classical measure of productivity, but in the robe of monetary units. The output is the provided service, including human resources and properties, i.e. all coordinative and interactive activities, and other resources, that are necessary to deliver the service. Cost efficiency can be improved at the same output by a lower input, which, in absolute terms, is equivalent to an economy of scale or the same input by an improved output, which corresponds to an innovation effect, e.g. in the form of improving the quality of the service (see again the formula 2).

As effectiveness ("doing the right things") we define the target achievement for the client. Will the mix of personnel and appropriate resources prove satisfactory? That is, is the developed structure and process quality of the facility able to provide a high quality social service organization? The focus of the effectiveness assessment is whether the interaction can be improved with the customer work to provide good, timely, target appropriate coordination work, particularly with regard to more time for interaction work and thus for an improved service quality.

The normative challenge here is to demonstrate the potential of increased effectiveness and efficiency in the sense of balancing high service-quality for the client, service- and cost-efficient provision of the service, and high quality of work (cf. Hafkesbrink/Evers 2013). For this reason, in the choice of indicators and measurement scales as part of the comparative cost no absolute sizes will be used but it is argued with the respective relative (cost) shares.

Indicators used: Against the background described, we choose as indicators various quantitative measures, which we derive from the transaction cost analysis of the social service processes (cf. Hafkesbrink 2013). Thus the desired efficiency and effectiveness improvements are set as follows:

An **improvement of effectiveness** arises when an investment in and routinization of coordination work leads to an improvement of interaction work. Coordination work should prepare efficient and effective interaction work. A good operational planning of a home care service will improve the provision of interactive services to the customer -- the right material and the right skills for the care of a wound at the right time and at the right place will bring better results, as good documentation about the wound makes the therapy course for other caregivers transparent, questions are avoided, etc. The payback for the investment in coordination work is an improvement of time for the customer, improved quality of work (e.g. by time de-stressing) and improved service-quality (e.g. better wound care). In the language of transaction cost analysis, an efficiency improvement is assumed in this context if the current transaction costs for support processes and backstage processes will decrease in favour of more added-value costs of interaction and value creation related costs for onstage processes. In the illustration as a measure (relative number), this would result in the following:

Formula 2. Used measure of productivity for the transaction cost analysis.

There is an **effectiveness improvement** for:

- a) Output $t_1 - \text{Output } t_0 > 0$ with constant input (innovation effect for the service)
- b) $(\Delta \text{TKS} + \Delta \text{TKB}) + (\Delta \text{WKO} + \Delta \text{IK}) = 0$ (innovation effect for interaction work for $\Delta \text{TKS} < 0 \wedge \Delta \text{TKB} < 0 \wedge \Delta \text{WKO} > 0 \wedge \Delta \text{IK} > 0$ with constant input)
- c) $(\Delta \text{TKS} + \Delta \text{TKB}) - (\Delta \text{WKO} + \Delta \text{IK}) < 0$ (Pareto effect from coordinative to interaction work)
- d) $(\Delta \text{TKS} + \Delta \text{TKB}) - (\Delta \text{WKO} + \Delta \text{IK}) > 0$ (Learning costs from coordinative to interaction work, missing of routines)

When the shift of transaction costs for support and backstage processes is higher than the shift of related-added value costs and interactional costs, a learning process is supposed with associated learning costs. With the increased routinization of the skills, there should be a declining balance in the transaction cost curve associated with a transition to the innovation case a) or rather b) and the Pareto case c).

We measure the extent of routinization by the share of planned and unplanned work (TKS+TKB+WKO) in coordination over time.

An **efficiency improvement** in this classic pattern is present for the case of:

Input t_1 -input $t_0 < 0$ with constant output (Rationalization effect)

Thus, the given output can be provided with an improved utilization of resources with less input. Here transaction-cost analysis helps to identify the sources of efficiency improvement:

- Routinization of coordination work: as long as learning effects and thus economies of scale in coordination activities arise, there are free spaces generated for employees in the sense of work time (e.g. for resource exploration), that is, innovative activities to ensure the ability of organizational change. These could apply to new processes, products or services to develop or to improve the resource exploration (new interaction work) or to establish new routines for resource utilization. In this sense coordination work than is equal to innovation work.
- Routinization of interaction work: learning effects and thus economies of scale in interaction work arise when a professionalization of the exercise takes place, e.g. in the transition from a trainee relationship towards an employment as a professional employee. There also exists the effective presumption of good coordination work on interaction work, namely where targeted coordination work secures efficient interaction with clients. We do not want to speculate about the use of such work time here, but to suggest that this is discussed from the normative viewpoint of improvement of work and quality of service and not under the label of rationalization.

Survey methodology

In the social service organizations, primary research was conducted in the form of a questionnaire survey. It was aimed to separate the differentiation of coordination- and interaction work and added-value work processes, which lead to transaction costs. The employees and (middle) managers of social service-organizations were asked to rate their percentage of working time, they need for specific work processes e.g. for social care of clients, for organizational development, or for documentation activities. This was based on the expert knowledge of employees and managers who had often worked for a long time in the organization. On the basis of their experience, they were asked to assess what percentage of working hours they spent, on average, for the described processes. These were categorized as planned and unplanned work processes, which we have assigned as part of the evaluation of the proximity to the value creation (see Fig. 4)

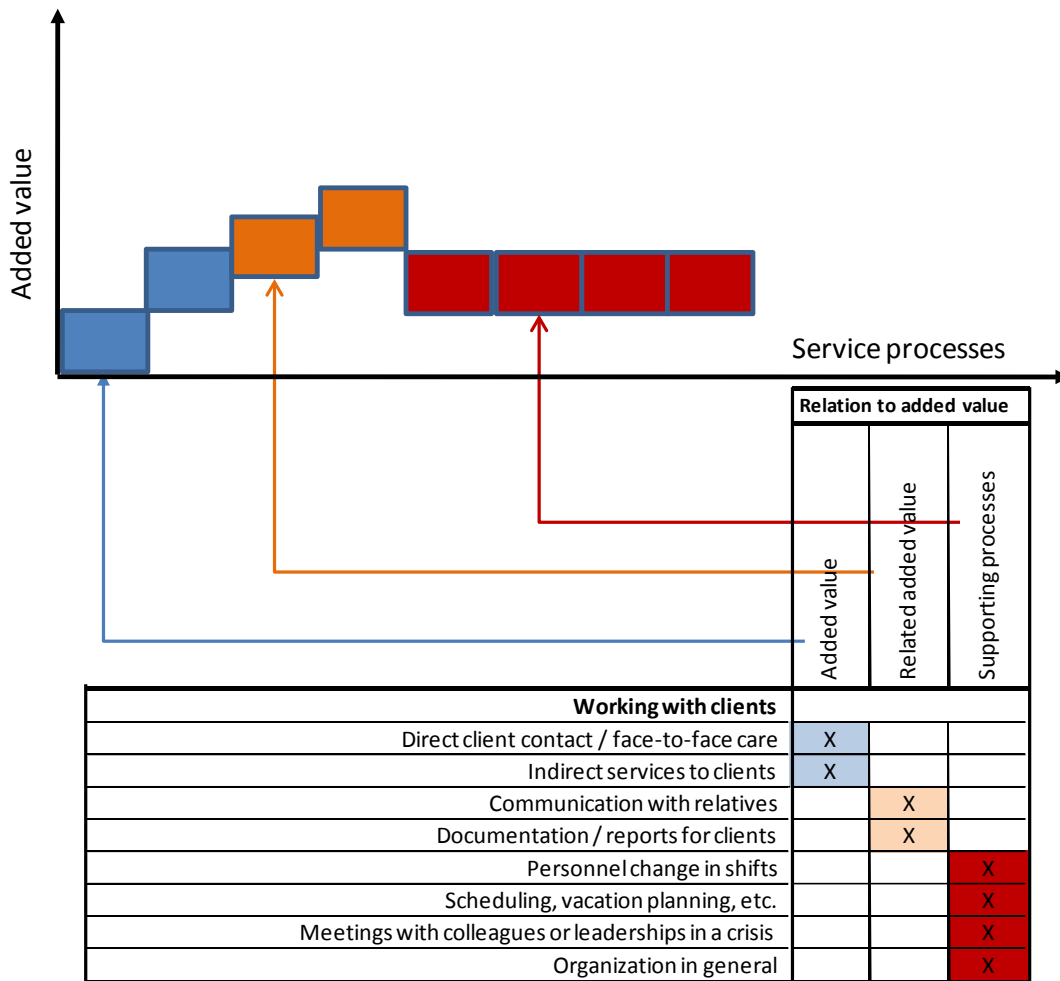

Figure 4. Mapping of care process steps with respect to their contribution to service added value.

The questionnaire survey took place before and after each intervention to reveal the effect of measures to support good coordination work and the dismantling of sub-optimal coordination work for the distribution of value-added and supportive related activities.

3 Empirical results

3.1 Pareto-Effect of coordination on interaction work (case 1)

We tested hypotheses 1 and 2 based on results of two in-patient units for persons with psychic disorders and mental illness.¹⁵⁸ The first questionnaire survey was conducted at a time when no measures had been implemented (baseline) yet. The second survey was conducted after the measures were developed and implemented. At this point, the process of the merger of the institutions was completed; the process of change thus had a defined beginning and a defined end. The questionnaire surveys were conducted in 2011 and 2012. Participation in the questionnaire survey was voluntary and anonymous assessment was carried out. 44 employees and managers were involved in the survey.

A total of 30 meetings were conducted between board, management and employees (and in different combinations of these groupings) as part of the OD-process. The organizational costs invested into the project can roughly be estimated as follows:

- Work time of employees: about 1,150 hours including pre- and postprocessing
- Work time of (middle) managers: about 165 hours including pre-and postprocessing

After the first questionnaire survey the following measures were implemented, which were supposed to support the restructuring of the organization.

¹⁵⁸The research underlying this empirical case relates to the joint research project 8iNNO, supported by the German Ministry for Education and Research (BMBF) and the European Social Funds (ESF), reference number 01FH09003.

Structuring of the overall team meetings' processes:

- Cross-divisional meetings for mutual information
- Organization of joint qualification for efficient competence development and mutual information- and experience discussion
- house newspaper

Structuring of the vertical communication processes:

- Implementation of company meetings
- Regulars' round-table meetings with managers
- Discussion of rumours in the change process, for example, in team meetings

The results of these measures in terms of the development of the working hours for coordination and interaction work are presented and explained below. Here, the coordination and interaction times of managers and employees will be discussed separately because the interactive, added-value work time of managers is naturally lower and the working hours for coordination work prevail.

The results from 2011 and 2012 reveal that both employees and managers show a reduction of coordination activities in favour of an increase of value adding activities due to the implemented measures and instruments (see above), as Figure 5 shows:

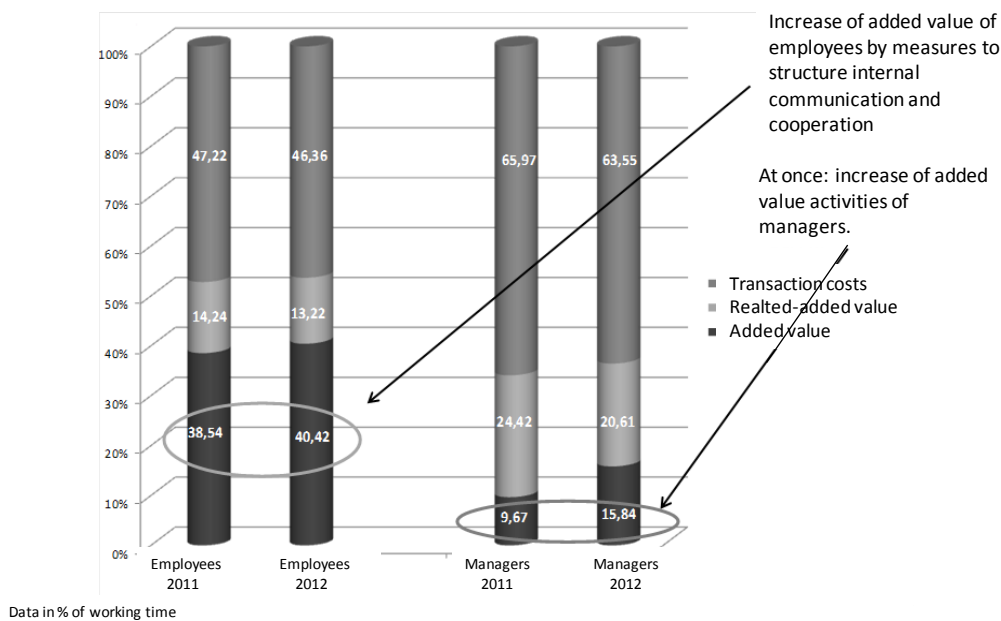

Figure 5. Impact on the cost structure of employees and managers in comparison to years 2011 and 2012 (case 1).

For employees, as well as managers, the organizational development measures lead to a noticeable change of coordinating activities (Fig. 6).

Figure 6. Development of transaction costs in comparison of the years 2011 and 2012 (case 1).

Of interest were also those working time percentages which were spent on unplanned coordination. These unplanned coordination activities were partially caused by negative organisational slack, as they arose due to the sub-optimal organization of the coordination work.

At the beginning of the restructuring process the employees and managers had a high level of unplanned coordination activities. New structures and routines had to be found, and employees were to be involved as often as possible. This led to an overall high degree of unplanned coordination, which leads to the point that managers needed almost 23% of their working time for coordinative activities (Fig. 7).

Figure 7. Development of transaction costs in comparison of the years 2011 and 2012 (case 1).

For the managers it became obvious that the measures to structure the vertical coordination processes led to a decrease of information asymmetries and to an increase in reliability. Unplanned meetings in the working process were transferred to planned structures and were less spontaneous. This process also resulted in a decrease of unplanned coordination for employees. Due to scheduled meetings, information could be passed promptly to all employees (and not through spontaneous meetings to just a part of the employees).

The empirical results show that the above developed hypothesis of rationalization potential is applicable in the area of coordination work. Efficiency achievements in the work process were obtained by an appropriate structure of the coordination work in the change process, and working time could be gained for interaction work with clients.

The payback out of invested organization costs can be estimated as follows:

Payback among employees: the redeployment of 1.88% of coordination on interaction work corresponds, on the basis of 42 employees participating in the questionnaire survey, to approximately 1,350 hrs. In relation to all employees affected by the change (60), a reallocation volume of approximately 1,930 hours could be achieved, assuming that the organizational measures apply equally to all employees of the merged residences. With an investment of approximately 1,150 hours in the OD measures a payback period of approximately 0.6 years can be calculated. Thus, after about 7 months, the investment in the organizational change has paid for itself as a gain in efficiency in the interaction work.

Payback among managers: the redeployment of 6.17% of coordination on interaction work (see fig 5) corresponds, on the basis of the two sets of executives involved in the questionnaire survey, to about 210 hours. When an investment of 165 hours in the OD measure is calculated analogously, in a payback period of 0.78 years, i.e. after 9 months, the investment has paid for itself.

The Pareto-effect of the investment in coordination work accounts for employees:

$$\frac{1,930 \text{ hrs. (time saved for interaction work)}}{1,150 \text{ hrs. (Invest in coordination work)}}$$

This corresponds to a leverage of 1: 1.68, that is, every hour invested in coordination work (for the present OD project) provides an increase of 68% in the interaction work.

for managers:

$$\frac{210 \text{ hrs. (time saved for interaction work)}}{165 \text{ hrs. (Invest in coordination work)}}$$

This corresponds to a leverage of 1: 1.27, that is, every hour invested in coordination work (for the present OE project) provides an increase of 27% in the interaction work.

3.1.1 *Routinization of coordination work in the process of organizational learning for the creation of new social services (case study 2)*

In hypotheses 3 and 4, we referred to a social service organization which was founded due to a specific need for pre-outpatient support in the local environment of an inpatient care organization. In the early days, certain sub-organizational arrangements had to be founded and established. The coordination of these services was carried out by part-time managers, and the interaction with the customers by volunteers. Many, if not all, issues of professional and organizational nature were brought to the part-time managers, which lead to time overloads. Structures and routines were still weak. The organization was in a constant process of organizational learning. By participating in a research project,¹⁵⁹ the organization was able to initiate a structured process of professionalization. Full-time employees established structures and routines and, inter alia, new patterns of cooperation have been developed, such as the establishment of local quarters.

At the beginning of the project, the organization had a high percentage of coordination tasks in relation to other comparable in-patient care organizations. The development, implementation and possible adaptation of routines, and the continuous innovation and organizational development process, led to a high coordination effort. Here, the respective phase of development was shown to be relevant for the scope of the coordination work that needed to be done. Besides the coordination between managers and employees, the coordination of organizational development, particularly in the time needed to create a social service organization was important. This coordination, a phase of "trial and error" will be shown in the following as part of the empirical study. Especially in young service organizations, coordination work is essential: structures and processes must be defined and possibly discarded if they are inefficient.

In order to map these phase-related developments of interaction and coordination work, a questionnaire survey was implemented as described in Case 1.

A first survey at the beginning of the project showed that a high percentage of total work time applied to coordinating processes. With an involvement of 15 full-time and volunteer employees a substantial percentage of the employees, in the organization were involved (Fig. 8).

¹⁵⁹ The research underlying this paper relates to a joint research project, supported by the German Ministry for Education and Research (BMBF), reference number 01FL10030.

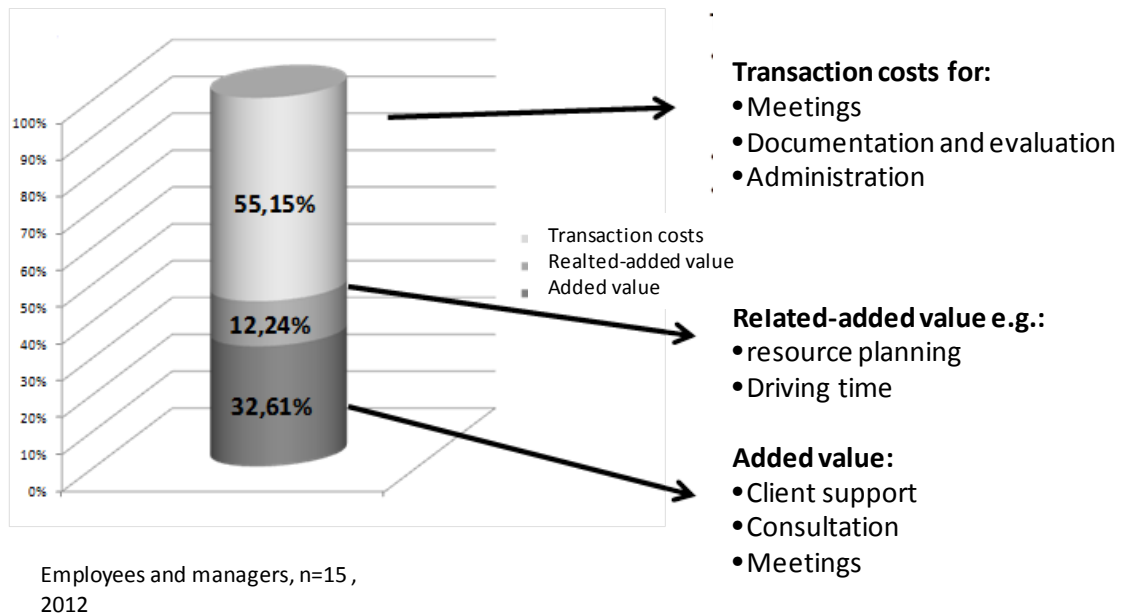

Figure 8. Percentage of work time for added value and transaction costs (Case 2).

As Figure 8 shows, more than half of the working time is spent on supporting processes, such as mutual coordination, but also for administration and organizational development processes. Compared to, for example, established residential care facilities this is a rather high proportion (Evers et al., 2013).

In addition to the proportion of coordinating and interactive processes, it was possible to distinguish between planned and unplanned coordination. The background is that unplanned coordination in the social services occurs quite often, because clients have spontaneous needs or emergencies exist. Nevertheless, this unplanned coordination exists to a certain extent because of suboptimal organizational design, for example, a lack of clarity about processes and decision-making responsibilities (see above). Such uncertainties are particularly not uncommon in the innovation and organizational development phases, as newly developed structures and processes have yet to establish organizational learning. In the organization under consideration here, there was a share of just over 8% of unplanned coordination in the work process.

To obtain suggestions for the improvement of organizational structures and processes, the reasons for unplanned coordination were included into the questionnaire. Results showed that various uncertainties appeared in the work process. So there was a lack of clarity about responsibilities and accountability, as well as unclear communication structures. Frequent demands and less structured opportunities for communication and information sharing in the work process resulted in a high percentage of unplanned work. Moreover, it was the aim of the organization to expand and develop external cooperation in the context of local involvement. For this reason, contact with various organizations in the local environment have been established. However, for this work a clear time window was lacking.

During the project, a gradual professionalization of the employees and the organization was achieved. There were not only established structures and processes for coordination of employees, but at the same time organizational development processes were initiated, which led to a further development and routinization of work processes and corporate structures. In order to better reflect the impact of these measures and instruments, the questionnaire survey was carried out again after about a year. The results of the second survey are shown in fig 9.

Figure 9. Results of implemented measures (Case 2).

As Figure 9 shows, the implemented measures and instruments helped to increase significantly the proportion of interaction working hours with clients significantly (Pareto effect). The objectives of the relief of the part-time managers and the structuring of communication within the team could also be achieved: the proportion of working time for meetings with employees declined, and the managers delegated tasks and responsibilities. Also, the share of mutual coordination with team colleagues was increased. Thus more working time for the coordination of external contacts arose, which increased local development. The percentage of unplanned coordination was reduced.

The results show that investments in routines and structures that counteract an "under-organization", initially lead to a high coordination effort, as can be seen in the first survey of 2012. However, these new structures, once they were established and recorded, lead to a higher percentage of working time for added-value activities.

In summary, the following effects of implemented measures and instruments were found:

- 1) Mutual coordination processes were systematized, which led to an increase in working time for communication with colleagues.
- 2) External collaborations were set up. The mutual proposals with external partners were consolidated. This led to an increase of working time for external communication and an increase in added-value activities that were closely related to customer-related communication with physicians, pharmacies and health insurance organizations.
- 3) This professionalization also related to the development of new business models, and to reach, for example, new customer groups. This also led to higher proportions of working time for quality management and for the development and implementation of new service concepts for different target groups.
- 4) The new structures continued to lead to increased working time for the advice and support of clients, and the working time components for interaction (added-value) were increased.
- 5) The overall result of the organizational development process was an increase of standardization as new structures and processes were developed within the framework of the project.

4 Resumee

Our investigation on the Pareto effect or to the leverage of good coordination work on interaction work (see Hypotheses 1 and 2) was confirmed empirically by the case studies. The leverage in this case of the OD project "merger" was 127% for managers and 168% for employees, i.e. an hour invested in good coordination work may gain 1.27 hours for managers and 1.68 hours for employees.

Our theses on the routinization of coordination work (see Hypotheses 3 and 4) were also confirmed by the 2nd case study (establishment of new social services). It turns out that the routinization of coordination work (decrease of unplanned coordination of 8.3% to 3.3%) led to a considerable professionalization of interaction work (increase from 32.6% to 49% percentage of work time).

From the examples presented here, an important message can be offered to social service organizations that derived from the presented examples: "Sharpen your saw regularly, and keep on sawing as this will lead to better results" Organizational development is worth it!

Building ‘glocal’ service networks for internationalisation and growth

Taru Hakanen, Tiina Valjakka, Outi Kettunen, Katariina Palomäki, Katri Valkokari

VTT Technical Research Centre of Finland

This paper brings together theoretical premises of service networks and entry modes used by companies in internationalisation. It explores how companies organise and manage so called ‘glocal’ service networks when combining global and local aspects in downstream service networks. This paper analyses three medium-sized industrial companies and their sales and distribution networks, identifies challenges that the companies face in building and managing glocal service networks, and outlines themes to be addressed with further research. Finally, it concludes emphasizing relational business practices when companies aim at internationalisation and growth via glocal service networks.

1 Introduction

Modern business models that follow the principles of service-dominant logic (Vargo; Lusch, 2008) have changed how the nature of business is perceived from transactional to relational. The change manifests itself in various, often complex service offerings wherein value is co-created in interaction among several suppliers and business customers within a business network (Gummesson; Mele, 2010; Jaakkola; Hakanen, 2013). Services play an important role as a source of specialisation in various global markets. Companies often adjust their service offerings to the characteristics of diverse local markets. Simultaneously, they aim for effective service processes globally. However, companies struggle to address the issue of how to combine *local* presence and the *global* dimension when organising and managing so-called ‘glocal’ service networks.

The trend of ‘servitization’ challenges the network models of manufacturing companies that operate globally. Multiple internationalisation paths and related entry modes are increasingly mixed (Rodriguez, 2007; Kontinen; Ojala, 2011; Ojasalo; Ojasalo, 2011), and companies may act downstream, towards the customer, via several distinct networks of agents, dealers, distributors, and other service providers. The external partners may be responsible for operations conducted locally such as sales, distribution, and after-sales work. Although global service business is commonplace in the business world, research related to the organisation and management of glocal service networks remains sparse. There is a need to study the phenomenon, along with the related challenges that companies face, and to build a research agenda for further, in-depth empirical research on the topic.

This paper brings together theoretical premises pertaining to service networks and entry modes used by companies in internationalisation. It explores how companies organise and manage glocal service networks along the downstream dimension for internationalisation and growth. The paper a) describes and analyses three medium-sized manufacturing companies and their sales and distribution networks and b) identifies the challenges that companies face in the management of glocal service networks. Finally, it c) outlines themes that should be addressed with in-depth research. In terms of the theory, the paper is intended to contribute to the research stream examining service networks by concentrating on downstream networks, which are rarely discussed in literature (e.g., Claro; Claro, 2010; Ehret, 2004; Kalafatis, 2000; Olsson *et al.*, 2013).

2 Theoretical background

2.2 Business networks in the downstream dimension

In addition to engaging in export via company-owned channels, globally operating companies commonly build and manage service networks consisting of several external service providers. The downstream (demand) dimension of business networks includes operations such as distribution, after-sales work, and other services. When one is considering the changes in the offering, it is important, therefore, to look at the demand and supply simultaneously (Holmström *et al.*, 1999; Hilletoft; Lätilä, 2012). Manufacturers need to understand and manage both the processes that create demand for their offerings and the supply network structure needed to meet those demands. It has even been stated that “the supply chain becomes the demand chain” (Christopher; Ryals, 2014).

The networked operations can be organised through various collaborative settings, such as business networks, alliances, and partnerships. A business network is a set of (at least three) connected actors performing various types of business activities in interaction with each other (Axelsson; Johansson, 1992; Halinen; Törnroos, 2005); alliances, on the other hand, involve detailed formal agreements (either equity or non-equity) between/among the business partners (Gulati *et al.*, 2012). In practice, companies may operate in several markets and use different network models accordingly. The networks may be composed of several agents, distributors, and dealers – actors familiar with the local settings of various markets.

A central challenge associated with downstream service networks is the need for companies to tackle the ‘glocal’ aspect of service business. They must simultaneously adjust and tailor their service offerings locally in response to the relevant market’s needs and characteristics and to ensure effective service processes globally with effective, generally standardised processes. How to organise and manage a complex set of downstream networks then becomes a central challenge if one is to succeed in global service business. Still, it is rarely discussed in the domain of service networks.

2.2 International entry modes among medium-sized companies

Entry modes typically refer to an incremental stepwise process of internationalisation. Sharma and Erramilli (2004, 2) define an entry mode as “a structural agreement that allows a firm to implement its product market strategy in a host country either by carrying out only the marketing operations, or both production and marketing operations there by itself or in partnership with others” (see Figure 1). Pan and Tse (2000) divide entry modes into two categories, the above-mentioned equity and non-equity, in view of the considerable difference with regard to investment requirements and control.

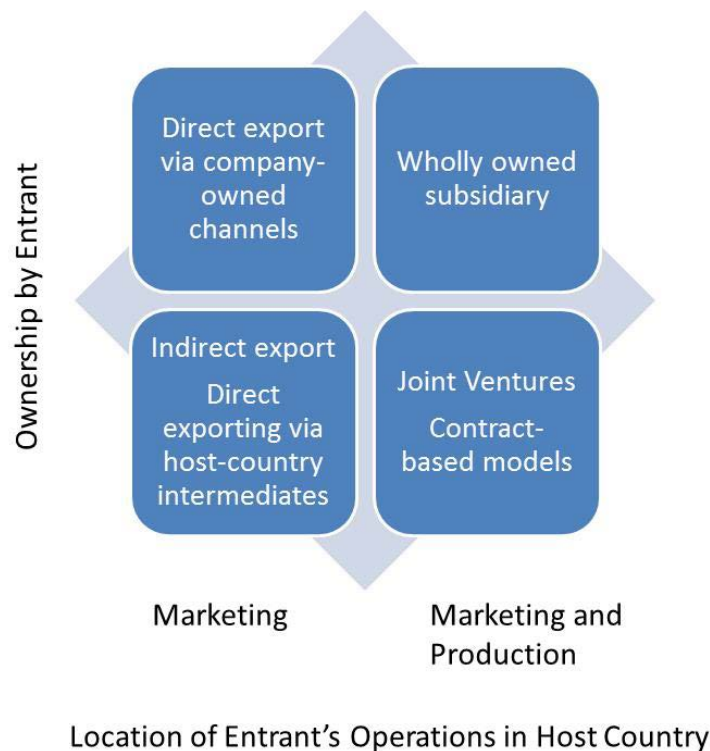

Figure 1. Entry modes by location and ownership (figure adapted from Sharma & Erramilli, 2004).

Research regarding international entry modes has gained increasing momentum among scholars over the last 10 years, and it represents the third most researched field in international management, behind foreign direct investment and internationalisation (Werner, 2002). Most of this research has studied large multinational enterprises (Canabal; White, 2008), although the entry modes of small and medium-sized enterprises have gained more attention recently. Prior literature has identified several internal and external antecedents (typically grouped into host-country- and home-country-specific factors) to the selection of an entry mode. Most of these studies rely on the transaction cost theory and focus on the economic factors that influence firms’ costs and benefits (Brouthers, 2002), although, for instance, the influence of cultural distance on entry mode choices and performance has been studied. However, the conclusions derived from empirical research represent no clear consensus on the effect of certain variables (Morschett *et al.*, 2010).

Johanson and Mattsson (1988) applied their network-oriented approach to the internationalisation of a company. According to it, a company internationalises by creating and maintaining relationships with counterparts in other countries in terms of a) international extension, b) penetration, or c) international integration and co-ordination. In other words, companies export directly to their customers, establish a subsidiary in another country, or manage a network of external partners. Coviello and Martin (1999) consider the selection between a) direct (i.e., based on wholly owned subsidiaries) and b) indirect (i.e., collaborative, network-based) entry modes to be central in the internationalisation of SMEs. Industrial service companies can also internationalise through direct and indirect channels (Grönroos, 1999). According to Grönroos, repair and maintenance services, for example, can be exported directly. A company may also export with a partner or establish a direct subsidiary in a foreign country. Indirect entries entail licensing, franchising, and e-commerce. Furthermore, Rodriguez (2007) emphasises that SMEs do not necessarily follow well-defined international strategies; i.e., more typically they move ahead through ‘trial and error’.

Clearly, companies' internationalisation has been extensively studied over the decades. However, the trend of servitization of industrial companies may still pose new challenges for companies, especially in comparison with the export of products. Services require special consideration of the local aspect, because they are undertaken in interaction between actors. For example, what kind of customer experience and value is expected by customers in various markets and cultures is an issue that has to be considered locally. At the same time, service processes must be designed to be smooth and effective globally. There is lack of knowledge of how to manage the 'glocal' aspect of service business through various downstream network models and of the types of related challenges that companies face in concrete business practice. The purpose of this study is to identify the challenges that companies face in the management of glocal service networks and to outline themes that should be addressed with further in-depth research.

3 Methodology

A qualitative, case-study-based design was selected as the research strategy for the study because 'how' questions were posed in this research, the investigators had little control over events at the companies studied, and the focus was on a contemporary phenomenon within a real-life context (Yin, 2003). The aim of the study, conducted in January–June 2014, was to increase understanding of a previously under-investigated topic (Gummesson, 2000). As the objective of the study was to support the ongoing servitization, internationalisation, and the related systemic change, joint problem-solving between industry and the research community was chosen for its execution. Researchers operated in close co-operation with the case-company representatives and gained in-depth insight via interviews ($n = 19$), themed discussions, and workshops.

Three medium-sized Finnish companies were selected as representative cases (cf. Silverman, 2006) on the basis of the research question: how do companies organise and manage glocal downstream service networks? Each of the case companies aims at growth in global markets, and their central interest is to develop their downstream service networks in order to achieve their strategic aims. All the case companies were already operating in global markets, although they differed in the extent of export and in the stage of development of their sales and distribution networks. Next, brief descriptions of the individual case companies are presented.

3.1 Case-companies

3.3.1 Company A

Case company A designs and implements compact industrially manufactured air-conditioning and heat-pump solutions as bespoke products for projects in several sectors, which involve office environments, hospitals, various industrial processes, electronics, and telecommunications facilities. Company A focuses on high-quality customer-specific solutions, and the projects typically include the design phase, not just assembly. That is, they cover the whole solution instead of single products. The strategic goals of Company A are to increase the proportion of international revenues and to increase the share of service business. All of their solutions feature remote monitoring possibilities, and the remote monitoring can be linked with various levels of maintenance services.

Company A started its international operations in the 90's. Nowadays, the main export countries are Sweden, Norway, and the Baltic States. The company has its own sales offices in Sweden and Norway, and local activities in the United Arab Emirates, the Baltic States, and Russia are carried out through partners. The path to the current situation is typical in that the company built its export operations little by little, sometimes also making side steps and learning from experience. The company have recently devoted significant effort to their most important export areas: In Sweden, they bought their long-term distributor's operations, and in Norway they established a local sales office. Along the way, they have tried export to countries such as Russia also, but sales volumes have varied. At the moment, the most significant efforts are being directed to the Middle East, where Company A has gradually taken a more intensive approach. They started with participation in, for example, the main industry fair in the area, after which they established connections with a local agent. At the same time, they performed many background studies of business in their field in the Middle East. They have hired a new agent, and plan to establish a subsidiary in the region.

3.1.2 Company B

Case company B is a manufacturer of arc welding equipment and a provider of solutions for highly productive welding in several international market areas. The offering includes physical products such as welding machines and barcode readers but also services such as consultation and training. The customers of Company B mainly represent the technology industry, business fields such as shipyard and offshore, transportation, and robot-based automation. At the core of Company B's strategy is strong expansion in global markets. To reach their strategic aim, they concentrate on the development of the solution offering, more effective channel management, and well-executed entry to new markets. Accordingly, development of the sales and distribution network is crucial for the competitive advantage of Company B.

Company B has operated internationally for decades, since nearly the beginning of the company's history. Nowadays, international sales account for around 90% of the production. Company B has its headquarters in Finland, and production and R&D take place in Finland and in India. Some R&D is conducted in China too. In addition,

Company B relies on a wide downstream network of companies responsible for sales, distribution, and repair and maintenance.

With Company B, the typical entry mode for a new market is through distributors. When the market is regarded as offering favourable business potential, a direct subsidiary is established. The subsidiaries take local responsibility for the business. They are in charge of the sales and distribution, and they manage their own stocks and the network of local dealers.

3.1.3 Company C

Case company C develops and manufactures machines for construction, multi-purpose machines, and utility machines for demanding applications. The company is a manufacturer of machinery and equipment for earthmoving, waterway, and environmental work and provides associated services. It specialises in production of machines for demanding conditions, and each machine is built in accordance with customer requirements. The main market area for Company C is the Nordic region, where the typical customer is a privately owned SME or an entrepreneur for whom the machine is the operation's primary investment. A different market segment is formed of larger customers, including public organisations involved in infrastructure construction and the maintenance industry.

The objective of Company C is growth and expansion to new markets. New areas are sought with focused spearhead applications and first with selected key customers. To support internationalisation and complement the offering, Company C recently acquired a business, where the product is more standardised and that already operates via a global dealer network.

The production facilities of Company C and most of its subcontractors are located in Finland and Sweden, which are the company's domestic markets. The operations in Sweden began some years back, after Company C analysed various acquisition possibilities and found a family-owned company there that was looking for a suitable new owner and 'home' for its business. Company C has its own regional salespeople in Finland, whereas in Sweden the sales network includes both its own sales company and sales representatives and independent dealers. Also, there are Norwegian dealers, managed by the office in Sweden.

One partner, a dealer, operates in all three of the Baltic States and has been collaborating with Company C since the 1990s. There are also collaboration partners in other parts of Europe, but sales there have been modest, on account of the economic downturn. In Spain, for example, sales and collaboration with a dealer started very well but ended when the crisis took hold in 2008 (large construction projects in Spain – for residential areas, highways, and even airports – are sitting unfinished). One designated target market is north-west Russia, where a project manager is surveying the market, customer prospects, and decision-makers for Company C.

Maintenance, repair, and spare parts are important services for all customers. The current maintenance network of over 20 companies in Finland was built in the last six years. The spare-parts network is a collaborative effort with another heavy machinery company. In other countries, the dealers are responsible for maintenance and spare parts. The main challenges in the development of sales and distribution at Company C are linked mostly to finding potential markets and building of global networks, since the existing network is small.

4 Results of the case study

The main challenges that the case companies face in internationalisation and downstream networking are as follows:

Entering new markets

- The investments necessary for entering a new market are relatively large for an SME. Hence, there is a need for adequate criteria and analysis, for selection of the most promising ventures for focus.
- Gaining references and trust in a new market. What are the global product features and service-offering requirements that create confidence in products from a manufacturing company, and how can these be identified?
- The brand is unknown. Building a global presence or even visibility in selected locations requires long-term marketing work and attending such events as industry expos.
- A company seeking a work machine wants to see, touch, and test the machine before making the decision. The presence of a demo machine may be a large investment thus conquering new market areas requires a lot of resources.
- There are many competitors, providing varying quality, and new competitors are entering manufacturing company's field from low-cost countries. Their positions vary with the market area. How can entry strategies be planned for the conditions of each market area?

Market and customer understanding

- The offering consists of solutions that bring long-term added value for the customers and also for the customers' customers. How can the company understand the value that the customers appreciate in each market area? What kinds of tools do the sales personnel need for demonstrating the total value that their solutions bring to the customers and the customers' customers in the long term?

- More knowledge is needed about customers, especially of end users and their current ways of working. The existing sales network lacks tools and examples for sales argumentation on the benefits, addressing how to compare this robust, productive, and versatile machine with other ways of doing the same work. Tools related to the offering require improvement, since each machine is tailored (e.g., looking at what new options there are to offer and which options are mutually exclusive).
- Companies lack real-time information about customers and markets when operating through dealers. How can it ensure knowledge flow from the customer interface through the dealers? How can it become familiar enough with its markets and customers when operating via a sales and distribution network?
- Decision-makers, buyers, and the end users are not a single entity; they may all be different actors. Also, this factor varies significantly from one market area to another. Identifying the right parties and approaching them with the right arguments requires good knowledge of the market structure and business culture.

Building downstream networks

- Finding the right collaboration partners is not straightforward, since a manufacturing company operates in a complex field with a large number of actors. With what kind of criteria and channels can the essential partners and those with the most potential be identified in each market, for purposes of ability to operate efficiently globally? How to find the 'right' people, in the right positions?

Organization and management of downstream networks

- Part of the sales and distribution network operates ineffectively, and sometimes the chain from the manufacturing company to the end customer is too long. How can the various sales and distribution channels be organised and managed in different markets?
- In part, the logistics and stock management operate ineffectively. How can the stocks be best positioned in global markets and logistics processes be managed effectively?
- Some dealers experience lack of information from the company. How can the company improve knowledge distribution and training? How can it make sure they have sufficient, real-time knowledge of the products and of the repair and maintenance procedures?
- There is a risk of not all actors within the sales and distribution network acting in accordance with the manufacturing company's brand and operation model. For example, cultural differences may pose an obstacle to coherent operation and customer experience. How can one guarantee a coherent operation model throughout the sales and distribution network yet still take into account the local characteristics of the market?
- More frequent communication between a manufacturing company and the dealer network is needed.

Competences and motivation of the networks actors

- Some actors in the sales and distribution network lack competencies that are needed as the product-based offering incorporates more services that involve software, solution selling and consultancy. How can the sales and distribution be developed in keeping with the changes to be undertaken for the solution offering? How can a company train the network actors and what tools should it use?
- Not all actors in the downstream network are as motivated in the sales work or the co-operation with the manufacturing company. The dealers typically represent several brands, and their motivation to sell the company's machines varies. The network-management personnel lack sufficient knowledge of incentive and motivation factors. How can the company manage, train, support, and motivate the actors in that network? How can it guarantee their value creation?
- Educating and training the network actors is necessary. The products of a manufacturing company are expensive, high-tech machines, and the sales, use, and maintenance of this machinery requires much technical knowledge, expertise, and experience.

5 Conclusions and research agenda

This study presents managerial insight into how companies organise and manage glocal service networks and which are the related challenges. Secondly, it provides a research agenda for further research. The three case descriptions show that the importance of service operations in the studied companies has grown remarkably. Accordingly, their local operations in different countries should be carefully considered when one compares and chooses entry modes and builds sales and distribution networks. Furthermore, the cases show that various internationalisation paths and related entry modes are increasingly mixed, a finding in line with current literature on entry modes (Rodríguez, 2007; Kontinen; Ojala, 2011; Ojasalo; Ojasalo, 2011).

Manufacturing companies; local end customers; and diverse intermediaries, such as agents, dealers, distributors, and other service providers, are the key players in glocal business networks (see Figure 2). The cases suggest, consistently with the service literature (Mathieu, 2001), that the glocal service business involves several third-party service providers, often specialised ones. Therefore, a need is evident for design and implementation of a business network within the downstream dimension if the company is to organise sales, distribution, and meeting the service demands of quite different glocal markets (Häkkinen; Kettunen, forthcoming).

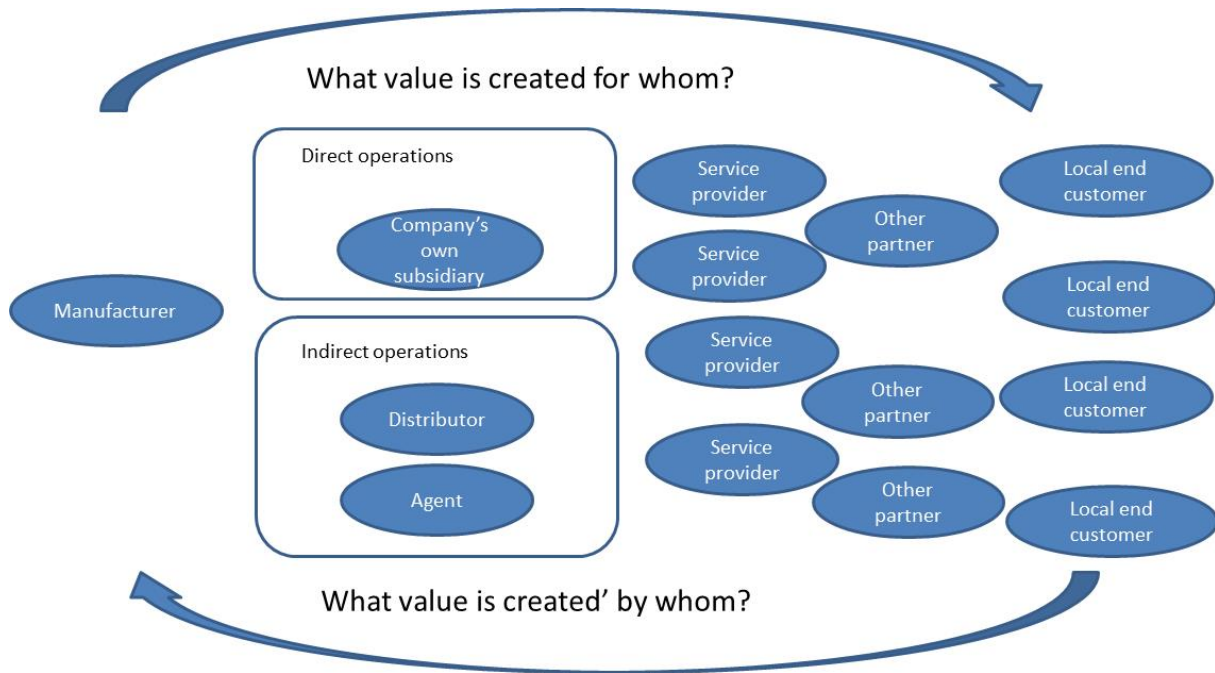

Figure 2. Mapping value co-creation in business networks in the downstream dimension.

It is important to understand the self-interests behind network-configuration choices and partner selection in varied market areas. Therefore, a network model (such as that in Figure 2) designed to map out value co-creation and exchange – i.e., both the value co-created for each actor and the value each actor provides to the others in the business network – could be utilised for further analysis of network configurations. Not all forms of value co-created for multiple actors can be directly measured in monetary terms: they may involve knowledge and other intangible value. Business network actors' commitment to networked operations is rooted in their perceptions about the present and future value added via participation in the network. At the same time, antecedents for networking such as complementary resources and strategic fit between product portfolios influence their choices related to the network.

Nevertheless, the level of commitment to the relationships is often more crucial than the presence of opportunistic behaviour in all of the various collaborative endeavours undertaken. Thus it is that **relational business practices** are needed for ensuring all parties' commitment by clarifying the mutual benefits and building shared understanding. In other words, it is more important to highlight the specific means that partners devise for implementing and operating the relationship that emphasise detailed agreement on goals, responsibilities, and the parties' rights.

Finally, as the result of this study, the following themes could be addressed in future research:

Selecting target markets and building downstream networks

What kind of analysis and criteria is needed in SMEs making decisions on internationalisation? How can one build a suitable sales and distribution network for various markets? More knowledge and tools are needed for finding the local actors that are the most suitable for collaboration in each stage.

Balancing between a coherent global brand and local requirements

How can a company build a glocal brand? A strong and well-distinguished brand supports internationalisation and aids the network with marketing and in building consistent operations. Simultaneously, the local offering often requires certain flexibility in the offering, arising from the needs of the dealer and/or customers.

Ensuring value creation for all actors of the network

How can a company motivate and engage the downstream network partners? This calls for understanding the various factors affecting their motivation and for finding the right incentives and a distribution of tasks that is optimal for the network.

Understanding the culture and motivation of the end customer

How can a company formulate glocal sales arguments? To serve customers properly, one needs to understand the local competition, the customer's business as a whole, and end users' day-to-day work environment.

Focusing on efficiency of glocal operations

How can glocal operations be standardised? There are areas where global optimisation is possible and profitable – e.g., in logistics services. Finding ways of combining local specifications with global efficiency is one balancing-oriented challenge.

Sharing knowledge and communicating

Which means of communication are appropriate for real-time following of changes in the markets and customer needs and of the service process? How can a company utilise new e-business solutions and virtual tools?

Continuously developing the downstream networks and collaboration

Buyers, users, salespersons, and other members of the network need to be trained (in new technology, the company's solutions, the brand, etc.). How to ensure continuous improvement and utilise the innovation potential of the whole network?

However, this study merely opened up the managerial side of the phenomenon and more research is needed on how to build and manage glocal service networks successfully. In order to create new theoretical knowledge on the topic, theoretical ground requires further focusing. In addition, the viewpoints of other network partners could also be included in research.

Green principles in SMEs innovation activities

Lea Hannola, Nina Tervonen, Saara Kaikkonen, Helena Virtanen

Lappeenranta University of Technology (LUT)

This study explores the effects and future possibilities of applying green principles in SMEs innovation activities. The most significant benefits of developing green innovations were identified such as an increase in revenues, improvement of competitiveness, costs savings, energy efficiency and respect from customers. However, the recognition of the benefits in the early phases of the innovation activities was seen to be challenging. The study revealed that the most significant and probable changes in the future are changes in customer requirements and new regulations and laws required by authorities, which will tighten and change business operations. These influence also on the development of SMEs green activities.

1 Introduction

Green and sustainable innovations are recognized worldwide as a significant part of a competitive business. With innovations companies aim to increase the level of competitiveness, market share, growth, quality, productivity and profitability. By green innovations companies also aim to maintain and advance the condition of the environment and to promote sustainability objectives. Green business means the reduction or prevention of negative environmental effects in business with the usage of clean technology, products, services and processes. This can also be referred as Cleantech business. Challenges related to Cleantech business in Finland are the incoherence of SMEs and a credibility gap in international markets caused by the small size. Especially SMEs and their business activities have strong effects on the growth of the economy in Finland. In addition, SMEs have an important role in European competitiveness by creating jobs, new business ideas, innovations and promoting entrepreneurship.

According to Hilke and Bos-Brouwers (2010), many large companies put a lot of effort on reporting and monitoring of sustainability, but in case of SMEs the amount of published sustainability reports remains very limited. This is due to the characteristics of SMEs, such as resource poverty and lack of public visibility, but also low general reporting priorities of SMEs. Despite of the different reporting activities, the sustainable innovations can bring advantages also for SMEs. According to Clements (2006), SMEs that have good environmental performance, also manage well and are financially the most successful small companies.

The previous literature identifies several benefits that greener ideology and development actions can bring to companies, such as improving company image, new market opportunities and improvements in environmental performance (see e.g. Ameer and Othman, 2012; Hilke & Bos-Brouwers, 2010; Ambec & Lanoie, 2008; Orsato, 2006). However, sustainable innovations are often considered as activities of large companies, and there exists several studies considering merely sustainable business of large companies (Spence, 1999). Characteristics of SMEs, such as the dominant role of the entrepreneur, resource poverty, focus on short term, flexible organizational capabilities, low degree of formalization and strong local/regional focus and customer need orientation, have significant effect on innovation capability of companies (Hilke and Bos-Brouwers, 2010). The objective of this study is to explore the benefits, requirements and possibilities of green principles in SMEs business and innovation activities. To address these issues, the research question of this study is “How green innovations are shown in the development of SMEs business?” The results of the study clarify the effects of green principles on the business and innovation activities of SMEs, and highlight the company- and industry-specific perceptions about the future of green innovations.

2 Literature review

2.1 Concepts of green innovation

Green innovation is a broad concept, which has several definitions in the literature. Terms such as green innovation, ecological innovation and environmental innovation are often used in parallel to determine the concepts of green innovations. Often used term is also sustainable innovation, which is seen as a broader concept including also a social dimension (Schiederig et al., 2012).

Chen et al. (2006) divide green innovation into “green product innovation” and “green process innovation”. In addition, according to Chen et al. (2006), green innovation can be determined as a hardware or software innovation, which means green products or processes including technological innovations related to energy-saving, pollution-prevention, recycling waste, green product designs or environmental management of a company. One way of deciding whether a technological innovation qualifies as an environmental innovation is to consider whether a new technology contributes to increasing eco-efficiency and/or improving metabolic consistency (Huber, 2008).

Fussler and James (1996) define ecological innovation as new products or processes, which create value for customers and business, but par excellence, reduce substantially environmental impacts. According to Beise and

Rennings (2005), environmental innovations are comprised of new or modified processes, techniques, practices, systems and products to minimize or avoid environmental damages. Environmental innovations maybe developed with or without the explicit objective to reduce environmental harm, and they may be also motivated by business objectives, such as profitability or improved product quality (Beise and Rennings, 2005). As a contrast to other innovations, environmental innovations may lead to the so called “win-win” situations, where both economic and environmental benefits can be achieved (Holliday et al., 2002).

In this study, we define the green innovations based on the previous definitions including characteristics from all of the presented terms. The use of the definition “sustainable innovation” was seen too wide concept for the purpose of this study. Due to this, in this study we use the term “green innovation” which is seen as a combination of eco-, environmental- and green innovation characteristics, considering also a bit of the impact of social aspects.

2.2 Green innovation activities in SMEs

Green business is shown in SMEs rather different than in large international companies. 96–99% of all companies are SMEs (OECD, 2005), and thus circa 64% of all emissions come from SMEs (ECEI, 2010). According to Noci and Verganti (1999), the specialty of SMEs means that they innovate in different ways to sustainable development than large companies. Innovation processes of large international companies differ substantially from innovation activities of SMEs, thus similar practices and theories do not work in all-sized companies. Different practices are caused because e.g. the owners of SMEs may often have a dominant role and companies are often focused on the immediate surroundings of the area (Bos-Brouwers, 2010).

According to Jenkins (2009), SMEs have better prerequisites for green innovations because of their flexibility and adaptability. However, the exiguity and lack of resources is a huge challenge when executing innovations in SMEs (Biondi et al., 2002). Jenkins (2009) points out that SMEs should see the exiguity of resources as a challenge that could be overcome with innovations, when the scarcity of resources is good for the innovation capability of a company.

There exist several obstacles and restrictions, which have to be overtaken in order to reach green innovation activities in SMEs. These restrictions are the scarcity of resources, e.g. money, time, technical know-how and knowledge, undeveloped environmental culture, high-risk and unsecure technology, lack of short term strategic thinking, information and knowledge. As the motivators to green innovation activities in SMEs is the pressure from stakeholders: customers, supply chain, consumers and environmental offices and legislations, cost efficiency, reduction of waste and avoidance of risks. By networking and increasing stakeholders are the means for improving the birth of green innovations. (Biondi et al., 2002)

2.3 Benefits of green innovation activities

The previous literature identifies several benefits that the integration of the environmental aspects to the development actions and innovations of a company can bring to companies. The society appreciates the investments to the environment, but among the public benefits, for companies the identification of company profits and other benefits is crucial (Orsato, 2006). The benefits of the development of green innovations include e.g. the product differentiation, improved company image and reputation, increased sales, creation of new markets, and return of investments. Among these benefits, the development of green innovations can lead to significant environmental performance improvements, and thus create benefits for companies but also to the society (e.g. Ameer and Othman, 2012; Hilke & Bos-Brouwers 2010; Ambec and Lanoie, 2008; Orsato, 2006).

The motives to the development of greener business can rise from urge to improve the cost-effectiveness and desire to differentiate the company’s solution from competitors’ offerings. In an optimal case, green innovations can be seen to offer more value to the customer, which together with the improved cost efficiency can increase the company’s competitiveness. (Porter & van der Linde, 1995) In the long run, especially for SMEs expecting to grow, it is important to ensure the sufficiency of resources and energy. By taking the green ideology to the innovation process of the company, can ease the long term planning and make it possible for company to increase the productiveness of the used resources. For forerunner companies green innovations can create benefits such as improved image, differentiation of competitors’ offerings and creation of new markets, which allow companies to set higher prize to their offering. These aspects can lead to higher revenues and help achieving competitive advantage. (E.g. Porter & van der Linde ,1995; Ameer and Othman, 2012)

On the other hand, in many cases the consideration of environmental aspects in product and service development processes can increase costs and thus reflect to customers as higher prices. The argumentation of the green innovation values for the customers is important but also very difficult. Also in the case of SMEs, the focus is often in the short term development actions, which according to Hilke and Bos-Brouwers (2010) often conflicts with the long-term focus and benefits of sustainable innovations.

Development of greener business can have significant effects on company’s economy. In the short term, new ways of acting, new technologies and products can decrease the company’s energy and material consumption. Also new market opportunities and the increasing demand of environmental offering can bring benefits. In that sense the green ideology have opportunities to increase revenues, but also decrease costs. (Ambec and Lanoie, 2008) By improving companies’ development processes, they have also an opportunity to improve the utilization of by-products (Porter &

van der Linde, 1995). By noticing environmental aspects and decreasing the environmental strain, companies can also decrease the amount of costs coming from environmental taxes, fees and environmental protection costs. It also lowers the risk of environmental accidents, which if occurring, can have significant impacts on small company's actions (Lovio and Kuisma, 2004).

Today, the pressure is on developing the condition of the environment and putting effort on protecting the environment. Putting an effort on developing the company's image is important and many customers, as well as employees, appreciate the actions, which enhance the condition of the environment. These actions and increased company reputation can also lead to increases in the motivation of employees. (Chang and Chen, 2013). Reforms of the operations may also raise the interest of investors and financial institutions who want to avoid financing risky businesses (Lovio and Kuisma, 2004). The life-cycle aspect is also one of the characteristic that connects to the green principles. Benefits of green innovations need to be examined through the whole life-cycle of a solution e.g. if solutions are easily disposable, it has an effect on total costs of the solution for customer (Porter and van der Linde, 1995). The benefits of green innovations to SMEs are summarized in Table 1.

Table 1. The summary of the benefits of green innovations to SMEs (e.g. Porter and van der Linde, 1995; Ameer and Othman, 2012; Hilke and Bos-Brouwers, 2010; Ambec and Lanoie, 2008; Orsato, 2006; Chan and Chen, 2013).

	<i>Direct</i>	<i>Indirect</i>
Short term benefits	<ul style="list-style-type: none"> • Reducing the energy and material consumption • Reducing the costs of environmental protection by new ways of action, technologies and solutions • Avoiding the environmental accidents • Safer products 	<ul style="list-style-type: none"> • Increased demand • Special (new) markets for green solutions • Decreasing the amount of by-products
Long term benefits	<ul style="list-style-type: none"> • Predicting the upcoming regulations of authorities • Ensuring the possibilities for growth • Enhancing the productiveness of resources 	<ul style="list-style-type: none"> • Developing the image of the company, reputation • Motivating the employees • Possibility of having an effect on upcoming regulations of authorities by being active • The interest of investors and financial institutions

2.4 Requirements of being green

The previous literature identifies different elements that drive companies towards the development of green innovations. Elements such as regulatory factors, market determinants and internal factors of a company can act as promoting or preventing factors of greener business (see Figure 1). How strong the impact of the characteristics of regulatory factors (such as strictness and predictability) is, depends on the adaptive capability of a company to external pressures. By predicting actions, companies can decrease possible risks and uncertainties. Competitive market situation drives companies to differ their offerings. Besides competing on prize and quality, the companies have noticed the growing attention and interest of sustainability issues and green innovations. In many cases, the most valuable green innovations offer benefits to customers and manufacturers, but also to the environment and society. (Bernauer et al., 2007)

Noci and Verganti (1999) identify two main drivers that drive SMEs towards green business: product and process environmental regulations and increasing social awareness of environmental issues. Especially for small companies, it is important to do preventing actions to fulfill upcoming regulations and emission limits. By being active, companies can also with their own actions have an effect on upcoming regulations of authorities (Lovio and Kuisma, 2004). For small companies, the informatics and effective bargaining with regulators is often easier than for large companies and SMEs are often less problematic to the government. This helps small companies in bargaining for special considerations and gives them room to propose green economic incentives (Scherer et al.,1993; Clements, 2006).

Figure 1. Background drivers for green innovations (Bernauer et al., 2007).

The size of the company usually has an effect on creation of green innovations. New regulations force companies to develop their processes and acquire know-how, which facilitates the development of innovations and improvements. This needs strong R&D activities, and in many times, large companies have more resources to use for R&D and environmental actions than SMEs. (Bernauer et al., 2007) In SMEs green innovations are usually process innovations which are developed to answer the new regulations. In many cases the bargain power of the SME towards their supply chain partners is also lower than in large companies, which makes it difficult to commit stakeholders into certain principles. (Noci and Verganti, 1999)

Implementing green principles into company actions is not an easy task especially for SMEs with limited resources. In many cases, the different environmental programs are quite comprehensive committing the whole organization. The changes usually need investments which can be significant especially for SMEs economy. Also the regulations and social pressure varies both geographically and between sectors, which can cause problems. (Noci and Verganti, 1999)

3 Research methodology

The objective of this study was to clarify the green principles in innovation activities of SMEs. The research approach of this study can be categorized as qualitative, where the data was collected by conducting semi-structured interviews in 12 Finnish SMEs. The companies represented different industries, such as industries related to the waste management, construction industry, mechanical and electrical engineering, and ICT industry. The average revenue of the companies was 10.1 million euros and the amount of employees was in average 33.6. Four interviews were made as phone interviews, one was a face-to-face interview, and seven interviews were conducted via email. The basic information about the interviewed companies is presented in Table 2.

Table 2. Information about the interviewed companies.

<i>Company</i>	<i>Revenue (M€)</i>	<i>Field of operation</i>	<i>Area of operation</i>
1	25	Construction industry	North-Europe
2	3	Industrial solutions	Worldwide
3	-	Stone refinery	Europe
4	13,5	Wholesale business of waste and scrap	South-Eastern Finland
5	3	Electro technical industry	Asia, Africa, Europe, Middle East
6	1	Waste processing technology	Worldwide
7	20,5	Construction industry, heat insulation	Finland and neighboring countries
8	33	Products of environmental technology: waste presses and balers	Nordic countries, Baltic, Russia
	10,3	Waste management	South-Eastern Finland
10	-	Production of electricity, wind power	Finland
11	0,95	IT software for energy and water companies	Finland
12	3,5	Environment industry, construction industry	Finland, Scandinavia, Russia, Middle East, South Korea

The interviews covered five main topics: 1) company information, 2) green principles as a part of companies' operations and innovation activities, 3) benefits of green principles, 4) requirements of green principles for a company, and 5) company- and industry-specific perceptions about the future related to green principles. This study concentrates especially on investigating and analyzing the current state, requirements, benefits and future perceptions of green principles in SMEs innovation activities.

4 Results

Green principles

In the first part of the interviews, the interviewees were asked to describe how green principles are shown as a part of their operations and innovation activities. Companies mentioned energy efficiency in their operations, especially focusing on energy efficiency in the manufacturing processes and the utilization of energy. Other green principles highlighted were such as the improvement of recycling, reduction of landfill, conserving water and chemicals, waste-free production, green raw-materials and the location of raw-materials near the production plants. Companies also pay attention to the raw-materials of their products, e.g. the re-usage of organic products or organic materials were mentioned. Some of the companies mentioned that their products save energy in their customers' business (energy-efficient construction), and in the biggest companies environmental aspects have been taken into account throughout the whole product life-cycle.

The results related to green principles in innovation activities were rather distinctive. The smallest companies, which have no innovation activities, had naturally nothing to share, but also the bigger companies had some difficulties to identify green principles in their innovation activities. Usually green values are seen just one part of innovation activities in SMEs. However, interviewees mentioned the development of processes and products more energy-efficient by means on innovations, disruptive-free operations and the development of electric security.

Benefits of green principles

In the second part of the interviews, the interviewees were asked to describe the benefits of green principles in their business. In general, the adherence to green principles was considered to be positive for companies and their business. The benefits of applying green principles mentioned were as follows:

- Enables the business growth or increases of the revenue
- Certificates have brought about best practices
- Effects in attitudes toward green principles
- Energy efficiency
- Improvement of competitiveness
- Competitive advantage
- Cost savings (e.g. decrease in manufacturing costs)
- Improved visibility and credibility

- General acceptance
- Positive customer feedback
- Customer commitment and satisfaction

One company highlighted the difficulties in measuring the benefits of green principles in the short term, but in the long run, they expect cost savings and an increase of sales when applying green principles in their operations. In the field of waste management, due to applying green principles as a pricing basis, it enables customers act more economically, e.g. when making it more expensive to leave the waste unseparated in a dump.

Requirements of green principles

In the third part of the interviews, the interviewees were asked to highlight the requirements of green principles in their business. In the case companies, there can be found very different levels of environmental know-how. In the biggest companies, environmental know-how is highly developed, and e.g. as a part of an orientation phase of new employees, there can be separate environmental training where environmental aspects of their products are introduced. However, a few of the companies mentioned that they do not have any environmental know-how.

Several companies mentioned that legislative factors are the most significant change in their operational environment that have effected on the green operations of the company. Many companies expect that there will be remarkable changes in the legislation, which will cause new effects and thus brings new changes to their business. Requirements and needs of customers concerning e.g. the amount of waste and cost savings are constantly increasing. The marketing of green values is also getting tougher and the justifications for green marketing are missing from some of the players in the field. In addition, marketing arguments are met differently depending on the geographical locations, e.g. in China the savings in water consumption is more remarkable advantage than in Finland.

Perceptions about the future

Finally, the interviewees were asked to describe company- and industry-specific perceptions about the future related to green principles. Most of the companies were satisfied with their current state of green activities. However, couple of companies brought up the fact that currently they have not received the level they want to be in the future, but development activities are already underway. The study also showed up that if companies want to keep up with the regulations and laws, it requires innovations in several fields. For instance, there are expected to come up clampdowns in the regulations of waste management in the future.

When preparing for changes in the future, one of the companies highlighted that the stakeholders will change and new kinds of cooperation models will develop e.g. with universities. A company mentioned that they are continuously investing in improving their operations, but positions themselves more like a quick adapter than an inventor. Companies also believed that requirements especially from customers are increasing, which drives them to change their practices in order to response the rising customer demands. Only couple of interviewees did not believe that there will be any changes related to green principles in their field. In general, the study revealed that the most significant and probable changes in the future are new regulations and laws required by authorities, which will tighten and change business operations, and in addition changes in customer requirements. Other trends related to green principles in the future were mentioned such as:

- Increasing demand for companies following green principles, e.g. ICT industry
- New regulations for applying green principles in public procurements
- The definition of “green products” is too vague and it don’t necessary have as substantial value in marketing in the future
- The measurement of carbon dioxide emissions in products will tighten and public notifications will be made obligatory, which makes green business more transparent
- The creation of new green products, services and the development of organizational changes are needed in the future.

5 Discussion and conclusions

Based on the results of the study, green innovation activities have not yet been considered and developed enough in Finnish SMEs. The results indicated that companies find it challenging to identify green innovation activities in their own operations. Green values and innovations were considered mainly as product innovations, but other innovation types (e.g. process or organizational innovations) were harder to identify, because the definitions are unclear and the distinction between an innovation and improvement is considered to be vague. Nowadays, green values are merged with several operations, which make the separate inspection of green principles rather difficult.

Also the level of an environmental expertizes varied between companies. In the biggest companies, environmental training is well developed, but some of the companies do not have expertise in the area or it isn’t considered to be necessary. Companies have used the know-how of various kinds of stakeholders, such as environmental consultants and the research conducted in universities. As a conclusion, SMEs which do not have enough resources to apply green

principles in their innovation activities, could utilize more the possibilities of their stakeholders, especially the utilization of their environmental know-how.

The increase of the revenue, energy efficiency, costs savings and respect from customers were identified as the most significant benefits of applying green innovations. However, the recognition of the benefits in the early phases of the product development was considered to be challenging, which makes companies to shun the investments to green innovations. Most of the benefits are seen not until in the long run, e.g. the financial benefits or the increase of reputation. Respectively, companies found it rather challenging to recognize the disadvantages of applying green principles in their operations. However, aspects such as increased purchase prices, diminishes quality, and the diversity and ambiguity of green values were mentioned.

Further, the studied companies found that the requirements are bigger than the received benefits of adapting green principles. One of the major drivers for developing green innovations is the legislative factors. Currently, Finnish SMEs act more as followers than forerunners in the area of green innovations. However, green innovations are found in companies, where the company's business is completely based on green business models. Also the customer demand of green innovations and sustainability is expected to grow. Some of the SMEs have sprung up from the need and customer demand of green innovations. Even though companies were satisfied with their current operations in the area of green principles, to keep up with the competition, companies saw that business development actions are needed in the future. This includes development actions in innovation processes, designing products and services as well as organizational changes. The concepts and requirements of green innovations are about to change in the future, therefore an interesting area for further research would be the identification of new possibilities of green innovations in SMEs and their capability to respond to these requirements.

Tackling the “unknown sustainability” with service design methods: two case studies

Hanna Hasselqvist¹, Cristian Bogdan¹, Ahrum Jeon², Anu Kankainen²

¹KTH Royal Institute of Technology, ²Aalto University/HIIT

In this paper we will present two explorative service design cases focusing on sustainable services in smart cities. After an introduction to our thematic area we will describe the two cases and the service design methods used. In the conclusion we will discuss the lessons learned from applying service design tools in collaboration with citizens and other stakeholders.

1 Introduction

Quite often “smart city” models are top-down approaches to optimize the consumption of primary resources (such as energy, water, materials and food) and other resources (such as time, money and space). However, “smart cities” do not exist without “smart citizens” that ought to be “smart consumers” (Giovanella; Baraniello, 2012). Moreover, “smart city” infrastructures are run by different representatives of organizations that are stakeholders in co-creating services for and with citizens. This does not mean that the stakeholders should be there to just educate “smart consumers” to behave according to sustainable policies (Giovanella; Baraniello, 2012) but rather providing sustainable everyday services experienced as part of quality of life.

In this paper we are looking at methods for designing such sustainable services. In our two explorative sustainable service design cases presented in this paper we have faced this challenge of integrating the top-down approach of optimizing energy and space consumption with more socially oriented approaches including also individual experiences. In both cases we have had a chance to try out several different service design methods and ways of collaborating with a variety of stakeholders relevant for our design briefs.

1.1 Sustainable service design approach

Service design as a means towards sustainability has, in recent years, received attention both in the private and public sector. Big companies such as DuPont, Hewlett-Packard Co, IBM and Xerox are moving from a product focus to a service focus for environmental, as well as financial, reasons (Rothenberg, 2007). ICT services are considered to have a great potential of reducing energy use in cities (Kramers et al., 2014) and participatory design methods can be used to create innovative and sustainable public services with and for citizens (Manzini; Staszowski, 2013). Services are of course not sustainable per se and service design methods have to be applied with all aspects of sustainability in mind in order to support sustainable service development.

The World Commission on Environment and Development defines sustainable development as development that “meets the needs of the present without compromising the ability of future generations to meet their own needs” and stresses that we cannot address environmental issues alone but only together with social and economic aspects (Brundtland, 1987). Therefore, working with sustainability requires a holistic perspective.

Our approach to sustainable services development is to apply user-centred and participatory design methods in the service design and to include sustainability as a permeating concern through the design activities. Participatory design has been described as a mutual learning activity (Carroll et al. 2000) and in our approach, sustainability is an object of learning between stakeholders through concrete representations of activities and artefacts. We will illustrate these principles with two service design cases.

2 Two cases

Both our cases include multidisciplinary teams that needed a shared vision in the very beginning while communicating about how sustainability can be incorporated into everyday life of the communities we were designing for, within certain technological frameworks.

2.1 CIVIS

The CIVIS project (2014-2016) is carried out by twelve European partners from seven different countries, with backgrounds in Computer Science, Telecommunications, Sociology, Energy and Economics. The goal of the project is to reduce energy use and carbon emissions in smart cities by leveraging on the potential of social networks and communities. This means combining local energy production and data on energy use from sensors in buildings with social interaction in communities and ICT services. A key challenge in the project is how to motivate people to behave more sustainably, and in addition to financial and environmental incentives, the project also focuses on social aspects.

In CIVIS we are designing interactive services for test beds consisting of apartment buildings owned by housing cooperatives in Stockholm (Sweden) and individual homes grouped as energy cooperatives in the Trento area (Italy) but at the same time keeping in mind how the services can be taken into use in other cities in Europe as well.

2.1.1 CIVIS design process

In the first stages of CIVIS we used a modified stakeholder mapping technique, internal storytelling groups, local (per test bed) creation of “user stories”, and “hackathon” events as service design means.

User stories and hackathons are our most important modifications to a traditional user-centred design process. User stories are narratives produced by project stakeholders to agree on a common vision. Hackathons are intensive design and implementation contests where people from outside the project are given energy and social data, user stories and other inputs and are asked to create service concepts.

The need for these changes comes from the way the project was initially specified, with not many resources allocated to exploring the design setting. Therefore we first started with the internal project team and only later included citizens and other external stakeholders into our vision work. The initial activities did not include any involvement of citizens and we needed buy-in from the other partners before engaging with people in the test beds. Instead, the initial focus was on using the methods to agree internally on a vision, create a common understanding of the contexts of the test beds and expressing individual research interests of the different partners. Agreeing on a common vision with twelve partners on a complex topic like sustainable service design was thus our main challenge.

Our next step is to increase the involvement of test bed stakeholders to further analyse the context, create and implement solutions, and test and evaluate our ideas. To add to the ideation phase we are also planning to arrange more hackathons as part of an iterative process. We will provide data generated by sensors in a couple of households to the participants via a prototype ICT platform, then test the best concepts and with the input from that adapt the data collection and platform.

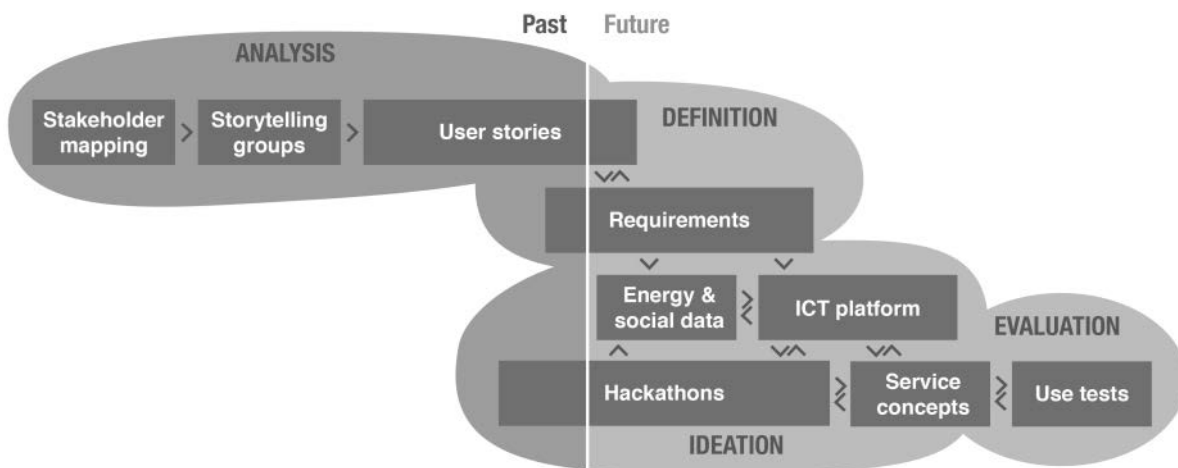

Figure 1. Design process in CIVIS up to now and with preliminary activities for the future.

2.1.2 Service design methods in CIVIS

Stakeholder mapping

In the very beginning of CIVIS project we asked different stakeholders from both the Stockholm and Trento pilot sites to draw a personal map illustrating people, organizations, artefacts and places relevant to the pilot site activities. We instructed the stakeholders in our face-to-face meeting to draw and write on their map how these different elements are linked to each other and what kind of value they create for them. Moreover, we asked the stakeholders to mark with red and write descriptions on the map if there were any obstacles for them to participate in CIVIS. This service design tool helped us to get an overview on what kinds of activities the different stakeholders have related to CIVIS sustainable goals. It also helped us realize that the two different test beds – Stockholm and Trento – have very different ecosystems that we will have to adapt our work to.

Figure 2. Stakeholder map by one of the participants.

Storytelling groups with internal experts

In order to create a shared vision among the partners in the multidisciplinary CIVIS project early on, we organized a use scenario workshop for all project members. In the workshop we applied a service design technique called *Storytelling group* (Kankainen et al., 2012) that combines narrative use scenario creation and focus group type of discussion. The purpose was to start an internal discussion on our project goals and find a common language to discuss about them. As an outcome of this workshop we got several narrative use scenarios for the two test beds. Moreover, in the discussion parts of the workshop we clearly had better shared understanding on our project goals and local energy use practices in the two pilot sites.

User stories

According to the project specification we were supposed to produce use cases as one of the first outputs of the project. However, we decided that use cases were too formal and too detailed, and were not grounded in test bed realities or in stakeholder interests. Instead we worked with narratives, which we in the project called “user stories”, including fictional characters of the test beds taking a number of actions to reduce their energy use and carbon emissions, and other actions that would lead to a more sustainable life and city. Since the test beds differ in many aspects we assigned the responsibilities of the stories to partners with good knowledge of the respective local context.

We continued with building on the draft narratives of the storytelling groups during workshops including only project members who are familiar with the respective test bed. For the workshops we prepared props representing the characters, the places they move between and technologies they might use. With the props the workshop participants drew up the stories of how the characters interact with each other through various tools and which behaviours this can address. The stories were written down and shared with all project partners for feedback, both written and during online sessions, in several rounds. With the stories we were aiming to create a tangible picture of what the project vision and the research interests of the partners would mean for the people in the test bed and their energy related habits and decisions. During the many revisions of the stories they went from being rather ordinary to being more visionary and better representing the goals of the project, with clearer descriptions of sustainable practices.

Figure 3. Creation of user stories during one of the workshops.

When the project partners had agreed on a few interesting stories we took them to citizen representatives in each test bed, such as energy managers from housing cooperatives. The energy managers have a high impact on decisions related to collective energy use, while they at the same time are citizens of the test bed. With the energy managers’ input we could further adapt the stories to the local needs, limitations and interests.

Hackathons

Even though hackathons are not usually considered a service design method we use it in CIVIS in order to get fresh ideas from outside the project team. The first hackathon, CIVIS Green Campus Hackathon, was organized at Aalto University campus in May 2014 with approximately 60 students participating. The aim was to create ICT applications and services utilizing energy data collected from campus buildings and social media data. During the two-day event the participating teams built a variety of ICT tools that could be used in the campus. The teams tackled everyday energy consumption issues related to living, working and studying in the campus area.

One team built a Tetris-like game for campus people to learn how to recycle waste in the campus area: which piece of trash belongs to which trashcan? Another rewarded team build a playful social media tool for sharing everyday activities linked with information about the user’s energy efficiency level. In the tool the users gradually build their own energy efficiency profiles and can compare that to other users or groups of users. For example, different teams in office buildings in the campus area could compete with each other.

Figure 4. Screenshot of the social energy tool that was built during the hackathon.

For the future hackathons we will give the participants access to household energy data similar to what we expect to have access to in the test beds, and focus on solutions based on that data.

Table 1. Service design methods in CIVIS.

METHOD NAME	DESCRIPTION	WHY IT WAS USED	POSITIVE ABOUT THE METHOD	NEGATIVE ABOUT THE METHOD	WHEN IT IS BEST TO USE
Stakeholder mapping	Stakeholders drawing a personal map that connects people, tools, places and organizations and describes how they co-create value and what obstacles they might have in their own value network.	To get an overview on different stakeholders and their role in the ecosystem	Provides a quick overview on what kinds of roles, activities and possible obstacles stakeholders might have in the ecosystem.	Without following interview the interpretation might suffer.	In the beginning of the sustainable project when learning to know different stakeholders.
Storytelling group with internal experts	Multidisciplinary, internal project team creating narrative use scenarios and participating in discussion on local energy consumption practices.	In order to set up sustainable project goals and having common language to discuss about them	Everybody can participate and contribute to use scenario creation and discussion from their own perspective.	The outcomes could be more visually documented for efficient communication.	With internal experts in the very beginning of the project.
User stories	Narratives including fictional characters using the technologies and services that may be distributed or developed later in the project.	For discussions with internal as well as external stakeholders on what should be implemented in the project.	Concretizes project goals and their effect on the users, and facilitates adaptation to the local context and culture.	It requires substantial effort of all partners to read all revisions of the stories and provide feedback.	In the first stages of the project while defining the project goals and requirements Reference in later stages, e.g. at hackathons.
Hackathon	Multidisciplinary teams of potential end-users design and build ICT tools to be used by their community. Best solutions are rewarded.	To get fresh ideas for sustainable ICT tools outside CIVIS project team.	Nice and fun ICT solutions were built that were very suitable for Aalto campus life.	The participants did not look beyond current technologies such as producing energy with solar panels in the campus but concentrated on technologies currently used in the area.	To quickly get implemented some ICT tools tackling local everyday life challenges regarding energy consumption.

2.1.3 Intermediary results in CIVIS

After the storytelling groups and many revisions of the user stories the project partners believed that the vision as well as individual research interests were reflected in the user stories. The stories turned out to be an important tool in concretizing the vision and in clarifying that social aspects can be both a means to sustainability (e.g. saving energy together or being motivated to behave more sustainably because of peer pressure) as well as a sustainable goal in itself (e.g. donate the savings from reduced energy use or increased local production to a socially good cause). Involving all partners in the design process also helped in creating a common understanding of the important particularities and differences of the Italian and Swedish test beds, which is crucial for everyone to properly adapt the project activities.

When creating and discussing the stories together with the project partners it became obvious that there were many things that we did not know about the test beds and that we needed to involve local stakeholders. Hence, by involving the project team in the story creation process we got the mandate to also involve citizens.

Figure 5. Illustration of a user story where collective saving efforts contribute to a social goal.

CIVIS is now moving towards a stage where more data and software (energy and social platform APIs) are available for hackathons to create innovative service concepts. As shown in Figure 1, we are using the hackathons also to improve on the CIVIS platform software, not just to produce innovative services for end-users.

2.2 SPIRE

The aim of our second case, SPIRE (2013-2014), is to create a flexible smart parking and guidance system that enables: 1) car users to find parking space and their way to a final destination with less time and energy spent and 2) parking operators, including real-estate owners, to manage parking spaces efficiently and intelligently. The technical core of SPIRE for collecting information is an event based software architecture linking data from different sensors and other sources.

In the project we looked into novel approaches that not only improve car users' parking and navigation experiences but also help car users reconsider taking the car by suggesting alternative travel modes. This required a very different approach from only supporting the user goal of "how to find a free parking space".

Although the SPIRE project involves a business model for parking operators and real-estate companies, in this paper we will share the process and methods that we used for designing SPIRE mobile app service concept.

2.2.1 SPIRE design process

The SPIRE project process rested on the double diamond design process (British Design Council, 2014) with four iterative steps of discover, define, develop and deliver, each step embracing various design methods.

Figure 6. SPIRE design process and used methods (adapted from British Design Council, 2014).

In the beginning, we focused on gaining a clear understanding of the contexts and people around parking and guidance information service. We conducted field observations, street interviews and a co-creation workshop with potential end-users. A benchmarking research trip to Korea was executed to study services and technologies that were similar to ours and to see how they performed in the market.

After the discovery phase we sorted, clustered and organized the collected data to find user needs and market opportunities. Many graphic visuals were created to share the data within the team and we were able to find insights and patterns that repeatedly emerged from the visual analysis.

The insights and ideas were developed further into concept ideas by adopting user-centred, empathic and holistic thinking. We focused on synthesizing insights by exploring the relationships and connections of stakeholders, contexts, and our service concept.

Before developing the SPIRE app service concept for a smartphone we created a paper prototype for user tests and feedback. Feasibility, usability, desirability, pleasurable and utility of the app were tested with potential end-users. It was useful to verify the main features of the concept and refine them.

The SPIRE app service concept is currently in the process of being prototyped as a mobile app version. When it is ready it needs to be tested in a real physical environment with end-users, because we believe that implementation is not the end of the service design but the beginning of a new step that requires co-creative and multidisciplinary approaches for long-term use of the service.

2.2.2 Service design methods in SPIRE

User journey map and idea generation

In the early stage of the SPIRE project, a co-creation workshop with 16 potential end-users was facilitated in Aalto University Otaniemi Campus. The aim of the workshop was firstly, to explore various experiences and identify critical touch points in users' travel journeys especially by car as their transportation mode, secondly, to find out what users expect and need when they interact with a service and lastly, to brainstorm ideas that could bring behaviour changes of car users. For these purposes the workshop had two sessions; user journey map creation and idea generation of a service.

In the first session in order to find out how users' travel experiences and behaviours were different when they knew their destinations well and they did not, each group created two travel journey maps, routinized one and un-routinized one. For example, for un-routinized journey, each participant in a group discussed their own experiences of visiting a conference or a meeting place for the first time. Especially they needed to specify how their experiences were like in the order of 'before – arriving – arrived - after' visiting their destination.

Figure 7. Workshop participants creating a user journey map.

In the second session, each group started to think about how to improve their current experiences and situations through a service, and drew or wrote ideas, needs and expectations on the created journey maps. The groups also had to think of ideas that can change the behaviours of car users. For the last part of the workshop each group presented their outcome, which led to more dynamic discussions and many new insights.

The co-creation workshop with potential users was a great chance to look into drivers' experiences, problems and challenges that they were facing during the whole journey. More importantly, it was clear that a routinized journey usually was accompanied by habitual behaviours of a user, but an un-routinized journey required the user's efforts from planning to finishing the journey. The overall results gave an opportunity for the SPIRE team to consider a service from the bigger social context with more dynamic users and stakeholders.

Persona creation and role-playing ideation

The SPIRE project involved many different types of potential stakeholders, but because of lack of time it was difficult to have interviews with all of them to explore their needs or challenges. For this reason, it was decided to look into concepts from the stakeholders' point of view through persona creation and role-play ideation. First, all the stakeholders around a service area were listed and then categorized into three groups: service receiver, service provider and authority. The service receiver group included everyday car users, sporadic car users and public transportation users coming to Aalto University campus either as everyday workers, students or visitors. Service providers included real-estate managers, parking operators and HSL (Helsinki public transportation service). The authority group included parking authorities, city planners and traffic planners.

Based on the stakeholder groups the team created fictional profiles of each stakeholder with background details such name, age, occupation and living status. For example, Kate, a 53-year-old woman, works in Nokia research centre (at Aalto University Otaniemi campus) as a senior researcher, lives in Espoo, commutes by car everyday and goes abroad often for work. Each team member was assigned 15 minutes to generate concept ideas from the perspective of a selected role that reflected the contextual intricacies of the stakeholder (e.g. "If I were Kate, I would like to book parking spaces for my visitors at work and invite them through an mobile app so that they don't have to worry about parking spaces."). The team then clustered the ideas and scored them while having discussions. The method promoted user-centred thinking and discussions on empathy among the team and enriched the quality and quantity of concept ideas.

Figure 8. Ideas based on persona creation and role-playing.

Service ecology map

In order to have the holistic view of the ecosystem of a potential parking and guidance app service, a service ecology map was developed. The map was designed in six zones of who, what, when, why, where and how with three levels of stakeholder groups around a potential parking and guidance app service.

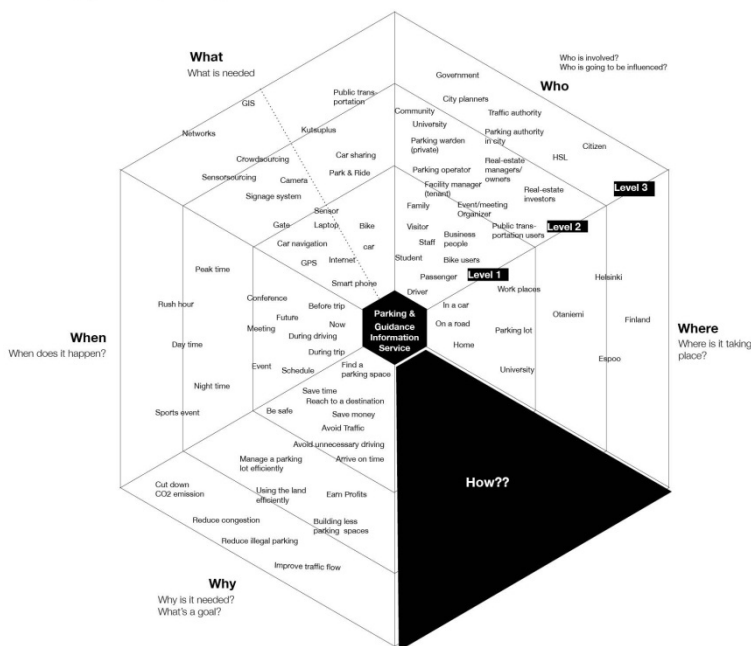

Figure 9. The service ecology map of SPIRE.

The development of the service ecology map not only helped investigate relationships of stakeholders and the service in a bigger context, but also helped make connections between different elements or services that normally would have been overlooked. As an example, park and ride service located between level 1, an automobile and level 2, public transportation could be one of the services reaching both needs of governments and car users, however, it is difficult for the first time users to utilize it without having information. So, the proposal was to include the parking and ride service information in the service concept so that the car users had more access to convenient public transportations with financial incentives.

The service ecology map was useful for the team because it presented the scope of the project by visualizing a series of levels that enabled the project team to focus in and out on the essential relationships of the service. By analysing the

service ecology map it was also possible to reveal opportunities for new actors to join the system and new relationships among the stakeholders.

Service concept scenarios

After narrowing down the SPIRE app service concepts, concept scenarios were created to share and refine the key elements of the service concepts with the team. There were two concepts proposed, and the main features of each concept were explained through potential user group scenarios having a series of situations in one’s travel journey.

Figure 10. Service concept scenario for finding car parking or choosing alternative transportation.

For example, one of the main features was that users needed to share parking space availability information with other users through the app when they arrived to a parking lot in Aalto University Otaniemi campus while using the app for free. The scenario described the whole process of using the information and sharing it with others through the app. Seeing each concept through scenarios helped the team communicate the essence of the concepts, identify hurdles and prototypes for future refinement.

Paper prototyping and user test

Before making an actual mobile app prototype of the SPIRE service concept, a paper prototype was created for a user test and feedback session. The paper prototype was designed as almost the same size of a smartphone, visualized the main functions of the service. Five regular car commuters to Aalto University Otaniemi campus and five visitors coming either by car or public transportation to the campus participated in the test. The test was conducted through one-on-one interviews in a research room. In the beginning, basic questions such as age, gender, everyday transportation modes and some information of their smartphone use were given to support validation of the test outcome. While going through the paper prototype, the participants explained whether the features and process were clear, the visuals were intuitive, and the functions were useful or not.

Figure 11. Paper prototypes used in the tests.

The results of the test were very useful for the team to reconsider some of the features and user interface design of the app. For example, many participants did not understand the meaning of the green-yellow gradation on the parking map (see Figure 12) while the team strongly assumed that people would understand it intuitively.

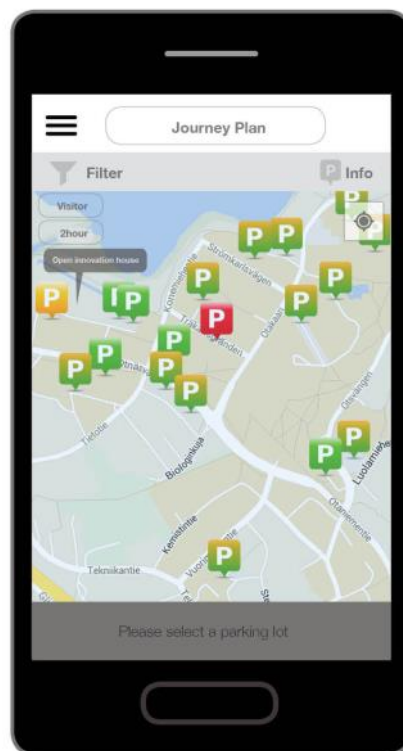

Figure 12. The meaning of the green-yellow parking symbols turned out to be difficult to understand.

Table 2. Service design methods in SPIRE.

METHOD NAME	DESCRIPTION	WHY IT WAS USED	POSITIVE ABOUT THE METHOD	NEGATIVE ABOUT THE METHOD	WHEN IT IS BEST TO USE
User journey map & idea generation	A Group of potential users create journey maps from their own experiences. After that, the users draw and write their expectations on a service generally and specifically based on created journey maps.	To explore user experiences and identify critical touch points in the user's travel journey. Also to find out what users expect and need when they interact with a service, and to brainstorm ideas together.	Everyone can participate in creating journey maps while sharing their own experiences. Shared experiences are easy to become a trigger of more dynamic discussions, which can reveal unknown needs.	More tools are needed for idea generation in order to support users thinking.	To understand users' various experiences and to gain insights from their needs and expectations in the early stage of the project.
Persona creation & role-play ideation (internally)	A project team creates personas, which are fictional profiles of stakeholders. Then, the team starts role-playing as if they are one of the stakeholders, which is one of the ways to brainstorm concepts that can take the team members out of their usual mindsets and assumptions.	To promote user-centred thinking and discussions on empathy, since the focus is on generating concept ideas that are of potential value to key stakeholders.	It enriches the quality and quantity of ideas and generates useful discussions among a team.	Team members should be more actively involved in role-playing.	To define and engage the different interest groups within and around a service. To think and generate concepts from another person's point of view.
Service ecology map	After collecting information about the key stakeholders and contexts around a service, a service designer maps collected data according to who, why, what, when, where and how, and get a holistic perspective of where a service exists and how it interacts with others.	To get a systemic view of the service and its contexts, which helps a service designer explore new opportunities and ideas, and establish the overall service concept by recognizing relationships around the service.	It can enable service designers to think beyond their ideas and see how the ideas fit into the wider context of people's lives and society.	It might be difficult to narrow down the focus area if boundaries are not set in the beginning.	In the early stage of the project, to get an overview of a complex system of a service and how the key stakeholders can work together in the wide context. To consider the sustainability of a service.

METHOD NAME	DESCRIPTION	WHY IT WAS USED	POSITIVE ABOUT THE METHOD	NEGATIVE ABOUT THE METHOD	WHEN IT IS BEST TO USE
Service concept scenarios	Visualizing and describing real-life scenarios as a series of situations that express how service concepts will be used by potential users in a certain context.	To explain key elements of service concepts, and to refine and develop concepts.	Seeing a concept as a scenario helps a team identify problems easily and support good communication and conversations.	There could be too many situations and scenarios generated even with one concept because of potential users and various contexts.	To facilitate storytelling and refine ideas. Also to support communications within a team.
Paper prototyping & user test	Before marking a real mobile app prototype of service concept, embodying a service concept in a paper version of mobile app. Then, going through the paper prototype with potential users through one-on-one interviews.	To get feedback of the overall service concept and specific functions. To test the basic usability of the app.	Results of user test and feedback are very valuable to develop a concept further.	User test and feedback session takes time because it should be done individually. Taking a test in a real environment (context) might bring more dynamic results.	To verify a concept or function together with end users, and to get unexpected feedback.

2.3.3 Results of SPIRE app service concept

The SPRIE app service concept supports two target groups with its functions. They are a staff group commuting to Aalto Otaniemi campus by car and a visitor group visiting the campus with different types of transportation modes. A staff group experiences routinized travel journeys that involves strong habits but less efforts while a visitor group experiences un-routinized travel journeys that involves strong efforts but less habit. For example, if a person goes to work everyday, they take the same transportation mode like a car, driving route, parking lot and even an entrance door at work. However, if a person has a meeting at a place they never visited before, it is useful to select the travel mode that ensures being there on time, no matter what travel mode habits one has.

Figure 13. Differences between routinized and un-routinized journeys.

The SPIRE app service concept has different approaches for these two groups. For a visitor group, the app helps plan one’s travel journeys from a starting point to an ending point with transportation mode selection, navigations and indoor

guidance service. The app compares selected travel modes by showing time, price, and carbon emission so that users can choose their travel modes based on their preferences. Especially the app includes available parking spaces close to one's final destination if a user selects 'a car' as travel mode. If there is no parking space available, one can easily select other travel modes through the app.

Figure 14. Interface for choosing travel mode.

For the staff group, the SPIRE app exposes them to opportunities to use public transportation by utilizing their car use habit. For example, by sending them a notice message through the app saying their usual parking lot at the campus is going to be full, they can either reconsider their travel modes or go to other parking lots a bit further from the work. Also, suggesting reconsideration of car use can be done through a campaign message. As long as the campaign has a meaning to the users, it seems that they are more willing to participate in rethinking their travel modes.

Figure 15. Favourites and notifications for the staff user group (left and middle) and a campaign message (right).

3 Conclusion

Sustainability is a complex issue, both when assessing existing practices and especially when creating possible future processes and practices such as within service design. Such “unknown sustainability” that is being designed presents important challenges to the project participants. Within our two cases we found that classic user-centred and co-design

methods that we employed are well fit for sustainable service design as in their case sustainability becomes one of the complex issues that the participants (from within or from outside the project) need to focus on. When such complex issues are properly introduced through examples and other concrete representations, stakeholders will start to engage with their complexity and take them into account in the creative process.

Since our two cases are very different, with a wide design brief in CIVIS and a much narrower project specification in SPIRE, the processes and selection of methods could not be the same. In CIVIS we first needed to work internally with agreeing on a project vision while in SPIRE we could start straight away with observations and end-user collaboration. Also the sustainability challenges in the two projects are rather unlike, but what the projects do have in common is the importance of outlining the “unknown sustainability” for each of the cases.

Concretizing the “unknown sustainability” perspective in the early stages of technology-oriented service design projects is needed in order to 1) focus the work of the internal project teams on the right issues and 2) finding a common language to talk about sustainability within a certain technological framework both internally and with end-users and other stakeholders. Based on our experiences from our two cases we summarise below our main learning points on how service design methods can facilitate this work.

We believe that service design methods can support good communication and discussions within a project team as well as with external stakeholders. It is because service design methods usually include maps, graphs, visuals or narratives that describe the complexity of contexts, stakeholders, systems or services. With a tangible output the methods can also support the team in finding *missing* aspects, such as in the case of CIVIS where the project vision (strongly focused on sustainability) was at first not properly incorporated in the user stories and not well understood by all partners.

In multicultural teams it is important to establish a good understanding of the place of the intervention and the people living there in order to be able to focus the work on the right issues. By involving internal stakeholders in applying the service design tools we all practiced thinking from the citizens’ perspectives and learned more about the test beds. It also became obvious that there were many things we did not know, and that we needed work closer with the local stakeholders.

While collaborating with stakeholders, internal or external, it is important to have an attitude of “listening openly”. As facilitators we should let the stakeholders or research participants guide the discussion towards what is important to them and our job is to create an atmosphere that triggers creative thinking.

Meeting in person to carry out the methods is not always possible in a big project with partners are spread out over different countries. It can be hard to receive useful input when sending documents forth and back and in CIVIS we found short online sessions to be a good complement to the documents. During the session we could discover and sort out misunderstandings, and new questions and ideas were raised. This, together with the workshops and meetings where all partners gathered, greatly helped us in concretizing the project’s sustainability aspects.

Employees and users as resource integrators in service innovation: a learning framework

Mervi Hasu¹, Marja Toivonen², Tiina Tuominen³, Eveliina Saari¹

¹Finnish Institute of Occupational Health, ²Technical Research Centre of Finland, ³Aalto University

In order to exploit the emerging opportunities in the marketplace or in society, service organizations are increasingly interested in new innovation models and effective innovative practices. The involvement of users and stakeholders is an essential aspect in these models. This is also the basis of the service-dominant logic (SDL). This framework replaces the traditional producer-centric view with an actor-to-actor perspective and considers the integration of resources an essential activity in the co-creation of value. Even though SDL has apparent implications for theorizing about service innovation, managerially-oriented research in this area is at an early stage. Product- and producer-centric practices and in-house R&D are still the focus of innovation studies, and they also dominate innovation efforts in organizations. The particular interest of this paper concerns the integration of user-based and employee-driven perspectives in innovation. The two perspectives have until now developed separately, the latter having very few linkages to the SDL discussion. However, grassroots level employees are in a key position as receivers of user insights and as collaborators with users. We suggest a new integrated approach by analyzing the user-employee interaction in innovation both theoretically and in two empirical cases.

1 Introduction

Continuous change, which is based on intensifying global competition and quickening technological development, is a central characteristic in today's economies. It has made rapid learning, i.e. the adoption and creation of new knowledge, an essential ability in organizations. Innovation activities have come to the fore and our understanding about the successful ways of carrying out these activities has deepened and become more versatile. In order to make innovation more efficient and effective, two developments are particularly important: the opening and the democratizing of innovation. The former is a result from the insight that organizations do not possess all the valuable knowledge in-house, but the utilization of external sources is necessary (Chesbrough 2006, 2011). The latter highlights that innovations do not emerge from expert groups only, but also emanate from 'non-experts' in communities of practice (Lave and Wenger 1991). In these communities, people learn with others while engaging collectively in creative efforts (John-Steiner 2000). Both views emphasize users, i.e., citizens, communal members, or service customers, as active agents (von Hippel 2005).

The earlier view on innovation focused mainly on radical technological inventions. Without broadening this view, the majority of service innovations and other intangible innovations would have remained hidden (Miles 1993, Howells 2004). Service innovations are not usually radical breakthroughs, but incremental in nature. Recombination of pieces of existing knowledge is typical. However, these small improvements may gradually lead to radical changes; hence neglecting them would be a serious mistake (Jensen et al. 2007). The pioneers of service innovation theory have pointed out that the cognitive inputs behind the individual outcome may be widely applicable, although the visible change would be minor (Gallouj and Weinstein 1997, Preissl 2000). The point is to reconcile the top-down managerial activities with the grassroots level activities that also include 'management' in the form of resource integration. This paper focuses on the resource integration carried out by employees and users.

In recent years, service-dominant logic (SDL) has become one of the most influential approaches in service research (Vargo and Lusch 2004, 2008). It suggests the adoption of an actor-to-actor perspective, instead of the currently dominant provider-centric view, in the analysis of economic and social practices. In this sense, it is in line with the user-based views of innovation. However, the proponents of SDL have focused more on the general economic development and everyday business behavior than on innovation. Connecting SDL with the broad view of innovation is a tempting perspective, but also a very demanding task.

We take a step in this direction: we examine and integrate the approaches of user-driven and employee-driven innovation and apply SDL and its 'neighboring' theories – effectuation and bricolage – in this framework. Based on the close linkages between innovation and learning noted above, we supplement our analysis with learning theories, especially with the theory of expansive learning (Engeström 1987). We argue that the actual interaction between frontline employees and users is a unique learning opportunity that organizations should utilize more effectively in the development of novelties.

We have structured the paper as follows. We start by reviewing the present discussions of user-driven and employee-driven innovation. Thereafter we summarize those points of SDL, effectuation and bricolage, and the theory of expansive learning, that we will apply in the creation of an integrative view about the role of user-employee

collaboration in innovation. We demonstrate the suggested framework with two case studies and discuss the framework's contribution to the theory and managerial practice of service innovation.

Please note that this paper in a shortened version of book chapter that will be published in “A Guidebook to Service Innovation” (Chapter 9) edited by Renu Agarwal and Willem Selen (eds.) (In press ISBN 978-1-4471-6589-7, Springer).

1.1 Perspectives on user-driven and employee-driven innovation in services – A need for an integrated view

Employees' and users' involvement has been considered fundamental in service innovation literature. This is because an innovator needs to understand a variety of activities involved in value creation linked to a particular service (Fuglsang and Sundbo 2005, Sundbo and Gallouj 2000). In addition to analyzing the service providers' activities, the interactions in the user interface and the users' activities that are not visible for the organizations are important to understand (Grönroos 2012). Users and employees are key actors in innovation because they co-create value in intangible service processes and thus have best knowledge of them. The perspectives highlighting their role are discussed in more detail in the forthcoming book chapter mentioned above. Here, we summarize only the main points in order to further our argument.

The point that organizations do not create innovations alone was first highlighted during the 1970s (e.g., von Hippel 1976, 1978). Later on, a large body of literature has indicated the importance of users for innovations; here, we refer to these studies as *user-driven innovation* perspectives (hereafter UDI). *Employee-driven innovation* (hereafter EDI) refers to “the generation and implementation of ideas, products, and processes – including the everyday remaking of jobs and organizational practices – originating from interaction of employees, who are not assigned to this task” (Høyrup 2012 p. 8, see also Kesting and Ulhøi 2010).

The studies show the importance of users' and employees' involvement and describe practices through which UDI and EDI take place. While this knowledge is developing rapidly, we recognize two research gaps. Firstly, UDI and EDI theories have developed in isolation from each other, as the focus is either on user-driven or employee-driven innovation. Even though studies show that many innovations take place in the user interface, only a few empirical studies provide insights into how users and employees practically innovate *together*. Secondly, even though grassroots level activities are viewed as important, they are not necessarily recognized and supported with managerial models. Without managerial support they may never transfer into replicable solutions (Fuglsang 2010, Brandi and Hasse 2012). Particularly management models that would integrate UDI and EDI are still scarce (Hasu et al. 2011).

Next, we will suggest several promising concepts for addressing these gaps. First, service-dominant logic (SDL) can provide a sound theoretical background for conceptualizing users' and employees' interaction in service innovations. Second, the concepts of effectuation and bricolage address situations where changes happen in an experiential way; even in circumstances of resource constraints, entrepreneurial employees and users can find innovative solutions based on ‘whatever is at hand’ (Baker and Nelson 2005, Fuglsang 2011). This viewpoint is especially relevant in public services, which face demands for cost-cutting and structural renewal. Third, the theory of expansive learning provides understanding of the emergence and development of these processes and helps integrate perspectives.

1.2 Service-dominant logic applied in the innovation framework

During the last two decades, the focus on use value has gained ground in innovation theories (Normann and Ramirez 1998, von Hippel 2005). This viewpoint is particularly suitable in the service context, in which it is difficult to think about value as inherent in specific outputs. A strategy based on the pursuit of use value is tightly linked to the pursuit of innovations: redefining the users' problems and discovering hidden demand, and providing users (or together with users, i.e. coproduction of value) solutions which they can make use and benefit in their everyday life (e.g. make vital improvement, achieve important goal, acquire anticipated change, enhance wellbeing etc.). When innovations are examined as new values, it is not enough to pay attention to individual services, but broader solutions and systemic changes are often under the spotlight. In these, the re-arrangement of existing items may be the core of innovation (Kim and Mauborgne 1999, Normann and Ramirez 1998).

Value-based analysis has much in common with the broad view of innovation (Kline and Rosenberg 1986, Lundvall 1992). In recent years, similar thoughts have been presented within the framework of service-dominant logic (SDL). As a service marketing -based approach, SDL is not directly linked to innovation theories. On the other hand, it aims to change our traditional thinking even more profoundly than any other theory towards the appreciation of users as central economic and social actors. Next, we first summarize the core propositions of SDL and then analyze its implications from the viewpoint of innovation.

In addition to its own theoretical postulations, SDL has analyzed and integrated views that are dispersed in various scientific ‘schools’ and disciplines, and which are relevant in the development of non-linear, user- and actor-based understanding of innovation. SDL-related approaches that are particularly useful are *effectuation and bricolage*. Next, we discuss the similar views of these two approaches on behaviors related to innovation in uncertain, resource-constrained environments. These notions can be used as a ‘bridge’ between SDL and innovation theories – regarding the theories on the management of innovation in particular.

Core propositions of SDL are presented in more detail in the forthcoming book chapter mentioned above.

1.3 Effectuation and bricolage as frameworks to tackle the uncertainties in innovation

How do people take action in uncertain, resource-constrained environments in order to innovate? Prominent theoretical perspectives on entrepreneurial action, particularly effectuation (Sarasvathy 2008) and entrepreneurial bricolage (Baker and Nelson 2005), suggest that instead of selecting between means to achieve a predetermined goal, in these environments individual entrepreneurs may rely on already available resources in identifying and exploiting opportunities (Fisher 2012). Effectuation replaces predictive logic with a *means oriented approach*, which begins from available resources and allows the goals to emerge in the courses of action. In line with SDL, it highlights that any given resource can be made more or less valuable and capable of producing long-term advantages: thus, what participants do with resources matters. *Expanding cycles of resources* characterizes effectuation, including the process of partner acquisition. (Sarasvathy and Simon 2000, Sarasvathy 2008). In iterative processes of *adaptive trial and error*, participants try out strategies that enable direct control, co-creation, and transformation of situations towards positive outcomes. Quickly realized *small successes and failures* help avoid the risk that some action would put the entire effort in jeopardy. (Sarasvathy and Kotha 2001). For the present study, effectuation provides means to recognize and understand the often messy potential of service innovation processes in the making.

Bricolage gives us a view of the *grassroots problem-solving practices of participants*. It suggests that when faced with resource constraints, employees may find innovative solutions based on 'whatever is at hand' (Baker and Nelson 2005, cf. Lévi-Strauss 1967). The participants create and combine their scarce resources in a novel way in order to develop some useful and novel outcomes (Baker and Nelson 2005, Fuglsang and Sørensen 2011, Salunke et al. 2012). Bricolage is a process of co-shaping an emerging path: participants offer inputs to generate a virtuous learning circle. The boundaries blur between design and implementation, and between rulemaking and rule following (Garud and Karnøe 2003).

Effectuation and bricolage both emphasize the significance of *individuals' actions and control over resources* (Fisher 2012). In order to explore how 'ordinary' interaction between employees and users can lead to innovations, we chose to use the concept of bricolage in the empirical analysis. Bricolage serves as a bridging concept between inherently abstract notions of UDI, EDI and resource integration. While being a theoretical concept, it is also a mode of individual practice which can be observed empirically. Bricolage incorporates contributions and resources of all participants in a given situation. Personal experience of bricolage, signaling the motive/need of an individual or a group, and the benefit that bricolage provides for meeting that motive/need, is often required for resource integration to begin (Engeström 2001a, also Baker and Nelson 2005).

1.4 Development of value co-creation: the theory of expansive learning

Practice-based (Blackler 1995, Ellström 2010) and situated (Lave and Wenger 1991) views on learning are especially relevant in the context of service innovation. New knowledge created in innovation activities is not only incorporated in new products, processes and services, but also in organizational practices; it is internalized by the people involved in the activity (Lundvall 1992, also Ellström 2010). Due to the intangibility of services, opportunities for unique value constellations may emerge during everyday service delivery, and the actors involved may improvise on the spot by creating and testing new tactics for value creation (Gallouj and Weinstein 1997). Service ideas are developed and elaborated in action without detailed a priori planning and new opportunities are rapidly used to revise the goals and value offerings (Toivonen and Tuominen 2009, Toivonen 2010).

As discussed above, service dominant logic, effectuation and bricolage all open up new perspectives on the *significance of multiple relations and activities* in acquiring resources for value creation in service innovation. We also acknowledge that these views inherently approach the idea of learning, i.e. the development of communities and capabilities related to new value creation (e.g., John-Steiner 2000, Miettinen 2013). The idea of resources as 'becoming' (Vargo and Lusch 2004) suggests that *resources emerge in social action*. Correspondingly, the argument that what people do with resources matters (Read et al. 2009) proposes that *people's context-specific actions* related to resources are significant. These views imply that integrating or expanding resources for innovation require concrete 'making': creative and laborious process in which contexts, participants, and relations are constantly being reconfigured in order to create new value.

Why and how would participants make the effort to reach beyond their known resources and capabilities in order to collaborate creatively (John-Steiner 2000)? This question is the interest of inquiry in the theory of expansive learning (Engeström 1987) which derives from the cultural-historical activity theory (Cole and Engeström 1993, Leont'ev 1978) and which is also closely connected to practice-based, situated and cultural theorizing of learning.

Expansive learning in a community begins when, during the course of activity, some individuals begin to question the current goals, patterns and norms, sometimes even the basic motive/need of the activity, and search for new practices. In some cases, this escalates into collaborative envisioning and a deliberate collective change effort at grassroots level (Engeström 1999, 2001a, 2001b), after which a new motive and expansive cycle follows. Engeström (1987) proposed this as a new form of learning: *expansive learning* of cultural patterns of activity that are not yet there, and which therefore involves *horizontal or sideways* learning and development (Engeström 2001a, 2001b). Hence,

actions in situations that require innovative solutions often take the form of improvisation and bricolage (ibid.). Individuals' and groups' transformative agency is at the core of expansive learning: a firm cannot be the subject of expansion. Therefore, *expansive learning perspective offers theoretical and analytical means to explore, in a nuanced way, the emergence and development of resource integrator roles and practices in service innovation.*

1.5 Integration of resources as a new perspective in innovation management

We suggest an integrative framework in order to better understand and enhance users' and employees' interaction, especially the integration of resources for co-creation of use value in service innovations. We apply ideas from three sources discussed above: service dominant logic (Vargo and Lusch 2004, 2008), effectuation and bricolage (Read et al. 2009, Garud and Karnøe 2003), and expansive learning (Engeström 1987). Together these theories tackle the following interrelated processes:

- (1) Practice-based emergence of motive, relations and capabilities related to resource integration and configuration (this involves opportunity recognition by experimenting with resources for tackling the unknown, i.e. what is not yet there).
- (2) Integration and configuration of resources from multiple actors (this relates to the actor-to-actor -perspective, the expansive use of resources comprising of users, employees, and other parties, and the ensuing creation of new resources).
- (3) Adoption or transformation of integrated resources for sustaining and diffusing/re-innovating the use value (effectuation through expanding cycles of resources).

The three interrelated processes can be seen as a dynamic development process or a temporal trajectory of resource integration and configuration. Expansive learning takes place – or needs to take place – across all these processes, but especially in the second and third processes. Shifts between processes are critical for the expansion to continue, as it does not necessarily proceed smoothly (Hasu 2000a, 2000b, Hasu and Engeström 2000). Figure 1 presents the focus of the present study and the linkages to its three theoretical backgrounds, hereafter formulated as *the learning framework of resource integration.*

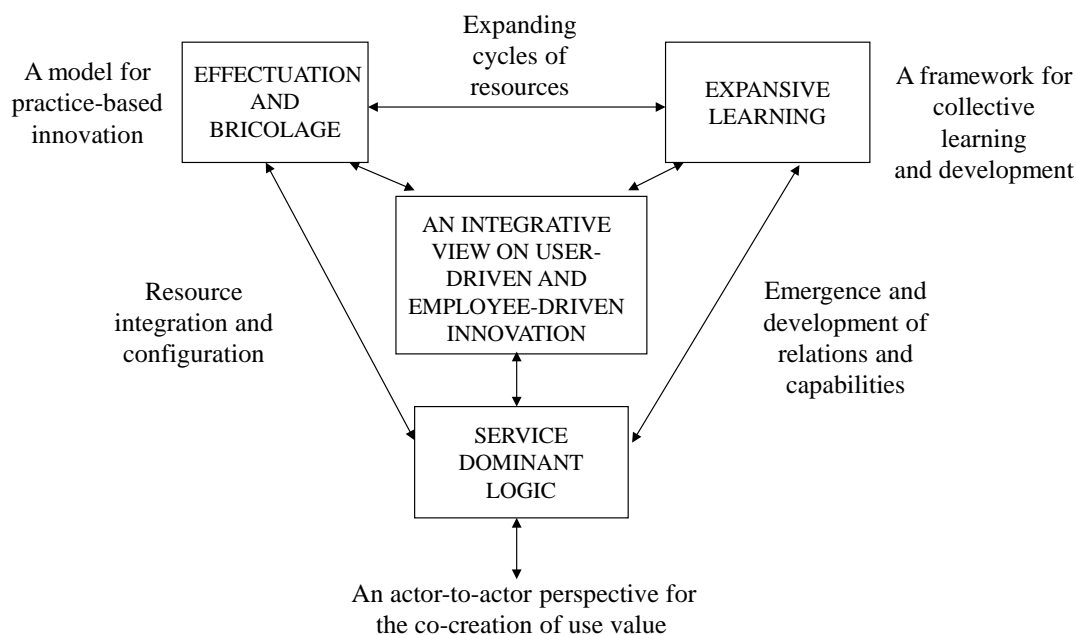

Figure 1. The focus of the study and the linkages to its three theoretical backgrounds: learning framework for resource integration in service innovation.

2 Learning-based resource integration in practice: Two case examples

We provide two in-depth case studies from the Finnish public sector to illustrate the developmental dynamics of the resource-integrator roles of employees and users in a resource-constrained environment. We apply the framework developed above and highlight these groups as 'practical bricoleurs'. Both case studies, *Elderly day club* and *Forest pre-school*, come from a middle-sized city in the southern part of Finland. Next, we present the analytical challenge, the data and the methodology used. After that we summarize our results as three phases of resource integration. In order to explore the role of resources of employees and users in micro level interactions, we apply the learning framework for resource integration developed above. The framework provides the analytical means to make visible the emergence of

various cultural resources and the expansion of these resources from one mode of activity or one participant group to another.

2.1 Data and the case study methodology

The data collected from 2011 to 2013 included thematic interviews of 4 informants involved with the Open day club for elderly and 8 informants involved with the Forest pre-school, each lasting approximately 1,5 hours. In addition, few on the spot interviews of managers, employees and users were conducted during participant observation. Interview themes covered the interviewees' perceptions concerning their prevailing – current and future – intentions, roles, practical tasks/duties, benefits and ideas related to the novelty under scrutiny. The interviews also included narratives about everyday life at the sites. All the interviews were recorded and transcribed. Field notes and reports were written during and after the observations. Also documents, such as planning documents, brochures, journal articles, webpages and a book, were collected from both cases.

Our case study included both the temporal and the social-material point of view of expansion, i.e. what actions had been taken in particular point of time, and what material and social resources had been used at that time (methodology of analyzing expansion, see Hasu 2005, 2000a). Among the *potential dimensions of expansion* (Engeström 2001a, Hasu 2000a), the *social-spatial* ('who else should be included?') dimension refers to the inclusion of employees, users and potential other parties as resource integrators in service innovation. It characterizes the interactional practice in the context in which resource integration takes place and new relationships are built up in order to create, sustain and spread a novelty. Accordingly, we aimed at examining and interpreting the temporal development of value co-creation in resource integration activities as social-spatial expansion. Our analysis was conducted in three phases. First, the development trajectories of both cases were written into rich narratives bearing the resource integration (of all the actors involved) in focus. Then, the trajectories were divided into three phases of expansion and finally, the elements in social-spatial expansion in each phase were investigated and considered in detail.

Please note that the following presentation of results is a shortened version from the forthcoming book chapter.

2.2 Results: development of resource integrator roles and the co-creation of use value in two cases

We identified three phases of resource integration and related roles in the two cases:

1. Origin and emergence of the resource integrator capabilities of employees (employee bricoleur)
2. Emergence of collaborative resource integration of employees and users (the most critical phase of expansion in the resource integration)
3. Transformation of resource integrator roles of employees and users

The findings suggest that the second phase is critical especially from the viewpoint of employee-user interaction. It opens up an insight into the previous and preceding phases of resource integration accordingly. Next, we will first describe both cases by briefly introducing the overall context, and then concentrating on the second phase of the resource integration.

Elderly day club: Emergence of collaborative resource integration of employee and elderly

This case describes a municipal service which provides the elderly with an opportunity for social interaction and stimulating social activities. The aim was to promote the physical, social and mental well-being of the elderly who were living on their own. The case illustrates how an employee, working as a facilitator of the elderly day club, together with the users, creatively integrated available human and material resources (her own and those of the users) in order to develop novel activities. The facilitator actively sought new resources by developing collaboration with volunteers and other groups. As an outcome, the elderly day club covered a much wider range of social activities than originally budgeted for.

In the first phase of resource integration, the responsible employee had learned how to gather and nurture scarce material resources to test her service ideas. However, a new service idea, carpentry workshop, was the outcome of collaborative resource integration. The engaged employee convinced the local manager that separate, dedicated groups were needed for men and women in order to keep men participating in the club. She made an application with an action plan, got a few rooms and acquired some funds and donations; when the workshop project started, she was the motor of the project.

Critical expansion in this second phase marked the emergence of collaborative roles of the employee and elderly users as resource gatherers and integrators. Because of scarce resources and without former experience of woodwork, the responsible employee asked the future users, i.e. the elderly men, to help finish the carpentry workshop facility. She 'hand-picked' a small group of recently retired men and collaborated with them intensively in gathering donations, materials and equipment from their personal and former occupational networks. The men were eager to help. Instead of being the sole bricoleur, the responsible employee and the elderly users became co-bricoleurs.

New activities, abilities and energy emerged in the participant groups. This resulted into rich production of crafts, which were then sold outside to get new funds for materials and trips. For instance, men renovated old furniture and donated them to the campus. The men's group sustained: more men came in and stayed. The most inspired participants recognized the unique potential of the service and volunteered to spread the activity. The responsible employee felt empowered as she succeeded and learned new competences.

The carpentry workshop project proved successful, and as the word spread, also the upper management recognized the work and praised it in public. Ideas of the elderly were heard and appreciated in the planning of the activities. In the third phase of resource integration, however, a major transition started in the organizing of many services for elderly, and the management's target shifted to systematization of all services instead of developing single services. The roles of the responsible employee and the elderly in the local campus changed: the employee was given a new assignment as a general coordinator of the elderly day activities in the city, and the elderly users adopted the role of facilitators of their own activities.

Forest pre-school: Emergence of collaborative resource integration of employees, managers, children and parents

This case study illustrates how a pedagogical novelty called Forest Pre-School evolved from a local service improvement in a children's day care center into a forest pedagogy concept covering the entire town. The first experiment was created by employees, and nurtured by several training occasions, contacts with foreign forest pedagogy researchers, and the forest surrounding the day care center. During a period of scarce financial support, resources and knowledge were actively sought from the parents of the children. However, spreading the local service improvement required help from the service director. The expansion of resources and ideas from the employee-bricoleur to the service director, and the resulting collaboration between them, served as a springboard for the wider diffusion and sustainability of the novelty.

In the first phase of resource integration, a nature-enthusiast local manager had encouraged her employees to integrate nature in their educational practices. She had asked one outdoor-hobbyist employee to plan how nature could be integrated to the early childhood education and even solve the shortage of facilities. The outcome of the ensuing broader collaborative resource integration was the forest preschool - with a hut in the woods - as a local attraction. Two employees made a plan, actively participated in the start-up, and solved many practical problems while organizing the educational activities outdoors. In the early phase, the group stayed only a few hours a day in the forest but later on they started to spend there more time to fully benefit from the idea. In spite of many practical problems, the employees persistently developed the nature-related educational activities outdoors, and stayed outdoors even during the winter.

Critical expansion in the second phase was the emergence of collaboration between employees, parents and children as resource gatherers and integrators. The children kept a diary on their nature observations, which formed a basis for learning and documentation of the novelty. The parents were welcomed to join right from the beginning and their occupational competences served as a resource in enriching the education. Especially fathers became enthusiastic collaborators: some of them joined winter-fishing trips and loaned their fishing equipment to children. Employees, parents and children became co-bricoleurs.

Pre-schoolers became active observers, explorers and bricoleurs of their surroundings. One of the two responsible employees became known as an expert of forest pedagogy, and started to write a book about the endeavor and to give lectures for early childhood educators. The other responsible employee became a skillful photographer of the nature and the pre-school activities. Fathers in particular became involved with early childhood education in a new way, and the residential area became attractive for families.

The local manager and upper management (a service director) reacted quickly to the needs of the forest pre-school group: for instance, a milk trolley was acquired in order to serve lunch outdoors. The local manager often acted as a partner in problem solving and bricolage. In the third phase of resource integration, one responsible employee, the local manager and the service director joined forces and started to spread Forest pre-school as a service concept in the municipality. All parties broadened their competences, but the capabilities and responsibilities of the individual employee expanded the most as she became an active agent in diffusing the substance of the novelty.

Summary of the two cases in the critical phase of resource integration

The cases have similar characteristics, but they also differ in some respects. The cases illustrate, first, that the ability for expansive resource integration between employees and users was actually rooted in the *preceding experiences of small successes and failures* (Sarasvathy and Kotha 2001) and *relations in the wider network contexts*, in which the motivated employees had learned to replace missing or incomplete resources with other available sources (e.g., Vargo and Lusch 2004, 2011). The employees had become bricoleurs, equipped with a work pattern of dynamic resource utilization and confidence on self-determining and creative problem solving.

Second, employees' *ability to recognize users' experiences, networks and competences* as meaningful resources was an important prerequisite for successful collaboration. Users were respected as co-bricoleurs, i.e. hands-on partners in service development. Inspired by a challenging opportunity, employees and users together collected and nurtured partial resources and combined them in a novel way. Through this laborious activity they built control over the idea and resources (Fisher 2012) that were meaningful and available for them. The service opportunity was materialized in new

facilities and equipment, and manifested in new supportive and rewarding relations (social-spatial expansion). Both employees and users learnt new capabilities and agency as they co-created new value.

The case examples also reveal the challenges in creating service innovations through bricolage: *the work methods were not replicable as such, as they depended on creative combinations of unique resources in the local context*. However, the features and principles of forest education were generalized, or as they themselves call it, productized (cf. Valminen and Toivonen 2011). This was not yet the case in the Elderly day club, as the managers were reconsidering the role of the service.

Third, the cases show that these combinations may involve different sets of actors and the lack of some actors' involvement can be replaced by others'. Here, the cases differed in some respect. In the Elderly day club, resource-integration became a shared capability between a single employee and the elderly users, while in the Forest pre-school, collaborative agency emerged within a larger community, which included employees, managers, children and their parents. In the Elderly day club, discovering the capabilities and social support of the elderly at least partially replaced the management's support. Constant managerial support was not critical, implying that learning and agency of elderly users as producers of their own services was strengthened. When the role of the employee later changed into that of general coordinator, the elderly partially replaced her as the facilitator at the site. In the Forest pre-school, on the other hand, the employees could not rely solely on children's own willpower. The broader community comprising parents and managers had to be mobilized for nurturing the novelty, which also strengthened the resource utilization from the very beginning. In spite of scarce and partial resources available in the two cases, both succeeded in expanding the novelty.

3 Summary and concluding discussion

The motive of our study derived from the observation that even though the resource integration perspective in the co-creation of value is increasingly discussed in the context of service innovation, producer-centric and R&D-based practices still dominate both innovation studies and practical innovation efforts. Although interest in 'lay knowledge' in service innovation has increased, research on grassroots users' and employees' practical activities and, in particular, their interaction in resource integration, has not attracted much research interest. In this paper we analyzed the user-employee interaction as a source of innovation both theoretically and on the basis of empirical cases. We aimed to contribute to this research gap and suggested *a new integrated approach* via combining several theoretical frameworks, namely, user-driven innovation, employee-driven innovation, SDL, effectuation and bricolage, and expansive learning.

We demonstrated the benefits of this framework in empirical analysis: it enabled exploring resource integration as a practical, dynamic activity which is sensitive to practice-based interaction and learning between users, employees and other potential stakeholders. Our study showed that grassroots-level collaboration between employees and users was critical in the development of the novelty.

This approach provides several contributions. First, the framework established a connection between *user-driven and employee-driven views of innovation*, both of which can be placed at the center of open and democratic innovation debates addressing widened participation and 'lay knowledge' in innovation from the point of view of resource integration. Second, the approach links *SDL with the theory of expansive learning*, which – supplemented with effectuation and bricolage – provides SDL with new analytical means to explore how, in micro-level practices, use value is co-created in dynamic processes of expansion. The integrated view therefore represents the *learning framework of resource integration*. Third, we applied SDL to study innovation in the *public sector* which is also a new contribution in the SDL field.

The framework also suggests theoretical and managerial implications. First, it has implications for the research and management of *service innovation processes*. Earlier research addressing co-creation have either focused on planned activities or on practices at the organizational level (Kowalkowski et al. 2012, Mele et al. 2010, Salunke et al. 2013). Our study implicated, on the contrary, the *significance of improvisational practice-based activities*. Effectuation and bricolage provide useful analytical perspectives for studying these activities. From a managerial point of view, effectuation and bricolage can be considered as alternatives for linear, predetermined managerial processes (Fisher 2012). Our cases indicate that these bottom-up managerial patterns do emerge also in the public sector, where renewals are traditionally initiated by policy or structural changes and managed top-down. The bottom-up practices enable the emergence of novelties by providing the employees not only with a frame for service but also with control over resources and freedom to use creativity. The *combination of frame, freedom and control of resources* supports the employees and users to utilize opportunities perceived.

Second, implications address fostering of *service innovation culture*. Our study suggests analytical and methodological means to understand the *nuances of practical contexts, actions and roles* in the emergence of new services. Recognizing the dynamics of resource integrator roles requires sensitivity from managers. Service employees and users do not necessarily recognize the innovative potential of their practices. In addition, they typically lack the time, motivation or capability to conceptualize their novelty in order to be able to transfer it from one context to another. A successful resource integrator needs to be able to expand his/her role and related interactions (e.g., Wrzesniewski and Dutton 2001). An essential managerial capability is that of being able to *identify the role of both employees and users in service processes*, and of sensitively *guiding the dynamics* of the resource-integrator roles.

Third, the implications of the research on *diffusion of service innovation* include the *view of resource integration as developmental process* in which collective, practice-based learning is critical. Prerequisites for the diffusion of the

novelty do not just exist there to be discovered by an outside party, but they are rooted in the preceding cycles of expansion: experiences of small successes and failures and relations in the contexts (e.g., Sarasvathy and Kotha 2001). A theoretical perspective able to analyze development is needed. From the managerial point of view, our study suggests *that the replication of novel solutions is a separate learning challenge which is often unrecognized, and consequently left unmanaged*. It requires that a broader group of actors learn from the novel value-creation processes. Managers may initiate these collective learning processes, if they are able to recognize the significance of a solution, and provide resources and support for subsequent developmental activities. Another option is to create a collaborative service culture in which service employees within and between organizations actively share novel solutions, and in this way gradually develop the services. Thus, although novel solutions often emerge at the customer interface, *a single employee cannot leverage the solutions without managerial support*.

Our study also suggests a few new directions for *further research* which we were not able to cover in detail, but which are connected to the implications discussed above. The current views on service productivity highlight that it is not enough to focus on efficiency of resource utilization, but the interactive process between the provider and the user and the impacts on the use value (effectiveness), have to be taken into account (Grönroos and Ojasalo 2004). The suggested theoretical framework contributes to this interactive view of creation of use value in service innovation. Further research will be needed to explore how the proposed learning framework of resource integration can be applied to study service productivity and quality.

Factors Influencing Organizational Purchasing of Knowledge Intensive Business Services

Eija-Liisa Heikka¹, Mekhail Mustak² (equal contributions)

¹Oulu Business School, Finland ²Turku School of Economics, Finland

Business organizations often purchase knowledge-intensive services from outside rather than making them in-house. However, not much is known about the reasons that influence the business customer's decisions to purchase knowledge intensive services. Thus, the purpose of this study is to explore factors that influence organizational purchasing of knowledge intensive business services. A qualitative case study is applied to gain multi-dimensional understanding of the phenomenon. Findings indicate that customers want a trustworthy long-term partner, which facilitates superior value creation through their knowledge intensive services. Service providers need to be alert for changes that happen in customer's spheres, and proactively match with those changes.

1 Introduction

In the business-to-business context, customer organizations often acquire knowledge intensive services from other organizations specialized in particular fields (Toivonen, 2008 Matthyssens and Vandenbempt, 2008; Kowalkowski et al., 2011). These services include management consultancy, legal assistance, computer and information related services, accounting and auditing, specialized training, advertising, and R&D services, just to name a few (Miles, 2005). These knowledge intensive service activities play crucial roles in developing and progressing the businesses of their customer organizations further (Bettencourt et al., 2002).

Often customer organizations already possess the necessary expertise and capabilities, or can develop them within a reasonable timeframe, to produce these service activities inside the organization. Some organizations actually choose to do so, whereas others prefer to source them from outside. These make-versus-buy decisions carry many important implications for both the customer and the service provider, including the focus and development of core competencies, organizational structure, necessary resources and capabilities, formation of business relationships, and revenue and profit functions (Valk and Rozemeijer, 2009; Fitzsimmons et al., 1998). However, extant literatures do not provide clear understandings on why some customers outsource knowledge intensive services and others refrain from doing so. In order to gain greater understanding on the dynamics and mechanisms of business-to-business markets, it is both academically and managerially important to explore and analyze the factors that lead firms to outsource knowledge intensive business services.

Previous researches have focused on various dimensions of organizational outsourcing and purchasing, including general conceptual developments (eg. Smeltzer and Ogden, 2002; Fitzsimmons et al., 1998; Webster and Wind, 1972; Sheth, 1973), factors that affect an individual's influence in organizational purchasing decisions (c.f., Kholi, 1989), length of time requires to make major purchase decisions (eg. Dholakia et al., 1993), effect of word-of-mouth on buyer's behavior (File et al., 1994), decision criteria and relationships (eg. Eriksson and Vaghult, 2000; Sonmez and Moorhouse, 2010; Lian and Laing, 2007), and use of information technology (eg. Ellram, 2002). Nevertheless, much of the existing literature on organizational purchasing focus on acquisition of tangible physical resources, and the knowledge is not always applicable to understand the purchasing of services from KIBS (Valk and Rozemeijer, 2009). Hence, not much is known about the factors that influence the business customer's decisions to purchase external knowledge intensive inputs to conduct business activities. Also, the issue of knowledge intensive business services has seldom been studied empirically. We aim to fill-up some of these knowledge gaps through this study. Therefore, *the purpose of this study is to explore the factors that influence the business customers to purchase knowledge intensive business services rather than creating the same themselves.*

By addressing the above mentioned purpose, this study provides improved insights into the factors that influence business customer's "make or buy" decisions regarding knowledge intensive services, and thereby extends theoretical knowledge regarding organizational outsourcing of business services. The factors have been examined in the context of modular engineering services, and thus allow generating context-specific knowledge. This study also carries practical implications. The customer organizations may find the study helpful to take more informed decisions on purchasing knowledge intensive inputs from other organizations, whereas the service providers can gain practical insights on the key factors that lead business customers to purchase their services.

This study is exploratory in nature. Therefore, it requires an approach that allows extending prevailing theoretical knowledge, and thus closing the gaps in existing literature to some extent. Accordingly, the study approached the phenomenon with an open frame, drawing on range of theoretical arguments to explore and analyze the factors influencing purchasing of knowledge intensive business service (c.f., Coviello and Joseph, 2012). 26 narrative interviews have been conducted to gather empirical data including both the customer and the provider perspective. Primary data collected through the interviews have been supplemented also with secondary data.

In the following sections of this study, a succinct review of existing literature on features of knowledge intensive business services as well as features of organizational purchasing is presented, followed by the description of the methodology of this study. The subsequent section presents the findings of this study. The last section includes further discussions in relation to the findings, the potential theoretical and managerial implications, and the limitations of this study.

2 Theoretical framework

In this study, we have used several streams of literature to understand the phenomenon under question, including conceptualization and development of knowledge intensive business services, and organizational purchasing. Below, we provide a short and concise review of the existing knowledge on these topics. However, bearing in mind that each of these topics are considered as distinctive research streams in their own right, we do not intend to provide any literature review with a broader scope, but limit our focus only on the relevant literatures.

2.1 Knowledge intensive business services – concept, development and characteristics

Knowledge intensive business services (KIBS) are service organizations whose primary value propositions include knowledge intensive inputs to the business process of customer organizations (Miles 2005, 39). The service offerings, or the service activities provided by these organizations, are complex in nature, are based on professional knowledge, and are mainly performed by people with formal and specialized training and education.

As suggested by Hertog (2000, 505), KIBS firms depend profoundly on professional knowledge, i.e., knowledge or expertise related to a specific (technical) discipline or functional-domain. The term was first used by European Commission the NACE classification (an European Commission classification of economic activities) to denote a specific set of service activities. KIBS have an increasing role of in our society, since they are growing fast, owing to changes in other sectors demanding knowledge inputs to deal with changing technologies and social conditions (Miles 2005). In spite of that research concerning KIBS is quite scarce compared to research concerning manufacturing organizations (Muller & Doloreux 2009).

The distinctive characteristics of KIBS are in the knowledge intensity of their value propositions or core offerings. Based on knowledge intensity, three principal features of KIBS can be identified: (a) their profound dependence on professional knowledge, (b) they either are themselves primary sources of information and knowledge or they use knowledge to (co) create value propositions or core offerings to support their clients' value creation processes, and (c) they are of competitive importance and serve primarily to other businesses (Miles et al., 1995). Knowledge intensive business services often need to be customized to meet the particular needs of business customers (Bettencourt et al., 2002), which is possible by the means of modularity. Also, by nature KIBS tend to be more technical compared to consumer services due to the greater complexity of organizational needs of the customer. This suggests that the factors that lead business customers to purchase KIBS offerings may differ depending on the services being purchased (Fitzsimmons et al., 1998).

2.2 Purchasing of knowledge intensive business services

The issue of organizational purchasing has been addressed mainly by three stream of research, namely economics, purchasing, and to some extent, marketing. Irrespective of the research stream, the literature normally emphasize on variables related to the task of purchasing itself, and has mainly focused on the "rational", economic factors. In addition, research on organizational purchasing focuses on issues such as emotions, personal goals, and internal politics (Drumwright, 1994). The purchases are influenced by budget, cost, strategy, and profit considerations, and involves multiple personnel in the decision making process with complex interactions among people and among individual and organizational level goals (Webster Jr. and Wind, 1972).

Academic research on purchasing of knowledge intensive business services seems narrow in comparison with purchasing to tangible items, including raw materials and finished products (Valk and Rozemeijer, 2009; Sheth, 1996). The unique characteristics of knowledge intensive business services influence multiple aspects of the purchasing process, as certain dimensions become more important or difficult compared to purchasing goods (Axelsson and Wynstra, 2002; Smeltzer and Ogden, 2002). In comparison to purchasing goods where the customer organization can create specific criteria and requirements, agreements concerning knowledge intensive business services are relatively ambiguous between customers and service providers. The quality of tangible goods is often pre-specified and measurable by the customers, whereas the measurement of service quality is subjective and user-dependent. Similar kind of differences can be identified in cost, pricing, delivery and payment between goods and services (Sonmez and Moorhouse, 2010).

Purchasing knowledge intensive services often requires considerable amount of information on various aspect of the service offerings, the service provider, potential risks, costs and benefits, and strategic options (Lau et al., 2003). Generally, organization purchasing is more risky than that of the consumer due to the high degree of cost involved and the potential effect on a larger group of people (Sonmez and Moorhouse, 2010). In addition, purchasing of knowledge intensive business services comprise even higher risks compared to basic and generic services due to the credence

qualities and costs involved (Mitchell et al., 2003). When compared with purchasing products, the main difference arise from expectations; quality; predictability of demand, cost, verification of contract completion, and payment (Sonmez and Moorhouse, 2010). Often in the case of knowledge intensive services offerings, it is difficult for organizational buyers to analyze value outcomes of the potential service activity in advance, or even after the purchase (Valk and Rozemeijer, 2009). In other words, it is difficult to determine the value-in-use of the offering beforehand, or evaluate the same objectively afterwards. When compared with purchasing goods, the main difference arise from expectations; quality; predictability of demand, cost, verification of contract completion, and payment (Sonmez and Moorhouse, 2010). In addition, business customers may need to provide input at several stages of the creation and purchasing processes of services, and hence they play multiple roles throughout the process, namely that of the co-designer, co-developer, co-producer, co-implementer and co-marketer of services (Aarikka-Stenroos and Jaakkola, 2012). The prospect of multi-role playing may increase the complexity of the purchasing process of knowledge intensive business services even further (Valk and Rozemeijer, 2009).

3 Methodology

This study is exploratory in nature. Therefore, it requires an approach that allows extending prevailing theoretical knowledge, and thus closing the gaps in existing literature to some extent. The study approached the phenomenon with an open frame (c.f., Coviello and Joseph, 2012), drawing on range of theoretical arguments to explore and analyze the factors influencing purchasing of knowledge intensive business services.

3.1 The Empirical Setting

The empirical setting for this study consists of one knowledge intensive service provider and four of its customer organizations. The service provider delivers modular engineering and consulting services. The customers are engaged in metal and chemical industries, water supply and security and support businesses. These customer organizations employ the knowledge intensive business services from this specific service provider for various purposes, including planning, implementation and supervision. This specific research setting has been selected due to the fact that the offerings of modular engineering services are highly knowledge intensive in nature, and therefore provide an in-depth understanding of the factors influencing the purchasing of knowledge intensive business services.

The service provider, referred to herein as ABC Engineering, is a large global service provider of modular engineering and consulting services, operating mainly on project basis. The first customer organization of ABC Engineering, referred herein as Steel, is a large global manufacturer of stainless steel. The second customer organization, referred herein as Chemi, is a large global chemical company serving customers in water-intensive industries. The third customer organization, referred herein as Water Pur, is an SME that provides water supply and the waste water drainage and cleaning. The fourth customer organization, referred herein as Secur, is an SME that provides a wide range of security and other support services. The name of the case company and its customers as well as all the interviewees were agreed to remain confidential. The research process of this study can be divided into two distinctive but interconnected and overlapping phases: data collection, and data analysis and interpretation.

3.2 Data Collection

The empirical data has been collected based on the five projects between the service provider and their customers, where the service provider has supplied crucial knowledge-intensive inputs. The main source of data collection has been face-to-face narrative interviews. Data has been collected from both the customer's and the provider's side with the expectation that it will provide complementary information about the total scenario, and also help in data triangulation (c.f. Aarikka-Stenroos and Jaakkola, 2012). In total, 26 interviews have been conducted over a period of 3 months. The interviews included 16 representatives from the solution provider, and 10 representatives from the customer companies. Table 1 in the next page shows further information regarding the interviewees and the respective interviews.

Table 1. Details of the Interviews.

Organization	Function	Firm Size	Interviewee	Date and Time	Duration	Place
ABC Engineering	Service provider	Large	Head of northern Finland	11.2.2013	57 min	Oulu, ABC Engineering
			Structural engineer	18.4.2013	60 min	
			Project manager	29.3.2013	73 min	
			Head of department	18.4.2013	53 min	
			Structural engineer	18.4.2013	58 min	
			Head of department	3.5.2013	40 min

			Group manager	27.3.2013	56 min	
			Head of department	13.3.2013	83 min	
			Water facility engineer	18.3.2013	63 min	
			Water facility engineer	18.3.2013	65 min	
			Design manager	5.3.2013	60 min	
			Structural engineer	6.3.2013	64 min	
			Design manager	11.2.2013	50 min	
			Group manager	13.2.2013	48 min	
Water facility engineer	16.3.2013	57 min				
Steel	Customer	Large	Foreman of ore line technicians	13.5.2013	36 min	Oulu, VTT
			Head of mining department	13.5.2013	39 min	
Chemi	Customer	Large	Oulu site manager	13.3.2013	61 min	Oulu, Chemi
			Professional buyer	13.3.2013	52 min	
			Manager	13.3.2013	80 min	
Water Pur	Customer	SME	Head of municipal establishment	16.4.2013	45 min	Oulu, Water Pur
			Structural engineer	19.4.2013	62 min	
			Manager of design team	18.3.2013	37 min	
Secur	Customer	SME	CEO	24.4.2013	103 min	Oulu, VTT
			Network manager		(joint interview)	

The interviews have been conducted based on open-ended questions and discussion themes, which provided several advantages: (1) not to limit the interviewee responses with predefined choices, (2) uncover the various factors leading to the purchasing of knowledge intensive business services not mentioned in the existing literature, (3) to raise matters that were not specifically queried. Thus, narrative interviews provided the formality to analyze complex phenomena, and enabled the emergence of unexpected issues. Each interview has been recorded with the consent of the interviewee using a digital data recorder.

3.3 Data Analysis

To start analysis of the empirical data, the recorded interviews have been transcribed first, resulting in 241 pages of written scripts. The empirical data was analyzed with classifying various recurring patterns in order to identify the variables that influence the purchasing decision of knowledge intensive business services, while also allowing new themes to emerge from the data. The analysis started by reading each transcript carefully to in order to obtain a first impression. Thereafter, each transcript was compared with the other transcripts.

Next, data which have been collected through secondary sources, for example, company brochures, meetings minutes and workshop details, have been compared with the preliminary findings. Some dissimilarity was identified there, which have been sorted out through cross-checking and cross-matching. In case of any confusion, the respective person from the companies has been contacted to ratify the issue. In the next section, the key findings of this study are described.

4 Factors influencing the purchasing of knowledge intensive business services

We have identified six different factors that may influence the business customer’s decision to purchase knowledge intensive business services from other organizations. One individual factor, or a combination of multiple factors, can affect the purchasing decisions.

4.1 Potential to Create Superior Value

The empirical data shows that business customers are interested to realize superior value in line with their business operations and strategies. Customers' perception of the probability of realizing additional value affects the purchasing decision positively. As it is reflected by one of the interviewees from a customer organization:

"The value proposition should be what we think is worth paying for --- if they get ten euros from us, we should get savings of twenty euros from something else." (Manager, Chemi)

If the customer's own analyses demonstrate that compared to developing in-house, outsourcing the knowledge intensive business services will generate greater value-in-use, they are more inclined to purchase the service offering from a service provider.

4.2 Individual Preferences

Organizational purchasing often involves multiple personnel in the purchasing process, and there are also complex interactions involved between people. The empirical data indicates that at a more micro level, certain actors play more crucial roles compared to the others. These people often hold the positions of power inside the organization, and their individual choices and preferences influence the purchasing decisions regarding the knowledge intensive business services. Also, it is possible that due to organizational systems and bureaucracies, certain purchasing decisions are made by specific personnel, whose options carry more importance than others. One interviewee from a customer organization indicated:

"When it comes to big enough amounts of euros, we talk to sourcing manager, who is located in Sweden. --- Purchases over 30 euros go to the sourcing manager. It will be discussed with the sourcing manager, whether to make the purchase or not." (Professional buyer, Chemi)

4.3 Perception of Quality

In knowledge intensive business services, it is not possible for the customers to evaluate the quality before purchasing the services. Therefore, customer's perception of the quality of the service is another important determinant of the purchasing decision. The Head of department, ABC Engineering emphasized:

"First, they check company references and they check personal references. --- Company does not do the work, it is the personnel who does it. If the personnel, that has references, has changed, it makes selling the project much more difficult."

The customer's perception of service quality is formed and shaped by multiple factors, including past experiences, the provider's reputation, and referrals from peer groups.

4.4 Geographic Proximity

The location of the service provider, and their spatial distance with the customer, can influence the purchasing decision. In case of higher distances, the customers often consider that service providers located in other cities or countries cannot serve them properly, as challenges may arise due to the distances in problem identification, service formulation, and appropriate implementation. As the CEO of Water Supp comments:

"We chose the service provider because of the location is within a reasonable distance from here."

Too long physical distances also hinder two important aspects of services: face-to-face interactions and after sales support. In situations like this, the customer often decides to develop the services internally rather than outsourcing the same.

4.5 Availability of Information

The empirical data suggests that purchasing knowledge intensive business services requires considerable amount of information on various aspect of the service offerings, the service provider, the potential risks, costs and benefits, and the strategic options (c.f. Lau et al., 2003). Empirical data show that if sufficient information regarding the service provider and their offerings are available which allow the customer to make relatively objective and informed decisions, the probability to outsource the solution becomes higher. Statement made by a professional buyer from "Chemi" supports this finding:

"If we need to buy something, we need to have really specific information. Technical people will gather sufficient information and then we use them to get an offer and then our internal people will possibly negotiate with the supplier."

4.6 Risk Perception

It became evident from the empirical data that organizational purchasing is considered rather risky venture especially due to the intangible nature of the offerings, the high costs involved, and the strategic importance of developing and implementing the service offering. The customer is more likely to source the service offering from outside if the risks are minimal in relation to the possible benefits. The service offering can also carry the potential of creating competitive advantage for the customer organization in the long run. Hence, the customer might decide to own the proprietary rights of the service, which will create barrier for their competitors to acquire very similar types of service, and thereby protect their competitive advantage.

4.7 Flexibility

The service provider offered modular engineering and consulting services to its customers. This means the service offerings of the provider are divided into smaller modules rather than a coherent whole, and different modules can be selected and united into various combinations to serve the specific needs of the customers. This modular nature of the service offerings made it flexible compared to the legacy knowledge-based service offerings, and increased the probability to serve the customers according to their requirements. This, in turn, enabled the customers to create the right kind of value-in-use. As the empirical data shows, for the customer organization, these kinds of flexibilities which meet dissimilar conditions are very much difficult to develop in-house, especially if they do not fit with the customer's core business. Hence, business customers tend to outsource the services from outside organizations.

5 Discussion

In order to gain greater understanding on the dynamics and mechanisms of business-to-business markets, it is central to explore and analyze the factors that lead firms to purchase knowledge intensive business services, which allow them to create and realize superior value. To achieve this, we have conducted a qualitative empirical study, which we expect to add to the existing understandings regarding the phenomenon and provide crucial context-specific knowledge.

According to our study, customers purchase inputs from knowledge intensive business services for six main reasons: potential to create superior value, individual preferences, perception of quality, geographic proximity, availability of information, and perception of lower risks. In case of purchasing knowledge intensive business services, the perception of service quality is strongly subjective. According to the findings, factors such as location of the service provider, neutrality, and the overall value proposition can play significant roles along with the price in making the purchase decision. Customers want a trustworthy long-term partner organization, the ones which may facilitate superior value creation through their knowledge intensive services. Findings indicate the importance of the service provider being on the same page with the customer, and delivering modular offerings supports the customer's value creation processes. In addition, it is crucial to be alert for changes that happen in customer's spheres, and act proactively to match with those changes. It became evident from the data that business customers are demanding and they might have urgent needs, which emphasize even more the important role of sensing opportunities and customer needs proactively.

5.1 Theoretical Implications

The importance of studying both organizational purchasing and knowledge intensive business services are supported in the existing literature. This paper may contribute to the literature through expanding the existing knowledge. From a theoretical perspective, this study provides improved insights on the factors that influence business customer's "make or buy" decisions regarding knowledge intensive services in the business-to-business markets. As the factors have been examined in the context of modular engineering services which have received relatively little empirical attention in marketing literature, it allows generating context-specific knowledge that contributes new knowledge to the current literature.

5.2 Managerial Implications

The study also carries crucial practical implications. The service providers may benefit from gaining practical insights on the factors that lead business customers to purchase their knowledge intensive services. In certain situations, the understandings can help to manipulate the factors in such manners that will generate favorable outcomes for the service provider. The increased understanding can also help to target marketing efforts to the right direction. The findings may also be useful to customer organizations to take more informed decisions on purchasing knowledge intensive inputs from other organizations.

5.3 Limitations and suggestions for future research

Although the study has been conducted in the context of engineering and consulting services, the factors that influence purchasing of knowledge intensive business services from external sources have been analyzed at a general level in this study, and suffer multiple weaknesses from these generalizations. It does not detail specific purchasing situations with

rich details to make the findings operational (c.f., Webster, Jr., and Wind, 1972). Also, the findings cannot be quantified at this stage without further developments. Nevertheless, the generalizations offer a reimbursing set of benefits.

The findings provide an overall perspective on organizational purchasing, which allows evaluating the importance of specific variables, leading to greater insights into the antecedents of organizational purchasing of knowledge intensive business services. Geographical boundaries imposed another limitation to this study. The empirical data have been collected only from Finland, thus making it harder to generalize the findings to other geographical contexts. Data collection only from engineering service providers and their customers also create similar challenges against generalizations to other services.

In our findings we discovered that there is need for future research concerning market sensing, which is very essential for anticipating opportunities and changes in the markets that influence purchasing decisions of business customers. Anticipating these changes proactively enables service providers to adjust their procedures, processes and offerings to correspond to those needs.

Netnography in marketing research: A review and recommendations

Kristina Heinonen, Gustav Medberg

*Hanken School of Economics, Centre for Relationship Marketing and
Service Management*

The purpose of this paper is to systematically review the use of netnography in marketing research and propose recommendations for use of the method in future marketing studies. A total of 193 articles published between the years 1997–2013 were systematically identified and collected. In a following filtering process, a final selection of 149 articles was chosen for further analysis. Our review reveals that marketing researchers increasingly use netnography in a variety of ways across different marketing research contexts and topics. We also see many future opportunities for netnography in, for example, service marketing and business-to-business research. The study outlines and discusses theoretical, empirical, and methodological issues and opportunities associated with netnographic marketing research.

1 Introduction

In recent years, the interest for the qualitative method of netnography has increased tremendously among marketing researchers. The Internet enables researchers to deepen the understanding of consumers' lives and experiences for example in online communities (Kozinets, 1998; Puri, 2007; Helkkula; Kelleher, 2010). Consumers are increasingly active online and the boundaries between the online and offline worlds are blurring, and online consumer behaviour is highly transparent and permanent. Netnography has been acknowledged within the field of marketing research as an important source of consumer information (Kozinets, 1999; Bickart; Schindler, 2001; Catterall; Maclaran, 2002) and it has become an important tool for understanding today's customers (Tikkanen et al., 2009; Simmons, 2008; Rokka, 2010). Netnography can be defined as a form of ethnography conducted online and it provides qualitative insights of consumers' symbolism, meanings, and consumption patterns (Kozinets, 2002). Compared to traditional ethnography or other qualitative methods, netnography is a relatively simple, inexpensive, and unobtrusive marketing research technique (Kozinets, 2010). Consequently, we expect the interest in netnography among marketing researchers to continue.

Netnography has been employed in the marketing literature in studies of a wide variety of topics, for example, brands (Schau et al., 2009), tourism experiences (Björk; Kauppinen-Räsänen, 2012), and e-WOM (Colliander; Hauge Wien, 2012). It has been used in different ways. For example, the role of the researcher differs between netnographic studies, from an active participant in the online community to a passive observer (Kozinets, 1997, 2001; Brown et al., 2003). Netnography has proven to be an especially useful approach to access and elicit data on, for example, sensitive topics (Langer; Beckman, 2005; Keeling et al., 2013). Because of its unobtrusive character, netnography offers the marketing researcher a view of customers' own realities (Giesler; Pohlmann, 2004).

Despite the recent increase in popularity of this methodology (Larsen, 2014; Pihl, 2014; Key et al., 2013; Richardson, 2013), no systematic review of studies utilizing netnography has been published. As a consequence, no overview or comprehensive summary of netnography studies within marketing exists, and this paper seeks to fill this gap. A systematic review of this type is needed to systematically analyse, integrate, and critique past netnographic marketing research, and by that, help future marketing researchers employing netnography. Therefore, the purpose of this paper is to systematically review the use of netnography in marketing research and propose guidelines for using the method in future studies. The paper addresses two research questions:

RQ1: In what research contexts has netnography been used?

RQ2: How has netnography been employed?

The study is based on an extensive synthesis of 149 articles employing netnography published over the last two decades. The review indicates how the use of netnography has increased since the first articles were published in the late 1990's. The paper contributes to the literature of marketing and netnography by providing a comprehensive overview and analysis of the use of netnography in marketing research. The findings reveal several gaps in existing research and suggest what and how future netnography studies could be focused upon. Managerial implications are related to how netnography could be used for gaining further insights about customers.

The remaining parts of this paper are structured as follows: First, the method of netnography is presented. Then, the methodology of the systematic review undertaken in this paper is outlined. The next section describes the findings from the systematic literature review, and finally, conclusions are drawn and discussed in the last section of the paper.

2 Netnography

Internet is nowadays an integral part of life in the developed world with a population usage rate of more than 90 percent in some European countries (internetworldstats.com). Consequently, consumers share more and more of their lives and

consumption experiences online, often through online communities organized around shared interests. Internet has thus opened up new avenues for marketing researchers to gain consumer insights (Kozinets, 1998, 1999; Catterall; Maclaran, 2002; Puri, 2007). As the number of Internet users continues to increase around the world and more of the social life moves online, marketing researchers have increasingly embraced the research methodology netnography.

Netnography was developed by Kozinets (1997) as a response to the increase in use of Internet by consumers to gather information and discuss consumption-related issues with fellow consumers. A reason for the drive to discuss and form consumer communities online is the assumption that fellow consumers provide better and more objective information than corporations (Kozinets, 2002). The netnography approach utilizes an ethnographic research method to study and understand consumers' lives online (Kozinets, 2002). The method "allows the researcher to gain access to consumer discussions by observing and/or participating in communications on publicly available online forums" (Nelson; Otnes, 2005, 90) in order "to identify and understand the needs and decision influences of relevant online consumer groups" (Kozinets, 2002, 62). As netnography is "based on primarily on the observation of textual discourse", qualitative content analysis or discourse analysis is often used to analyse data (Kozinets, 2002, 64). However, the difficulties of generalizing results to groups outside the studied online communities should be noted (Kozinets, 1998).

3 Methodology

As systematic review approach was chosen to map out the usage of netnography in marketing research. Originating from the medical sciences, systematic or evidence-based literature reviews have increasingly been adopted by business researchers in order to reduce bias and provide a comprehensive body of knowledge (Denyer and Tranfield, 2006; Bryman; Bell, 2011). A systematic review investigates the literature on a particular subject with explicit and transparent methods that follow a standard series of stages (Mulrow, 1994). As a consequence, systematic literature reviews are regarded as more objective, unbiased, and trustworthy than traditional narrative literature reviews (Egger et al., 2008).

The methodology of this review follows general guidelines for conducting systematic literature reviews in business research (Tähtinen; Halinen, 2002; Tranfield et al., 2003; Gremler, 2004; Helkkula, 2011). The main steps of this study was the following: (1) define search terms, (2) identify the databases and search engines, (3) decide and apply inclusion and exclusion criteria, and (4) repeat the filtering process to ensure a representative article selection.

The search for articles for this review was conducted during January and February 2014. In order to identify and gather all the marketing studies utilizing the netnography, we used the descriptors "netnography AND netnographic" in our literature search. The following databases were searched to identify relevant articles: ABI/Proquest, Business Source/EBSCO, Emerald, ScienceDirect/Elsevier, JSTOR, SAGE, Springer Link, and Wiley Online. These databases provide a large selection of peer-reviewed business journals and were thus considered appropriate for this study.

In a next step, criteria for inclusion and exclusion were established. The first criterion for an article to be included was that it had to be in the field of marketing. The second inclusion criterion was the existence of the term netnography or netnographic in the title, keywords, and/or article text. Conference papers, doctoral dissertations, business magazines, articles in other languages than English, and textbooks were excluded. As a result, 193 articles published between the years 1997-2013 were identified and collected. In the following filtering process, all the articles were carefully read through, and a final inclusion criterion was established: for an article to be included in the study it had to be an empirical marketing study fully or partly employing the netnography method. In this step, we sorted out seven conceptual articles and additional 37 studies that were not labelled as netnographies. The final selection of articles for further review resulted in 149 articles that we later analysed according to our research questions. Next, the findings of the analysis are presented and a synthesis of the literature provided.

4 Findings

The analysis of the 149 articles reveals a rapid growth in utilization of netnography by marketing researchers. As illustrated in Figure 1, it took approximately ten years from the first publication on netnography until the method became widespread. From 2008 and on, we can see a sudden increase of netnography publications in marketing journals. From available data, it clearly looks like netnography is establishing itself as a recognized qualitative methodology within marketing. Due to societal social media and Internet trends, we expect the increase in netnography to continue in the years ahead before we see a flattening in the curve of publications per year.

Figure 1. Growth in number of marketing studies using netnography 1997–2013.

Along with the growth in number of marketing studies using netnography since its birth 17 years ago (Kozinets, 1997), also the number of publication outlets for netnographic studies have increased. The journal *Advances in consumer research* was the first journal to publish a netnography (Kozinets, 1997) and is still the journal with most published netnographic studies. And among the top ten journals in terms of netnography publications, seven can be considered as consumer research journals. As can be seen from Table 1, a majority of netnography articles included in this review have been published in *Advances of Consumer Research*, *Journal of Marketing Management*, and *Journal of Business Research*. Also, the top ten journal accounts for over half of all netnography publications. More and more journals, however, publish netnographic studies and we can see from our analysis of the articles how the distribution of netnographies across marketing journals increases yearly.

Table 1. Top 10 journals publishing netnographic marketing studies.

<i>Journal</i>	<i>No. papers</i>	<i>Percent</i>
Advances in Consumer Research	15	10,1
Journal of Marketing Management	14	9,4
Journal of Business Research	13	8,7
Qualitative Market Research	8	5,4
Journal of Consumer Behaviour	7	4,7
Journal of Customer Behaviour	6	4,0
Consumption Markets & Culture	5	3,5
Research in Consumer Behavior	5	3,4
Journal of Consumer Research	5	3,4
International Journal of Consumer Studies	4	2,7
Other marketing journals	67	44,7
Total	149	100,0

4.1 In what research contexts have netnography been used?

A closer analysis of the 149 netnography articles included in this review reveals three marketing fields in particular that have adopted netnography. Approximately half of them are studies of consumer behaviour or consumer culture, whereas branding studies covers 22% and the tourism sector covers 15% of the netnography studies (see Table 2). The rest of the netnography studies represent 9% of the articles and are found in fashion marketing, healthcare service, and service marketing. Taken together, however, the general service sector (tourism, healthcare, and other services) represents approximately a fifth of the netnography articles in this review.

Table 2. Contexts and topics of netnographic marketing studies (n=149).

<i>Context</i>	<i>Topic</i>	<i>Exemplary studies</i>
Consumer research (54%)	Consumer culture, e-WOM, green consumption, anti-consumption, innovation, cross-cultural consumption	Kozinets, 1997; Hernandez; Vicdan, 2013; Walther; Sandlin, 2013; Kozinets; Handelman, 2004; Füller et al., 2007; Takhar et al., 2012
Branding (22%)	Online brand communities, value creation, brand relationships, retro-branding, brand defending, luxury brands	Schau et al., 2009; Brown et al., 2003; Koivisto; Mattila, 2012; Pongsakornrungsilp; Schroeder, 2011; Colliander; Wien, 2013
Tourism service (15%)	Food tourism, tourist experiences, tourist motivations	Mkono; Wilson, 2013; Podoshen, 2013; Hsu et al., 2013
Fashion marketing (5%)	Fashion blogs, online fashion communities,	Kulmala et al., 2013; Cervellon; Wernerfelt, 2012
Healthcare service (3%)	e-WOM, online health communities	Liang; Scammon, 2011; Keeling et al., 2013
Service marketing (1%)	S-D logic, service quality	Patterson; Brown, 2009; Yang; Fang, 2004

Netnography has been employed in the study of a variety of consumer research topics. For example, in his initial reflections, Kozinets (1998) presented netnography as a method for consumer research and emphasized its usefulness in the study of cybercultures and virtual communities. Since the introduction of netnography, consumers have increasingly become active in online communities and social media, and netnography has thus proved its usefulness and become a popular method among consumer researchers. As a variant of ethnography, netnography particularly show advantages over other methods in the study of online cultures of consumer groups. Like face-to-face ethnography, it offers the researcher a window into the cultural (online) reality of a particular consumer group (Kozinets, 2006). For example, Giesler; Pohlmann (2003) used netnography to understand the consumption meanings and communal activities surrounding the file sharing system Napster.com. Through collection and analysis of cyber-interviews, emails, websites and entries on message boards, the authors conceptualized the file sharing system as a community based on a gifting culture. A more recent example of cultural understanding through netnography is Healy; Beveralands (2013) study of the Furry consumer culture. The exploration of Furry online communities helped the authors to explain the zoomorphism of “Furries” as a means of self-authentication.

Consumer researchers have also used netnography to understand all kinds of consumer behaviours online. Today, many consumer behaviours and activities are reflected online as well as offline. A typical example is word-of-mouth (WOM), which traditionally spread between family, friends, and colleagues, but with the Internet became a considerably more powerful phenomenon with the possibility to go viral (Dellarocas, 2003; De Bruyn; Lilien, 2008; Ferguson, 2008). A netnographic approach provides guidelines for researching online phenomena and several marketing researchers have employed netnography for the study of electronic WOM (e-WOM). Liang; Scammon (2011), for example, adopted netnography for their study of e-WOM on health social networking sites and revealed how more informed e-group members provided less-informed members with advice, guidance, and support. Buying behaviour is another traditional marketing topic which in its new online form has been researched through netnographic inquiry. From the netnography of e-procrastination by Negra et al. (2008), we learn that online purchase delay results from negative attitudes and experiences of online shopping, perceived risk and price, locus of control and purchase task complexity.

In addition to consumer research, netnography is a popular method for studying and understanding brand-related phenomena. Kozinets (1998) explains how netnography is a suitable method for the study of online or virtual communities. With the rise of online brand communities, netnography became a way for marketing researchers to understand different brand-related phenomena from the inside of these communities. In an ethnography of three brand communities (Ford Bronco, Macintosh, and Saab), Muniz; O’Guinn (2001) realized the importance of web sites for brand communities and the consumers’ everyday life. Since then, much research has been conducted on brand communities online with the help of netnography. Examples include brand communities and co-creation (Cherif; Miled, 2013), brand communities embedded in social networks (Zaglia, 2013), rivalry within and between brand communities (Ewing et al. 2013), anti-brand communities (Hollenbeck; Zinkhan, 2010), counter-brand and alter-brand communities (Cova; White, 2010), brand communities and value creation (Schau et al., 2009), and brand communities in relation to brand meaning creation (Broderick, 2003). However, not all brand-related netnography studies have investigated brand communities and several other brand-related topics are commonly discussed online by consumers. Consequently, netnography has also been used to examine, for example, retro-branding (Brown et al., 2003), brand defending (Colliander; Wien (2013), and luxury brands (Tynan et al., 2010).

Moreover, tourism service is another popular marketing research area for netnographic studies. Similarly to the above discussed marketing topics, an abundance of web sites and online communities devoted to travel and tourism have emerged during the last decade. For example TripAdvisor, the world’s largest travel site, offers more than 150 million consumer reviews and had more than 260 million unique monthly visitors during 2013 (TripAdvisor.com). In other words, travel sites are platforms for consumer discussions around tourism and provide the marketing researcher with a wealth of information about consumers’ experiences and opinions about travels and destinations. Netnography has thus been a natural methodological choice for a number of tourism service studies. Several topics have been explored, for example, food tourism (Chhabra et al., 2013; Mkono et al., 2013) and tourism experiences (Rageh, 2013; Hsu et al., 2009; Tussyadiah; Fesenmaier, 2009). Björk; Kauppinen-Räsänen (2012) provide an illustrative example of how TripAdvisor can be utilized for marketing research purposes. The authors used TripAdvisor’s discussion forum for risk to explore consumers’ perceived risk for four different destinations. Also blogs have been used as sources of stories about tourism experiences (Woodside et al., 2007)

Netnography studies in the context of fashion marketing frequently cover fashion blogs. A reason for this focus is the popularity of fashion bloggers and their influence on consumers. In recent years, the fashion industry has shown interest in fashion blogs, and to exploit their marketing potential, fashion companies often provide fashion bloggers with incentives to promote their products. Kulmala et al. (2013) used netnography in the study of six popular Finnish fashion blogs to understand this conflict between naturally-occurring e-WOM and marketing-influenced e-WOM. Another example of a netnographic study of fashion blogs is Phil’s (2013) study of fashion bloggers’ personal brand building. Also, because of its unobtrusive nature, netnography has helped researchers to understand, for example, how over-weight women experiences mainstream fashion norms through the study of fashion blogs by female “fatshionistas” (Gurrieri; Cherrier, 2013; Scaraboto; Fisher, 2013). But netnographers within fashion marketing have not only studied blogs. We can also find examples of studies of online communities related to fashion. An example is Thomas; Peters’ (2011) netnography of brides’ discussions of wedding dresses on the popular wedding online community, Brides.com. The authors concluded that the online community plays an important part in the wedding dress purchase decision of brides.

A common service industry to be researched with netnography is the healthcare sector. Netnography offers the option of covertness which sometimes might be necessary for researchers to approach sensitive health-related topics. For example Keeling et al. (2013) conducted a netnographic study of an online community for breast cancer sufferers and illustrate how the community members, on the basis of their own experiences, negotiate their understandings of healthcare services and medications. Also Langer; Beckman (2005) used netnography to research a sensitive topic, namely cosmetic surgery. A covert netnography of an Internet message board on cosmetic surgery allowed Langer; Beckman (2005) to gain deep insights into consumers’ opinions, motives, and concerns regarding cosmetic surgery.

Netnography has also been used for a variety of other service-related topics. Basically all sorts of service experiences consumers openly and publicly share online can be used as an input to a netnography. Yang; Fang (2004) adopted netnography for analysis of consumer reviews of online financial brokerage experiences to identify key online service quality dimensions. Another netnographic contribution to service marketing is Brown; Patterson (2009). By means of a qualitative study, including a netnography, of the Harry Potter phenomenon, the authors added an empirical dimension to the otherwise largely conceptual service-dominant logic discussion.

4.2 How has netnography been used?

Netnography has been used in various ways by marketing researchers. Table 3 summarises the main applications in terms of the researcher role, degree of use, combination with other methods, purpose, contents, and domain of data collection. As table 3 indicates, netnography is a diverse and all-encompassing method, applied in various ways for different purposes.

Table 3. Summary of how netnography has been used within marketing research.

<i>Application</i>	<i>Description</i>	<i>Exemplary studies</i>
Role of researcher	Passive observation without direct participation, lurking, spying	Hernandez; Vicdan, 2013; Chan; Li, 2010; Quinton; Harridge-March, 2010
	Active participation: initiation of conversations, quizzes, uploading of videos/pictures, answering to quizzes, commenting	O’Sullivan et al., 2011; Pongsakornrunsilp; Shroeder, 2011
Combination with other methods	Online surveys	Chan; Li, 2010; Janta, 2011
	Interviews, focus group interviews, phenomenological interviews	O’Sullivan et al., 2011; Fisher; Smith, 2011; Hernandez; Vicdan, 2013; Luedicke, 2006
	Videography, ethnography	Fisher; Smith, 2011
	Physical observation	Black, 2011

<i>Application</i>	<i>Description</i>	<i>Exemplary studies</i>
Degree of Use	Partly: data collection/ data analysis	Seraj, 2012; Luedicke, 2006
	Full: entry, data collection, data interpretation, and ethical standards	Colliander; Wien, 2013, Närvänen et al., 2013, Quinton; Harridge-March, 2010
Use purpose	Exploratory research/pilot	O’Sullivan et al., 2011; Chan; Li, 2010
	To explore multiplicity	Yazicioğlu; Borak, 2012
	Illustrative examples	Kozinets, 2002
	To explore interactions and sense-making	O’Reilly et al., 2007; Sandlin, 2007
Content included	Text such as comments, discussions, reviews	O’Sullivan et al., 2011; Ismail, 2011; Mikkonen et al., 2011
	Pictures	O’Sullivan et al., 2011
	Quizzes, votes, questions	Black 2011; O’Sullivan et al., 2011; Kelleher et al., 2011
	Videos, vlogs	O’Sullivan et al., 2011; Luedicke, 2006; Kelleher et al., 2011
	Online commercials, webpage marketing messages	Luedicke, 2006; Mkono, 2012
	Textual web diary, consumer journal stories	Leipämaa-Leskinen, 2011; Martin et al., 2007; Martin; Woodside, 2011
	Tweets	Kelleher et al., 2011
Domain of data collection	Online communities, , discussion forums, opinion sites, online support groups	Mikkonen et al., 2011; Lindblad; Ostberg, 2011
	Blogs, weblogs,	Mikkonen et al., 2011
	Mailing lists, Online newspapers, news reports	Luedicke, 2006
	Twitter	Kelleher et al., 2011
	Firm-maintained forums	Luedicke ,2006

The role taken by the researcher varies among netnographic studies. A trend, however, is that netnography researchers increasingly stay passive, silent and do not participate in the researched online communities. According to Björk; Kauppinen-Räsänen (2012), marketing researcher can adopt four different positions in netnographic studies: observer, lurker, spy, or participant. The observer notifies the community about his/her research, but stays passive. The lurker also stays passive and do not inform the community about the conducted research. The spy is an active participant in the community, but do not reveal his/her role as a researcher. The participant is active and notifies the community of the research. From our literature review, we can conclude that lurking is the most common netnography position among marketing researchers. As Kozinets (2002, 65) puts it, “Netnographers are professional “lurkers”...”.

The unobtrusive nature of netnography is a key reason for its attractiveness but at the same constitute a real risk. If marketing researchers conduct netnographic studies in an irresponsible way that consumers find to be disrespectful, the image of netnography will be seriously damaged and the future potential of the method spoiled. Kozinets (2002), therefore, recommend the following guidelines for netnographers, they should: (1) fully disclose his/her presence, (2) ensure confidentiality and anonymity to informants, (3) seek and incorporate feedback from members of the online community, and (4) take a cautious position on the private-versus-public medium issue. Kozinets (2002) thus recommend the netnographer to contact community members and obtain their permission to use the postings to be quoted in the research. Following the guidelines of Kozinets (2002) requires a deep involvement in the online community under study. From our review, we can see the opposite, most researchers seem to prefer to triangulate across a large number of online communities or sites, downloading large numbers of messages without asking the members for permission.

Netnography has also been used in combination with several other qualitative methods. Slightly more than 60 percent of the articles use only netnography while the rest combine netnography with, for example, traditional qualitative interviews, ethnography, videography, or physical observations. Many articles complement a traditional ethnography with a netnography. Ideally, the research problem at hand should guide the marketing researcher’s decision to perform a full netnography or use the method as a complement to traditional qualitative inquiry.

A good example of a full netnography approach is Scaraboto et al. (2013) who examined the complications of closing down Disney's adverworld (virtual world created for marketing purposes) "Virtual Magic Kingdom" (VMK). By observing blogs, websites, YouTube videos, online communities, photos, and screenshots from VMK, the authors revealed areas of tension between consumers and marketers in connection to the closure of adverworlds. Another example of a full netnography is provided by Radford; Bloch (2012) who, through netnographic inquiry, examined consumers' expressions of grief and consumption-related emotions posted on online communities in response to the death of a celebrity. On the other hand, Fisher; Smith's (2011) study of value co-creation in brand communities is a good example of a combined approach where the authors employed ethnography, videography, netnography, and traditional interviews of consumers. According to Fisher; Smith (2011), the combination of these data collection techniques provided several benefits that any of those methods by themselves could not and hence allowed for a deeper understanding of the nature and process of consumers' co-creation of value.

Other studies use netnographic inquiry as a complement or pre-study to larger quantitative studies. Mixed methods has become a popular research approach in marketing and bridges the gap between qualitative and quantitative methodologies (Bahl; Milne, 2006; Harrison; Reilly, 2011). A mixed methods approach is generally pragmatic, driven by the research questions, and not constrained by paradigmatic assumptions (Creswell, 2003; Creswell; Piano Clark, 2007; Johnson; Onwuegbuzie, 2004, 2007). Chan; Li (2010), for example, combined a netnographic study and a quantitative survey to understand reciprocity in consumer-to-consumer interactions in online communities. More specifically, Chan; Li (2010) used the quantitative survey to validate the findings of their exploratory netnography. A limitation of netnography is the difficulty to generalizing findings to groups outside the specific online community sample (Kozinets, 2002). Kozinets (2002) recommend marketing researchers interested in generalization of the findings to employ multiple methods for triangulation. A quantitative study is a credible way to triangulate and validate the findings of a netnography. With a continued interest for mixed methods among marketing researchers, we expect the mix of netnographic studies and quantitative surveys to become more common.

Consequently, netnography is often used as a qualitative data collection technique rather than a full ethnographic method. We can thus see a difference between the original guidelines for netnography provided by Kozinets (2002) and how the method later has been used by marketing researchers. Langer; Beckman (2005), for example, argue that netnographic data is no different from other sources of data found in conventional mass media communication such as newspapers, magazines, or TV-programmes. According to Langer; Beckman (2005), traditional qualitative content analysis can therefore be applied for the collection and analysis of netnographic data. Kozinets (2006), however, remains critical to the idea of treating netnographic data as content to be content analysed. If the ethnographer is removed from the netnography, and the data treated as any type of mass medium content, the possibilities for cultural understanding are removed according to Kozinets (2006). Kozinets (2006), a trained anthropologist, emphasizes the need for cultural knowledge and cultural investigation in a netnography for it to build valid understanding of the studied phenomenon. If a trained and experienced ethnographer is a requirement of a reliable netnography, it poses a challenge as most marketing researchers do not fulfil that criterion. Our impression from this review is that most marketing researchers are more comfortable utilizing netnography as a technique for data collection rather than performing a full ethnography. Hence, the levels of usage of netnography are needs to be further addressed by future research.

The way netnography has been applied also relates to the research purpose and role of netnography in the study. In its beginning, Kozinets (2002) used netnography to provide illustrative examples of the studied phenomenon. Subsequently, netnography has frequently been used in exploratory research, either as a sole data collection method, or as a pilot study for further studies. For example, O'Sullivan et al. (2011) successfully used a netnography to explore the process contributing the genesis of a brand community. However, the review also uncovered other use purposes, such as using netnography to explore multiplicity and variety in behaviour and attitudes between cultures (Yazıcıoğlu; Borak, 2012) and to explore consumers' interactions and sense-making (O'Reilly et al., 2007). The in-depth nature of netnographic data also enabled, for example, Sandlin (2007) to understand how education and learning occur in online communities.

Many marketing researchers see great benefits in the dynamic and flexible nature of netnography, allowing for in-depth, rich, timely, and continuous naturalistic data. Netnographic data is typically text-based such as customers' comments, discussions, and reviews. However, netnography has also been applied to pictures and videos. Luedicke (2006), for example, downloaded and analysed 200 pictures and 40 minutes of videos in his netnography about the role of social environments for brand communities. As the aim of the study was to explore how the HUMMER brand community negotiated a set of core distinctions with and against its social environment, ads (pictures and videos) became an important complementary data source. More in-depth qualitative data into specific themes is also found through textual web diary and consumer journal stories (Leipämaa-Leskinen, 2011), whereas simpler information is found related to customer opinions through quizzes, votes, and questions (Black, 2011). Also webpage marketing messages represent an interesting type of netnographic content related to firm activities. For her study of how authenticity is projected onto cultural objects, Mkono (2012) downloaded and analysed not only online tourist reviews, but also the webpage marketing messages of two Victoria Falls restaurants which offer cultural experiences for tourists.

A large variety of domains have been used to collect data in netnographies. Common domains are online communities, discussion forums, opinions sites, blogs, where customer behaviour is not directly linked to companies, but rather related to interest areas (e.g. Mikkonen et al., 2011). The reason can be found both in the consumers' great interest for these virtual hangouts (a netnographer needs to be where the consumers are) and in the origin of

netnography as a method for studies of virtual communities (Kozinets, 1998). But as social media and online services has evolved, so has the domains of netnography. Popular domains for collecting netnographic data today involve Facebook, Twitter, Youtube, TripAdvisor, mailing lists, or online newspapers. A good example of the use of social media is Kelleher et al. (2011) who used blogs, Twitter, Facebook, and Youtube in their netnography on value co-creation in an online crowd-sourced community. In that sense, the authors complemented the information on the online community under study with information from social media domains linked to the community. Although customer-dominated forums are the most frequently used, netnographic data has been collected also from firm-maintained domains (e.g. Luedicke, 2006; Mkono 2012).

5 Discussion and implications

This study synthesised 149 netnography articles published between 1997 and 2013 and it contributes to the marketing literature by its comprehensive overview and analysis of netnography in marketing. The findings reveal an increased use of netnography in marketing research, especially in the last six years. This increase reflects the intensified online activity of consumers and the blurred boundary between consumers’ lives online and offline. As consumers’ lives increasingly move into online worlds, marketing researchers must follow, and netnography provides that opportunity (Kozinets, 2006; Rokka, 2010). Our systematic review of netnography articles reveals a wide variety of research contexts and marketing topics covered. The review also shows the diversity of ways in which different marketing researchers have employed netnography. The variation of netnography studies within marketing literature gives the picture of a flexible and adaptable qualitative method with a great potential for future use in marketing research. As the first generation of “digital natives” grow up to become the consumers of tomorrow (Palfrey; Gasser, 2008; Thomas, 2011), we expect the interest of, and need for, netnography among marketing researchers to continue to increase.

We believe the use of netnography in marketing research has only started and see a great potential for future use of the method. Indeed, netnography is a naturalistic, unobtrusive, and adaptable method with analytic depth and rich and dynamic data (Kozinets, 2002, 2006; Podoshen; Hunt, 2011). Netnography, however, also brings challenges such as huge data sizes, ethical issues, and anonymous informants (Rokka, 2010; Lu, 2011). This review has several implications and interesting research opportunities for researchers. We also see issues that need to be addressed to secure quality and trustworthiness of future netnographic research. Table 4 summarises the main theoretical, empirical and methodological issues that emerge from the review of existing netnography studies.

Table 4. Future research directions for netnography in marketing.

<i>Emphasis</i>	<i>Future research directions</i>
Theoretical issues	<ul style="list-style-type: none"> • Exploring the offline/online border in consumers’ lives and how the adoption of new technology affects service usage • Increased focus on service innovation, S-D logic, value creation/value destruction online, customer sense-making, customer logics, customer-to-customer interactions
Empirical issues	<ul style="list-style-type: none"> • What customer insight can be gained by using netnography? • Is the information trustworthy? • Moving beyond tourism and healthcare services into other service contexts • Exploring social networking sites rather than only brand communities • Using netnography for studying business customers • How does the domain of data collection influence the nature of the data retrieved?
Methodological Issues	<ul style="list-style-type: none"> • Synthesizing how netnography can be integrated with other qualitative and quantitative methods • Establishing different procedures for researcher input (active/passive) • Development of longitudinal studies • Establishing ethical procedures for data collection and analysis • Establishing how the data collected be used in the most efficient way • Outline different forms/ways/levels of netnography use

The review reveals that, as netnography was developed by Kozinets (1998) as a consumer research tool, marketing researchers in the fields of consumer behaviour and consumer culture have largely paved the way for netnography into general marketing research practice. This early adoption of netnography is also reflected in the publication outlets and research contexts. Consequently, we see the potential for netnography use also in other areas of marketing research. The business-to-business researchers, for example, are yet to discover netnography. Although a few articles were published in general business journals, we did not find any netnographic studies focused on business-to-business or industrial settings. In fact, the netnography method seems closely connected with business-to-consumer research. Partly it is probably due to its origin in the area of consumer research and consumer culture (Kozinets, 1998, 2002). Also, consumers are more prone to share their consumption stories online than, for example, managers or other corporate

representatives. In fact, it would in many cases be unethical by employees to openly share company information in public online communities. Netnographers normally collect data from such publicly available online forums, and access to internal corporate online communication from, for example, intranets, is difficult without the permission of the company. Despite of its challenges, we still think the business-to-business setting is an underexplored area for netnographic inquiry that deserves future attention. Similarly to traditional ethnographic studies in business contexts (Watson, 2011), we expect a netnographic approach to have the potential to capture things of relevance other methods would not. As any real netnographer, however, the netnographer needs to seek permission to be granted access to company communication. A netnography of, for example, a company's intranet could be a useful complement to a traditional ethnography of the same organization.

We also believe that netnography has the potential to serve a broader range of service marketers and encourage more use of the method in this particular field. Services along with consumer goods are the typical type of everyday consumption that is discussed every day online by consumers all over the world. In contemporary service marketing, the customer's role as a value (co-)creator (Vargo; Lusch, 2004, 2008; Grönroos, 2008, 2011) has been emphasized and it is widely agreed that value actualization takes place in the customer's consumption process during usage (Gummesson, 2007, Grönroos; Raval, 2011). Arguably, to understand how value is formed in customers' processes, marketing researchers need to understand how services are "embedded in the customer's context, activities, practices, and experiences" (Heinonen et al., 2010, 533). Netnography with its unobtrusive nature and ethnographic characteristics is a useful tool for entering the customers' context and understand the realities and everyday lives of consumers (Kozinets, 2006). We therefore believe netnography to be a suitable method for learning about how service firms can support customers in their everyday life and thus facilitate value creation.

We also encourage a diversification in the use of netnography among marketing researchers. The method was developed as an adaptation of ethnography for studies of consumer behaviour of virtual communities and cyberculture and Kozinets (1998) strongly emphasize full participation in the community under study. To participate and gain recognition as a cultural member constitutes an important part of the field work according to Kozinets (1998). Most netnographers today, however, stay passive observers and triangulate across several online communities rather than actively engage themselves in one particular online community. Netnography is also often used as a complement to traditional qualitative data collection techniques, such as interviews. In a way, netnography has developed into an umbrella term for various forms of online data collection and analysis. It is clear from our review that few articles follow the outlined steps and guidelines of Kozinets (2002, 2010), including, for example, full disclosure of the presence and agenda of the researcher in the online community. We thus need to address what forms netnography can take and if diversity in use of the method is a problem or something positive. A key issue here is which criteria netnography studies should be evaluated against, Kozinets' (1998, 2002, 2010) original guidelines or general principles for quality in qualitative research? To avoid confusion, we recommend netnographers to disclose the methodological assumptions of their studies.

Also, as Dumitrica; Gaden (2008) show, the online and the offline world can no longer be neatly separated as consumers bring their offline identities, values, meanings etc. online. If the offline world and the online world are intertwined, it makes sense to combine netnography with traditional qualitative inquiry. Several successful examples of such an integrated approach exist (see, for example, Kozinets; Handelman, 2004; Patterson; Brown, 2009; Schau et al., 2009; Brown, 2012, 2014). In other words, netnography can serve as a means of triangulation and thus contribute to a broader and deeper understanding of the topic (Flick, 2004). Based on our review, we want to emphasize how a netnography can contribute in many ways to the overall qualitative study, for example by giving the researchers insights that could not have been obtained offline or add a longitudinal dimension to the investigation. Longitudinal research offers the researcher a possibility to capture and understand changes in consumers' processes but is seldom used in marketing research because of the time and costs involved (Bryman; Bell, 2011). Both time and costs are lower for an online longitudinal study than a traditional longitudinal study design. As ethnographic studies are longitudinal in nature, we believe netnography can constitute a valuable longitudinal part of a qualitative study or complement an offline longitudinal study.

Managerial implications can also be drawn from this study. For companies, netnography provides a window into the lives and realities of their customers (Kozinets, 2006). Netnography for managerial purposes, however, needs to be used with caution. Customers may feel like the company spies on them. Table 5 summarises the main managerial issues that can be drawn from our review of netnography studies.

Table 5. Managerial implications of netnography in marketing.

<i>Emphasis</i>	<i>Managerial implications</i>
Context of study	<ul style="list-style-type: none"> Insight into a broad range of business contexts is lacking B2B sector is underemphasised Evaluate how netnography can be used in the company's industry? Business customers can also be studied, through for example communities of practice
Role of researcher	<ul style="list-style-type: none"> Is observation sufficient or should managers be more involved in data collection? How can managers retrieve data? Who should be responsible for data collection and analysis? Can managers be more involved in different communities?
Combination with other methods	<ul style="list-style-type: none"> Netnography is typically used in combination of other studies Strengthen the role of qualitative data in understanding key topics What other methods could be used?
Degree of Use	<ul style="list-style-type: none"> What are the resources available for data collection and analysis? Should netnography be used in combination with other methods?
Use purpose	<ul style="list-style-type: none"> What are the research objectives? Deep insight or comparable differences? Is netnography used to connect to and engage with customers? Should existing or potential customers' be studied?
Content included	<ul style="list-style-type: none"> Is textual information sufficient, or should other types of content be retrieved? What types of content can be meaningful and useful to elicit?
Domain of data collection	<ul style="list-style-type: none"> What is the best forum for data collection? How does the domain of data collection influence the nature of the data retrieved? Should companies do several netnography studies in different domains?

Based on our extensive review of the netnography literature in marketing, we would encourage companies to utilize netnography in order to better understand their current and future customers. By being online together with their customers, companies can take part of their customers' thoughts, opinions, and ideas in a way that previously has been very difficult. The companies who grasp the opportunities provided by netnography for consumer insight will have an edge against their lesser informed competitors (Kozinets, 2010). We already see this trend in terms of an increasing presence of companies and organizations on, for example, Facebook. Moreover, most of the netnographic studies in our systematic literature review are conducted in online communities, with a particular focus on online brand communities. But we think marketing researchers need to move beyond the traditional online community. As suggested by Kozinets (2006), blogs, networked gamespaces, instant messaging chats, and new forms of mobile communication technologies are increasingly interesting and most likely the places for future netnographies. The flexibility of netnography allows for pure observation as well as active participation and makes the method adaptable for most virtual arenas.

Mobile forest berry map service: co-creating value from open public data

Teppo Hujala, Mikko Kurttila, Ron Store

Finnish Forest Research Institute (Metla)

Grounding on emerging wild food phenomenon among urbanizing citizens, established everyman's rights in Finland, publicly open forest resource data, scientific wildberry crop models (bilberry, cowberry) and weather data in the future, this study analyses mobile berry map service as a new business opportunity. Customer-value interviews (n=52) and two business model CANVAS workshops are used to outline the main features of a potential berry map service as well as related risks. Identified values-in-use associate with lifestyles in urban-rural continuum. Open data gives promise, but value-creation is still complex. A more thorough value-network survey and user exercises employing participatory design are suggested.

1 Introduction

While general servitization of societies has recently increased public discourse about the role of services in fostering economic growth, service research has focused much on value co-creation and value-in-use perspectives. In service-dominant logic (Vargo; Lusch, 2004; Lusch; Vargo, 2014), service is understood as exchange of service, goods provide value only in use and in context, and value creation is an interactional process. The task of companies is to offer value propositions to their customers, and companies' resources and skills are key to their competitive advantage. Recent developments in service design may help companies to strengthen their service orientation in enhancing their business (Wetter-Edman et al., 2014). This is particularly relevant with business models targeting those sections of society that are entering a systemic change, such as green economy, digitalization, or new governance, etc.

Emerging everyday life values within Finnish society, e.g. wild food and homing phenomena in particular among urban people create space for new value-creating service innovations. The above trends are connected with the recognized rise of the lifestyles of health and sustainability (LOHAS) and sustainable food consumption (Kirveennummi et al., 2013). There is a reason to presume that new service business around sustainable consumption will be designed along with social innovations (Mont et al., 2014), meaning that companies' new services will increasingly foster novel kind of interaction for which the role of the government is to provide open public data.

Together with traditionally established everyman's rights in Finland, the above consumer trends indicate that picking of wild forest berries could become more popular in Finland. However, urbanized people might not be well aware of good berry picking places. In addition, the well-known picking places near major cities may become overcrowded and over-utilized. This indicates needs to provide urban berry pickers with information on potential berry picking places. This information can be augmented with other relevant information as well as various navigation tools that are useful and support this hobby. A well-functioning berry map service could benefit also other nature-based businesses such as tourism and berry processing industry, and it could thus contribute to economic growth and rural livelihoods. Furthermore, it could serve educational purposes and improve citizens' nature relations. Interdisciplinary (biology, ecology, geography, sports, communication...) educational use of berry map software could be used in schools, and the whole pedagogical concept could be exported.

The amount of open public data grows rapidly also in the area of natural resources. Recently, Finnish Forest Research Institute (Metla) released the multi-source forest inventory data openly available. This information, open map information from the National Land Survey and open weather data from the Finnish Meteorological institute, comprise a set of open public data that could be combined and delivered in a form of a forest berry map service. To make this vision a reality, some research work needs to be done with berry crop models as well as with the service preconditions.

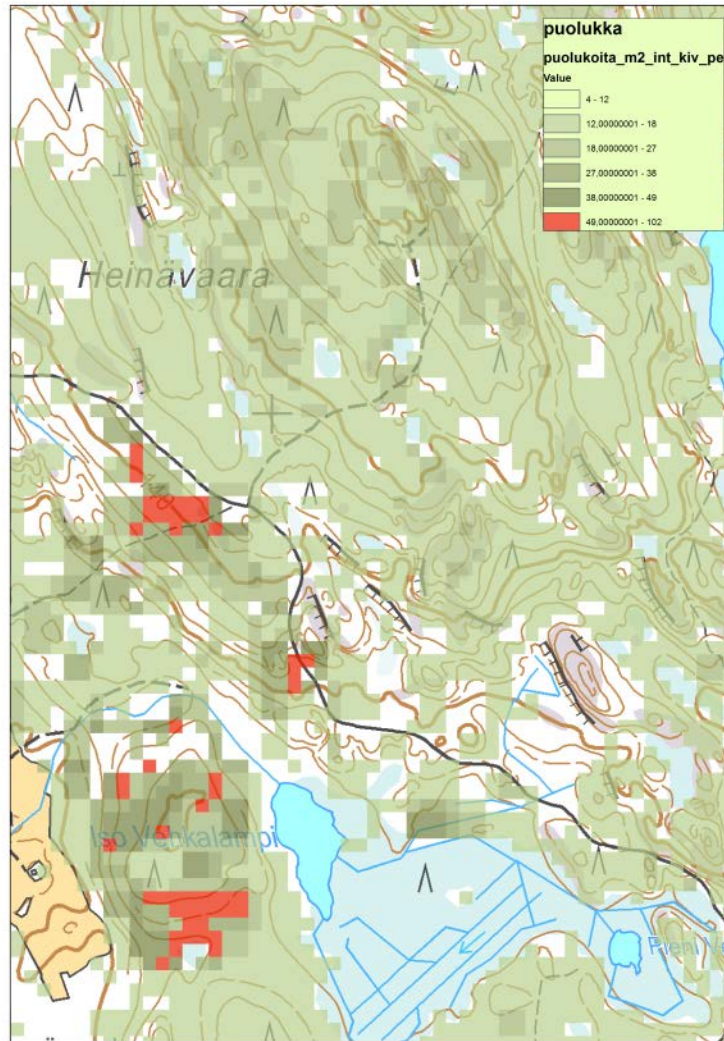

Figure 1. A piece of an estimated cowberry crop map (width: ~1,1 km) from Heinävaara, Liperi, close to Joensuu airport in eastern Finland. In this map, each berry-map pixel represents 20 x 20 metres on the ground and shows the average number of cowberries by square meter.

Typically, the yield models for e.g. berries or mushrooms predict the yield of the non-wood forest product (NWFP) based on the value of forest-stand-level biometric variables (e.g. basal area, density, age etc.) that are controllable by forest management. Therefore they provide the information needed to assess the impact of management options on the provision of NWFP. In addition, it is evident that also environmental variables reflecting the topographic and climatic conditions, which cannot be controlled by the forest manager, affect the yield of NWFP. In Finland, models for bilberries (Miina et al., 2009) and cowberries (Turtiainen et al., 2013) have been recently published. In addition to forest planning calculations, their use situations include drawing digital maps in which potential berry picking places could be shown to interested ones (Figure 1). In fact, these berry crop models may be the glue that helps to combine the various open forest data sources together as a service in a meaningful way. Directing research efforts from data collection to data analysis and utilizing new interdisciplinary open source data sets make a strong basis for new service innovations.

2 Objectives

This study analyses mobile forest berry map service as a new business opportunity in the frame of green economy. More specifically, the study aims at i) learning on urban and rural berry-pickers' value-creating processes as a basis for the berry map service; ii) clarifying the added-value opportunities and underlying risks that the open public data for berry maps involves; and iii) identifying the core components and prioritized action steps when approaching an operable and profitable, customer-oriented business model around the forest berry map service.

3 Materials and Methods

New service opportunities may be investigated with multiple alternative conceptual perspectives (Zott et al., 2011). While this study represents the first steps in studying forest berry maps as business, it was reasonable to rely on an established and well-structured framework that can be easily learned and adopted from practical examples. Therefore

this study applied the CANVAS business model (Osterwalder, 2004; Osterwalder; Pigneur, 2010) as a conceptual framework. The original CANVAS model comprises nine building blocks (Figure 2), but in this study the business model concept was augmented with three additional building blocks in order to strengthen the competitive advantage viewpoint as suggested by Kajanus et al. (2014) (Table 1). The twelve building blocks structured the contemplation of berry map business (Figure 3). In essence, the theme customer and competition was expanded by adding the building blocks customer need, company solution, and competitors.

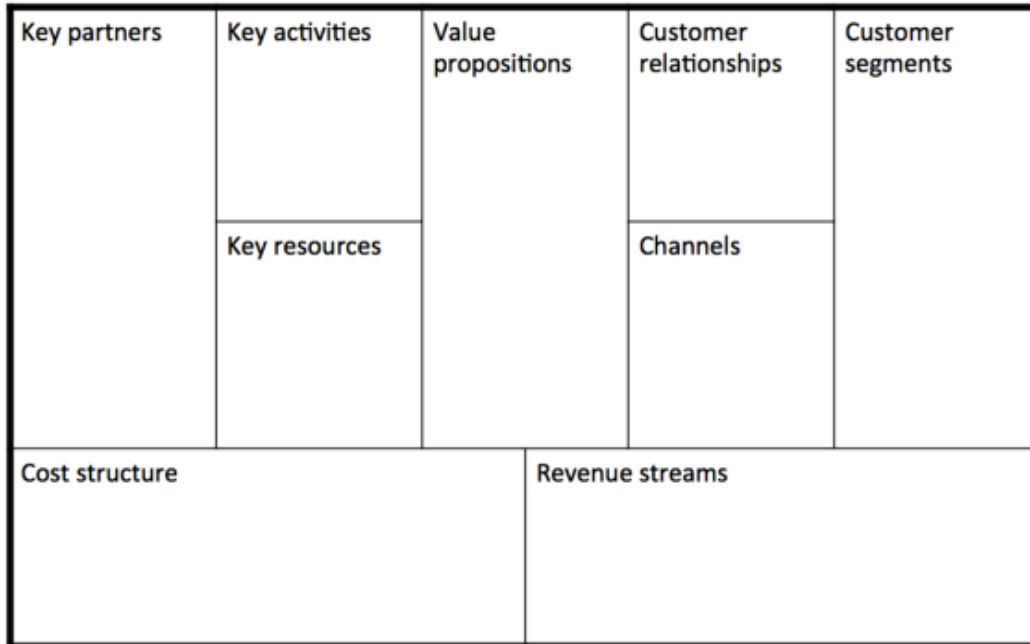

Figure 2. The building blocks of the original business model CANVAS by Osterwalder and Pigneur (2010).

Table 1. The themes and building blocks of the expanded business model CANVAS according to Kajanus et al. (2014). The added building blocks are marked with *.

Themes	Building blocks
Customer / competition	Customer segments *Customer need *Company solution *Competitors
Offering and service touch points	Value proposition Channels Customer relationships
Resources	Key resources Key partners Key activities
Profit formula	Revenue streams Cost structure

Content to the business model was produced in two facilitated workshops, held in Kuopio in May 11, 2014 (Figure 3), and in Joensuu in July 31, 2014 (Figures 4 and 5), involving 9 and 6 participants, respectively. The workshops represented expertise in the multiple-use of forests, berry crop models, forest information logistics, social applications, GIS and map-based services, service design, and business model generation. The first author of this paper participated in both workshops, and the second author participated in the second workshop, thus the study may be seen as participatory action research in which the researchers had an active role.

The both workshops started with a 10-minute introduction to the initial berry map ideas and a 5-minute introduction to business model CANVAS. After that a paper of each CANVAS building block was put on the wall and small groups of participants circulated between the papers, discussing and adding content. At the end of the first workshop, each participant rated all generated ideas using SMART numeric rating technique (Edwards, 1977). After that a core value calculation, a simplified version of robust portfolio modelling (see Kajanus et al. 2014) was employed to identify the

most promising combinations of ideas. Finally, the rating exercise was summarized with discussing the implications from the viewpoint of berry map business model.

Between the two workshops, a simple query to 52 potential berry pickers was conducted in order to find out why and how they would use a berry map service and for what they would be willing to pay. The interviewees represented western, eastern and southern Finland and varying backgrounds with respect to age, urban-rural lifestyle continuum, occupational status and berry-picking experience.

The interview data was qualitatively assessed and classified into values-in-use. The second workshop made use of the acquired knowledge on berry pickers' value creation and developed further the CANVAS outcomes of the first workshop. The second workshop also contained an in-class simulation of how to use mobile berry map software using an artificial model of a forest (Figure 4) and principles of participatory service design (Steen et al., 2011). Finally, the participants identified important next step actions and prioritized them with the SMART technique.

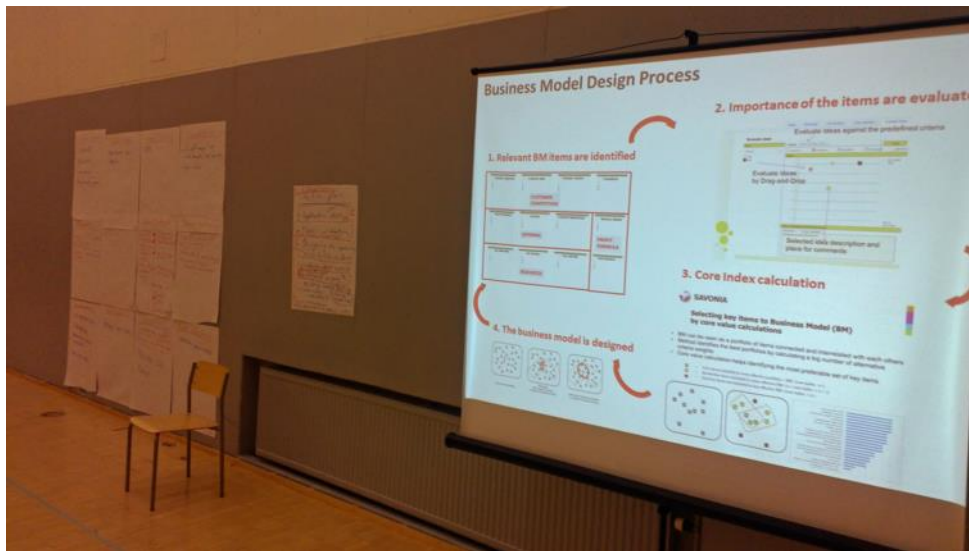

Figure 3. Instructions for business model design process on the slide and CANVAS exercise output on the wall at the end of the first workshop.

Figure 4. Simple indoor-simulation environment at the second workshop: an artificial forest with bilberry sites of varying crops and a mobile device with berry map opened.

Figure 5. Part of the CANVAS outputs on the wall during the second workshop.

4 Results

The qualitative analysis of potential berry-pickers' interviews yielded four values-in-use categories (Figure 6) that represent the meaningful purposes for which the interviewees might use the berry map software in their everyday task environment. Exploration category includes values that emerge when using the berry map enables to find new berry

sites in different circumstances; it feeds curiosity. Problem-solving category contains values that relate to receiving contextual information as answers to practical questions before or during the berry-picking trip. Convenience category contains values that are related to easiness and efficiency. Amusement category comprises values that emerge when playing and having fun.

Exploration	Problem-solving	Convenience	Amusement
<ul style="list-style-type: none"> • Encouragement, motivation, pushing effect • No familiar forests or anyone to ask: advice on where to start picking • Enlarging one's own berry picking territory • Interesting to see tracks on map afterwards 	<ul style="list-style-type: none"> • Planning a berry picking trip (desktop use) • Finding berries during domestic travelling • Finding new sites nearby if old ones are empty or if berry season in general is poor • Checking how to get there and what the terrain is like • Helps to see from the track which corners of the site are still unvisited • Using berry maps as a proxy for grouses when hunting 	<ul style="list-style-type: none"> • Efficient in everyday life and with children • Avoids useless wandering in forest: saves time and helps to get berries • Sharing berry site information within a family network • Helps in navigation and walking distance estimation • Functional exercise 	<ul style="list-style-type: none"> • Entertainment, adventure (comparative to geocaching) • Getting to know new places, variety

Figure 6. Identified values-in-use, classified in four value categories.

It appeared in both CANVAS workshops that the most promising target group in the first phase of launching the berry map service might be urban berry-pickers who lack the local knowledge of berry sites. They occasionally pick smaller amounts of berries. One to three yearly berry-picking trips for them are special and they tend to plan those trips carefully. For this berry-picker group, the social features of such a service are by default important, but the interviews indicated that they hesitate to share their own berry site information openly and would rather share it within their family network of with friends. However, this user segment would benefit from the fresh and updated berry crop information if somebody would share it for them. At least they were willing to store berry site information for their own personal use. In addition, they could use related services during their berry trips, such as accommodation or restaurant.

Overall, the interest towards the development of the service is broad – almost all workshop participants and interviewed people could easily identify use-situations where the service could help them to create value. It is notable that the values associated with the berry map idea were diverse, thus offering rather broad opportunities to service companies to start designing the marketing of their berry map service. However, the service will not sell itself: it was recognized in the second workshop that launching the service with the aid of active first users, advocating associations and change agents will be extremely important to the success of social uptake.

The interviews of potential service-users indicated that more experienced berry-pickers in rural areas know the berry picking places quite well. Their responses revealed that they could use the service in a case where their own berry-picking place is not providing them enough berries. However, most of them were not willing to pay for the use of the service.

The interviews and workshops indicated several risks related to the berry map service concept. Most prevalent of those risks are:

- Forest owners' negative reactions when berry-pickers are guided to enter their forests; unwritten interpretations on what everyman's rights include in practice.
- Historically strong culture that berry sites are secrets and not to be shared.
- Errors in information given in the berry map service. It can be so that the berry crop models are not good enough for predicting the yields and the data may not be updated regularly enough. This problem relates to the fact that recent forest management activities immediately affect the yield.
- High between-year variation in berry yields. The models predict the mean berry yield, and those estimates may not be very accurate on a certain year.
- In a case that the service is a commercial product, the willingness-to-pay of the users is not very clear yet and thus the business attractiveness of the service to companies is unclear. In the case of public service, the maintenance of the service demands resources, which are also uncertain.

Table 2. Identified prevalent next action steps and their importance ratings.

Action	Average priority score
1 Survey/market study in pilot area (Customers, berry buyers, advertisers, associations)	0.210
2 Project application for external funding enabling building a pilot version of the service	0.194
3 Risk analysis (model accuracy, landowners' opinions, updating resources etc.)	0.169
4 Define the information content of the first berry map version (NTFPs to include, information content etc.)	0.147
5 Collect key research partners	0.142
6 Identify and commit commercial IT company partner(s)	0.137
Sum of priorities	1.000

The simple rating exercise of the six important next step actions revealed that the participant highlighted the importance of a more thorough market study and resource pursuit for piloting the service (Table 2). The market study would target the whole value co-creation network, i.e. not only the ordinary berry-pickers but also berry buyers, advertisers, third sector associations, etc. The project application for external funding would enable defining the berry map software the values-in-use perspective in mind. These two actions were clearly more highly rated than the other four.

5 Discussion

The customer need for a berry map service and new kinds of use situations seem to be emerging. This study mainly concentrated on the needs of private households when studying the basis of the service. However, other potential users of the service are e.g. rural tourist entrepreneurs who offer accommodation services. An attractively delivered berry map service could support their main business – if tailored to the needs of their tourist customers. In addition, commercial berry picking could benefit from the service in two ways: first, the berry map service would help the logistics and guidance of employed berry-pickers, and second, the berry buyers could use the service to encourage people to pick more berries for selling. Both these potential benefits of the service may have impacts on the global markets of forest-based bioeconomy. Together with the added value on tourism entrepreneurship, the open public data cultivated to forest berry map service could induce important indirect impacts, thus boosting the economy of several business sectors and mobilizing green growth. However, the challenge remains how to collect enough payments from all potential berry map users in the first phase so that profitable business around the actual berry map service becomes a reality.

Converting the yield prediction information to potential berry picking place application for smart phones and tablet devices needs a lot of development work. Numeric yield calculations should be presented in maps of such a format and visual outlook that they are coherent and clear on small displays. Also technically working computer application, which is tested on different platforms and smartphones and provides all needed features have to be programmed. Luckily enough, recent development in mobile location-based social applications has provided tested solutions and components that are probably relatively easily adoptable in the berry map service as well. The more challenging part than the user interface is the server software. It is evident that a skilled team of participative software designers needs to combine their experience in the berry map software project in a near future.

The study was an initial attempt to shed light on forest berry maps as business involving value co-creation. As such it yielded a preliminary understanding of the diverse values that using the forest berry map mobile service may create among berry pickers. The resulting ideas for business model CANVAS elements serves the purpose of refining the content as well as the technical details of producing forest berry map information for the mobile service (e.g. thematic layers, classification, resolution, etc.). The expanded CANVAS (Kajanus et al., 2014) appeared to emphasize the company solution as a response to customer need, which is very essential in the business model concept. The rating of CANVAS ideas using SMART technique was simple enough but still provided a sophisticated base for summarizing the exhausting idea generation phase: based on this experience the business model design process is recommended to be conducted combining qualitative and quantitative parts sequentially.

The workshops produced necessary information for defining a demo application and organizing user tests of the service in an authentic environment. Furthermore, the identified business opportunities and risks will enable ICT-companies to assess their interests for getting involved in berry map service business in collaboration with public service providers and third sector collaborators. The study represents collaborative service design in the service-dominant logic framework (Steen et al., 2011). In the future it is recommended to continue the efforts with the aid of systematic co-design. The combination of service logic and service design approach (Wetter-Edman et al., 2014) will be an asset when targeting new kind of value-creating services based on open public data. However, the open public data as such is not a magic key to success: understanding value-creating processes is more important, and the availability of necessary data enables the new service experiences and new company strategies.

Hand in hand: When design put things into places

Jaana Hyvärinen¹, Helena Sustar¹

¹Aalto University School of Arts, Design and Architecture

The aim of this paper is to explore the role of design in supporting user-centred development of services and transformation of service organisations. Especially the focus is on bottom-up and top-down service development approaches in the context of service ensembles provided by multiple, interlinked public, private and third sector organisations. The paper presents findings from two separate design case studies. The first study focuses on the organisational perspective in the context of services for elderly, and the second on the customers' perspective in the context of services for immigrants. The findings highlight how the designerly ways of gathering, visualizing, analysing and sharing information may enhance service development.

1 Introduction

In recent years governments all over Europe have faced challenges to respond to the increasing needs for public services. For example, providing services for a growing number of ageing population and the integration of immigrants, are challenging current public service systems. Furthermore, due to economic meltdown the funding of public services is more inadequate than before. In this situation it is increasingly important to make the services more effective and sustainable, and look for alternative service solutions. For example, overlapping service processes and lack of communication, information sharing and coordination between service organisations result inefficient use of scarce resources. At the same time citizens struggle to find their way in the bureaucratic 'service jungle'.

Recently public organisations have become interested in novel approaches for developing services, such as service design among others. Service design is an approach that utilises design methods for developing new and improving existing services. The holistic understanding of the service systems, the process-nature of services and the human perspective in service development are emphasised in service design. Concepts such as touchpoints, service encounters and service journeys have been used to denote the interplay between the customers and their environments. Such service encounters and journeys are often explored as interactions between an isolated service provider and its customers. However, especially in the context of current challenges with the public services it is crucial to understand services more holistically from customers' perspective. Thus, it is important to explore service networks that are formed as the service encounters with various service actors are embedded in the customer journeys. In this paper customer journey is defined as series of service encounters customers have with complementary public, private and third sector organisations, as part of their process to achieve the desired objective.

Recent advances in the field of service design have approached services as complex systems. For example, according to Junginger and Sangiorgi (2009) service interactions and experiences occur within wider systems of actions and actors whose behaviour can't be predicted and designed in details. Different approaches for service development has also been studied by Sørensen and his colleagues (2013). Traditional top-down approach concentrates on development based on strategies, taking place at research and development units, under the supervision of managers. Top-down directed service development is usually based on organisations' strategy and often involves systemised processes led by management, marketing, and research and development departments of the organisation (ibid). Bottom-up approach, on the contrary, takes the customers' and frontline employees' perspectives as the starting point for the development. Bottom-up approach is often based on small, scattered changes and non-systemised processes; such as customer or frontline employee may unintentionally create a new solution or detect a new demand (ibid). For example, employees may adjust their daily practices to particular customers' problems. Sørensen et al. (2013) suggest that it is crucial to understand also in the bottom-up development as only the back-office has resources to develop an idea further, test it and implement it.

There is also a growing interest in to develop public services. For example previous research on design in the context of public services includes themes related to design methods and tools suitable especially for public sector (e.g. Bason, 2010; Botero et al., 2012; Vaajakallio et al., 2013; Kronqvist et al., 2012). In addition design is seen as an approach and a process that can enhance the organisational transformation while developing new services (e.g. Junginger; Sangiorgi, 2009; Junginger, 2009; Sangiorgi, 2011, Deserti; Rizzo, 2014). This organisational transformation is especially important since the citizen-centric 'bottom-up' perspective entails changes in the traditional 'top-down' led public organisations. The bottom-up approach challenges also the role of design and designer. For example, Sangiorgi (2011, 31) states, "*the service design practitioners have been moving from providing solutions to specific problems, to providing organisations with the tools and capacities for human-centred service innovation*". Furthermore, Junginger and Sangiorgi (2009) claim that this change in focus is particularly true when designers aim to have a transformative effect on organisations and the emphasis is on open, participatory and iterative design processes that build capacities from within, and see users and service employees as co-producers and co-designers of the final solution.

As identified before, public organisations are in need for novel tools and approaches to cope in the changing environment. They need to question the current organisational structures and decision-making procedures to support the continuous bottom-up service development. However, they still lack feasible tools and approaches for enhancing continuous collaboration inside organisations, between organisations and with the service users. In this paper we explore how the designerly ways of gathering, visualizing, analysing and sharing information within and between organisations could enhance combination of bottom-up and top-down service development approaches in context of public services.

This study combines recent findings from the fields of service research and design research. The study contributes to the discussion on enhancing the efficiency of public services through more customer-driven, bottom-up approach. In addition this study examines design tools and approaches that public organisations may utilise for combining bottom-up and top-down service development. The aim of this paper is, thus to explore the role of design in supporting user-centred development of services and transformation of the service organisations. Especially the focus is on bottom-up and top-down service development approaches in the context of service ensembles provided by multiple, interlinked public, private and third sector organisations. The approach is illustrated through two case studies; the first is in context of services for elderly living at home and the second, in the context of services supporting immigrants' integration to a new country. The first study focuses on the organisations' and the second one to the users' perspectives. In addition, the studies look at the needs and possibilities for horizontal inter-organisational collaboration.

The paper is structured as follows: Firstly, we briefly introduce recent literature related to service design in the context of public services, service design methods, and design in the context of organisational transformation. Secondly, we introduce the two design case studies. Thirdly, we discuss the findings from the cases and the literature together. We end the paper with the concluding remarks.

2 Service design, public services and organisational transformation

In this section we review relevant literature from the fields of design research and service research. We start by focusing on designing for public services and service design methods. We then continue with the role of design in organisational transformation.

2.1 With service design towards more customer-oriented public services

Recently service design researchers have increasingly become interested in the designing for public services (e.g. Bason, 2010; Junginger, 2013; Sangiorgi, 2011; Vaajakallio et al., 2013). For instance, Mattelmäki et al. (2014) anticipate the applications of empathic design approach in development of public services in the future. Researchers are interested also on larger changes in the public sector, its services and their development. For example Bason (2010, 14) calls for public sector innovation ecosystem built through four simultaneous shifts: "1) a shift from random innovation to a conscious and systematic approach to public sector renewal, 2) a shift from managing human resources to building innovation capacity at all levels of government, 3) a shift from running tasks and projects to orchestrating processes of co-creation, creating new solutions with people, not for them and 4) shift from administrating public organisations to courageously leading innovation across and beyond the public sector". These shifts aim at continuous design of whole public sector; it's organisations and services. It is evident that public organisations need to change, but what organisational transformation is about? And how design can enhance it? Junginger (2013) discusses the role of design in the policy-making and implementation as problems of design and as activities of design. According to Junginger (2013, 1) "*policies themselves are not yet fully acknowledged as design outcomes in contemporary policy studies. Instead, this literature treats design almost exclusively as an isolated, in-itself-closed activity, part of problem-solving that begins after a policy problem has been recognized as such and defined.*" Junginger (2013) critically engages with this view of design and identifies it as an obstacle for the kinds of innovation and transformation public sector now seek to initiate and materialize. Service design tools enable policymakers, governmental organisations and service users to explore current services and anticipate future possibilities collectively.

There are many innovative cases of design for public services that were initiated by policymakers and in which changes were implemented also from bottom up, or by active citizens mobilising a local community. First, one of the most respectful governmental digital service run by UK government cabinet office is www.gov.uk website because of its size and complexity (Design Council, 2013). The website offers British citizens information about taxation, help them to find jobs or benefits; the website is user focused rather than siloes structured governmental service website. Another good example is Casserole, a peer-to-peer service designed to support neighbours who are not always able to cook for themselves. The neighbours, who want to share extra cooked food with older people in their area provide the meals. A private service design company designed the service, the boroughs are responsible for service organisational structure and the neighbours run the service (FutureGov, 2012). Both cases represent user centred design approach that is based on the understanding of the service users and their needs. Casserole is linking traditional governmental service structures and the emerging citizen-driven action. A third example is the Danish tax authority that engaged their users, a group of young people, to help service providers, the Danish Tax and Customs Administration, to communicate their services more efficiently to younger users. The project was done in collaboration with MindLab. The same cross-governmental innovation unit conducted a project on Nordic schools together with the Danish Ministry of Education. In

this project the change was implemented from bottom-up with involving individual pedagogues, teachers, and headmasters with the children and their parents. At the policy decision level, a school committee councillor was interviewed from two different municipalities. This is quite unusual for the school system, which is normally developed from top-down (MindLab, 2014). A fourth example comes from Helsinki where a community worker initiated an idea of refuge hospitality club over Facebook to get the newcomer refugee seekers integrated into local community. Nearby residents were acting as hosts and refugee seekers were gussets performing different cultural and sports activities. Together.

Empathic design aims at establishing empathy between different actors involved to service provision and development with its visual, tactile, experience enhancing and playful ways of making. Such methods can help stakeholders to avoid abstractions and make discussion more concrete. Empathic approach also aim at building trust and better understanding of sometimes-opposite opinions towards more equal partnerships. Typically different approaches are used to understand and design for service users' experiences. For example, Vaajakallio et al., (2013) adopted co-design workshops and generative tools, such as image collages and design games, narratives, and customer journey boards when designing for public services. These tangible tools and props helped non-designers and people from the public sector to envision and articulate what could be desirable in the future (Vaajakallio et al., 2013). Vaajakallio et al. (2013) suggest that adopting an empathic approach, i.e. building on service users' experiences, processes and practices open opportunities for solutions over more traditional approaches. Hence, designers act as a bridge between different participants' views and help them to create their own ideas instead of giving them direct solutions to evaluate or choose from. However, based on the case studies the authors recognised that it is important to have a change agent (e.g. designer) in the organisation to ensure the implementation of these -sometimes radical- solutions. Recently, the empathic approach has been applied in the context of supporting collaboration in networks. Tools for exploring the systems perspective include for example, communication maps, modelling networks, customer journey mapping and service blueprinting (Stickdorn; Schneider, 2011). These tools can be used in various contexts and phases during the design process. For example, Kronqvist et al. (2012) used customer journey map as basis for a game board. The aim of their project was to develop new services in hospital context and the game board was used for supporting interviews with patients and employees. The game board acted as a design medium to express very personal and sensitive experiences about the current service.

2.2 Transforming service organisations through service design

Existing public services can be seen as products of the current organisational structures that have developed during past decades. Now as the public services are facing the needs for change, also the organisational systems behind the services need to change. For example, Junginger and Sangiorgi (2009) argue that services cannot be isolated from the elements of the organisation. According to them these elements include the people with their norms, values, beliefs and behavioural patterns; the structure of the organisation such as its procedures, hierarchies and tasks; its resources and an organization's vision, which gives purpose and guidance for how resources might or might not be used (ibid). Junginger (2006, 26) presents three ways to organisations to change; drifting, accommodation and transformation. According to Junginger (2006, 26) drifting denotes to passive change linked with the past, accommodation is responsive change to present circumstances, and transformation targets the future of the organisation. Transformation is more profound than drifting and accommodation; during the transformation values, assumptions and beliefs inside the organisation change (Junginger, 2006).

Previous research has recognised the need for more continuous development based on the bottom-up insights (e.g. Bason, 2010). For example Sørensen et al. (2013) investigate the organisational conditions for service encounter based innovation, during which ideas and new practices are developed and integrated in the organisation based on frontline employees interactions with users. Sørensen et al. (2013) pose a question how organisational features may facilitate such innovation processes? According to Sørensen et al. (2013, 1448) *“the service encounter-based innovation processes depend on three general interdependent elements of an integrated process: (a) facilitation of the innovation process by organisations, especially in order to sustain (b) creativity among front-line employees based on service encounters and (c) integration of the results of the creative processes in the organisation.”* Organisational support system can support communication and integration of front- and back offices, as well as facilitate *“creative front-office innovation climate”* (Sørensen et al. 2013, 1448). Support system may facilitate the transfer of ideas from frontline employees to back-office. For instance, it can support processes through which back-office acquire and handle the customer insights and practice-based changes in the front office. What role design process and methods can have in this kind of organisational support system? According to Deserti and Rizzo (2014, 42) *“design challenges the natural organisational attitudes of preservation and resistance to change, generating a constant tension between the search for innovation and the necessity of relying on established ideas and solution”*. They see these contradictions as the sources of change in all situations in which innovation overcomes the constraints to its own development by generating new artefacts, knowledge, beliefs, processes, structures and technologies that become part of the organisation by modifying it (Deserti; Rizzo, 2014, 42). According to them the constant tension between the development of new products and the organisational attitudes of preservation and resistance to change builds a significant link between design and the problem of managing organisational change (Deserti; Rizzo, 2014, 36). In their opinion design introduces bottom-up perspective to organisational change (Deserti; Rizzo, 2014, 36). The development of new kind of services implies

relevant changes in all the elements that compose the organisation. Thus, bottom-up perspective assumes that designing significantly new solutions may bring unexpected changes in the organisation because contradictions might arise between the current culture and the one needed to implement the new solution (see also Deserti; Rizzo, 2014, 37). Also Junginger and Sangiorgi (2009) reflect on the potential of service design to generate and implement internal changes within an organisation. They suggest that successful and sustainable new services, which aim for lasting transformations, require reflective inquiries into organizational systems (Junginger; Sangiorgi, 2009).

Junginger (2006; 2009) investigates the human-centred product development process as a way to enhance organisational change. Junginger (2009) advocates the notion of designing outside-in as key to organizational change. According to her human-centred design process introduces the perspectives and experiences of people outside of the organisation (e.g. customers and suppliers) to the organisation. These people are not familiar with acronyms, processes, hierarchies or standards created by internal experts (Junginger, 2009, 235). She states that as the design process is an activity of making and creating, the learning is put to action. Learning and acting on the learned are necessary preconditions for fundamental organizational change (Junginger, 2006, 15). Furthermore, this process may also give people confidence in making decisions and taking actions (Junginger, 2009, 235). She sees human-centred product development as a path for organizations along which they can transform themselves. Thus, this process of designing from the outside makes organizations and their products work for people inside and outside of the organization. There is also a need to understand the changing customer needs continuously and act according the findings simultaneously (e.g. Bason, 2010). Junginger (2006, 17) states that her findings document that human-centred product development cannot only generate the possibilities for organizational change but also offer the means to implement them. Design offers tools for exploration, visualisation, iterative prototyping and testing. Thus, design outcome may also give a concrete form to what is uncertain and undetermined between the organisation's vision and the user insights, in other words combine the top-down and bottom-up approaches.

To summarise, design has been recognized as a potential approach for combining the top-down and bottom-up approaches in service development. For example, design can have inevitable role in organisational transformation by exploring the organisation from the outsiders perspective e.g. customers' or partner organisations' employees' perspectives. Design process can be seen as an inquiry to the organisation and as a vehicle for organizational change (Junginger, 2006; Junginger, 2008). Design tools and processes can support continuous front-line employee and customer-based service development, for example by enabling organisations' to see the strengths and weaknesses of the organisation from the outsiders' perspective. Employing methods familiar to design such as co-design workshops and generative tools, such as image collages and design games, narratives, and customer journey boards and prototyping, can be used to enable organisations to learn about their customers and about themselves.

3 Case studies: Combining organisational and customers' perspectives

In the following paragraphs, we introduce two cases. Both cases focus on gathering, analysing and visualising experiences of different stakeholders (e.g. managers, frontline employees, customers) involved to service development, provision and use. Cases illustrate what kind of needs and challenges exploration of new service solutions may face in public sector and how the design tools may help to overcome those obstacles. First case concentrates especially to the organisational perspective and the second to the customers' perspective. Analysis focus to three themes: 1) needs and barriers for novel approaches for develop public services from organisations' and customers' perspectives, 2) experiences related to the inter-organizational customer journeys from the customers' perspective, and 3) the role of design in enhancing and combining the top-down and bottom-up service development approaches. These cases are used as examples how design has been used for developing public services and organisations providing the services.

3.1 Case 1: Designing for organisational transformation in inter-organisational service network

The first case study focuses on the collaboration within and between organisations during two successive projects. The first development project took place 2010-2013 and the second on-going, evaluation project takes place 2013-2014. The aim of both projects is to facilitate customer-centred inter-organisational collaboration in context of services for elderly living at home. The aim of the municipality-initiated development project was to create local, customer-centred service network from public, private and third sector organisations to support elderly citizens living at home. The focus of the project was especially in the caregiver families living at one neighbourhood at Helsinki metropolitan area. The focus of the on-going evaluation study is on assessing the role of design during the development project. The evaluation is based on the experiences of the employees (e.g. frontline employees and managers) involved to the service development and collaboration during the first project. In addition the on-going project aims to develop tools for modelling complex networks and prototyping new collaboration possibilities within and between the organisations in the network. Some of the findings are reported also in previous papers related to the projects (e.g. Nykänen; Jyrämä, 2013; Hyvärinen et al., 2014).

3.1.1 *Methods: Gathering the experiences on design through interviews*

Preliminary findings presented in this paper are based on interview data and project materials, such as reports, memos and presentations produced during the projects. Interview data was gathered through semi-structured interviews with different service network actors. Interviews took place in the spring 2012 when the development project was in midway. A design researcher working in the project carried them out. Altogether 16 employees from public, private and third sector organisations were interviewed: twelve employees from the public sector (e.g. social services department, health care department, city's central administration), two persons from the private sector, and two persons from the third sector. The selection of the interviewees was based on snowball sampling. First part of the interview included questions related to the project preparation, interviewees' role in the project, and experiences of the collaboration during the project. The second part of the interview focused on the role of design and how interviewees perceived it. Each interview lasted from one hour to one and half hours. Transcribed interview data was analysed qualitatively. Analysis focused on identifying themes related to the collaborative intra and inter-organisational service development efforts and use of design during the development project. The materials produced during both projects were used to gain more holistic understanding about the projects and to support the interview analysis. Project materials were acquired from the archives of an organisation that participated to the first project. However, the findings presented in this paper focus especially on individuals' insights and experiences as expressed in the interviews. The interview quotes presented in this paper were translated into English by the one of the authors.

3.1.2 *Findings: Engaging people to the transformation through design*

Especially public organisations were structured to provide standardized service for all citizens interdependent what customers really needed or wanted. The organisations were organised according to functional silos and there were no established practices for collaboration between different units and departments. From customer perspective this led inefficiencies and breaks in communication, coordination and information sharing. This was especially evident during the customer journeys that spanned across organizational boundaries and across different channels. According to the interviews, employees from the public sector have recognised that the elderly customers struggle to manage the interrelated social and health care services. At the time of the interviews, none of the service providers had holistic view to the services provided for a specific customer. Thus the customer was responsible for the communication, coordination and information sharing between different service providers. However, all interviewees had recognised that fluent collaboration within and between organizations would result better service from customer's perspective and resource savings from organisations' perspective. One problem in the public organizations was that the customer insights and frontline employees' knowledge about the customers reaches the management level only randomly.

The hierarchical organizational structures did not support the bottom-up insights and innovations to be systemically utilized in service development. Furthermore, the hierarchical structure and bureaucracy reduced employees' and customers' opportunities to participate to the service development efforts. According to the interviews, also the management level understood that the organisation-driven way of providing and developing services was not producing required kinds of results. The development project was strengthening their opinion, that bottom-up approach was only way to provide services that really benefit the customers. Especially in case of the elderly citizens, right kind of support may prolong the time they are able to live at home. This kind of personalised support can only be provided by understanding the customer's everyday life, providing right kind of service ensembles and enhancing the collaboration between different service organisations. As one interviewee stated, the customers' are not really interested in the back stage processes and who provides the services.

Developing collaboration from the customers', not organisations' perspective, calls for tools for gathering and sharing customer insights continuously. Transformation of beliefs, values and attitudes can be enhanced by enabling employees to look their own organisation from outsiders, for example from customers' perspective. Thus, the organisations need to be more proactive with the bottom-up insights, and therefore the organisational structures need to be updated to support this kind of processes. However, the interviews revealed barriers for transformation as illustrated next. According to the interviews the public organisations lacked feasible tools for gathering bottom-up insights from the citizens and the employees. In addition they lacked organisational structures and procedures for implementing the findings in their everyday service operations. However, the development project was seen as a platform for developing and testing these kinds of tools and practices. The process of gathering customer insights and developing and piloting novel service concepts based on them, catalysed also the transformation in the organisations. The project involved customers and other stakeholders from outside the organisation and enabled the learning among the people inside the organisation. Furthermore, the project was seen as an opportunity to question the traditional ways of operating.

Interviewees recognised that design may have different roles in enhancing organisational transformation. For example, the designerly way of gathering, visualizing, analysing and sharing information enhanced more holistic and user-centred service development. Various design methods were used during the development project. The methods included contextual interviews, design probes, personas created based on the gathered customer insights, co-design gatherings, and creating service network visualisations and customer journey maps. The design probes were used for collecting information about the elderly customers' everyday life. Bottom-up insights were collected through interviews. Service design consultants conducted contextual interviews with the caregiver families in 2011. They created personas describing the typical user groups, based on the interviews. In addition they shared the customer

insight with video clips for example in workshops arranged to different stakeholders of the project. The co-design workshops were arranged to share and analyse information and ideate new service solutions together with different service network actors. According to the interviews especially the customer video clips showed in the meetings had a great impact to the management level in the organisations. Also the customer journey visualisation and service network maps were used as a basis for discussion in the workshops.

Design tools and approaches were appreciated especially because of their ability to bring people together and thus combine the bottom-up and top-down approaches. For example visualisations helped different stakeholders to share and analyse collected insights. The design probes were used during the development project for collecting knowledge about the customers' everyday life and service needs. The first version of the probes package was designed and implemented by a design student working in the project. According to the interviews even front-line employees, who had worked with the customers for years, got new information about their customers through this method. Interviewees also recognised that a design process can bring change to the organizations regardless of the results of the process. For example, the workshops were seen as important platforms for people to meet and vision for the future collaboration opportunities. Co-creation took place in the borders of different expertise and practices, as one interviewee from the private sector stated the workshops presented the challenges and opportunities of this kind of collaborative service development setting in a miniature size. However, design did not provide only tools for learning through exploring the future possibilities but also implementing them through iterative prototyping. The main outcome of the design process might be new knowledge about the own work and organisation as well as opportunity to get familiar with people inside the own organisation and from other interrelated organisations. Service prototyping and piloting processes enabled different level employees from frontline to management to think about their own organisation in a new way.

3.1.3 Discussion: Towards continuous organisational transformation in all levels

The preliminary findings indicate that in 1) the current organisational structures and decision-making procedures need to change to support combining of the bottom-up service development to current service development practices, 2) thus, the organisations are in need for new feasible tools for enhancing continuous collaboration inside the organisations, between the organisations and with the citizens, and 3) the designerly way of gathering, visualizing, analysing and sharing information enhance both bottom-up approach and developing practices for combining bottom-up and top down approaches.

The elements of the organisations, such as the employees; the structure of the organisation; its resources and the organization's vision (e.g. Junginger; Sangiorgi, 2009) have an important role in facilitating the creativity as well as integrating the results of the creativity. It seems that especially in the public sector, bureaucracy and current decision-making routines hinder the information generation and sharing about users' needs and limits responsiveness to these needs (e.g. Sørensen et al., 2013, 1448). Thus design process must involve different units and departments and possibly take into consideration ideas, experiences and the knowledge of employees from all levels of the organisation. Continuous service development can be achieved by integrating the front-line employees' work-related experience and by supporting bottom-up knowledge sharing. Internal barriers such as current divisions between front-line employees, management and research and development units, can be seen as a barrier to bottom-up service development. According to Sørensen et al. (2013, 1448), such internal organisational barriers may also consist of cultural, social and/or psychological 'divisions' between front- and back-office work-groups. Design methods can enhance the understanding between the 'silos' of the organisations and across borders of different expertise. Furthermore, design tools, such as prototyping, may help to collaboratively decide whether or not to develop an idea further by making abstract service concepts more concrete.

The findings presented in the previous section form a basis for the on-going modelling and prototyping process of the on-going follow-up project. Future research directions include modelling and prototyping the future collaboration possibilities together with stakeholders from different units and organisations. Service prototypes and the iterative prototyping process are used as a shared platform for discussion about the current situation and future possibilities. Especially aim is to prototype different communication, collaboration and information sharing practices with-in and between different organisations from the employees' and customers' perspectives. Aim is to enhance the sharing of customer insights within and between the organisations and support the organisations capacity to facilitate the frontline employees' service encounter based idea creation. This entails also changes in the organisational processes and structures since the back-office processes need to facilitate creative problem solving in service encounters and observing, recognising and accepting changed practices, which can then potentially be distributed and reproduces as innovations (Sørensen et al., 2013, 1448).

3.2 Case 2: Standing into someone else's shoes

The second case study focuses on mapping and visualising immigrants' service experiences throughout service journeys by using touch point cards and emoticons. This preliminary study was conducted to investigate state-of-the-art of public services provided for immigrants when relocating in to Finland. To do that informal interviews with the service users - immigrants and the service providers – the City of Helsinki employees were conducted. The aim of this study was to gain understanding of the immigrants' everyday life and how people with different cultural background use services

specifically related to their relocation. For example, acquire the residence permit by registering at the local police station, obtain health insurance card, finding a job or learn local language. Series of seven interviews with university level educated immigrants and two with civil servants working on immigrant services were completed.

Interviews were conducted from mid January 2014 to the end of April 2014 in English language and they lasted from 40 minutes to one hour and a half. Interviewed subjects (two men and five women) represented immigrants coming from Japan, Slovenia, Russia, China and Afghanistan. One participant had the status of the refugee and two had individuals Swedish/Finnish descent who were born outside Finland. Interviews with the immigrants were conducted at the university campus, apart two from which one was done at the participant's home and the second one at the adult language centre. Five participants were recruited from the university, two from the language course and one over the marital relationship. Interviews with two (female) civil servants were done at the City of Helsinki premises.

3.2.1 *Methods: Mapping and visualizing services journeys*

Visualisations of service journeys included services that interviewees used before, and after moving to the country nevertheless, they have not been asked about other public services (for example doctor or library visit). Interviews with civil servants were conducted as standard informal interviews, and no additional (visual) material was adopted. Customer service journey visualisation used with immigrants acted as a boundary object to discuss issues related to services and to establish more informal relationship between the researcher and the immigrant. The researcher asked immigrant beforehand to think of its favourite object that reminds him/her of home country. Telling the story behind the chosen object acted as icebreaker and in many cases made participants very emotional. After that the participant was asked to map out their service journey with the use of touchpoint cards and big, blank sheet of paper. To do that the participant was given a set of touchpoint cards (including blank ones) representing an image and word of service touchpoint (e.g. police, bank, the registration office). The interview followed four themes: before moving to country, coming to country, interaction with the service and integration (if it happened). In addition, the participant was given a set of eight different emoticons – visual representation of different facial expressions (for example smile or frown) to express their experiences and feelings when were using different services, service encounters or service touchpoints. In order to get, more compelling story the researcher was asking participant prompt questions such as, “*How did you feel about that?*”, “*Where did you go next?*”, “*What happened then?*” through the interview.

3.2.2 *Findings: Service journeys paths between different service providers are incomprehensible for everyone*

This section discusses issues that they were pointed out by immigrants' service users, together with the City of Helsinki civil servants employed on immigrant services. Findings reveal five issues concerning immigrant services.

First, inadequate intra-organisational and inter-organisational collaboration between different immigrant services providers' organisations was reported. Interviewees were stressing out non-transparency of the system and poor communication. Settling in obligations, which are required to be completed by the individual immigrant are in several different locations in the city. Furthermore, the civil servant reported that different service encounters provide only the certain types of services and they have limited competence “*We used to have Infopannki website [this is often the first informative website for immigrants], but it is not interactive. Then we have Virka office [face to face support for immigrants provided by the City of Helsinki], but they don't make any decisions, they only give advice and 'In to Finland' [tax office information point] they can give you only tax number.*” In addition, individual service encounters act as independent bodies (e.g. registration office) and they are able to undertake autonomous decisions in different parts of the country. This contributes to further incoherency and reduced communication between different service providers' organisations (e.g. registration office, police, tax and health insurance office) in immigrant services. Moreover the civil servant reported that in order to centralise all immigrant services in one place, it was planned to place at the City of Helsinki in person immigrants support, tax office information point and the national healthcare office, nevertheless because the city is providing services for all residences that were not possible.

Second, more holistic understanding on how the service system works. Individual user's service journey paths are incomprehensible to both service users and immigrant services providers' organisations, which are not familiar with the most appropriate paths for different types of service users. Immigrants coming to Finland are mainly divided into three different categories: EU, non-EU and third countries citizens. However, their service journey differs if they are students, married to the Finnish person, labour immigrants, or they are coming from Nordic countries. The civil servant reported that it is unclear what service journey path certain type of immigrant has to take “*the problem is that this is really unclear, but for us as civil servants we can map out [service journey] here and there, but from the user point of view, it is a jungle*”. Similarly service users reported the lack of understanding on how the Finnish immigration system works “*Maybe because of my language barrier or lack of understanding of system living in the social state, I still don't understand how things works and what to expect of certain services.*” Furthermore, the reason why they have to visit the particular service encounter is not reasonable to the service users cultural background “*You have to go to the police office and you have applied there, which is really the strange combination. Why we have to go to the police office, already you sound like criminal. I don't go to these places regularly.*”

Third, service users reported complicated and unclear procedures and protocols with rigid rules and no alternatives, which they made them frustrated. Complicated service encounter procedures cause task duplication for service users. For instance, the person can apply for the residence permit online, but then has to go to the police office to prove its identity in person. Moreover, the procedures are rigid and they are not an necessary offer any alternatives or taking on board already established similar services protocols. Service user reported the following incident: *"I went to the bank and they said "We can't give your electronic identity because you don't have ID card", I said "I can confirm my identity with my passport." In our rules, you have to have ID card."* Complex and demanding procedures cause long waiting queues and uncertainty at the service users not knowing how long the process will take. The case was illustrated with the following user's words *"Did you not receive any letter?" I said no, no letter, no e-mail, nothing like that, no notification. She was ashamed. "Actually, it is ready, it was ready already in December." What? So they didn't notify me about that at all and I spend two months in uncertainty. So, by that time service didn't work. That is what I can say. I was not angry, I was just happy that is ready. But I was little bit upset that they did not notify me."*

Fourth, touchpoints' information incoherency was reported, for example lack of integration between different channels e.g. websites, non-informative personal communication, written correspondence available only in local language and insufficient spatial communication. Service users as misleading, difficult to understand, badly maintained reported websites, which are often the first contact point with the service; they felt confused and frustrated. For example, the service user reported the following occasion at the embassy *"Ooo, my got it was so complicated and the thing is that I checked the website then, I decided to call because, it was not clear. They had so weird website and beside that it was in Hungarian. So, I call them. I didn't cry I was like... I was angry."* Furthermore non-informative personal communication was identified by service provides and users. The civil servant reported, *"What I am hearing from the people that they are trying to settle down... Finnish offices have the tendency only to reply the questions that you ask; they don't give you the additional information, [] for example, what is the next step that you have to do...."*

When visiting the public place (e.g. the police office) immigrants expected information in different languages and clear spatial communication, but this was the case. User reported the following experience *"When I went there it was so unclear where you have to go.... They have one big room and another big hall with electronic view and all that stuff. And, I went there first and everything was in Finish and something about fire licenses and all these strange stuffs. Ok, they don't have anything the like information desk, someone who can explain to me where to go. I take that long queue just to ask."*

Fifth, social platforms and peer-to-peer guidance were seen as important when users proposed improvements. Overcrowdings of current immigrants' services and huge apparatus require from future public services to think of providing alternative peer-to-peer services, as a support to existing public services, which can substitute special needs of different profiles of immigrants.

3.2.3 Discussion: Development of peer-to-peer support services as a alternative to existing public services

This preliminary study designates 1) inadequate intra-organisational and inter-organisational collaborations between different service settlement services providers, 2) more holistic understanding of how the service system works, 3) complicated procedures and protocols with rigid rules, with no alternatives 4) touchpoints' information incoherency, and 5) social platforms and peer-to-peer guidance.

Current inter-organisational immigrant services structure needs more transparency and better communication between different service providers or centralisation of the services in one place for different types of immigrants. More user centred approach (bottom-up) is needed, as existing system not necessary fit to immigrants' needs as is developed more for home residents. This bottom-up approach need to be facilitated by the back-office, thus transforming the current traditional organisation structures is needed (e.g. Sørensen et al., 2013). For example, home residents get social security number by birth and the entire system base on that. Immigrants struggled to get this number. Furthermore, current governmental service structure is silos oriented and understand immigrants thru their employment, housing, health, and social care rather than as individual person with its specific cultural background, life-story, skills, knowledge and needs.

Complicated service journeys paths between different service providers require implementation of design thinking via visual representation of user actions points, service journey maps and different immigrants' profiles based on latest legislations. This will help both service users and providers for more fluent service navigation through settlement services user journey. Furthermore, implementation of design thinking in system and service design or even more radical "designer in residence" can smother complicated procedures and protocols. Service design with its empathic service design tool can visualise and examine separate touchpoint and contribute to more informational coherency.

Botero et al. (2012) are observing flourishing new citizens' lead event initiatives and urban planning development plans. Relationship with the citizens and the state is changing; it is necessary to imagine and organise common affairs in new ways. The authors notice intension in developing new partnerships between public, private and third sector and citizens to create and produce more public services. Active forms of citizenship, broader public participation, and the role of 'peers' have emerged as key issues (ibid, p.6). Botero, et al. (2012) recognised different types of alternative peer-to-peer services arising from people initiations as well as non-profit and non-governmental organisation. The findings also triggered new questions, such as is the design process about implementing a current strategy or re-

inventing the strategy? Who defines that what is developed, how it is developed and how the process and end result is implemented and evaluated? We are planning to address these questions in our future research.

4 Discussion

The two cases presented above illustrate how design can be utilized on different levels of organisations for developing public services and transforming the organisations providing the services. The literature on design in context of organisational transformation recognised the design process as a way to renew the organisations from inside-out and outside-in. The literature on design emphasised the role of design in supporting collaboration between various stakeholders with different backgrounds. Especially design methods were appreciated because of their ability to bring customers' perspective inside the organisations. In addition to the novel ways of gathering and sharing customer insights, also the collaborative settings in the workshops enable novel relationships between stakeholders to emerge.

The following table (Table 1) summarizes the findings from the case studies and the literature.

Table 1. Development needs identified from the literature and cases and suggestions about the role of design.

Identified development needs	Suggestion for the role of design
<p>Need for continuous inter-organisational collaboration and holistic understanding how the service system works. People that are part of the system and the people who are using it are not aware about the different actors and their relationships. Need to move from random development projects to a conscious and systematic approach to public sector renewal (Bason, 2010).</p>	<p>Collaborative system mapping through visualisations (e.g. actor maps, communications maps) make the abstract service system visible. Develop feasible tools for enhancing continuous collaboration between organisations in different scales and levels. Design tools (such as design probes, visualising customer journeys, story telling over video about daily life of users) enable new ways to gathering and sharing customer insights.</p>
<p>Need for continuous organisational transformation. Organisations are not customer-oriented but working in 'silos'. Insight from frontline employees and customers don't reach the management level. Organisational structures need to support Implementation of bottom-up innovations. Organisations lack tools and procedures for collecting and sharing the front-office insights and using them as a basis for continuous development (e.g. the lack of communication between front and back-offices, lack of back-office support for the creative attitude in the front office).</p>	<p>Introduce the perspectives and experiences of "other" people to the organisation (Junginger, 2009) for example by applying tools for understanding the everyday practices of customers and service employees (e.g. contextual interviews, design probes). Develop feasible tools for enhancing continuous collaboration inside organisations and with the service users. Support innovation capacity at all levels of organisations (Bason, 2010). For example, apply design process and tools for lowering the borders and enhancing the understanding between different organisational or expertise 'silos'. Apply design tools to make abstract service ideas more concrete (e.g. scenarios, prototyping) to enable discussion and evaluation of the ideas before implementing. Create organisational conditions for combining the top-down and bottom-up approaches for example by providing platforms for collaboration (e.g. co-design workshops, design games).</p>
<p>Need for clear and smooth procedures and touchpoint information coherency. Complicated, unclear procedures and protocols with rigid rules, which do not allow any alternatives. Incoherency between different touchpoints within a service journey (e.g. lack of integration between different channels) e.g. spatial communication, frontline employees are not providing information, written correspondence available only in the local language.</p>	<p>Clear visualisations of procedures and protocols in multichannel information delivery. Mapping the service journeys from the customers' perspective, mapping the different channels of communication of certain service provider, to form coherent multichannel customer journeys.</p>
<p>Need for visual and tangible tools complementing the traditional verbal communication. Support communication between service users and service providers.</p>	<p>Design is not just about providing solutions to specific problems, but providing organisations with the tools and capacities for human-centred service innovation (Sangiorgi, 2011). Introduce visual tools for easier communication and collaboration during the service encounters (interaction between the frontline employee and the customer) and service development (between different stakeholders) (e.g. customer journey visualisations, service system maps) For example tangible tools and props help non-designers and people from the public sector to envision and articulate what could be desirable in the future (Vaajakallio et al., 2013). Design can give a concrete form (e.g. prototype) to what was uncertain and undetermined between the organisation's vision and the user insights (Junginger, 2006).</p>

Identified development needs	Suggestion for the role of design
<p>Need to overcome the resistance to change. Employees at all levels of the organisation need to be encouraged to be innovative in daily basis. Support creativity at all levels from frontline employees to management. Need to support transformation process (learning) where the values, assumptions and beliefs inside the organisation change (Junginger, 2006).</p>	<p>Design tools support processes of co-creation, creating new solutions with people, not for them (Bason 2010). Designing can be seen as tool for exploring problems, not just part of problem solving that begins after a problem has been defined (Junginger, 2013). Designing new solutions also challenges the natural organisational attitudes of preservation and resistance to change, and provides tools for exploring the contradictions that might arise between the current culture and the one needed to implement the new solution (Deserti; Rizzo, 2014).</p> <p>Design process can involve all levels of the organisation, and this involvement supports transformation of attitudes, values and beliefs. Designer may act as a bridge between different participants' visions and help them to create their own ideas instead of giving them direct solutions (Vaajakallio et al., 2013). It is important to have this kind of change agent in the organisation (e.g. Vaajakallio et al., 2013). Embedded designer can be responsible for developing organisational design capacity and specific service redesign programmes (e.g. Helsinki Design Lab) (Design Commission, 2014, 31)</p>
<p>Need for more peer-to-peer support. Alternative service solutions provided by the community.</p>	<p>Alternative forms of peer-to-peer support complementary to current governmental services (e.g. Botero et al., 2012).</p>

5 Concluding remarks

This paper has illustrated through literature and two case studies how design can be used for enhancing organisational transformation that may result to more effective and efficient public services. Especially public sector is in need for new approaches to develop their services continuously to be able to survive from the difficult economical situation. Design can help the organisations to transform in various levels by providing tools for collaboration and for the individuals to be more active in developing their own daily work. In this framework design is seen as a way both explore the organisations and change it simultaneously and continuously. Design is a way to put things into the places.

Evaluation of services linked to the sustainability: a dynamic and multi-criteria approach

Kirsi Hyytinen¹, Sampsa Ruutu¹, Mika Nieminen¹, Faiz Gallouj², Marja Toivonen¹

¹VTT Technical Research Centre of Finland, ²Université de Lille

The purpose of this paper is to study the challenge of the evaluation in the context of the services in the sector of environment and energy. Because of the specific nature of service innovation the traditional evaluation methods and measures are not able to capture neither the diversity of the innovations nor the multifaceted dimensions of performance. This paper aims to contribute to the need for a more diverse evaluation approach. We study the use of multi-criteria and system dynamic perspectives in the evaluation of services, and we develop a new type of methodology to evaluate their dynamics and multifaceted performance. (10 lines max)

1 Introduction

The focus in the definition and the evaluation of innovations has typically been on traditional S-T indicators orienting highly towards their technological and economic aspects. This approach has been criticized in the service studies (e.g. Djellal & Gallouj 2010, 2013; Toivonen 2010; Rubalcaba et al. 2012). Because of the specific nature of services, especially their immaterial and interactive dimension, the traditional evaluation methods and measures are not able to capture neither the diversity of the innovations nor the multifaceted dimensions of performance in the sector (Djellal & Gallouj 2013).

The increasing “servitization” of society has also put pressure to develop a more advanced approach to evaluation and in some recent studies (e.g. Djellal & Gallouj 2010, 2013; Rubalcaba et al. 2012), both the “plurality of methods” (Dyehouse et al. 2009; Williams & Imam 2007) and the basics for new evaluation criteria have been suggested. According to them, impacts should be assessed on the basis of a multidimensional approach to take into account their aspects of quality, reputation, social innovation and social value (Djellal & Gallouj 2010, 2013; Rubalcaba et al. 2012).

Systems thinking have often been applied hand in hand with these views. Reasoning is rooted in the modern “broad view on innovation” that highlights the interactivity (including multiple sources and actors in it), complexity and uncertainty of development and implementation of innovations. These arguments and perspectives affect both to the definition of innovations and to the evaluation of their effects and impacts (e.g. Kline & Rosenberg 1986; Lundvall 1992; Freeman 1991; Nelson & Rosenberg 1993; Dosi 1999). And it directs to consider the dynamic nature, interrelationships and feedbacks between multiple actors within the process (Smith 2000; Edquist 2005; Cabrera et al. 2008).

The evaluation challenge concerns especially services that are linked to the sustainability and environmental issues. In such services, the technological perspective (especially “end-of-pipe” technologies) typically dominates discussions. However, the most urgent problems in the present society cannot be solved via the development of individual technologies or services. Instead, the focus is in service solutions which can be characterised as complex innovations integrating technological, non-technological and service-based elements and developed and implemented in the interaction with various actors (e.g. Djellal & Gallouj 2013b). The emerging role of service solutions is not sufficiently taken into account (Djellal & Gallouj 2010, 2013) in the current evaluation approaches.

This paper aims to contribute to the above described need for a more diverse evaluation approach. The objective in this paper is *firstly* to study the system perspective and the evaluation challenge in the context of service innovation and *secondly* to develop a new type of *dynamic multi-criteria evaluation* approach. Suggested approach integrates the multi-criteria perspective (Djellal & Gallouj 2010, 2013) and system dynamic modelling (Sterman 2001). In the methodology multi-criteria perspective describes the various impacts by giving insight to different societal spheres and their principles and values in the sens of Economics of Convention (Gadrey 2005; Djellal & Gallouj 2010, 2013). System dynamic modelling pays attention to the interaction of various actors and their values in the evaluation situation (cf. Giddens 1987) and provides information how the system structure creates complex dynamic behaviour over time. It helps to explain the role of feedback loops between different actors and factors that promote or hinder the emergence of impacts.

The following research questions are guiding our work:

- How and by what means should the outcomes and impacts be evaluated in order to take into account the multifaceted and dynamic nature of service innovations in the sector of environment and energy?
- What are the dynamic impacts of service innovations in the sector of environment and energy?

As a result of our study we provide a two dimensional approach to evaluate the impacts of services. The focus is in understanding the dynamics of service creation in the environmental sector and the use of evaluation methods and indicators in it. At more detailed level, our study provides analytical material about complementarities and contradiction

between different indicators. The results will illustrate how the technical and non-technical aspects of service innovations interact in the area of sustainability.

This paper is divided into three sections. The second section after this introduction is based on literature and discusses the current evaluation challenges in services. The third section presents the two main perspectives that we apply in our framework to evaluate the services. In the fourth section our case study context and methodology are described. In the fifth section we present the application of our frameworks and present the main results of our study. Final section sums up the discussion and makes the concluding remarks.

2 Theoretical background

2.1 System approach to services

The current social, economic, and environmental challenges are too big to be solved via individual product and service innovations created in individual organizations. Conversely, the challenges require various innovations and simultaneous development of organizations, technologies, services and multiple network relationships (Gallouj 1994, 2002; Windrum and García-Goñi 2008; Harrison et al. 2010; Rubalcaba et al. 2012). A crucial question is how to combine various innovations effectively and disseminate them rapidly on the basis of continuous interaction of different organizations. In other words, examining and developing innovations at the systemic level has come to the fore.

While innovations are increasingly combinations of many technologies, organizational changes and services, they are also embedded in a wider social environment which supports or restrains the development of new innovations. This wider context could be described as socio-technical system in which radical changes take place only rarely due to such phenomena as “path-dependency” and “lock-ins”. These concepts refer to the fact that past decisions and choices may steer and restrain new developments. Wide socio-technical change based on radical innovations becomes possible only if system faces e.g. a performance crisis which is not possible to solve with incremental improvements. In essence, a wide change requires complex interaction between actors, resources, institutionalised practises and regulation in a system. (Geels & Schot 2007; Geels 2004; Geels 2002) This means that we need a more systemic view and system oriented methods when we are assessing the dynamics and performance of the system. The focus on separate service or technological innovations needs to be replaced by a wider view taking into account the context and its complex interactions.

This kind of view is emphasized in recent studies on innovation ecosystems. The idea of innovation ecosystem emphasizes the idea of a system of various actors with mutual dependencies and causal linkages. For some writers the concept means innovator-distributor-retailer-end customer relationships and how the innovator/producer is dependent on other firms in its innovation and market activity (e.g. Adner 2012). Some other writers replace the whole concept of innovation system with the concept of innovation ecosystem (e.g. Heller 2013). The more elaborated versions of the concept refer to systems theory and use such concepts as co-evolution, co-specialization and co-opetition (Carayannis & Cambell 2009). In here we suggest that an ecosystem is a multi-actor and co-evolving system of private and public actors working together to create economic and societal advantage.

2.2 Evaluation challenge in services

For two decades, service studies and specifically the studies on service innovation have argued that the traditional tools, indicators and measures do not capture the performance, innovativeness and impacts in services (Sundbo 1998; Metcalfe & Miles 2000). A central background reason for the existence of the gap is the “assimilation” perspective adopted in the early service research (Coombs and Miles 2000; Gallouj 1994). This perspective analyzed services innovation as an imitation of technological and manufacturing innovations. The perspective was based on the traditional definition of innovation as an invention which results from an R&D project (Howells 2004). The linear, stage-gate model of an innovation process, which was raised to the position of a norm and marketed as a prerequisite for success (e.g. Cooper & de Brentani 1991), increased the bias.

These arguments and perspectives have been developed in the context of service innovations. However, they are strongly rooted in general innovation theories basing on the Schumpeter’s definition of innovation that has afterwards been regenerated to “the neo-Schumpeterian” theory of innovation or a broader view of innovation (Lundvall 2007; Toivonen 2013). These traditions are interlinked by several common aspects that affect both the definition of innovations and evaluation of their effects and impacts. Important cornerstones are complexity and uncertainty of innovation process, intangible nature of innovation (focus in new solutions and processes) and systemic view of innovation encompassing multiple sources and actors taking part into the innovation process. (Kline & Rosenberg 1986; Lundvall 1992; Freeman 1991; Nelson & Rosenberg 1993; Dosi 1999). Also from the perspective of general innovation literature conclusion has been parallel: current practices in defining innovation and evaluating them do still follow the mainstream linear innovation thinking which simplifies too much the innovation process as well as the complex dynamics between actors contributing innovation (e.g. Smith 2000; Arnold 2004; Edquist, 2005; Smits & Kuhlmann 2004; Djellal & Gallouj 2010, 2013; Patton 2011).

In addition to the narrow view on innovation, the dominating view on performance is also mechanical and narrow. It is usually linked to the concept of productivity which refers to the linear and mechanistic input-output function (e.g.

Djellal and Gallouj 2010, 2013; Kellogg foundation 2004; Patton 2011). Its' traditional definition is unable to recognize the "hidden performance" concerning the societal aspects of services and innovations like equality, ecological sustainability and societal well-being. It also often excludes the aspect of social innovation (e.g. Rubalcaba et al. 2012). Djellal and Gallouj (2010) have described the interaction between performance and innovation by referring to the visible vs. invisible nature of this phenomenon. Whereas technology-based innovations are visible, non-technological innovations are invisible. As regards performance, the authors link the visible-invisible dichotomy to short-term vs. long-term influences. Both in scientific and the managerial discussions, short-term influences of performance are often analyzed in terms of productivity and growth. Longer-term influences are increasingly analyzed in terms of environmental or social sustainability. There are four possibilities in the relationship between innovation and performance as Figure 1 illustrates (ibid., 668).

Figure 1. Innovation and performance gap in measurement of services (Source Djellal & Gallouj 2010).

The most apparent relation is between visible innovation and visible performance, but visible innovation may also lead to invisible performance by promoting the long term ecological sustainability or societal well-being. Correspondingly, invisible innovation may be a source of visible performance, i.e. growth and productivity, or promote sustainability.

The idea of "double gap" has been noticed to cause significant implications to public policies, which are still very technologist oriented and do not take into account the innovation and performance gap included. Thus, the invisible innovation and performance remain invisible in the policy making, causing problems – not only in the performance measurement as such – but also in target setting, and in steering and policy planning. In order to improve the situation, both the visible and invisible aspects in innovation and performance has to be included in an integrative way (Djellal & Gallouj 2010).

2.3 Opening the specific characteristics of service innovation and performance

After the realization of the narrowness of the assimilation view, two alternatives have gained ground. The first is the differentiation perspective – also known as the demarcation perspective (Coombs and Miles 2000; Gallouj 1994). It focuses on the specific characteristics of service innovation and has highlighted the difficulty of recognizing "newness" and its creator in the service context (Preissl 2000). The second alternative is an integrative or synthesis perspective (Coombs and Miles 2000; Gallouj 2002) which has become increasingly relevant due to the blurring lines between goods and services. It highlights the production and consumption that focus on integrated solutions and systems. The role of integrative services is emerging especially in the area of environment and energy (e.g. Hyytinen & Toivonen 2014).

Recently, these approaches have also been applied when searching better indicators for innovation and performance in services. The peculiar characteristics of services that specifically have been pointed out in this context are intangibility and the central role of interaction; the latter refers to the central role of co-production between the provider, customers and partners. An important implication of intangibility is the difficulty of defining the "unit of output" and differentiating the product from the process. These aspects challenge the definition of innovation and quality improvements in it. Interactivity increases the complexity of the development of services innovations (Gallouj et al. 2013). Ignoring these complex and dynamic relationships (cf. Arnold 2004) is often linked to the traditional technologic measures and the linear innovation model (Smith 2000; Edqvist 2005; Ahrweiler 2010). It may lead to the oversimplification of the reality and to the biased understanding – not only of the impacts of services and innovations – but also of their drivers and dynamics (Arnold 2004).

New aspects in the analysis are inclusion of the time factor and the social nature of services (Djellal & Gallouj 2013). Time highlights the dynamic nature of services, focusing to their evolution over time. Considering time as a dynamic factor leads to the differentiation of short-term outputs from medium and long-term effects. The social nature of services derives from the fact that the value and benefit of services is always defined by users. This means that different actors have different values, and it is just this multiplicity of values which makes it necessary to include various criteria in evaluation. In addition to immediate users, it is important to take into account the multiple values of indirect users as well as those of different actors participating in the development, (Djellal & Gallouj 2010, 2013). Thus, in service innovation boundary lines are blurring – not only between products and processes – but also

organizations often change simultaneously (PreIssl 2000). These kinds of combinatory innovations and their broader socio-economic impacts cannot be tackled on the basis of the traditional linear and industrialist models.

3 New framework for the evaluation of services

3.1 Multi-criteria approach to diversify the perspectives of evaluation

These above described challenges in measurement and evaluation of services intend to assess the performance and impacts on the basis of a multidimensional approach which takes into account the special characteristics of services as well as their aspects of quality and social value (Djellal & Gallouj 2010, 2012; Rubalcaba et al., 2012). Like writers have argued one potential and diversified way of analyzing the various impacts is by giving insight to different societal spheres “worlds of services” and their principles and values in the sens of Economics of Convention (Gadrey 2005; Djellal & Gallouj 2010, 2013).

In that model the outcomes are evaluated from the perspective of different goals encompassing both the traditional measures and the modern evaluation criteria taking into account the needs of knowledge society. In addition to the different target areas the model takes into account the long time-scale in the generation of impacts by dividing outcomes into the direct, short-term outputs and indirect, long term-outcomes (or impacts). The table 1 below illustrates the different worlds given the specific justification criteria related to the each of the worlds (Gallouj 2002; Djellal & Gallouj, 2013).

Compared to original model, we have made some minor modifications into it. Referring to the recent literature, the concepts concerning the aspects of social innovation, sustainability and responsibility should be taken more clearly into the consideration in the analysis of impacts (Rubalcaba et al. 2012; Djellal & Gallouj 2013). Our modifications concern especially the aspect of “the civic world” that originally was focused to social relations characterized by the ethical issues such as equal treatment and fairness. In this model we suggest to integrate the concept of societal value and responsibility into the idea of civic world and also rename it “responsible world”. By the addition our aim is to better take into the account the aspects concerning the social innovations, environmental sustainability and societal well-being.

In the original model also the word of innovation (referring to creativity and inspiration) is differentiated. Because in our study the focus is in analysing service innovations, the specific perspective of innovation world is excluded from our table. Instead we clarify the different elements of innovation by adding that perspective horizontally to the table and by analyzing these aspects in the light of each world.

Table 1. Different justification criteria to evaluate outputs and outcomes of services (modified from Djellal & Gallouj 2010, 2013).

Worlds	Industrial and technical world	Market and financial world	Relational and domestic word	Responsible word	Reputational world
Innovation	Central aspects of the innovation from the perspective of each world				
Output (direct, short term) <i>Performance related</i>	Volumes, flows and technical operations	Value and monetary and financial transactions	Interpersonal and organizational relations, trust, quality of relationship	Values like sustainable development, responsibility, equal treatment, fairness and justice	Brand, image
Outcome (indirect, long term) <i>Performance related</i>					

Analysing the impacts from the perspective of different worlds makes visible the multifaceted nature of service innovations. However, analytical table remains static and does not increase understanding of their dynamic and complex nature. It does not show how the different impact criteria are mutually interlinked and may reinforce or contradict each other. This perspective in our framework is considered with the system dynamic modelling tools more carefully described in the following sub-chapter.

3.2 System dynamic modelling to evaluate the dynamics of services

One key insight behind systems thinking is that interlinkages between different elements in a system can create complex behaviour. This complex behaviour and non-linear nature in the evaluation of impacts can remain unnoticed if each component, such as the elements in the table above, is analysed separately.

Systemic problems cannot be identified directly because systems involve several characteristics that make them counter-intuitive. The following features are important to take into account in particular (Sterman 2001):

- Systems are tightly coupled, i.e. the actors interact with another and with the outside world. Feedback is a central characteristic of systems: decisions of the actors trigger others to act, which again alters the next decisions of the original actors.
- The central position of feedback makes systems history-dependent: taking one path precludes many others.
- Systems are non-linear, i.e. effect is not proportional to cause. It is also difficult to identify immediate cause-effect relationships – instead of that cause and effect are often distant in space and time.
- Systems are constantly changing at many scales that interact. They are also self-organizing and adapting: small, random perturbations are often amplified by feedback, and capabilities of actors change as a result of learning.
- Systems are policy-resistant: the complexity makes it difficult to understand the system and as a result many seemingly obvious solutions to problems fail. Time delays in feedback often mean that long-run response of the system is different from the short-run.

System dynamics (e.g. Sterman 2001) is a methodology that focuses on the underlying feedback structure of a system. System dynamics models incorporate causal connections between system elements that can be mapped using causal loop diagrams. Simulation modelling is used to understand how the interaction of various feedback loops creates certain dynamic behaviour (i.e. change over time in variables of interest). Even though the role of simulation is emphasized in the system dynamics methodology, even qualitative diagrams that show the interactions and feedback loops in a system can increase understanding of a system.

4 Case context and methodology

In our empirical analysis the focus is in service innovations in the area of environment and sustainability. According to some recent studies (e.g. Djellal and Gallouj 2010, 2013) the technologist perspective dominates typically the discussion of sustainable innovations although the role of integrative services is emerging especially in that area.

In this paper the focus is in analyzing the complex combinatory innovations. By that we mean that they all encompasses both technological and non-technological ingredients and are developed in the collaboration between multiple actors. As regards their targets they are aiming to tackle with prominent societal challenges, among which the environmental sustainability is primary. Specific service innovation we are interested in is *Environmental data platform* that aims to be a comprehensive platform to support continuous data gathering and real-time environmental monitoring, analysis and reporting.

Innovation has been developed in research and development program built on public-private innovation network that aim to promote systemic change in the field of environmental measurement in Finland. The program is carried out by a Strategic Centre for Science, Technology and Innovation – a new Finnish innovation policy instrument. The centres (abbreviated ‘SHOK’) operate in various industrial and service sectors as limited companies and are built on public-private partnerships. SHOKs can be characterized as public and private innovation networks generating complex and architectural services and innovations (Djellal & Gallouj 2013b).

We have applied the case study methodology and qualitative approach in our study. The main method in data gathering in our study was face-to-face interviews (30 in total). The interviews were gathered between February and June 2013. We applied snowball sampling in the identification of interviewees: the first respondents were Managing Director of Cleen Ltd and the Program Managers. Based on their suggestions, we thereafter selected the other interviewees among the members of the program consortiums. The final sample represented actors in the area of sustainable energy in a versatile way. It consisted of representatives of private companies (e.g. energy companies, companies developing environmental and industrial measurement), and universities and other public research organizations. All interviewees were managers or experts in their organizations and had a significant role in the research programs. Typically they were acting as a work package leaders or leading the service demonstration development.

For the data gathering we applied a semi-structured interview method: the topics were decided beforehand but within them the respondents were given a great deal of freedom (Bryman and Bell, 2011). The main topics focused on the manifestations of new innovative solutions within the programs, factors that promote or slow down their generalization, impacts of the innovations and their evaluation. The duration of the interviews ranged from one and half to three hours. All interviews were recorded and transcribed. Documentary data on the general development of energy technologies and markets were used as supplementary material.

In the analysis and interpretation of empirical data we applied the modified multi-criteria and system dynamic perspectives. We started the analysis by studying how the environmental data platform is impacting in a short and long term from the perspective of different worlds of services. In the analysis we are reflecting impacts both from the traditional and modern perspectives. Thereafter we moved to system dynamics modelling that aims to increase understanding of the dynamics in the system that results from interactions between the parts of the system – including reinforcing and balancing feedback loops.

5 Research results

Environmental data platform (table 2) is from an industrial perspective a prototype platform to gather and share environmental data. As a short term output it integrates real-time data sources (e.g. measured data of water quality and

satellite data concerning environment and atmosphere) and provides visualized maps based on the data. In a long-term the goal is to integrate multiple data sources in it and provide “cloud-based comprehensive solution” to produce and share environmental data. Cloud-based solution would make the access to big data possible. In addition the architecture for real-time monitoring, analyzing and reporting will be created to improve the quality and reliability of environmental information, weather forecasts and warnings. New architecture helps in developing new end-user applications and thus accelerates business start-ups generation. Our respondents highlighted that services are in the central role in the development of comprehensive solution and new information architecture.

In the market world the main characteristic of the innovation is economically free access to the multiple data sources and especially to public sectors data. According to our interviewees free access to data is considered to be an important social goal and also a starting point for the development of data platform. In a long term goal is in opening new markets based on environmental analysis and in creation of new export possibilities.

Preferences and valuation principles in the relational world highlight the interaction between multiple actors and a role of end users is the development and use of service. Central innovative aspect here is the connectivity via one mediator to multiple data sources. As an output goal trust in the public-private innovation networks is enhanced. From the performance viewpoint enhances actors’ connectivity and consolidates the networks. Long-term goal is to integrate citizens to the data provision, to better take into account the specific users’ needs and requirements and hence provide personalized environmental data. That affects in a long term to users ability to be integrated part of the environmental data generation. Like our interviewees highlighted that development removes the clear distinction between the production and use of data: citizens are becoming data producers. That has been considered as a prerequisite for a systemic change in the sector.

From the perspective of responsible world overall sustainability is highlighted as a central value in development of new solution. The other value based aspects highlighted are transparency and the citizens’ equal rights to participate to the data provision. Innovative aspect relates to the open and equal access to public sector data. As a short term goal platform enhances transparency, availability and multifaceted use of public data. As a long-term goal respondents have considered the possibilities to apply new end-user applications for example to the game and school worlds to support the environmental education and thus increase the awareness of environmental issues from the early age. From the performance viewpoint that may increase responsibility as a value in decision making in individual, firm and policy level.

Table 2. A multi-criteria framework to analyse the impacts of environmental data platform.

	Industrial and technological	Market and financial	Relational	Responsible	Reputation
Innovation/Input	A prototype platform for environmental data gathering and sharing (integrating real-time data sources & data storage)	Free access to public sector data	Connectivity via one mediator to multiple data sources and end-users	Open and equal access to public sector data	Image as an innovation to enhance sustainability
Output (direct, short term)	Varied measured and satellite data concerning environment and atmosphere (e.g Weather radar visualised on the map)	Economical of free access to multiple environmental data sources	New connections and actor networks created (via new solution)	Transparency of public data; Easy access	Short term image
Performance related to output	Ability to process increasing amount of environmental data more quickly and more effectively	Reduced cost of sharing data Reduced cost of providing data	Increased connectivity between multiple actors	Increased transparency of public data Increased availability and better use of public data	Improvement/change in reputation and image
Outcome (indirect, longterm)	“Cloud-based comprehensive solution” for producing and sharing environmental data Architecture for real time environmental monitoring, analysing and reporting, bid data New end-user applications created New start-ups crated; new jobs	New market opening based on environmental monitoring New opening export possibilities	Integrating citizens and citizens’ requirements to the data provision “Users as a data providers” (<i>Social innovation</i>) Personalised environmental data Trust	Equality in sharing information (data) Quality controlled data Platforms applied e.g. in education: environmental education and awareness	Long-term reputation and image
Performance related to outcome	Improvements in weather forecasts, environmental information and warnings Increased quality and reliability of environmental data Increasing number of business start-ups based on environmental data; Increasing number of new jobs	Improvements in the generation of various types of revenues based on environmental data	Increased usability of environmental data /knowledge Increased trust	Increased awareness of environmental issues Increased responsibility in decision making (individual, firm and policy level)	Long-term improvement/change of reputation and image

Finally in the world of reputation innovation is analyzed from the perspective of brand and image effect. From a short and long term the aim is in analyzing how the innovation impact to the attractiveness of different actors. The aspects concerning the image and brand needs to be analyzed from the perspective of specific actors and are thus analyzed in details in the following sub-chapter.

To summarize the central findings from the perspective of different type of evaluation criteria following aspects have been recognized. According to our interviews services have important role in renewing the environment sector. To solve the most urgent societal problems, like sustainability, there is need to develop technologies and services as systemic wholes instead of individual technologies or services. The emergence of comprehensive service solutions in renewing the environment and energy technologies can be perceived by traditional measures. However the focus from the perspective of industrial and financial world is on technical characteristics of the concepts and solutions, not so much in their social and systemic nature.

To capture the interactive and social nature of service development as well as its' interlinks to the social goals and system level changes the other criteria are needed. Like our example show, relational and responsible worlds are particularly important to make these aspects visible. Like our respondents highlighted the changing roles of data users and producers ("from user to producer") plays a central role in the renewal and a system level change in a sector. That can be perceived only from the perspective of relational world. In addition our example shows that impacts generated in the different worlds are often interdependent and complementary to each other. Some factors in relational and responsible worlds can be seen as a prerequisite to effects generated from the viewpoint of technical and financial worlds. For example for the development of environmental data platform the transparency and open access to public sector data is seen as a precondition. However, the dynamic nature and interlinkages between different justification criteria are not comprehensible for readers because the analytical table remains. It does not show how the different impact criteria are mutually interlinked and may reinforce or contradict each other. This perspective in our framework is considered in the analysis carried out with the system dynamic modelling tools.

From the systems perspective (Figure 2) free access to data increases open and equal access to data, which creates new connections between actors. This in turn increases the ability to process multiple data sources quickly and efficiently and creates new market openings and new end user applications. An increased number of end user applications increases people's awareness of environmental issues, due to which new actors start producing data. These new actors then create more demand for transparency of data and political pressure to provide even more access to data. (Reinforcing feedback R1 "new connections between actors"). Increasing free access to data also leads to new market openings because of the reduced costs of sharing and providing data (reinforcing feedback R2 "reduced costs").

Figure 2. Systems perspective to environmental data platform.

As already noted, an increased awareness of environmental issues leads to citizens becoming active in producing data. This raises awareness even more (reinforcing feedback R3 "awareness raising"). An increased number of new actors

producing data also leads to more data and personalized data being produced, which can lead to new market openings (reinforcing feedbacks R4 and R5: “amount of data” and “personalized data”).

There are also balancing feedback loops in the system. Once the number of actors producing data grows, data quality may become an issue and can decrease the ability to process multiple data sources efficiently (balancing feedback B1 “data quality”). However, a low data quality that creates a need for data verification can lead to new criteria for data gathering, which then improves the quality of data (balancing feedback B2: “new criteria for data gathering”). The development of an environmental data platform can also be started in order to improve the ability to process multiple data sources (balancing feedback B3 “platform development”).

6 Concluding remarks

The purpose of this paper is to study the challenge of the evaluation in the context of the services. Because of their specific nature – especially immaterial and interactive dimension – the traditional evaluation methods and measures are not able to capture neither the diversity of the innovations nor the dynamic nature and multifaceted dimensions of performance in the sector. This paper aims to contribute to the need for a more diverse and dynamic evaluation approach. We focus on the context of service innovation in the area of environmental measurement in which we develop further multi-criteria and system dynamic perspectives. Multi-criteria framework describes the impacts of new sustainable services and system perspective analyses dynamic impacts of service innovation.

As a result we identified that services have an important role in renewing the services in environmental measurement. To solve the most urgent societal problems, like sustainability, there is need to develop technologies and services as systemic wholes instead of individual technologies or services. Furthermore the collaborative interaction between societal fields and multiple actors (including citizens) is extremely important.

The emergence of new technologies and new solutions in environmental measurement can be perceived with traditional measures. However the focus from the perspective of industrial and financial world is in technical characteristics of the concepts and solutions. From this traditional perspective neither the role of new solutions in renewing sector (social and value based aspects) nor the importance of interactivity in developing new solutions can be captured. To perceive and make visible the societal goals of the new solutions as well as their interactive nature relational and responsible worlds are particularly important. In addition relational world also focuses for example to the changing role of end users (“from user to producer”). That can be seen as an enabling factor for the systemic change in the sector and thus a central goal in renewing the sector.

Our analysis also shows that impacts generated in the different worlds are often interdependent and complementary to each other. Some factors in relational and responsible worlds can be seen as a prerequisite to effects generated from the viewpoint of technical and financial worlds. For example cornerstone and reinforcing feedback in developing new service innovations for environmental measurement relates to the free access of data (the perspective of market world). To attain it political decisions to open of public sector data sources (perspective of responsible world) are required. That development facilitates the equal access to the data for multiple types of actors and thus enhances the creation of new connections and provides the new type of collaboration between actors (relational world). This development supports the emergence of new market opening and the development of new end user applications. Like example shows, the relational and responsible aspects are needed to generate long-term technological and economic impacts.

The complex dynamics, interrelationships and multiple feedbacks between the different impact criteria remain invisible without systemic perspective. By integrating multi-criteria and system dynamic perspectives we aim to offer a dynamic alternative to create understanding of development and impacts of service solutions.

Regarding to the further studies more studies would be useful to test the generalizability of our results. Furthermore to go deeper to the dynamic relations studying the role (and impacts) of different actors in service ecosystem could be the next step. In addition generating indicators based on these findings would be both interesting and useful.

Exploring the future use of forests in Finland: perspectives from sustainability oriented forest owners

Liina Häyrinen, Markus Närhi, Sami Berghäll, Osmo Mattila, Anne Toppinen

Department of Forest Sciences, University of Helsinki

The objective of the study was to explore the views of sustainability oriented non-industrial private forest (NIPF) owners on the future use of forests in Finland. Findings from qualitative analysis based on 4 focus group discussions show that generally NIPF owners have a strong emotional attachment towards forests and are interested in more diversified opportunities of forest use in the future beyond dominant raw-material driven mindset. They also presented a lot of insight for enhancing intangible value creation based on forest ecosystem services. Even though groups of forest owners also recognized factors that inhibit the more diversified development of the forest-based services, they saw the overall future of forests in bringing welfare to society as positive. They identified unused possibilities in e.g. peer-to-peer learning via organized forest owner forums and cross-sectoral co-operation between forestry and nature-based tourism. Finally, results elaborated the high diversity between four groups in NIPF associations to forest use and their inherent service and information needs, which can be considered as a challenge for current service organizations. However, further research is needed beyond these findings to generalize them, as well as to study the business potential in sustainable lifestyle aspects of forestry.

1 Introduction

Finnish forest industrial sector is today facing multifaceted challenges such as low profitability caused by oversupply and volatility in traditional paper and wood product markets, changing institutions and many environmental issues are also perceived as controversial at societal level (e.g. Mattila et al. 2013). Traditionally, forest industry can be described as very raw material and production oriented sector that could be described by aspects of capital intensiveness, high cost competition and strategy towards production efficiency (Toppinen et al. 2013). However, in order to retain its legitimacy in the future, the competitive advantage for the whole sector needs to be sought also from the intangible values of forests and enhancing the role of services (e.g. Hetemäki et al. 2011).

Growing societal emphasis on sustainable development has raised the importance of bio-based economy, enhancing green consumers that emphasize sustainable choices in their everyday consumption patterns (see e.g. Roberts 1996, Young 2010). As a highly sustainable resource, forests offer huge potential for developing more sustainable products and services also in terms of intangible values, including food, health, leisure time and tourism possibilities (Hetemäki et al. 2006).

As a majority of forests are owned by hundreds of thousands of small-scale non-industrial private forest (NIPF) owners in Europe and United States, they have a control and an important effect on numerous tangible and intangible forest based ecosystem services. Comprehending the perceptions and preferences of NIPF owners have been the aim of several studies as they provide useful knowledge for the forest sector due to their high involvement role in natural resource utilization (e.g. Kuuluvainen et al. 1996, Kline et al. 2000, Butler et al. 2007, Häyrinen et al. 2014a). Organizations' closer collaboration with NIPF owners can also lead a better comprehension of customer value more generally, due to their dual role as consumers, especially in the countries where forest owners comprise a significant proportion of the whole population (Häyrinen et al. 2014b).

Our study approaches the value creation process from the sustainability perspective. We hypothesize that forest owners could be in an important role when considering new innovative ideas for forest utilization. The emphasis shift in forest owners' objectives towards intangible valuations must be explored greater depth. The aim of this study is to explore whether forest owner could recognize the future utilization prospects of forests. We specifically concentrate on owners who are considered to be representing sustainability oriented lifestyle.

2 Sustainability orientation of production and consumption in the bio-based economy

Global awakening to environmental protection and call for corporate responsibility, as well as rapid technological development, have changed industrial structure and affected significantly the use of forests in Finland (Hetemäki et al. 2006). The traditional forestry sector has been heavily dominated by the raw material dominant mindset and pursuit for production efficiency (see also Mattila et al. 2013, Näyhä & Pesonen 2014), but nowadays alternative value creation is emphasized increasingly for the future of forest use.

Increasing concern over sustainable development has directed the discussion towards individuals' sustainable lifestyles. A growing number of consumers have realized that their consumption behavior have an impact on

environmental problems and choose products that are more ecologically friendly (e.g. Laroche et al. 2001). Numbers of studies have e.g. attempted to understand and identify the underlying determinants of sustainable consumerism such as demographic and psychographic characteristics of consumers who represent sustainable orientation (see e.g. Straughan and Roberts 1999). Quite often, however, discussions on characteristics of environmentally conscious consumers have presented conflicting views and socio-economic background has not been found to accurately segment consumers' sustainability orientation any more (e.g. Diamantopoulos et al. 2003, Roos and Nyrund 2008), and more focus should be put on psychographic variables (Straughan and Roberts 1999). Consequently, also marketing managers are increasingly interested in the green segment of the consumers.

According to Korhonen (2012) in Finland a third of population belongs to segment of so called LOHAS-consumers (acronym for lifestyle of health and sustainability). These consumers represent lifestyle, in which ecological, ethical and social responsibility as well as healthy consumption options have an important role. According to Mohr (2011) LOHAS is a new social majority that will revolutionize the consumption markets in the upcoming years. There is also evidence on consumers following ecological lifestyle, also seek for information and like to experience new challenges (Chen 2014). According to Belz and Peattie (2012) LOHAS-consumers can come from any demographical background. Nevertheless, the concept of LOHAS is also criticized of being just a new phenomenon that allows consumption without a bad conscience (Bilharz and Schmitt 2011).

The global rise of green values is reflected also in the changing attitudes and values of non-industrial private forest (NIPF) owners in Finland. There are certain groups of owners whose forest ownership objectives have shifted towards intangible emphasis such as aesthetic, recreation and conservation values (Häyrinen et al. 2014b). While already one fourth of NIPF owners primarily emphasize recreation, nature, and landscape protection (Hänninen et al. 2011), there is also evidence on that a segment of forest owners don't find raw-material driven services in forestry service markets suitable to their specific needs (Häyrinen et al. 2014b, Mattila and Roos 2014). These owners are inherently passive in the timber market, but they can still be highly involved in owning forests. As NIPF owners in Finland comprise the most significant owner group, controlling 60% of the productive forestland (The Finnish Statistical...2013), their forests offer also significant societal benefits like recreation services in form of public right of access.

The benefits of customer involvement into new service development have been discussed in a number of studies (e.g. Alam and Perry 2002; Lundkvist and Yakhlef 2004). Service-Dominant Logic (SDL) mindset, which has been introduced within the field of marketing by Vargo and Lusch (Vargo and Lusch, 2004; 2006; 2008), highlights the mutual and reciprocal value co-creation between actors. Contribution of SDL for service innovation is that customers should be involved in several stages of service development process (Edvardsson et al. 2012). Hence, apart from being a necessity, the customers are seen as an opportunity for new service development (Matthing et al. 2004). Consequently, forest owners could act as co-creators in new business development regarding forest use.

The key issue arising from the findings of Berghäll et al. (2014) (the quantitative part of this study), suggests that environmentally oriented forest owners emphasize multifunctional aspects of forest ecosystem services more than owners who are less environmental concerned. Within this background, we assume that also environmental lifestyle of owners has an effect on how they utilize or value forest. Further, question is, could sustainability oriented forest owners be understood as lead users (see e.g. Von Hippel 1986)? Therefore, we hypothesize that sustainability orientation could lead to more in-depth views on the sustainable use of natural resource, contributing to future service and product provision. Hence, we aim at combining the sustainable oriented consumer logic to explore the future of ecosystem services provision. More precisely, we hypothesize that consumers who have higher sustainability orientation in their life, might also have deep insight on how to think outside the box in the context of creating novel value in traditional raw material dominated industry sector.

3 Research data and methods

The research was conducted as an explorative study. The data that was needed to accomplish the study's objective came from two sources: quantitative forest owner data and forest owner focus group interviews.

This study is a part of a broader research project "Fortune - A Radical Approach to Forest Sector Renewal". The project has several field phases ranging from qualitative to quantitative. While this study reports the results of a focus group qualitative phase, the feed and setting came from a quantitative phase. In the quantitative phase, the quantitative survey data was collected in August 2013 via telephone interviews (n=402) from a nation-wide registry of Finnish forest owners. The sampling and contact information were based on the customer database of The Finnish Forest Centre, which includes around 300 000 private forest owners in Finland. As Finnish forest owners' average age is relatively high (60 years according to Hänninen et al. 2011), we fixed the current age structure of forest owners in order to concentrate on owners that are younger than an average owner. Against this background, the aim was not to achieve an absolutely representative sample of landowners, but more to show also the future behavior of the owners. Hence, the sample was collected by selecting circa 20% of forest owners from five age class (under 30, 31-39, 40-49, 50-59 and over 60 years olds). Findings of the quantitative data analysis are not reported in this paper (see Berghäll et al. 2014) since we aimed at identifying forest owners who represent environmentally oriented lifestyle. The quantitative data was utilized to select a sub-sample of forest owners, who show high-involvement in environmental and social sustainability and forest ownership issues. However, as practice showed, it was not possible to reach only those owners presenting the ecological lifestyle. Hence, we also had to accept few other participants that didn't receive so high score in

sustainability orientation scale in the survey. The qualitative research data was collected in 4 focus group meetings in January and February 2014 consisting of total of 17 NIPF owners.

Characteristics of participants are presented in table 1 below. The length of focus group meetings ranged between 0:40 h and 1:29 h, with a mean of 01:09 h. Focus groups interviews were audio recorded and transcribed and were led by a moderator. The transcribed focus group citations were categorized on the basis of our study questions.

Table 1. Focus group information.

Group	Participants	Location and time of focus group interviews	Duration
1	3 females & 1 male, age: 29-57 years	Helsinki 22.1.2014, klo 10.00	73 min.
2	4 males, age: 26-67 years	Helsinki 22.1.2014, klo 17.00	40 min.
3	3 males, age: 42-68 years	Hyvinkää 30.1.2014, klo 17.00	89 min.
4	5 females & 1 male, age: 27-58 years	Tampere 24.2.2014, klo 17.00	72 min.

The objective of these focus group interviews was to give forest owners a topic, that they could discuss and form their own opinions freely and not to influence too much the course of the discussion.

The outcome of focus groups discussion could be categorized in three different themes: (1) importance of forests and forest ownership, (2) perceptions on the current state and future of forest sector and (3) group visions on emerging utilization potential for forest use and challenges related to these new possibilities.

The data was analyzed using inductive qualitative analysis and thematization. The relevant themes were identified by pattern matching.

4 Results

4.1 Perceived importance of forests and forest ownership

The discussions on importance of forests and ownership revealed that the most of the participants had a strong emotional attachment to their woodlots. Almost all owners had inherited their forests, which meant a strong emphasis on heritage value and economic security.

“I’m still always there whenever possible. I hike, pick mushrooms & berries, ski, I’ll do whatever in forests whenever I need to chill out.” (Group 1)

“The money is in safe, when it is invested into forests and apartments.” (Group 3)

“It involves lots of emotional aspects...my grandfather planted a small birch grove back in the day about the same time that I was born so the birch grove grew with me at the same rate and at some point it was higher than me... That’s the emotional bond...” (Group 4)

Forests wouldn’t be sold to market, even though they were a cost. In many cases the value of forest as such was seen as more important than the economic income from selling wood.

“I will hold on to it (forest) , even though I know that it will cause only costs over coming years... but it is nice to think that children and grandchildren could benefit from it even though purely in economic terms.” (Group 1)

Forests as a stand were seen more valuable when compared to being cut down. For some forest owners the importance of forests and strong emotional bond formed through forest self work. Practical benefits from forests were also brought up in the discussions.

“Of course I become attached to it (forests), when I work there. Then again, when one needs to cut down the large timber forest, one will grieve...” (Group 2)

“Forests have been my best playground already as a child... I remember where I played and where the paths were and those paths aren’t there anymore...” (Group 1)

Clear-cuttings were criticized in general. On the other hand, owners who hadn’t owned forests very long time wanted to learn more and hear different and more diverse possibilities on how to manage their forests. In group 1 the wish was to network with other forest owners to discuss about forest and forest ownership issues e.g. in pursuance of forest fairs.

“...My objective is to understand something about these things that I could sell some timber and manage it properly, but I want to avoid situations, in which I have to regret something. So the idea is to understand these things better and familiarize myself with these issues.” (Group 4)

“I really wish that someone would begin to think some options for clear-cuttings...I’m so disappointed to actions of Espoo (town). Isn’t there any other use for the old trees than cut them down to make money, at least they could do it differently.” (Group 1)

4.2 Perceptions on the current state and future of the forest sector

When the conversation turned to NIPF perceptions on the current and future state of the forest sector, the general consensus was that the traditional sector is too much controlled by large forest industry companies and the use of forest resources in Finland is orchestrated on the interests of the large companies.

“It is forest industry’s raw material. That’s what it is. It has been the largest industry in Finland and this is why the system exists.” (Group 1)

“Forests are less diverse [today]. If we think about this issue related to the wildlife, forests should be more diverse, but it has lost because of the current forestry. There are economic values behind.” (Group 3)

“These Finnish forests are plantations for forest industry... the nature conservation areas are the only real forests...” (Group 1)

On the other hand, in one group the benefits of loggings for recreational use were also brought up.

“I have nothing against commercially managed forests though, when you think about mushroom and berry picking...it is easier to find them from managed forests...” (Group 1)

Even though groups of forest owners also recognized factors that inhibit the development of the sector, they still saw the overall future of forest sector as positive. According to owners in general, the forest sector will be profitable also in the future due to long traditions, positive structural change, more diverse utilization of forests and emergence of new actors in the field.

“I believe that forest industry isn’t the thing that interests inventors and innovators at the moment...everybody is just developing these games. But I’m completely sure that in some point it will interest and someone will invent something totally different out of wood, and the industry will remain. But it isn’t these old stuff, it will need to be something novel.” (Group 1)

“I think that the forest sector remains stable in Finland.” (Group 2)

“It is not a great concern, because wood is always needed lots anyway... These other bio projects, especially the one that they make biodiesel from pine fiber...it is a quite interesting project.” (Group 2)

“It will consist of several small pieces...there won’t be only one large industry, but the industry is formed from all the little things in the future.” (Group 1)

Female forest owners underlined strongly the masculine image of the sector and they thought that increasing share of female owners was a positive aspect for the entire sector through novel utilization prospects and more ecological orientation. Especially in female dominant groups many participants saw e.g. forest owner associations as too traditional actors that only facilitate the industrial timber procurement. In addition, new forest owners with their novel perspectives and interests were seen as potential for renewal of the traditional sector.

“It is distressing that there is a huge masculine system behind. Now, when there are a lot of female owners who have inherited forests, then one might even make a difference.” (Group 4)

“People are more heterogenous. Forest owners are completely different today, and they have a variety of interests compared to old days when all of them were from the countryside... there is a totally different starting point.” (Group 4)

4.3 Visions on prospects of using forests

Across all four focus groups participants were generally well aware of expanding potential of the use of forests in the future and they presented a lot of insight for intangible value creation. According to forest owners (especially in group 4) more emphasis was put on developing forest based recreational services. Health and sport related activities also intrigued owners in group 4. Owners discussed e.g. about creating health yoga services and path running events as enhancing health and wellbeing. One of the owners had experience on organizing eco-psychology courses and also others in the focus group got excited about forests’ role in nursing.

“I’ve been in a path running school...there is more interest in it... There is a huge potential in Finland to organize this sort of events that can be very interesting for foreigners as well.” (Group 4)

“I’m a member of an association which will organize a course on “basics of ecopsychology” in March... It will deal with the nature-based methods and their utilization e.g. in nursing and education. In practice it means that a patient group will be taken out to nature and also plants are taken inside.” (Group 4)

“One of these is yoga, which has been a huge hit and people appreciate much all these “mindfulness” things. Forest as an environment is naturally giving you a peace of mind.” (Group 4)

Many participants emphasized the role of Finnish special nature to attract tourists. Some ideas were also based on owners’ own experience such as offroad safaris as a form of adventure tourism, but the organization was seen as problematic.

“We have a huge reserve in nature and forests...In my opinion it is worth of investing in intangibles...If you are able to sell the atmosphere and experience...of course you need an extra trick there...” (Group 3)

“As I have to travel due to my work, I will have to say that we spectacular sceneries and there is a broad potential to travel in forests, and also promote it. This is special. When I come from China back to Finland I can breathe freely again...” (Group 1)

“Those will require a huge amount of capital into the equipment. And are you allowed to establish an off-road track on your forest estate without a permission...I’m a bit suspicious of those safari recreation actions and other stuff because of all those different laws... all the environmental permissions are required and what if something like oil damage occurs, what about then...” (Group 3)

Importance of environmental aspects was discussed in general. Participants felt that Finns in principle are willing to support the more ecological or socially responsible consumer products, but they are not willing to pay for those. This has led to the situation, in which there isn’t sufficient demand, although for example demand for organic food is on the rise.

“At one time there was a much talk of organic products...which would be great, but then there wasn’t demand for them...It is just like that it fits costs more because it is produced in a different way, but consumers don’t want to pay for it.” (Group 3)

Converting forests to conservation areas was brought up as one of the potential uses due to carbon market. It was also considered that forests have a special value as they are and hence, forests could be left in natural state. Again, as the discussion continued, it was noted that natural values alone won’t be sufficient for forest owners. On the other hand, the participants acknowledged that the majority of the owners are not likely to be willing to convert forests into conservation areas without a financial incentive, because of the importance of financial security and income.

“Usually nature alone is not enough... one needs an economic viewpoint as well“ (Group 1)

“Then there are these carbon dioxide directives and others... as forests are renewable raw material... It has potential...” (Group 3)

However, it was brought up that due to their abundance forests are taken for granted in Finland, and the wide range of benefits provided by nature are not appreciated enough, let alone to be commercialized due to extensive everyman’s rights.

“For Finns these things are so self-evident, that one cannot think these things commercially.” (Group 4)

“Foreigners are able to understand the value of forests in a spiritual and mental sense. I’ve read that the Japanese have made a health forest certificate. Forest has health value... spending time in forests lowers blood pressure and level of stress hormone and enhances resistance etc. We as Finns should understand how incredible value we have, from which something like this could be created... then there are also recreation walking parks, but those are difficult for tourists to get to, those should be easily achievable.” (Group 4)

Potential of value added wood products were brought up in few focus groups. Their commercial potential of value adding was seen as good, because it was seen that consumers are willing to pay for high-quality native wood products, which would also be competitive advantages. Value added products would lead to higher revenues and competitive advantage through own expertise.

“There has been a lot of talk about increasing the degree of upgrading, it isn’t just the bulk that should be produced but the added value has to be found from further processed products. Consumers are willing to pay more for wood products, especially domestic ones.” (Group 4)

“It is always the costs that are counted. It should be made as very trendy... e.g. these wood constructions and wooden buildings... so even though the prices would be higher, it would pay off and find a market...” (Group 3)

“One thing that could interest in the world if it was more marketed could be our domestic log houses. It is a good because one can shake it a lot before it collapses... for earthquake zones...” (Group 3)

Yet, further development of NIPF-based business ideas and innovations was seen to be very challenging. The capital intensiveness of industry was considered as the most challenging barrier for individual owners. Forest owner should have a plenty of cash and good contacts in order to develop ideas any further. Also, development needs were found in marketing skills.

“We are poor marketers though. We would have so many things here, we just don’t see the potential and sell it. We take all the things for granted. If we looked at the American way, these things would be completely different in this country. We have lived so modestly... Enthusiasm for marketing is lacking in general.” (Group 3)

“Just like this, we need to find a niche. No matter how good the idea, we have limited demand, and when we think about e.g. some narrow sector or hobby, the demand is very limited. It’s a question how good you are at marketing and where is it located.” (Group 3)

When conversation turned to sustainable lifestyle and how this could be present in forest owners lives and their forest ownership, the topic turned out to be difficult. Participants in group 4 felt that alienation from the nature doesn’t only affect adults but also their children. One proposed solution was bringing forests into urban areas one way or another. However, some participants suggested that a general alienation from nature could create novel forests creation related commercial opportunities.

“It seems that many people in Finland have estranged from nature and forest, especially in larger cities. There would be a several kind of recreational opportunities to offer... As long as the potential would be applied.” (Group 3)

“Forests offer many sort of things, but everything has costs in the beginning, so one should start with selling of the intangible experiences. One wouldn’t be so tied to the entrepreneurship. And even though the return was lower, it would be easier on a smaller scale.” (Group 3)

5 Discussion and concluding remarks

The aim of this study was to explore how the future opportunities in forests-based services is perceived in the context of sustainability oriented Finnish forest owners. Although the qualitative research approach was able to provide very general views on the themes, some useful insights were recognized. More general, participants of the study can be considered as modern and future-oriented forest owners with diverse values, interest in many possibilities besides timber production and were eager to learn more. Due to diverse characteristics of participants, also the discussion themes were perceived differently. The summary of the findings are presented in table 2.

Table 2. Summary of main findings in focus groups.

Group 1	<ul style="list-style-type: none"> • Strong emotional attachment to own woodlots, forests wouldn’t be sold to market even though they were a cost • Forest sector needs to be renewed, sector is under many changes; general resistance to clear cuttings • Potential in recreational and tourism activities: especially the role of Finnish nature; emphasis should be on other possibilities rather than timber trade, though economic aspects have to be taken into account • Information needed on existing and alternative forest management practices or use, not just traditional; the wish was to network with other forest owners
Group 2	<ul style="list-style-type: none"> • Forests as economic security; importance of forests and strong emotional bond has formed through forest self work • Overall future of forest sector was seen as positive, new possibilities to use wood will be found in the future • Potential in travelling, construction, composites, technological solutions in forest planning; challenges in commercialization

<p>Group 3</p>	<ul style="list-style-type: none"> • Heritage and economic security values the most important ones, emotional attachment to own forest has formed through forest self work • Current state of forest sector is challenging, e.g. high productions costs; future of forest sector was seen as somewhat positive if forest will be used more diverse and rational • Interest in diversification of forest business through value adding and marketing: e.g. wood constructions; a lot of potential in forest recreational experiences: e.g. the role of Finnish special nature to attract tourists and adventure travelling; confidence in the Finnish know-how in forest sector
<p>Group 4</p>	<ul style="list-style-type: none"> • Authority to decide how to manage own forests is important; firewood, berries and mushrooms as important benefits, forests as economic security and heritage are important • The masculine image of the sector was emphasized but increasing share of female owners was seen as a positive sign; resistance to clear cuttings • More emphasis should be put on developing forest based recreational services: e.g. health and sport related activities, potential also in nature tourism and value added wood products; the wide range of benefits provided by nature are not appreciated enough, let alone to commercialized due to extensive everyman's rights • Information needed on forest owning as general as well as existing and alternative forest management practices

Based on the findings from the perspectives shared by the focus group participants, some generalizations can be made. The discussions on perceived importance of forest ownership brought up a strong emotional attachment towards one's forest. Some owners were even willing to compensate lower timber sales income with more ecological use of forests (e.g. no clear-cuttings). Total value of forest was seen higher than the economic benefits. Findings of this study showed that although forest owners might be inactive in timber markets, they can be at the same time be very dedicated to their forests and ecosystem services these provide (see also Häyrinen et al. 2014b).

The current state of the whole industrial sector was seen as somewhat in a flux. Focus groups interviews indicated that there are a broad range of opportunities, but their commercialization requires a new way of thinking for the whole forest sector. In some groups NIPF owners were annoyed that forest owner associations serve the needs for timber industry and also other service organizations provide mainly services that are focused on intensive wood production. Especially many of the female forest owners in focus groups desired a broader variety of options for forest management. This finding is in line with Häyrinen et al. (2014b), who found that timber trade oriented mindset of the service organizations doesn't attract all the owner groups (see also Hujala et al. 2013, Kuipers et al. 2013).

Generally NIPF owners in focus groups voiced for more diversified use of forests and they presented a lot of insight for intangible value creation. Yet, totally new ideas during the discussions didn't bring up. However, groups clearly wanted changes for the practices and services available in the sector. According to the findings of this study, more emphasis should be put on recreational service development. E.g. nature-based tourism prospects in Finland are seen as favorable due to socio-economic changes in population and increased awareness on health and environmental issues (Sievänen 2005). However, in generation of nature-based tourism and cultural forest ecosystem services the main challenges are related to development of new service business models, and more precisely to how appealing factors of nature are formed as service packages for different customer segments (Peltola 2007). However, free public access to forests in Finland challenges the implementation of commercial innovations in recreational services, as citizens are unaccustomed to pay for them (Weiss et al. 2007). In addition, as foresters have a main aim at timber production, they can have a reserved attitude towards recreational services and products. Also from the forest owners' viewpoint, economic benefits are not common, because it isn't very common to compensate use of forest for e.g. nature-tourism purposes (Matilainen and Lähdesmäki 2014). Enhancing the cross-sectoral co-operation between forestry and tourism are required for service innovations to occur (Weiss et al. 2007).

Many NIPFs (in group 4 especially) voiced for more opportunities to peer-to-peer discussions about potential of forest use and experiences. In this respect recently renewed Forest Act in Finland is aiming at more customer oriented thinking as it provides more freedom of choice for owners to implement their own management objectives. The Forest Act e.g. allows continuous-cover silviculture in all forests, which has earlier been more limited and also promotes more diverse forest management practises.

However, the focus groups interviews also emphasized, that creating profitable business around the intangible values will obviously be challenging. Therefore, highly committed forest owners (although not focused on timber production) could therefore more actively be involved in the discussion on potential of broader forest ecosystem service provision in the future. Customer integration for the service development is becoming increasingly important (Edvardsson et al. 2012). Introducing SDL perspectives could bring fresh ideas to a very traditional way of thinking lacking in depth sustainability orientation. In the forest sector, including forest owners into value creation process, could lead to emerging of new ideas and opportunities.

All in all, there is a need for more diverse and in-depth co-operation between political decision makers, forest owners, forest industry and research and extension organizations. In case of Finland, it is evident, that forests can't be utilized for the needs of the society without non-industrial private forest owners. As this study has also showed, a lot of diverse aspects were considered in different groups, underlining that modern forest owners can be also very future oriented with multiple thoughts and objectives.

Despite the limitation of a small data and relatively short interaction in the group, a rich data was created based on the focus groups interviews, so the choice of this method in this context can be considered as successful. During the discussion, opinions of others encouraged also other forest owners' comment and talk more. This led to multidimensional discussion and versatile themes. Yet, working within the confines of the available data, the study however contains limitations that can be pointed out. As being an explorative exercise to study ecologically oriented forest owners, one of the limitations of the study is the use of a convenience sample and hence, the results cannot be generalized to the broader population. In addition, while our measures in the quantitative part of this study was originally designed for gauging sustainable or green lifestyle, this was later seen to be a challenging task. Due to the difficulty of reach the forest owners and also the last minute cancellations, every owner in our focus group sample can't be classified as representative of a sustainable lifestyle. Further, by accident the structure of focus groups formed very homogenous in terms gender. Groups 1 and 4 consisted mainly of female owners, and conversations were related more on meaning of forests and new ecological utilization prospects, while groups 2 and 3 consisted of only male owners, that showed in a way that men were observing and analysing the forest sector from the practical perspective and from the basis of their own experience. Findings from the previous studies have also indicated that female owners appear to emphasize more ecological and preservation forest values than males (Nordlund and Westin 2011; Häyrynen et al. 2014b) and e.g. forest management activities are less common on properties owned (or in charge of) by females (Lidestav and Lejon 2013).

In face of a strong societal emphasis on sustainable development, the development of environmentally aware consumers is becoming increasingly important also among forest owners. Findings of the study conclude that forest owners presenting environmental conscious lifestyle could be seen as forerunners in the forest sector when considering the renewal and implementation of forest utilization and related services in Finland. Results of the study however, have to be considered as tentative and further research is needed to generalize beyond these findings to study business potential of sustainable lifestyle aspects in forestry. Because being an exploratory study from its nature, our study raises even more questions. In the future, it could be fruitful to investigate the means of creating networks of dialogues between the various actors in the field.

Assessing the impact of innovation on national competitiveness in the European Union

Alina-Elena Iosif

The Bucharest University of Economic Studies

Innovation, invention, research and development and provision of services represent pillars of a high productivity that supports competitiveness. The link between competitiveness and innovation represents the central point of the paper. The potential intensity of the connection is tested through an econometric analysis, where the national competitiveness in European Union is represented through Global Competitiveness Index or Country Competitiveness Index. As for the determinants of innovation, the eight dimensions of the Innovation Union Scoreboard will be used. The impact of the innovation's determinants on the national competitiveness of the 28 Member States of the European Union is the main aim of the current research paper. "Human resources", "intellectual assets" and "finance and support" determinants are validated as having a positive impact on national competitiveness in EU. Finally, several recommendations for the development of the innovation's determinants are presented.

1 Overview of the connection between competitiveness and innovation

1.1 Concepts and relationship

Even though there are various and even contradictory opinions on the definition of national competitiveness, the interest of public and politicians for the country's competitiveness has increased during the years. As Jovan and Bradić-Martinović (2014) sustain, policy makers focus on "achieving, maintaining and increasing the level of competitiveness, both at micro and macro level" for the development of corresponding policies at the national and regional level. The policy makers have a highly interest for the relationship between innovation and competitiveness and the proof consists in the strategies that are proposed to achieve the maximum economic impact of innovation.

In terms of concepts, Fagerberg and Nelson (2003) define competitiveness as "the creation of the locally differentiated capabilities needed to sustain growth in an internationally competitive selection environment". Particularly, competitiveness at the country level refers to "the way in which the pattern of international trade evolves over time to reflect changing patterns of capabilities and hence competitive advantage" (Fagerberg; Nelson, 2003).

"Human capital, technological progress, macroeconomic stability, institutions, and innovation" represent the main factors that influence the economic growth, which is frequently associated with competitiveness (Charles; Zegarra, 2014, 5371). Becker (2009) highlights that the relationships between R&D spending and innovation, as well as between innovation and economic growth, productivity, competitiveness and institutional structure is still unclear defined. However, based on the review of the scientific literature, Vieira et al. (2008) is pointing out that productivity and innovation are positively connected. Moreover, Oslo Manual (OECD; Eurostat, 2005) is specifying that innovation constitutes the central element for growth of output and productivity. Similar idea is sustained by Balalia (Iosif) et al. (2012) that remark the powerful interdependence between innovation and competitiveness.

Innovation is considered one of the main factors with influence on the current and future competitiveness of highly advanced economies. Additionally, location, specialization, and infrastructure may prove as important as innovation (Becker, 2009, 133). Similarly, innovation is perceived as one of the main drivers of competitiveness of emergent markets, next to internalization and institutions (Kumar; Mudambi; Gray, 2013).

The goal of this research paper is to provide support to policy makers, business, and academic community in their endeavour to improve national competitiveness in the European Union by means of stimulating innovation.

Starting from the positive connection between competitiveness and innovation, the main objective of the paper is to identify and assess the impact of the innovation's determinants that influence the national competitiveness of the 28 Member States of the European Union.

1.2 Measurement of the national competitiveness and innovation in the European Union

Competitiveness is measured in various ways, growth in productivity per hour and unit labour costs are some of the most relevant indicators. As Becker (2009, 134) stated, these particular indicators are imprecise due to their dependency on economic output and, possibly, rising or falling prices. Three of the most important instruments that capture the complexity of competitiveness are elaborated by World Economic Forum – WEF that is publishing the Global Competitiveness Report, the International Institute for Management Development – IMD that is elaborating the World Competitiveness Yearbook, and the Joint Research Centre within the European Commission - JRC that is developing reports on EU Regional Competitiveness Index. For this paper two indicators are used to capture the magnitude of the

national competitiveness in EU, namely the Global Competitiveness Index, elaborated by the WEF, and Country Competitiveness Index, developed by JRC. Each competitiveness indicator will be the explained variable in relation to the determinants of innovation included within the Innovation Union Scoreboard.

The Global Competitiveness Index (GCI) includes 12 main pillars divided by three main categories, as follows: institutions, infrastructure, macroeconomic environment, health and primary education are components of the “basic requirements subindex”; higher education and training, goods market efficiency, labour market efficiency, financial market development, technological readiness, and market size refer to “efficiency enhancers subindex”; and pillars like business sophistication and innovation belong to “innovation and sophistication factors subindex” (Schwab; 2013, 9). Some of the minuses of GCI that were identified by Lall (2001) refer to the undertaken assumptions, the type of variables used, the causal relations and the use of data within the competitiveness index. During the years, the competitiveness index was continuously improved by surpassing the shortcomings identifiable at the beginnings.

Based on the scores of GCI 2013–2014, the ranking of the 28 Member States is illustrated in graph 1.

Graph 1. The Global Competitiveness Index 2013–2014.

Source: own representation, based on Schwab, K. (Ed.) (2013): The Global Competitiveness Report 2013–2014. Switzerland: SRO-Kundig, p. 15–16.

Graph 1 shows that Nordic countries, such as Finland, Sweden, Denmark register a high level of competitiveness, while Greece and Slovak Republic are positioned on the last places of the ranking. According to the scores of competitiveness, Poland and Malta are among the countries situated at the middle of the ranking.

The distribution of the Country Competitiveness scores for the 28 member States of the EU for 2013 is shown in graph 2.

Graph 2. The County Competitiveness Index 2013.

Source: own representation, based on Annoni, P and Dijkstra (2013): EU Regional Competitiveness Index. Luxembourg: Publications Office of the European Union, p. 135.

Graph 2 indicates that Netherlands and Luxembourg are the top countries in terms of national competitiveness, while Romania and Bulgaria are situated on the last positions of the ranking.

There are similarities between the two indexes and the correlation is expected to be tight, as it was the case of CCI 2013 with GCI 2012-2013 (Annoni; Dijkstra, 2013).

As regards the measurement of innovation at the European Union's level, the Innovation Union Scoreboard (IUS) represents the main instrument used to monitor the implementation of Europe 2020 Innovation Union initiative. This instrument includes 25 indicators and offers an overview on the innovation performance among the 28 Member States of EU.

IUS is divided into three main categories represented by enablers, firm activities and outputs. Under these categories there are several dimensions, namely human resources, research systems, finance and support associated to "enablers", firm investments, linkages & entrepreneurship, intellectual assets corresponding to "firm activities", and innovators and economic effects considered as "outputs". Each dimension has its corresponding indicators. Particularly, under "human resources" the following variables are encountered: new doctorate graduates, population completed tertiary education and youth with upper secondary level education. Subordinated to the "open, excellent and attractive research systems" there is international scientific co-publications, scientific publications among top 10% most cited, and non-EU doctorate students. "Finance and support" are represented through the variables R&D expenditure in the public sector and the venture capital investments.

"Firm investments" is represented by R&D expenditure in the business sector and non-R&D innovation expenditure. SMEs innovating in-house, innovative SMEs collaborating with others, public- private co-publications are variables situated under "linkages & entrepreneurship" dimension. "Intellectual assets" includes the following variables: PCT patent applications, PCT patent applications in societal challenges, community trademarks and community designs.

"Innovators" dimension refers to the following variables: SMEs introducing product or process innovations, SMEs introducing marketing/organizational innovations, and fast-growing innovative firms. Employment in knowledge-intensive activities, contribution MHT product exports to trade balance, knowledge-intensive services exports, sales of new to market and new to firm innovations, license and patent revenues from abroad are positioned under "economic effects" dimension (Hollanders; Es-Sadki, 2014).

Each presented indicator has a score that by their unweighted average leads to the yearly composite Summary Innovation Index. Each Member State has its corresponding Innovation Index, scores for its eight dimension and scores for each indicator. The eight dimensions of the Innovation Index are the independent variables which will be tested in relation to the national competitiveness in EU.

According to the Innovation Union Scoreboard 2014, the differences of innovation performance generates four performance groups, as follows:

- Innovation leaders, where Sweden, Denmark, Germany, and Finland are included;
- Innovation followers, represented by countries such as Austria, Belgium, Cyprus and others;
- Moderate innovators, such as Croatia, Czech Republic, Greece and others;
- Modest innovators, represented by Bulgaria, Latvia and Romania.

This section has outlined the link between innovation and competitiveness, and their corresponding indicators, while the following part of the paper is presenting the methodology and the results obtained through the econometric analysis.

2 Econometric analysis

2.1 Methodology

The methodology corresponds to the main objective of the paper that is focused on identifying and assessing the impact of innovation, through its determinants, on the national competitiveness of the 28 Member States of the European Union. As presented in the previous section, the two main indicators that are associated to the national competitiveness are represented by GCI and CCI, while innovation is associated to IUS. The paper is elaborated based on the most recent data bases, identifiable in the Global Competitiveness Report 2013-2014, respectively Innovation Union Scoreboard 2014 that sums up the results for the 2013.

Econometric and statistical analyses, economic models, and micro or macro case studies are the main three types of studies dedicated for testing the relationship between competitiveness and innovation (Clark; Guy, 1997,12) Out of these three directions, the econometric analysis is used as the main method within this paper. The explained variable is considered to be the GCI or CCI, while the explanatory variables are considered the eight dimensions of the IUS. The main tools used for this research are represented by the documentary analysis and the data bases available at both the international and the European level.

2.2 Data analysis

The characteristics of the series of data corresponding to the dependent variable GCI are exposed in graph 3. Poland and Malta are associated to the median score of 4.48. Finland registers the maximum value with a score of 5.54, and on the opposite side the minimum value is allocated to Greece with an index of 3.93.

Graph 3. Descriptive statistics of the dependent variable GCI.

Source: Eviews results, based on the data extracted from Schwab, K. (Ed.) (2013): The Global Competitiveness Report 2013–2014. Switzerland: SRO-Kundig., p. 16.

Skewness indicates a distribution oriented towards left, registering more extreme values to the right side. With a value of 1.74 for kurtosis, the distribution is platykurtic, namely the data values are spread on a wider area around the mean, compared to a normal distribution.

The descriptive statistics of CCI is exposed in graph 4 and reveals that the median value corresponds to Austria. Luxembourg registers the maximum value, while Romania is the country with the lowest level of CCI.

Graph 4. Descriptive statistics of the dependent variable CCI.

In Table 1 are presented several issues of descriptive statistics corresponding to the eight dimensions of innovation, as independent variables.

Table 1. Descriptive statistics of the eight dimensions, part of the Innovation Union Scoreboard.

Source: Eviews results, based on the data extracted from Hollanders, H.; Es-Sadki, N. (2014): Innovation Union Scoreboard. Belgium, pp. 82–83.

Sweden is the member state of the EU that has the highest value in terms of “human resources” performance score, while Denmark is the leader at the “research systems” dimension. The minimum for the first dimension is allocated to Malta, while Latvia has the lowest score for the second dimension. Related to “finance and support”, Estonia is the leader, while Bulgaria registers the poorest score. As for the “firm investments” dimension, Sweden occupies the first place, while the last is occupied by Latvia. “Linkages and entrepreneurship” dimension is led by United Kingdom, while Romania is situated at the opposite side. In terms of “intellectual assets” and “innovators” Denmark is on the first position, while Romania, respectively Bulgaria are the last. In terms of “economic effects”, Ireland is placed on the first

place, while Lithuania is situated at the bottom of the ranking. The probability corresponding to Jarque-Bera statistics is higher than 0.05, meaning that the series of data follow a normal distribution.

2.3 Results

The correlation between the competitiveness at the national level in the EU and the determinants of innovation, represented by the eight dimensions of the IUS, takes the form of a multiple linear regression, as presented in equation 1. "COMP" is the general name for national competitiveness, weather is represented by GCI or CCI.

$$COMP = C(1) + C(2)*HR + C(3)*RS + C(4)*FS + C(5)*FI + C(6)*LENTREP + C(7)*IASSETS + C(8)*INNOV + C(9)*EEF \quad (1)$$

Further on, two cases will be presented as the national competitiveness in the European Union is represented through two indicators, namely GCI and CCI.

Case 1. The dependent variable is represented by the GCI and after applying the least square function the equation 2 is obtained.

$$GCI = 3.353442729 + 0.9937627192*HR + 0.8428399859*RS + 0.3054795663*FS - 0.00074774081*FI - 0.8036491689*LENTREP + 1.404967646*IASSETS - 0.07263914875*INNOV + 0.1469644145*EEF \quad (2)$$

(0.000)
(0.057)
(0.104)
(0.469)
(0.999)
(0.130)
(0.005)
(0.860)
(0.791)

In order to test the stability of the model, the Ramsey test is applied, based on the following hypothesis:

Null hypothesis (H₀) is that the correct specification is linear, while

the alternative hypothesis (H₁) is that the correct specification is non-linear.

F statistic < F critical, as 0.056 < F (0.05; 7, 20) = 2.514, meaning that the null hypothesis is accepted, and the model is correctly specified as linear.

After testing the stability of the model, by using the Ramsey test, and the linear relationship between the explained variable and the explanatory variables was confirmed, other tests are going to be applied on the regression. The purpose of the tests is to determine whether the regression is good or has some minuses.

Firstly, a good regression must be strongly fitted to data, meaning a high value of R². In this particular case, R² registered a value of 0.89, so it can be said that the regression is very good. This means that 89% of the dependent variable could be explained by the influence of the explanatory variables included within the model.

Due to the fact that the most p-values associated to the independent variables are above 0.05 level, the correlation between variables was tested. The correlation matrix indicated several strong relationships between variables, for example a connection of 0.84 is established between „research systems“ and „linkages and entrepreneurship“. Consequently, after various attempts of checking the potential connections between the independent variables representing innovation and the “global competitiveness index”, only two variables remained within the equation, as presented in equation 3.

$$COMP = C(1) + C(2)*HR + C(3)*IASSETS \quad (3)$$

Overall, the equation meets all the main rules for a good regression, but the number of validated explanatory variables is narrowed. The national competitiveness in the European Union is explained in proportion of 80% by the “human resources” and “intellectual assets” variables. The first dimension is positioned under the “enablers” category, while the second dimension is part of the “firm activity” category. Finally, equation 4 is expressing the influence that each independent variable has on the national competitiveness in the EU, represented by GCI.

$$GCI = 3.35255477 + 1.054443102*HR + 1.628281786*IASSETS \quad (4)$$

(0.005)
(0.000)

Equation 4 indicates that if “human resources” or “intellectual assets” variables goes up by one unit, then the competitiveness at the national level in the European Union is predicted to increase 1.05, respectively 1.63. If all the variables are zero, then the national competitiveness is expected to be 3.35.

Case 2. The dependent variable is represented by the CCI and after applying the least square function the equation 5 is obtained.

$$\begin{aligned}
 CCI = & -1.63921215 - 0.0904485854*HR + 0.4977504665*RS + 1.143991693*FS - \\
 & (0.000) \qquad (0.848) \qquad (0.303) \qquad (0.009) \\
 & 0.5784909089*FI + 0.6991365722*LENTREP + 0.8641023285*IASSETS - \\
 & (0.355) \qquad (0.165) \qquad (0.058) \\
 & 0.2217364123*INNOV + 0.799318014*EEF \\
 & (0.573) \qquad (0.142)
 \end{aligned}$$

The results of the Ramsey test indicate that the multiple regression is correctly specified as linear. Further on, a value of 0.92 associated to R-squared highlights a very good regression, meaning that the country competitiveness in the European Union is mainly explained through the determinants included within the Innovation Union Scoreboard.

Similar to Case 1, most of the p-values associated to the independent variables are above 0.05 level, due to the same strong relationships between independent variables. As a consequence, after various variants of checking the potential connections between the independent variables representing innovation and the “country competitiveness index”, only two variables remained within the equation, as shown in equation 6.

$$CCI = C(1) + C(2)*FS + C(3)*IASSETS \tag{6}$$

Overall, the equation accomplishes all the main rules for a good linear regression, but the number of validated explanatory variables is very low. In this case, the national competitiveness in the European Union is explained in proportion of 83% by the “finance and support” and “intellectual assets” variables. The first dimension is positioned under the “enablers” category, while the second one is part of the “firm activity” category.

Finally, equation 7 captures the influence that each independent variable has on the national competitiveness in the EU, represented by CCI.

$$\begin{aligned}
 CCI = & -1.455910675 + 1.227930104*FS + 1.683188549*IASSETS \tag{7} \\
 & (0.003) \qquad (0.000)
 \end{aligned}$$

Equation 7 reveals that if “finance and support” or “intellectual assets” variables goes up by one unit, then the competitiveness at the national level in the European Union is predicted to increase 1.23, respectively 1.68. Moreover, when the variables are considered to be zero, then the national competitiveness is expected to be -1.46.

Comparing the two cases, it can be noticed that there is similarity between them. Only two variables are confirmed in relation to the dependent variable and the positive impact of the “intellectual assets” variable on national competitiveness in EU is confirmed by both linear regressions. Consequently, no matter the dependent variable is represented by GCI or CCI, the intellectual assets have a positive impact on the national competitiveness in EU. On the other hand, the difference between the two cases is focused on the second variable that in the first case is represented by “human resources”, while in the second case by “finance and support”. Both variables have a similar positive impact on the national competitiveness in EU.

3 Conclusions

Initially, the paper is capturing an overall picture on innovation as a generator of competitiveness and highlights the positive connection between national competitiveness in EU and innovation. Further on, a snapshot on the main indicators used to quantify national competitiveness and innovation is included.

The second part of the paper is referring to the development of the corresponding multiple linear regressions between national competitiveness in EU and innovation and to their testing. The first case points out that human resources and intellectual assets have a positive impact on the national competitiveness in EU, represented by GCI. Regarding the other six dimensions that define innovation, the situation is unclear due to their corresponding probability level above 0.05 and the high correlation between the independent variables. The second case reveals a positive impact of the finance and support and intellectual assets on the national competitiveness in EU, represented by CCI. So, the determinants of innovation with the highest impact on the national competitiveness in EU out of the eight dimensions of innovation are represented by human resources, intellectual assets, and finance and support.

Consequently, stakeholders determined to implement and stimulate the innovation at the national level in the EU for a better level of national competitiveness should focus on three main directions, namely on developing human resources, by stimulating the increase of the number of new doctorate graduates, population completed tertiary education and youth with upper secondary level education, on intellectual assets, by supporting patent applications, community trademarks and designs, and on finance and support by a higher allocation of R&D expenditure in the public sector and through the stimulation of the venture capital investments.

Particularly, based on the suggestions of Arnold et al. (2009) some recommendations for stimulating the most relevant determinants of innovation in order to increase the competitiveness at the national level in EU regards the following:

- *developing the “human resources” dimension:*
- Investing in a national sustainable system of life-long learning in order to support the population along the educational process and afterwards;
- Developing an integrated system of higher education and qualifications that stimulate population complete the secondary, tertiary and doctorate level of education;
- Constant consultation with representatives of the market in order to adapt the university curricula in accordance to the employment market needs;
- Developing financial supporting schemes for each educational level, available through competition.
- *developing the “intellectual assets” dimension:*
- Providing incentives for the holders of patents, trademarks, designs in order to innovate in strategically relevant areas;
- Developing a network between the holders of patents, trademarks, designs and potential investors.
- *developing the “finance and support” dimension:*
- Increasing the R&D expenditure in the government sector and the higher education sector in order to support research in smart specialization areas;
- Stimulating venture capital investments in order to support enterprises with a high level of creation.

The current study has some shortcomings, mainly due to the high correlation between the innovation’s determinants and the impossibility of validation of six out of eight independent variables. Future research directions imply conducting a similar research analysis at the regional level within the European Union, with Regional Competitiveness Index as dependent variable.

Acknowledgments

This work was cofinanced from the European Social Fund through Sectoral Operational Programme Human Resources Development 2013-2020, project number POSDRU 159/1.5/S/134197 “Performance and excellence in doctoral and postdoctoral research in Romanian economics science domain”.

Consumers' assessment of international "meta-services": the case of Airlines Alliance

Vikrant Janawade, Daisy Bertrand, Pierre-Yves Léo, Jean Philippe

Aix-Marseille Université, CERGAM EA 4225, 13100, Aix en Provence, France

This paper presents a research on the "meta-services" delivered by networked firms and the way they are perceived by the customers. Our main hypothesis is that after experiencing such "meta-services" delivered by networked firms, the consumers synthesize their perceptions in terms of the perceived value of the network; furthermore, this assessment will largely determine their behavioural intentions. A quantitative survey allows verifying if the principal hypotheses are acceptable. This survey was conducted in the field of Airline passenger transportation, aiming to airline alliances in the context of long haul journeys. A structural equations model tested using the PLS-SEM method shows that satisfaction and perceived value of an alliance do explain passengers' future intentions, but that the value perception is by far the most powerful driver. It also shows how important to the consumers are some specific dimensions of an alliance, such as network geographical extension, co-ordination between the partners, shared information services or the smooth transits which influence the perceived quality of the alliance.

1 Introduction

The aim of this paper is to present the results of a research on the perceived value of "meta-services". We define this type of services as a grouping of multiple interlinked services provided by independent companies tied together by cooperation agreements. In "meta-services" situations, the consumers' choice is limited to the different integrated formulas offered by the networked firms. Consequently, these services will be partly delivered partly by firms not really chosen by the customers.

In services management research an evolution can be observed from simple single service activity towards more complex and integrated schemes. Such an evolution actually reflects the deep changes in the way some services are offered to consumers these days. Of course consumers continue to be serviced through 'servuction' processes (Eiglier; Langeard, 1987), but these processes often take place in more and more complex environments, due to the higher complexity of the customers' requirements but also to the growing complexity of the service providers' situation. Managing this new complexity leads service firms to develop networks, the reticular form being the most appropriate way to respond to the diverse needs expressed by the consumers (Gallouj; Gallouj, 1996). These networked service offerings can take various forms, ranging from controlled subsidiaries network to alliances with partner firms; they can cover diverse situations from the rather simple "service flowers" identified by Lovelock and *al.* (2008) to more or less large service "bunches" or clusters; Some researchers identify services constellation (Van Riel & *al.*, 2013) which differ from "meta-services" by the fact they are not produced by inter-firms cooperation.

Many "meta-services" belong to the transportation industry, because customers have to obtain a lot of information from the various independent service firms to travel in a satisfactory way. Similar situations can also be observed in the leisure services (holiday clubs, amusement parks, festivals or other popular events) though they face less complex situations due to the geographical concentration of most of the providers involved each time. The traditional way of analysing satisfaction or quality starts from the service experience of the core service and is generalised towards its peripheral services; it doesn't fit well with the whole service experienced by the customer in such contexts (Camelis & *al.*, 2010). Moreover, the customer loyalty cannot be correctly derived from such approaches. Hence, the networked services should be regarded as "meta-services" which requires a specific analysis to comprehend the consumers' behaviour.

This research is conducted within the specific context of airline alliances. Our approach is to place consumers in forefront and to study how the different networked services are synthesized by the consumer into a global perceived value attributed to the whole network.

This research tries to analyse how customers are experiencing and evaluating "meta-services" which are now part of the universal service consumption. The theoretical framework is followed by a description of the methodology and the theoretical model submitted to empirical testing. The exploratory results are then presented and discussed.

2 Theoretical Framework

Conceptual choices have to be made before collecting and analysing the opinions of consumers towards "meta-services", such as those offered by the airline alliances. Firstly it is useful to better understand how far "meta-services" are differing from simple services and then the growing complexity in services which tends to generalize in many service sectors and among them in the air transportation sector. The central question will be then examined: what

concept has to be privileged as the most pertinent when studying consumer attitude towards “meta-services”? The concept of value for the customer seems to be relevant in this context.

2.1 Simple versus networked firms' services

Researchers have always considered the question of the nature of services as an essential one, because it has statistical consequences for the economists or the geographers and managerial implications for management studies. Beside the definitions seeking to characterise the quintessence of service, as “as an act, a deed, a performance, or an effort” (Rathmell, 1966, 33), broader definitions including all the activities designed to meet a customers' specific need were proposed: “A service is an activity or series of activities of more or less intangible nature, that normally, but not necessarily, take place in interaction between the customer and service employees and/or physical resources or goods and/or system of the service provider, which are provided as solution to customer problem” (Grönroos, 1990, 27). To cast more light on these issues, Normann (1984) spoke of the ‘service package’, Eiglier and Langeard (1987) analysed a firm's service offering as composed of a basic service surrounded by peripheral services; more recently, Lovelock and *al.* (2008) used the concept of “service flower” to describe the arrangement of a core service with its peripheral services which increase its value and help a provider to be differentiated from competitors.

Eiglier (2004) stresses that these definitions are numerous, more or less complex, more or less inclusive, but that all give place to intangibility, which is an essential characteristic of services, as may also be considered the consumer's presence during the service “production”. Networked services have created new service situations for consumers and have recently called upon new approaches, both in marketing and in services management as well.

Gummeson (2005) argues that the relationships built by a company should be considered as a resource among the others classically identified by the services marketing. However he refers to the social networks more than to networks of service providers. Barile and Polese (2010) propose an integrated approach called “Viable system approach”. They describe a system connecting several elements, interdependent and communicating together; such a system can accomplish its goal through a selected activation of the relations between some elements. These relatively abstract developments can provide a general framework for analysing the contemporary services but they don't propose answers on how practically companies interlink their service operations and what impact it may have on the consumers.

When the service is offered by and within a network and in a complex context for the customer, as it is the case for “meta-services”, the issue appears to become more difficult to treat. However, it could be solved by multiplying dimensions of the analyses and whilst seeking to identify the different factors influencing the synthesis made by each consumer (Benedettini; Neely, 2012). With regard to the services offered by several firms which join or combine together to post a grouped offer, existing analyses are focused whether on the technical problems faced by the back offices or on the delimitations to be put at these alliances (Barile; Polese, 2010). The way in which these types of services are perceived by the consumer remains scarcely studied, as is the attitude she/he may develop towards these alliances. The customers, benefiting from the services offered by different companies, can make their mind on the quality of each service provider separately, but they will tend to integrate and synthesise these multiple experiences into a holistic final evaluation which they will probably attribute to the whole alliance.

2.2 The rise of complexity in networked services

When evaluating their experience of complex services the consumers will take into account very various aspects which are mainly related with the core services offered, the technology in use, the service brand and the price paid.

In “meta-services”, the service is not only co-created by the service provider and the customer as found in the basic definitions of services, but by numerous *interlinked* activities which mobilise the resources of other providers. These services appear to be much more complex with regard to their “production” and require the consumer to be much more involved. “Meta-services” use and combine information coming from several sources, with an objective to produce automated and harmonised services. Such processes are requiring proper collaboration between the participating actors to obtain a satisfactory service which can be split into separate stages, as indicated by Papazoglou and Dubray (2004, 11): “Complex services are coarse-grained and involve interactions with other services and possibly end-users in a single or multiple sessions. Enterprises can use a single (discrete) service to accomplish a specific business task, such as billing or inventory control or they may compose several services together to create a distributed e-business application such as customised ordering, customer support, procurement and logistical support. These services are collaborative in nature and some of them may require transactional functionality”. The consumers are not conscious of the back office processes. All that the consumers wish is to obtain a reliable service, delivered without any error or time delays, by a competent, courteous and responsive staff.

Information technology plays a pivotal role for supporting the networked services, but it also increases complexity. It constitutes the infrastructure of these multiple services and has hence become indispensable nowadays; however it generates a new kind of risks with the possibility of technological breakdowns that the front office personnel are rarely able to overcome. Moreover, the use of technology and the related innovations tend to enhance the performances commonly expected by the consumers. The benefits of using new innovating functionalities are rapidly assimilated by the consumers but they might be deeply disappointed if, by event, the technology fails when delivering the service.

A service brand plays a crucial part for the service firms, because it increases the trust of the consumers at the time of the purchase and helps the consumers to anticipate and understand what intangible services they will obtain. Different conceptions of the service brands were proposed, some suggesting that a service brand should be developed for each service concept like it is the case for products (O' Cass; Grace, 2003) when others propose to use the name of the service company as service brand (de Chernatony; Dall'Olmo Riley, 1999). The later conception, seemingly the most frequently used, integrates the characteristics of the places where the services are delivered (service scape perspective) and those of the personnel in contact. The front office staffs should not only have an appropriate knowledge of the services offered but also all the required relational competencies, because consumers form their opinion during the interaction process with the personnel. Therefore, as stated by de Chernatony (2010), the service brand exists in the minds of the consumers *"by virtue of a continuous process whereby the co-ordinated activities across an organisation concerned with delivering a cluster of values are interpreted and internalised by customers in such a way that enhances their existence and, through the organisation responding to feedback, enhances the likelihood of brand success"*.

In a networked firms' environment, brands bring their share of complexity to the consumer. Indeed, service alliances group together under one name, several service companies which are using their names as service brands. The name given to an alliance cannot be considered fully as a brand, because it reflects different symbols and different attributes. A brand is supposed to reinforce the trust of the consumer who buys the service and facilitate the identification of the values of the company. However, in an alliance context, the lack of homogeneity of the quality of the services among the partners is likely to reduce the meaning of the collective brand.

The last important source of complexity in networked services comes from the prices. By buying a service, the consumers would like to have the feeling that they got something substantial for what they paid. The consumers can face daunting tasks in comparing the prices of services offered in a network; this is because of inherent intangibility in the services, but also because the partners of alliance may have different pricing approaches. Additionally, much of the price issues correspond to services which are bundled together by integrating for example the airport services, reservation, the in-flight services and the airport services at destination (Gillen; Morrison, 2003). Lastly, prices may frequently vary deeply because of the revenue management practices in sectors where capacity thresholds are a constraint as it is the case with airline companies.

2.3 Perceived value, Quality and Satisfaction

How do the consumers select all these elements to build their perceptions on their service experience? Which aspects are of primary importance for them? Which among them will lead to favour a solution as against the other? What sort of criteria will guide the consumers to evaluate the "meta-services"? To answer to some of these questions, Schneider and Bowen (1995) proposed businessmen to focus on three elements which are found to explain the success of leading firms: effective human resources management to build proper relations between service staff and consumers, excellent co-ordination of back office activities with the aim of satisfying customer expectations, attention paid on basic consumer needs for safety (physiological, psychological and monetary), self-esteem and justice.

Each one of these elements is treated separately by businesses and constitutes a sub-system (human resources, operations and marketing), the challenge being to make them properly work together in such a way that the consumer will not realise their existence during a normal service experience. This sort of challenge is carried out at a higher level in networked services: independent alliance partners have to co-ordinate their activities, harmonise the service standards and increase the safeness feeling of the consumers because these elements play a key role for the consumers' evaluations.

The assessments of the consumer mostly turn into a globalised synthesis and several concepts have been put forward by researchers to measure the consumer's opinion. Among these, satisfaction and quality have often been used as global measures of performance in services marketing.

These two concepts, satisfaction and quality, seems to be useful to our questioning but a third one, the perceived value of the services appears to us playing a pivotal role for understanding consumer perception of networked services (Woodruff, 1997; Zeithaml, 1988; Woodall, 2003; Grönroos, 2008). The context of "meta-services" explains this theoretical choice. In such a context, the customer deals with several quite identifiable service providers, each one with his brand, his image and his tradition. An alliance can appear as an entity which interposes between the service brands and the consumer. It can also be viewed as an engagement between companies which have teamed up to provide better services through the network. Therefore, it is crucial for the consumer to perceive the advantages that can be gained from this alliance formation and she/he can derive the value of the network, which will determine her/his satisfaction and behavioural intentions.

Generally, perceived value is described as a trade-off between benefits and costs for the user, both being taken in a broader sense, integrating many qualitative dimensions (emotional, psycho-social, comfort, perceived risk, feeling of being downgraded *etc.*) beside the monetary or financial aspects. The benefits are exerting a positive influence on the value, and the costs a negative one. The value concept makes it possible to put together the very various aspects taken into account by a consumer after experiencing a service and such an approach seems highly appropriate in a networked context. On the one hand, the customer analyses the benefits obtained due to the alliance system used, and on the other hand, the costs she/he had to pay (or to suffer from) to obtain them. However, numerous researches that have used the concept of customer value obviously mix together the value concept in itself and the various aspects that are taken into

account by the consumer. This arouses questions that have to be in debate: should these separate aspects be considered as dimensions of the value concept or as its determinants? A multidimensional option would imply that the content given to the concept will considerably vary according to the studied field. The perceived value concept would indeed gain a much larger scope with a direct measure. Such a direct measure can be envisaged by considering it as a latent variable from which direct consequences accept more easily to be measured.

3 Methodology, theoretical model and sample

The context of the airline alliances offers a unique observation field: numerous services are offered by numerous companies, in general independent from the ownership point of view, joined together by the need to offer passengers a complete and seamless service on different routes and destinations (Gudmundsson; Rhoades, 2001; Morrish; Hamilton, 2002). Alliances appear as a strategic response from flag carriers or traditional airline operators, as against the low-cost airline companies, which engage only on point-to-point routes. For now, the airline market seems to be dividing into two segments: low price offers on short or medium haul routes, whereas airline alliances are predominantly hovering over the long haul market (Tiernan & *al.*, 2008). However, this segmentation remains likely to evolve and the consumers will probably come to adjudicate it according to the value they perceive in each of the offered solution.

The consumers of long haul flights must manage a situation marked by complexity to synchronise the flights, to put together necessary information and to organise the steps of the flight journey. In such a context the analyses of services marketing and management literature appear as uncertain solutions to understand the consumer's perceptions and attitudes. Much is known and penned about the attitude of the consumer facing simple services, whose level of quality was preset, and delivered by a single and easily identifiable service provider. The perception of a service experience was indeed well analysed in what it acts on the consumer's evaluations, in terms of satisfaction, perceived quality or brand evaluation, which will impact the future behaviour of the consumer, such as re-purchase intentions, loyalty, recommendations or even trust towards a service provider.

This research was initiated by a preliminary exploratory study by carrying out semi-structured interviews in the aim of identifying the main variables to be measured in our quantitative survey (Janawade, 2013). The exploratory interviews, lasting each from 15 to 25 minutes, were conducted with eighteen airline alliance passengers from Europe, North America, South America, Asia and North Africa.

A research model survey was then built, based on the theoretical framework and on the themes which had emerged from the analysis of participants' discussions. A survey questionnaire was also established in order to obtain measures for the different variables identified.

3.1 The Research Model

Numerous determinants of the perceived value were identified and analysed by scholars in previous studies. In this model, it is assumed that the value of an airline alliance for its passengers has six determinants, which should directly influence the perceived value. Among these determinants, four are commonly used by researchers when modelling the perceived value of a service: the perceived service quality (Hypothesis H5), the benefits of psycho-social nature drawn from consumption (Hypothesis H9) and the financial advantages, which can be split into two aspects : price competitiveness (Hypothesis H8) and loyalty programs (Hypothesis H7).

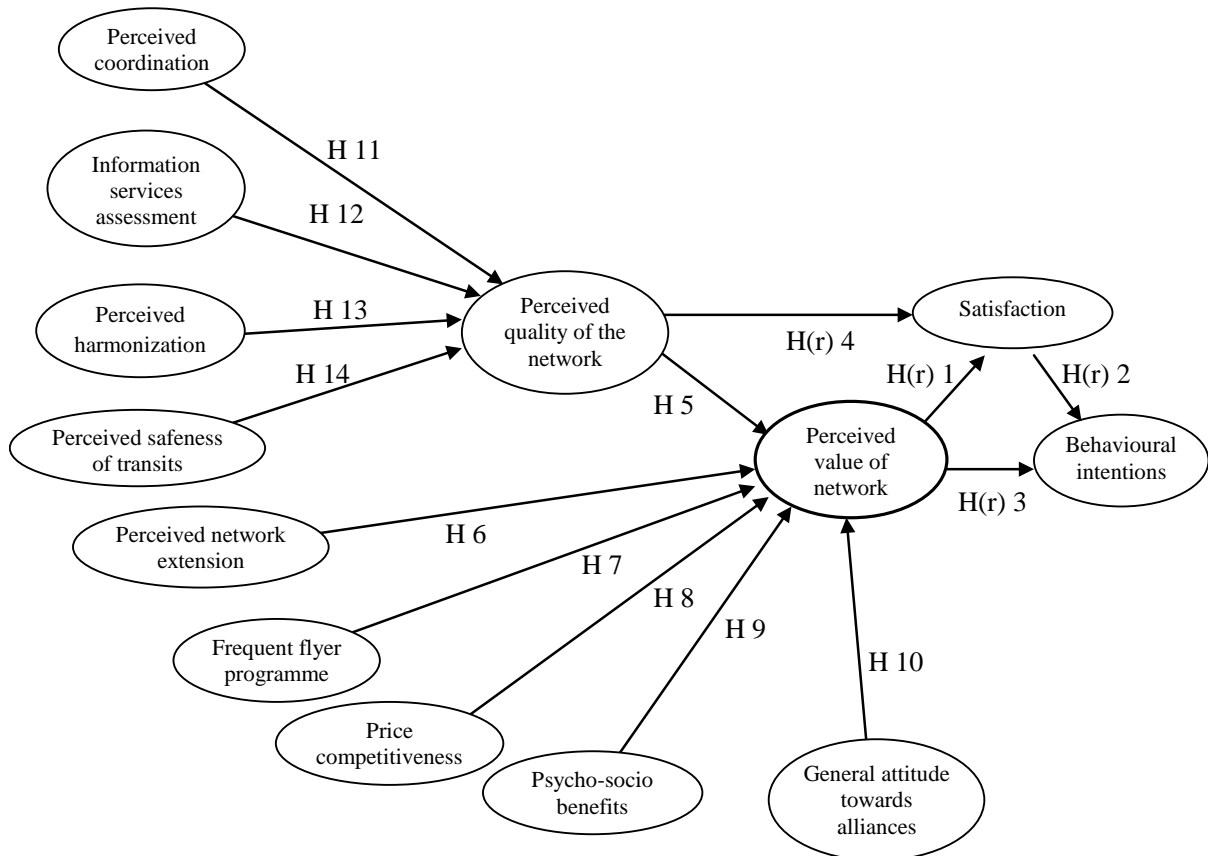

Figure 1. The research model: perceived value determinants and behavioural intentions of an alliance.

Two determinants were added due to the specific context studied: the extension of the network of flight routes and destinations is often put forward by airline alliances and should contribute to the value perceived by the customers (Hypothesis H6). Another influence is also to be expected from the general attitude developed by the users with respect to airline alliances as compared with the more traditional code sharing organisation between non-alliance carriers (Hypothesis H10). Indeed, an unfavourable general opinion about an alliance can emerge, if the consumer has the feeling that alliances are created with a sole aim of generating profits, rather than satisfying the consumers' needs. Such a negative attitude could prevent the customer from positively evaluating the value of the services offered by any airline alliance and should entail low quotations for the specific alliance flown. Four other determinants are introduced due to the specific context of the study: perceived coordination, perceived harmonisation, evaluation of information services and safeness of transits. Near concepts are acknowledged as contributors to the perceived quality of services and the model therefore assumes that the perceived quality should be a mediator between these above four mentioned determinants and the perceived value (Hypotheses H11 to H14).

The downstream part of the research model is much more traditional in marketing research and the concepts are not related to the specific context of airline alliances. It assumes that the perceived value exerts a positive influence on customer satisfaction (Replication 3), and that satisfaction influences in turn the future behavioural intentions of customers (Replication 2). In addition, the hypothesis stipulates that the perceived value also exerts a direct influence on the behavioural intentions (Replication 1). Moreover, perceived quality is traditionally considered as a powerful driver of satisfaction (Replication 4).

On the whole, thirteen variables are to be measured in this model; ten hypotheses and four replications are to be tested simultaneously. The general shape of the model will allow assessing the respective influences of perceived value, perceived quality and satisfaction as syntheses of service experience and drivers for behavioural intentions of the consumer.

3.2 The questionnaire and the survey

After being pre-tested in face-to-face with twenty frequent flyers of both sex, the questionnaire was adapted and made slimmer, making sure all questions would be understood the same way and could receive a easy and rapid answer (5 to 10 minutes). It consists of seventy two questions in total and all the items are to be quoted with a five points agreement Likert scale. The questionnaire was hosted online, using an internet survey website.

It begins with 8 questions about the participant's recent travel made within the framework of an airline alliance. The aim here is not to precisely describe the consumer's travel but to make sure that the respondents are well targeted to

give quality responses. The potential respondents were asked not to answer if they haven't recently (in the last 3 years) travelled with an airline alliance, using at least two different companies of this airline alliance during their journey.

Forty items are then proposed to the respondent's agreement to obtain her/his evaluations precisely relating to the concerned alliance. A dozen other questions were asked to identify the respondent's evaluative judgement about this experience: satisfaction, the value she/he attributed to the services delivered by the concerned alliance and her/his future behaviour. Her/his opinion towards airline alliances in general as compared with other independently operating non-alliance carriers was also measured. The remaining questions were devoted to specify the individual demographic characteristics (age, sex, profession, *etc.*) of a respondent and her/his flyer profile. Both types of variables may play a moderating role in the research model.

As far as possible, the formulation of the items followed those which had already been tested in previous studies on customer satisfaction, perceived value, repurchase intentions and on the evaluation of a service experience. The items were adapted as much as possible to the context of airline alliances to support the quality of answers.

3.3 The sample

The target population of our survey is constituted by passengers having a recent experience of travelling with an airline alliance, for a long haul flight with at least one stopover and two different carriers of the same alliance. Furthermore, quality answers were expected from travellers having developed a particular interest about long haul flights, because this consumer profiles are likely to act as opinion leaders in the market, a role with growing significance due to the internet development. People travelling often for professional reasons were privileged in the survey and answers were sought from university professors and foreign advanced students on the one hand, and, on the other, from international businessmen. The firsts were contacted through systematic emailing asking for help and answers, the latter through personal relations and through internet forums dedicated to air travels. This explains the strong proportion of professors and businessmen participating in the sample. Such a sampling can be considered as a convenience one but the characteristics of the target are hardly known and this compels to sacrifice external validity in order to obtain relevant answers.

The sample comprises about four times more men than women. Actually, women are less frequent in the people contacted and men are seen to travel more than women for professional reasons. The age distribution seems to be balanced as it leaves some space for younger and older people. The occupational profiles of the respondents are clearly influenced by the survey method, which privileged two professional environments. The business professionals, who travel frequently, having lots of travel experience, were found to give differentiated but experienced opinions. The incomes of the respondents are distributed in a rather unbalanced way. On one side of the spectrum, the high income group counts for about half of the answers and, on the other, the low income group represented by students for a sixth. The geographical origins of the respondents were rather open. However, a majority are from European countries, followed by North Americans and Australians. The rest of the world is definitely poorly represented, which limits the external validity of the results, while improving the homogeneity of the answers obtained.

According to their usage of airlines the respondents in this survey appear to have a good practice of airlines, which was expected to obtain answers only on behalf of people able to answer with a good knowledge on airline alliance services. Thus the sample represents some sort of a homogeneous set of people. More than three quarters of the respondents are found to have registered to an alliance carriers' loyalty program and more than half of the respondents declare themselves as being passionate about travelling with airlines. The sample thus gathers opinions from passengers, who have a certain level of information and experience about flying with an airline alliance.

Considering the travels which were used as reference by consumers to complete the questionnaire, it should be noted first that nearly half of the responses are concerning a specific alliance (Star Alliance). Indeed, this alliance has a greater market share than other players in airline industry, but trips made with Skyteam flyers are noteworthy under-represented in the sample (17 percent of answers).

More than eighty percent of the travels were long haul flights, lasting more than seven hours. In 44 percent of the cases, the long haul flights had only one stopover and most respondents (79 percent) travelled with two different alliance carriers belonging to the same alliance. The travels were related to professional work (study or business) in 46 percent of the cases, the rest being for leisure or tourism. In 55 percent of the cases, the flight tickets were paid by the respondents themselves and 35 percent by the respondents' organisation. This can explain why 47 percent of the respondents travelled in economic class, while 36 percent had the opportunity to travel on business class.

3.4 Data Analysis method

In this paper, we are trying first to verify that the variables identified by the qualitative survey actually exist in the respondents mind, that their measure by the selected items is acceptable and that they can be related together in a structural model. With respect to the data analysis, the Partial Least Squares, structural equation modelling (PLS-SEM) approach was used to validate a structural equations model describing how the diverse opinions expressed by the consumer could predict her/his behavioural intention, so as to reveal the respective weights of each determinant.

The PLS-SEM method is appropriated for exploratory studies using relatively modest size of sample. It is a multivariate analysis technique making it possible to test structural equations. It is a general method to estimate a

research model comprising of latent variables measured by numerous items, as is the case here. This method allows simultaneously taking into account all the variables and all the relations tested by the research model. PLS approach has been found to be very robust (Chin, 1998) and require only few statistical conditions for the data. It is also recommended by Wold (1982) for the predictive-causal analyses of complex problems, whose theoretical framework remains limited. For low size samples, the precision of the estimated parameters can be obtained whilst using the bootstrap method which randomly generates a very large number of alternative samples from the initial data collected.

The PLS-SEM analysis followed here refers also the two steps approach recommended by Hair and *al.* (1998) for the structural equation modelling: before analysing the structural equation model describing the relations between the variables, the measurement constructs of the model are analysed to check if the various latent variables created are under acceptable conditions. This step consists of evaluating the statistical quality of the measurement model and is necessary to legitimate the analysis of the structural model whose relations are examined and discussed as compared with the initial assumptions.

4 Results and findings

The confrontation to the empirical data collected leads to revise some points of the proposed conceptual model. These changes are presented first and then how the main variables were measured. The measurement model is analysed next and at last the structural model and the findings of this exploratory stage of the research.

4.1 The revised model

Among the first results of the empirical phase of the research, three are of some importance as they lead to slightly adapt the theoretical model, cancelling two variables and the related hypotheses, and changing the destination impact of two explaining variables. However these changes do not disturb the general shape of the model which highlights the central role played by the perceived value in the context of networked services.

The first change is derived from the observation that the four items that should have measured the benefits of psycho-social nature didn't produce an acceptable measure for a single latent variable: at least two dimensions were to be found there but none was measured in an acceptable way. Furthermore no significant relationship could be established with perceived value or satisfaction. Indeed, this could have been expected as this sort of benefits are closely tied to the brand image of a service provider and, as mentioned above, alliances are not fully service brands but mix different carriers brands introducing confusion into the passengers mind. The perceived psycho-social benefits were thus withdrawn from the model entailing the hypothesis H9 to be also dropped from the analysis.

Furthermore, price competitiveness didn't prove to be tied to any of the variables of the model, though it was measured in an acceptable way. This was also observed when limiting the field to the 169 passengers having paid their ticket. Seemingly, the price has become difficult to be assessed by consumers, due to the generalization of revenue management practices in the transportation sector. Therefore the hypothesis H8 was rejected and the variable was withdrawn from the revised version of the model.

The third change states that the relation between perceived harmonisation and perceived value, which was assumed as being mediated by the perceived service quality, should be a much more downstream one, influencing satisfaction and not at all the perceived value. The hypothesis H13 was therefore revised. At last, the empirical analysis suggests that the network extension does not exert a direct influence on the perceived value. Nevertheless it directly impacts the customer's assessment of the frequent flyer program of an airline alliance. Furthermore a direct link is to be observed with the behavioural intentions: actually, a wider offer meets the needs of a larger number of potential travellers. The hypothesis H6 was thus modified in the tested model.

4.2 The main variables and their measurement

The analyses of perceived value call upon many determinants which result in relatively high number of variables to be measured; a few more variables are requested due to the specific context of the research and two more variables (satisfaction and behavioural intentions) are also needed as they are immediate consequences of the perceived value and give sense to the whole modelling. Overall, 11 variables were used in the conceptual model and none can be measured directly. All are thus latent variables and each has to be assessed by a set of items selected as measuring directly assumed consequences of the latent variable. The precise formulation of the items can be found in Table 4 given in Appendix; in Table 5, in Appendix, are given the items that had to be rejected after empirical testing.

The purpose of the model is to analyse how the identified determinants combine to give birth to satisfaction, perceived value entailing behavioural intentions. Correctly measuring these three target variables is therefore essential to the quality of the model. These three latent variables are thus worth of being more precisely presented.

Satisfaction and behavioural intentions have been regularly featured in previous marketing studies dedicated to the consumers' behaviour. The measurement of the behavioural intentions is sought by asking consumers if they consider they are likely to re-purchase the services of the airline alliance and if this would result from a preferential choice. Another aspect of this attitude lies in consumers spreading a good word of appreciation about the service provider or

recommending it to their friends. These three items are well correlated in the data base and constitute the measurement scale of the consumer’s behavioural intentions.

The satisfaction of the user can be measured by a direct question about her/his global feelings with the experienced service. Satisfaction can also be measured indirectly by seeking consumers responses in terms of pleasure of consumption, service provider’s ability to meet the customer requirements, or by asking an evaluative judgement on the choice made when purchasing the service. Though the four items are well correlated together, the first one differs slightly from others which were asked at the end of the questionnaire. The last three were only kept for measuring the customers satisfaction with her/his experience of travel within the alliance, increasing the level of the Chronbach’s alpha from 0.79 to 0.87 and enhancing the share of the total extracted: 79% instead of 64% with the 4 items.

Despite its interest, the measurement of the perceived value remains largely in an unsatisfactory state. Scholars used mainly small scales, comprising one or two items, sometimes mixing perceived value with satisfaction. Items have to be directly referred to perceived value and not to satisfaction. It is commonly stated that, the greater the perceived value, the better the service provider is evaluated because of the feeling of getting a lot for the price paid. Symmetrically consumers should accept to pay a little more to obtain a service she/he considers of greater value. As a conclusion, a most valuable service will be seen by the consumer as fulfilling her/his true interest. The three selected items apparently give the first place to the financial aspects involved in the valuation process. But they actually stress the comparison between the price paid and all the various other aspects that are taken into account by the consumer, such as convenience, comfort, courtesy etc.

4.3 The measurement model

The measurement model was evaluated using the XLSTAT 2013 (Addinsoft) software program. It is evaluated by the indicators of convergent validity (Average variance extracted), of composite reliability (Dillon Goldstein’s Rho) which are presented in table 1.

Table 1. Composite reliability, uni-dimensionality and convergent validity.

<i>Latent variables (number of items)</i>	<i>Dillon- Goldstein's Rho</i>	<i>First eigen value</i>	<i>Second eigen value</i>	<i>Average variance extracted</i>
<i>REBUY: Behavioural intentions (3)</i>	.929	2.221	.274	.803
<i>SAT: Satisfaction with the alliance (3)</i>	.931	1.640	.230	.817
<i>PV: Perceived value of the alliance (3)</i>	.918	2.355	.325	.773
<i>HARM: Perceived harmonisation (4)</i>	.888	2.912	.634	.662
<i>COOR: Perceived co-ordination (4)</i>	.874	2.082	.529	.627
<i>INFO: Information services (3)</i>	.900	1.733	.403	.752
<i>EXT: Perceived network extension (3)</i>	.880	1.194	.330	.713
<i>SAFE: Safeness of transits (4)</i>	.906	2.121	.580	.703
<i>QUAL: Services quality (4)</i>	.867	2.106	.566	.619
<i>FFP: Frequent Flyer Program (3)</i>	.823	1.647	.695	.611
<i>GEN: General attitude towards alliances (4)</i>	.908	2.371	.409	.708
Minimum threshold acceptability	> .7**	> 1.0	< 1.0	> .5*

*according to Fornell & Larcker (1981)

** according to Nunnally (1978)

One can notice that all the latent variables are complying with the desired thresholds. The discriminant validity is also examined by making sure that the coefficient of determination R² between the variables are lower than the average variance extracted when constituting each variable. Table 2 shows that all the latent variables are also satisfying this condition. Correlations obviously exist between the various variables but remain always at a lower level than the average variance extracted, which in turn defines each latent variable. The analysis of the measurement model thus confirms that the variables can be used to model their relationships with PLS-SEM.

Table 2. Discriminant validity of items measuring latent variables.

	Squared correlations between variables and comparison with the average variance extracted (Rho)(given in the diagonal and bold)										
	<i>REBUY</i>	<i>SAT</i>	<i>PV</i>	<i>HARM</i>	<i>COOR</i>	<i>INFO</i>	<i>EXT</i>	<i>SAFE</i>	<i>QUAL</i>	<i>FFP</i>	<i>GEN</i>
<i>REBUY</i>	.803										
<i>SAT</i>	.626	.817									
<i>PV</i>	.758	.577	.773								
<i>HARM</i>	.116	.171	.129	.662							
<i>COOR</i>	.269	.330	.275	.259	.627						
<i>INFO</i>	.184	.219	.189	.091	.288	.752					
<i>EXT</i>	.291	.327	.214	.012	.143	.080	.713				
<i>SAFE</i>	.199	.275	.213	.221	.483	.245	.115	.703

<i>FFP</i>	.350	.324	.333	.114	.246	.243	.235	.226	.377	.611	
<i>GEN</i>	.326	.298	.340	.111	.200	.122	.189	.155	.237	.216	.708

Minimum threshold acceptability *: $R^2 < \text{average variance extracted (Rho)}$
* according to Fornell & Larcker (1981)

4.4 Findings from the structural model

The revised edition of the structural model as illustrated in Figure 2 was evaluated using the same software program, which was used for the measurement model. This model exhibits its overall explanatory power and the estimated coefficients for each relationship.

The latent variables are figured by ovals, and the items used by rectangles. The share of the variance (R^2) explained by the model is written inside the ovals and, of course, exogenous latent variables show no values for R^2 . The statistical accuracy of the coefficients measuring the relationship between the variables is figured by asterisks placed next to the estimated coefficient. It was established by the bootstrap technique as mentioned above: a thousand of sub-samples, with 150 answers each, were automatically created by randomly deleting observations from the initial database. The T tests obtained do accept not normally distributed data. All relationships tested appear significantly different from zero with a probability higher than 95%, which is the maximum confidence interval recommended by Cheung and Lau (2008). Moreover, among the 13 tested relationships, 10 have a probability greater than 99% and even 99.9% for five. The hypotheses are therefore not contradicted by the data collected. Overall, the goodness of fit of the model appears to be satisfactory: the calculated indexes are over the commonly used thresholds of .9 (or .36 for the absolut index). The predictive power of the research model appears to be fairly good: the behavioural intention of the consumer, which is the target variable for our study, has nearly 81% of its variance accounted by the proposed model, which is very satisfactory, considering the data collection method and the various contexts of use of airline alliances in the data.

The model appears as rather complex and it contains 16 cases of a variable playing as a mediator between two others. All were tested using an improved Sobel test proposed by Preacher and Hayes (2004) and all were confirmed as statistically significant, most accounting for more than 50% of the explained variance. The two direct impacts coexisting with an indirect one were confirmed: Perceived value impacts behavioural intentions directly and through satisfaction. Services quality influences satisfaction directly and through perceived value. No other direct link could be accepted when incorporated into the general frame of the model.

Above all, this model shows that the central role of perceived value is not invalidated by empirical data collected. Another important hypothesis appears consistent with the data: the perceived quality of an alliance plays a mediating role for a certain number of aspects specific to this context, which are therefore partly summarised by this variable. All the research hypotheses that were maintained in the revised model seem also to be acceptable. The changes that had to be made to comply with the first empirical testing are of course confirmed. It stresses firstly the importance of the frequent flyers' program which exerts a direct influence on the perceived value and identifies the double influence of the perceived extension of the flights network. Secondly, the perceived harmonisation does not come into play for influencing the perceived value. However, it seemingly influences the consumer satisfaction with the airline alliance, impacting thus indirectly the purchase intentions.

Figure 2. The structural model.

If we compare the coefficients organising the structural model, it appears that the most significant relationship is found directly between perceived value and behavioural intentions. Moreover this direct relationship is reinforced by an indirect relationship through the consumer satisfaction. This constitutes probably the main result of the research. The model shows indeed that consumer satisfaction is also narrowly tied to perceived value.

The sensitivity of the model to the context has not been extensively studied at this stage of the research. However, comparisons have been carried between sub-groups counting more than one hundred of respondents: higher incomes *versus* others, most frequent air travellers *versus* lesser, people having travelled for leisure or tourism *versus* professional reasons, people having paid their ticket *versus* trips charged to their organisation. They show that statistically significant changes in the path coefficients remain rare and do not affect the main conclusions that could be drawn from this analysis. The main change is that the perceived harmonisation between the alliance partners plays no significant role for the most frequent flyers (at least 10 flights per year).

Table 3. Direct, indirect and total influences of variables on behavioural intentions.

Latent variables	Types of influence:			Altogether
	Direct	Through perceived value	Through satisfaction	
<i>PV: Perceived value of the alliance</i>	.631	--	.140	.773
<i>QUAL: Services quality</i>	.000	.170	.104	.274
<i>GEN: General attitude towards alliances</i>	.000	.218	.048	.266
<i>SAT: Satisfaction with the alliance</i>	.253	.000	--	.253
<i>EXT: Perceived network extension</i>	.104	.077	.017	.198
<i>FFP: Frequent Flyer Program</i>	.000	.155	.034	.189
<i>SAFE: Safeness of transits</i>	.000	.059	.036	.095
<i>COOR: Perceived co-ordination</i>	.000	.043	.027	.070
<i>INFO: Information services</i>	.000	.033	.021	.054
<i>HARM: Perceived harmonisation</i>	.000	.000	.036	.036

Table 3 recapitulates all the direct and indirect influences that can be read in the model from the point of view of the customer’s behavioural intentions. Apart from the perceived value overwhelming influence, three other powerful determinants are influencing the consumer’s future attitude towards the alliance: The perceived service quality of services, the opinion towards alliances in general and satisfaction from the services obtained. Satisfaction apparently largely depends on the perceived value, and the attention of the researcher should be drawn on the two other drivers which are direct antecedents of the perceived value. Perceived quality is a rather classical way for the consumers to synthesize their perceptions of many “meta-services”: safeness of the connections at transit airports, co-ordination among the alliance carriers and the information systems they could use. What about the general attitude towards alliances? It can be assumed that previous experiences with alliances, at least partly determines this opinion which thus could be the result of a vicious or virtuous circle. It expresses an attitude developed by a consumer towards the “meta-services” that can be offered by firms working together in a same alliance: are they expected as useful and appreciated or does the customer prefer to remain fully free to choose the services and the providers she/he wants?

Two variables come next with comparable weights: the perceived network extension of the network and the frequent flyer program. The influence of network extension is twofold: on the one hand it acts directly on the behavioural intentions of some types of passengers. A wider offer always provides more opportunities to be taken into account by potential users. On the other hand it enhances the value of the frequent flyers’ program and may be of importance for some types of customers. Apart from these results, this study also suggests that, interestingly, the brand image and the pricing policies are not clearly understood by passengers and don’t affect either the perceived value of an alliance or the behavioural intentions.

5 Conclusion

This study sheds light into issues, which were not addressed in literature before. Therefore these results should be considered as exploratory due to the relative newness of the context investigated: as far as we know, it is the first empirically validated approach to the consumer perception of “meta-services” offered by separate firms cooperating together.

With respect to managerial implications, the primary interest of this research is to place the consumers in forefront to understand their concerns of the networked service. Whilst concentrating on the organisational models and the inter-firms agreements, the managers of alliance carriers are sometimes likely to overlook consumer perception of the services offered. This research should draw the attention of managers on the concerns which are of importance to their consumers. The extension of the network appears also to be a major concern for the passengers. Well-co-ordinated operations between partners, transits and connections made safer and well organised information services are expected by the consumers and directly impact the services quality of an alliance as perceived by its users.

From a more theoretical point of view, this research is a first step to provide a fair analysis of the consumers’ perceptions of “meta-services” in an airline alliance context. The sector of transport and tourism is embracing more and more networked services as key ingredient for its exponential growth. This research shows how important it is to take into account new variables when networked services are in concern: variables specific to the common organisation are valuable for understanding the consumers attitude and behaviour.

Appendix

Table 4. Recapitulation of variables and measuring items (standardised loadings in brackets).

<i>5 level scales: 1 Strongly disagree to 5 Strongly agree</i>	
REBUY: Behavioural intentions	
REBUY-1: I will travel again with this alliance in the future (.844)	
REBUY-2: Whenever I have a to choose, I will certainly prefer this alliance over others (.927)	
RECOM: Surely, I will warmly recommend this alliance to friends (.916)	
SAT: Satisfaction with respect to the alliance	
SAT-1: It was a wise choice to fly with this alliance (.876)	
SAT-2: This alliance provided me all the services that I needed (.903)	
PLEAS: It was a pleasure to fly with this alliance (.931)	
PV: Perceived value of the alliance	
PV-1: Travelling with this alliance is worth it, even if it costs a bit more (.923)	
PV-2: It is my true interest to travel with this alliance (.912)	
PV-3: The services offered by this alliance provide good value for money (.794)	
EXT: Perceived extent of the network	
EXT-1: This alliance facilitates travels to most parts of the world (.786)	
EXT-2: This alliance provides convenient schedules and a wide variety of flights (.873)	
EXT-3: This alliance provides easy access to the large world cities (.858)	
FFP: Frequent Flyers' Program assessment	
FFP-1: With this alliance passengers are well rewarded for their loyalty (.854)	
FFP-2: With this alliance frequent flyers get attractive bonuses (0.808)	
FFP-3: The airlines belonging to this alliance accept to redeem and use frequent flyers points obtained from any alliance member (.658)	
QUAL: Perceived quality of the services offered by the alliance	
QUAL-1: This alliance pays attention to the passenger's needs all along the trip (food, drink, comfort, health and hygiene) (.804)	
QUAL-2: This alliance provides good in-flight and on-ground services (.736)	
QUAL-3: This alliance pays attention to the comfort and well-being of passengers during transits (.837)	
QUAL-4: With this alliance it is possible to rest comfortably in an airport lounge. (.765)	
GEN: General attitude towards alliances	
GEN-1: Travelling with an airline alliance for a long trip is always better, when possible (.857)	
GEN-2: Travelling with an airline alliance for a long trip is always better for the same pricee (.822)	
GEN-3: Travelling with an airline alliance for a long trip is worth it, even if it costs a bit more (.881)	
GEN-4: Travelling with an airline alliance for a long trip allows better organising the trip (.795)	
HARM: Perceived harmonisation of the partners of the alliance	
HARM-1: The airlines belonging to this alliance offer very similar advantages, regardless of the company having issued the ticket (.832)	
HARM-2: This alliance ensures that the quality of the travel remains the same irrespective of the airline company flown (member of the alliance) (.814)	
HARM-3: The airlines belonging to this alliance provide services with very similar quality standards (.874)	
HARM-4: The airlines belonging to this alliance offer very similar frequent flyer program (.710)	
COOR: Perceived coordination between partners of the alliance	
COOR-1: This alliance provides smooth connections at transit airports (.795)	
COOR-2: Travelling with this alliance assures easy flight connections (.762)	
COOR-3: The airlines belonging to this alliance are very well coordinated to avoid any reservation problems (.803)	
COOR-4: The airlines belonging to this alliance are very well coordinated to avoid any baggage problems (.800)	
INFO: Perceived advantages in terms of information offered by the alliance	
INFO-1: The different channels used by that alliance (website, call centres, self-help kiosks) are useful and convenient ways to obtain flight information (.861)	
INFO-2: The different channels used by that alliance (website, call centres, self-help kiosks) are useful and convenient provide up-to-date and consistent flight information (0.886)	
INFO-3: The different channels used by that alliance (website, call centres, self-help kiosks) are useful and convenient offer very convenient ways to register air miles (0.846)	
SAFE: Safeness of the transits	
SAFE-1: This alliance well informs transit passengers on how to catch their connecting flights in time (.782)	
SAFE-2: In case of flight or connection problems, this alliance well informs passengers on how they will continue their travel (.872)	
SAFE-3: In case of flight or connection problems, this alliance effectively assists passengers (.812)	
SAFE-4: In case of flight or connection problems, this alliance makes proper arrangements to convey passengers to their final destination (.875)	

Table 5. Recapitulation of items that had to be rejected following the empirical study.

If not stated otherwise these items are measured with a 5 level agreement scale ranging from:
1 Strongly disagree to 5 Strongly agree

1) Rejected variables

PSY: Psycho social benefits drawn from travelling with the alliance

PSY-1: With this alliance all passengers are treated equally with respect.

PSY-2: Travelling with this alliance gives a good image.

PSY-3: Travelling with this alliance improves the way you are perceived by other people.

PSY-4: The airlines members of this alliance have rather prestigious names.

Variable is rejected due to poor convergence and no significant relation with other variables in the model.

PRICE: Price benefits drawn from the alliance

PRICE-1: With this alliance the ticket pricing makes travelling more affordable.

PRICE-2: This alliance provides attractive savings on airfares.

PRICE-3: This alliance provides attractive savings when reserving hotels, cars, etc.

Variable is rejected despite an acceptable measurement, but no significant relation with other variables in the model.

2) Rejected items

SAT: Satisfaction with the alliance

SAT-3: Overall, this travel experience left you : (1 Very dissatisfied to 5 Very satisfied).

This direct measure was asked at the very beginning of the questionnaire.

It slightly differs from the 3 other satisfaction items asked at the end, after recalling many precise aspects of the journey.

Item rejected to enhance the convergent validity of the scale.

PV: Perceived value of the alliance:

EXC: I would rank this alliance among the best in terms of excellence.

Item rejected as not specific to perceived value, mixed with quality and satisfaction

EXT: Perceived extension of the network

EXT-4: This alliance provides a wide choice of options for selecting transit airports.

EXT-5: This alliance provides an extended network of flights to numerous destinations.

Network density appears to be a separate dimension in customers' mind.

A third item would have been necessary to introduce this variable into the model.

QUAL: Perceived quality of the alliance's services

QUAL-5: The airlines belonging to this alliance provide attractive services to passengers.

QUAL-5 mixes two aspects (harmonisation & quality), being specific to none.

QUAL-6: With this alliance priority boarding is possible.

Relationships of QUAL-6 with other QUAL items are weak.

COOR: Perceived coordination between alliance partners

COOR-5: The airlines belonging to this alliance accept to redeem and use frequent flyers points obtained from any alliance member.

COOR-5 mixes two aspects (co-ordination & frequent flyers' program) being specific to none.

COOR-6: This alliance ensures that passengers' requests (dietary, seating, etc.) are properly shared between the different airline companies involved.

COOR-6 is poorly related with other COOR items

SAFE: Safeness of the travel / transits

SAFE-5: This alliance provides peace of mind during the trip.

SAFE-6: The airlines belonging to this alliance are selected as being highly reliable.

SAFE-7: Travelling with this alliance reduces the risk of being disappointed with a trip.

The safeness of the whole travel was initially aimed, but the transit alone is considered in the passengers' mind.

INFO: Information services assessment

INFO-4: This alliance ensures that passengers will have easy access to the relevant information in their transit airports.

Item rejected as it mixes two aspects (safeness & information), being specific to none.

Stakeholder integration for service innovation in German medium-sized enterprises

Julia M. Jonas, Angela Roth, Kathrin M. Moeslein

Friedrich-Alexander-Universität Erlangen-Nürnberg

Building on service systems and stakeholder integration literature, this multiple case study explores from a service-dominant-logic perspective, which internal and external stakeholders are being integrated in service innovation, in which stage of the process and in which mode. It identifies that only internal units are integrated in the mode of mutual co-creation – other stakeholders are integrated reactively. The paper discusses the indirect integration of customers and highlights interdependencies of stakeholder integration as a challenge for service innovation management.

1 Introduction to the topic

Building upon service dominant logic (SDL), service innovation is recently being discussed as a multi-dimensional concept embedded in service systems (Lusch, 2006; Maglio, Vargo, Caswell, & Spohrer, 2009; Vargo, Maglio, & Akaka, 2008). Since service researchers are elaborating about service innovation in interdependent service systems, networks and ecosystems, the selection, management and interaction of internal and external value co-creators for service innovation is gaining attention in recent research (Carlborg, Kindström, & Kowalkowski, 2013; Smith & Fischbacher, 2005).

In the past, research has put high emphasis on the possibilities and practices of stakeholder integration for specific groups, often in isolated cases of service organisations (Kristensson, Matthing, & Johansson, 2008). A variety of scholarly papers show the differences between specific types of users for innovation and describe either external (Frow & Payne, 2011; Mention & Asikainen, 2012) or internal stakeholder integration only (Melton & Hartline, 2012). But from a service systems' point of view, there is a strong demand to know more about stakeholders and their roles in interdependent systems, consisting of both internal and external stakeholders (Kindström, Kowalkowski, & Sandberg, 2013; Tossavainen, 2013). Additionally there is a need to find out about how this integration is practiced in reality (Ettlie & Rosenthal, 2011; Rusanen, Halinen-Kaila, & Jaakkola, 2014), especially in business-to-business settings, and other industries than core service organisations¹⁶⁰ (Carlborg et al. 2013; Ostrom et al., 2010).

Building upon scholarly work that investigated where and how specific internal or external stakeholders can be integrated in service innovation (e.g. Alam & Perry, 2002; Jonas, Möslin, & Roth, 2013; Perks, Gruber, & Edvardsson, 2012; Perks & Riihela, 2004), this study seeks to gain a better understanding of stakeholder integration, representing an interdependent system of both, internal and external stakeholders.

With an explorative multiple case study approach, this paper aims to answer the questions a) which actors from inside and outside the organization are being integrated throughout the stages of SI, b) in which mode the integration is happening. The research field of non-core service innovation was chosen since the multi-dimensionality in areas such as software development and manufacturing is expected to be high and yet, there are only few empirical studies investigating service innovation processes in this context (Carlborg et al., 2013).

The paper is structured as follows: after an introduction to the status-quo of research on service innovation in service systems, stakeholder integration and the modes of stakeholder integration, the multiple case study methodology will be described, followed by a presentation of the empirical findings. The paper ends with a discussion and conclusion, and an outlook for further research.

2 Theoretical background

2.1 Service innovation in service systems

From a SDL perspective, service innovation is a multi-dimensional process that aligns internal and external actors, their knowledge and resources as parts of interdependent service systems (Kindström, Kowalkowski, & Sandberg, 2013; Lusch, Vargo, & Tanniru, 2009; Vargo, 2008). The SDL implies that different actors of a service system are creating value by contributing their resources, skills and knowledge for service (Lusch & Vargo, 2014). It puts the user of the service, the beneficiary, in the center of service since the value of a service offering is always determined by the beneficiary (Vargo, 2008; Vargo et al., 2008).

The multi-dimensionality, along with the fact that a service innovation affects various dimensions of a service organisation and the service system it is embedded in, is gaining a broad support in research (Agarwal & Selen, 2011;

¹⁶⁰ Non-core service industries, such as knowledge-intensive domains like engineering and software, are often characterized by ad-hoc service development and a lack of clear service strategies, yet service innovation in these domains is being highly demanded and gaining attention amongst scholars, see e.g. Mathieu, 2001; Raddats & Kowalkowski, 2014; Kindström, & Brehmer, 2011.

Kowalkowski et al., 2012; Maglio et al., 2009; Rubalcaba et al., 2012; Smith & Fischbacher, 2005; Vargo et al., 2008). An example for the evidence of interdependencies is shown by Perks and Riihela (2004) where conflicts occurred internally due to the integration of outside suppliers. Whilst multi-dimensionality and potential interdependencies add to complexity for managing service innovation, it is also a competitive advantage differentiating and preventing imitation from competitors (Janssen, Castaldi, & den Hertog, 2013).

Already the organization itself is a system with different internal stakeholder groups. Different departments, disciplines and functions constitute actors in the service system that potentially have to be considered for integration (Carlborg et al., 2013; Kowalkowski, Witell, & Gustafsson, 2013). The alignment of the organizational resources, especially between those actors that innovate and design and those that deliver services (Payne, Storbacka, & Frow, 2007), is found to be a prerequisite to prevent market failure, together with a strategy and value creation for the customer (Edvardsson, Meiren, Schäfer, & Witell, 2013). Internal and external stakeholders participate in the co-creation of value and value propositions (service innovation) with their personal engagement and experiences (Ramaswamy & Gouillart, 2010).

2.2 Stakeholder integration in service innovation

Since service innovation “relies on the expertise and co-operation of individuals from different functions” (Perks & Riihela, 2004, 184), choosing the right people with the necessary skills, competences and knowledge is shown to be necessary and beneficial to participate in service innovation projects (Alam, 2011; de Jong & Vermeulen, 2003; Johne & Storey, 1998; Stevens & Dimitriadis, 2005). It is the challenging job of a service innovation project manager to decide about the right resources and stakeholders from inside and outside the organization. Stakeholder management entails to manage interdependencies, to embrace culture and environmental challenges as well as to balance resources, decide about timings and to communicate with stakeholders in the right way to establish or to maintain a stake they created with the respective project (Gottfridsson, 2012; Kindström et al., 2013; Payne et al., 2007; Perks et al., 2012; Perks & Riihela, 2004; Smith & Fischbacher, 2005; Stevens & Dimitriadis, 2005).

Looking at **internal stakeholders**, top managers, other units from the organization, peripheral innovators and customer contact employees are discussed as stakeholder groups for service innovation. Customer contact employees are given special attention in research since this stakeholder group is expected to share a deep understanding with the customers due to their frequent contact. It is expected that their daily customer contact leads to ideas (Alam 2006; Smith & Fischbacher 2005), but integration in the ideation phase can be reported in isolated cases only (Gustafsson et al. 1999). Training and education of such employees is stressed to make sure that customer contact employees have the ability to access and provide the organization with valuable insights on their customer needs and behavior (Brentani & Ragot, 1996; Lages & Piercy, 2012; Melton & Hartline, 2010). Nevertheless, empirical findings show that customer contact employees are not integrated as a source of ideas, but only during full launch and promotion, in service organizations (Melton & Hartline, 2010).

The commitment and constant engagement of top management as a major internal stakeholder group is considered to be vital for the success of service innovation. It is important that senior management constantly engages in SI (de Brentani & Ragot, 1996; de Jong & Vermeulen, 2003; Smith & Fischbacher, 2005). In smaller companies, the owner or manager and employees strongly contribute to service innovation (Gottfridsson 2011; Nicolajsen & Scupola 2011), especially during development and testing (Smith & Fischbacher 2005). In non-service organizations service innovation is often not a formalized process. Therefore, it belongs to the roles of top management to assign resources and give weight to service innovation throughout the service innovation process as well as to provide practical help to the project. (Ettlie & Rosenthal, 2011).

Other internal units and cross-functional teams are contributing in service innovation: especially during development, specialized skills from other departments might be needed and may help to identify and evaluate consequences of a service innovation project (Johne & Storey, 1998; Schleimer & Shulman, 2011). In research on service innovation in manufacturing it was found that even internal stakeholder integration can be challenging: the exchange of knowledge can potentially be limited by the units of the company because of different understandings, engagement and procedures (Kowalkowski et al., 2013).

External stakeholders for service innovation discussed in literature are customers, suppliers and partners, universities, competitors and consultants (Rusanen et al., 2014). Perks and Riihela (2004) found in their case study in service organizations that external stakeholders are integrated foremost at the beginning and at the end of the service innovation process.

The role of the customer or user has been given a special emphasis in the context due to their centrality in the service logic. Throughout literature, a deep understanding of the customer needs for service innovation is stressed (Bettencourt, 2010; Payne et al., 2007) especially in the context of organizations with multiple products and units (Payne et al., 2007). Previous research has revealed a variety of benefits of customer integration: innovations involving customers are found to be more successful, customer integration has the potential to enable service innovation that answers to the customer expectations (Melton & Hartline, 2010; Sandström, Magnusson, & Kristensson, 2009), it improves the effectiveness of service innovation (Magnusson, Matthing, & Kristensson, 2003; Martin & Horne, 1993; Ngo & O’Cass, 2013), and it can increase speed to market (Carbonell, Rodriguez-Escudero, & Pujari, 2012; Fang, 2008).

One of the challenges discussed by researchers is the fact that it can be difficult to identify customers as external stakeholders that are helpful (Matthing, Kristensson, Gustafsson, & Parasuraman, 2006; Nambiisan, 2002). Research by Carbonell et al. (2012) and Matthing et al. (2006) showed that the integration of specific types of customers and users affect the outcome of service innovation differently. Whilst e.g. lead users can contribute with very novel ideas, it is the integration of close customers that increases speed to market and supports access to critical information (Carbonell et al., 2012).

Even though customer integration is found to be critical for market success, Matthing et al. (2006) find that it is insufficiently practiced. This might be because it is unclear how to integrate customers (Matthing et al., 2006) or how to extract tacit knowledge from the interaction with customers (Berger, Möslein, Piller, & Reichwald, 2005; Mention & Asikainen, 2012). In both contexts, B2B and consumer services, Nordin and Kowalkowski (2010) and Smith and Fischbacher (2005) indicate that customers might not be able or willing to articulate their needs.

Other external stakeholders for service innovation are suppliers, partner organizations, outside collaborators (such as e.g. non-users) or the public (Lee, Olson, & Trimi, 2012). The integration of external resources and knowledge might foster unique service innovations and more radical innovation (Lee et al., 2012; Ordanini & Parasuraman, 2010; Schleimer & Shulman, 2011). Still, different experiences, knowledge and cultures are adding challenging complexity to service innovation projects, as Gottfridsson (2012) reveals. Processes are required to extract value from relationships. Universities are a special type of external partner that might be integrated to e.g. access basic knowledge and to improve problem solving capabilities (Perkmann, Neely, & Walsh, 2011).

Overall, in service organizations it is a challenge for stakeholder integration that the integration of customers and other external stakeholders demands major investments for the acquisition and conversion of their knowledge (Leiponen, 2012; Mention & Asikainen, 2012). The management of external stakeholder integration is taking away resources from internal functional stakeholders (Perks & Riihela, 2004). Furthermore, the communication of the service innovation, its benefits and requirements amongst stakeholders can be difficult (Perks & Riihela, 2004).

Based on the notion that service innovation is an organization-wide challenge, the integration of all affected stakeholders is required in theory (Edvardsson et al., 2013). But still there is a lack of frameworks on how to manage the co-creation process and how the co-existence of inter- and intra-firm collaboration is happening and eventually influencing each other (Payne et al., 2007; Perks & Riihela, 2004; Schleimer & Shulman, 2011);

2.3 Modes of stakeholder integration

For all types of stakeholders, internal and external, the choice of the right level of integration was found to be a crucial factor for service innovation by Perks and Riihela (2004). The interaction of an organisation with its stakeholders varies in intensity and emphasises different roles of stakeholders as well as different activities. This has been conceptualized in a variety of concepts. Russo-Spena and Mele (2012) refer to different activities of external stakeholders with their model of “5 Co’s”. Gottfridsson (2012) proposes a perspective of three different types of actors for knowledge transfer, whereas Carbonell, Rodriguez-Escudero and Pujari (2012) introduce the terms “breadth” and “depth” for customer integration. Hereby, breadth is reflecting how often customers are integrated, depth refers to the level of the integration, superficial or deep. Another model by Edvardsson et al.'s (2010) centre the role of customers. In their customer collaboration model, the customer can take the role of a buyer, be the subject of interest, serve as a provider for information, take the role of a co-developer or be the developer. Similar is the model by Blazevic and Lievens (2007) that distinguishes customer participation according to their active participation in the service innovation process. Customers can be active users, active informers and bi-directional creators of solutions.

In a similar vein with the latter, Alam (2002) presents four ascending levels of integration: the passive acquisition of input by the innovating organisation, information and feedback on specific issues, extensive consultation with users, and highest, representation, the user joining a development team. Building upon this framework with a stronger management perspective of customer integration, Jonas, Möslein and Roth (2013) have transferred the customer integration model to a stakeholder integration model. They adapted the model to categorize the degree of stakeholder integration in three stages, as presented in figure 1.

Presenting the model from left to right, the lowest degree of stakeholder integration is “passive integration”. In this mode, the stakeholder is being given the role as a “subject of interest”, meaning that he might be e.g. observed without even knowing, as in

Figure 1. The degree of stakeholder integration in three stages (Jonas et al., 2013).

market analyses or test purchases. In the next degree, reactive integration, stakeholders are serving as provider for information. They are responding to a request for feedback as in questions in an interview or a survey (Jonas et al., 2013).

The third mode, mutual co-creation is characterized by an active dialogue and joint development of new offerings (Pralhad & Ramaswamy, 2004). Here, the stakeholder is integrated as an equal partner for a discussion, to solve a problem jointly. This mode is called “representation” in Alams’ (2002) concept of customer involvement and happens predominantly in settings like joint workshops.

From the perspective of service project management, a fourth mode could be that the stakeholder is taking the effort and pro-actively approaches the organisation with an idea or request. This scenario can either be managed by a provided platform and would accordingly be seen as reactive integration or mutual co-creation. If there is not such a platform, it would not be regarded as a scenario of stakeholder integration that can be actively managed.

The integration of stakeholders and its mode is expected to be of high relevance in non-core service organisations, since services cohere not only with other offered services but also with products. Service innovation in non-core service organisations often happens ad-hoc without a formal procedure, and shows complexity in information handling and communication as well as there is a strong demand for deep knowledge of customer processes and interaction with sales (Gremyr, Löfberg, & Witell, 2010; Martin & Horne, 1993). Building upon scholarly work that investigated where and how specific internal or external stakeholders can be integrated in service innovation in service businesses (e.g. Alam, 2002; Perks, Gruber, & Edvardsson, 2012; Perks & Riihela, 2004), we seek to gain a better understanding of stakeholder integration in organisations other than service organisations. This is why this paper aims to explore a) which actors from inside and outside the organization are being integrated throughout the stages of service innovation and b) in which mode the integration is happening in non-core service organisations.

3 Methodology

To address these research issues, a qualitative explorative approach is chosen. Qualitative research in this rather new field of research allows to explore in-depth insights on real world experiences (Miles, Huberman, & Saldaña, 2013). Building upon first insights from previous in-depth single case studies of Perks et al. (2012) and Perks and Riihela (2004) in services industries and a case study on IT service innovation at a manufacturing company (Jonas & Roth, 2014), a holistic multiple case study approach is chosen to allow in-depth knowledge on a wider variety of cases. The case selection is based on the need to gather insights on stakeholder integration practices for service innovation in both, manufacturing and IT, both high knowledge intensity services (de Jong & Vermeulen, 2003). Since medium-sized and family-owned businesses constitute about two thirds of business volume in Germany (IfM Bonn, 2014), only companies from this segment were approached, resulting in four organisations with a manufacturing industry background and two in software development. The level of analysis are service responsible managers, product or innovation managers. The perspective of project managers was considered to be suitable since they decide about stakeholders to be integrated as well as the mode and timing of integration, as demonstrated by Stevens and Dimitriadis (2005). As Edvardsson et al. (2013) frame it, there is a need to understand managers since their “beliefs are put into practice” (Edvardsson et al., 2013, 26).

Table 1. Overview and background information on selected cases.

Name	Type of enterprise	Industry Background	Number of employees	Annual turnaround in €
ESC	family owned business	Manufacturing	2900	~ 400 mio.
BSN	family owned business	Manufacturing	460	~ 53000
RFS	family owned business	Manufacturing	1300	~ 140-160 mio.
EMS	family owned business	Manufacturing	1360	~ 120 mio.
LSC	cooperative society	IT, Software	6000	~ 800 mio.
OSP	family owned business	IT, Software	130	~ 10 mio.

Accordingly, the data collection for this multiple case study is foremost based on interviews with service responsible managers and completed by document-based data collection. Each case consists of two interviews, primarily product and innovation managers. Other sources such as internal presentations, student theses, sales material and other available documents were collected and used for verification and comparison during data analysis. According to Creswell (2007) and Yin (2014), making use of these different materials additionally to the main source of information, interviews, helps to verify and confirm interview propositions.

All in all, twelve interviews were conducted in the time between July 2013 and June 2014. A team of four trained researchers was involved in the conduction of interviews according to a semi-structured interview guideline. Interviews included the application of the critical incident technique to gain access to narrative and vivid examples from the near past of the interviewees’ experience with innovation activities (Gremler, 2004). Critical incidents were defined as a

typical or recent service innovation project, used to exemplify stakeholder integration in this project. This way, reflections on common routines and extraordinary behaviours could be triggered. All interviews were conducted face-to-face at the interviewees' office base and lasted about one hour in average. An overview on all interviews is provided in table 1.

All interviews were audio recorded, transcribed and categorized with help of qualitative data analysis software MaxQDA, as suggested by Miles, Huberman and Saldaña (2013). Thereby, codes were derived deductively according to analytic categories of literature in the area and inductively in line with the objectives of the explorative interviews (Coffey & Atkinson, 1996; Smith & Fischbacher, 2005). Following the guidelines by Yin (2014) and Stake (2006) each of the cases was analysed individually and summarized in individual case reports. Only after that, a comparative cross-case analysis and discussion was conducted.

Table 2. Overview on interviewees and interviews conducted for each case.

Company	Interviewee 1	Interviewee 2
1. ESC	Manager Service Engineering (MSE)	Product Manager 1+2 (PM1, PM2)
2. BSN	Sales Manager (SM)	Product Manager (PM)
3. RFS	Innovation Manager (IM)	Product Manager (PM)
4. EMS	Manager Sales & Service (MSS)	Head of Sales & Service (HSS)
5. LSC	Manager Product Management & Service (MPS)	Product Manager (PM)
6. OSP	CEO (CE)	Product Manager (PM)

Table 3 provides an overview and background information about the role of services and service innovation in the respective case company and indicates which projects were referred to as critical incidents in the conducted interviews.

Table 3. Services and service innovation – background information for the studied cases.

SC	BSN	RFS
Industry		
Engineering & Production of Electronics	Engineering & Production of Metalware	Engineering & Production of Metalware
Reported project(s)		
New solution for a customer process; new warehousing solution;	Software-based individual calculations and consulting	New coating solution for a specific customer request.
Role of service		
ESC operational services such as individualized engineering, calculations, simulations, warehousing. Supplementing services are currently in development. Services are accounted rarely and reflect only 1% of sales.	Services are consultant jobs offered for free, upon customer request. Services around the products like calculations are supporting long-term relationships with customers. Engineers in the sales team responsible for services.	Services provided are consultancy, engineering for future products sales, mostly customer pull and often for free. Training and repair as operational services on own products, providing solutions for the customer.
Role of service innovation		
The company has a referent for services driving service accountability and innovation in the respective organizational product units. A service engineering process is in use.	Rather informal and unsystematic processes guide service innovation, initiated by sales or customers. Resources for service innovation are few.	Services are being developed alongside products in the divisions. No systematic, but a step-by-step process, fulfilling the requirements of quality management.
EMS	LSC	OSP
Industry		
Production & Service in machine building	Software	Software

EMS	LSC	OSP
Reported project(s)		
Internal IT service; Customer information online platform	Customer online cockpit, software adaptations, development of consulting services.	Online sales platform for product presentation, office management software development.
Role of service		
Maintenance and repair reflect about 50% of the company's business. EMS offers even maintenance and security checks for third party machines.	Next to the development of software, infrastructure and counselling services account more than 1/3 of the organizations offerings. Still there is a product-centric culture.	Individualization and adaptations of software are the main services, consulting, helpdesk, office management consulting, legal consulting, software development.
Role of service innovation		
There is no clear service innovation process. Service development is steered by the responsible sales and services unit.	Service innovation is led by product management units and supported by a central innovation management. Innovation management initiates service projects independently, parallel. Even though there are various regular meetings, there is no clear service innovation process or guideline.	Service innovation is a top management topic, coordinated by product management and software development.

4 Findings

The empirical data identifies that for non-core service organisations internal stakeholders integrated in service innovation are top management, support functions and other units, local offices, sales and customer contact personnel such as technicians or consultants, production. The external stakeholders integrated in the examined cases are foremost customers and users. Further external stakeholders reported in this study are suppliers and external service providers, universities and competitors.

4.1 Stages and modes of integration

Concerning the mode of stakeholder integration, the case study analysis reveals that stakeholder integration is in the majority of cases happening in a reactive mode. The mode of mutual co-creation is shown for the integration of internal units, especially partner units in the very beginning of the innovation process and during development. Customers and users play an important part as a reactively integrated resource: they are integrated reactively and passively during idea screening, idea generation and idea evaluation. Further customers and users are, together with sales representatives, one of the two major stakeholders integrated for the testing of new offerings. These findings are summarized in figure 2 and will be depicted in detail in the following section.

Idea screening & idea generation	Evaluation	Development	Testing
Mutual co-creation - with members/ other units of the organisation	Reactive integration - of customers and users, informal	Mutual co-creation - with members/ other units of the organisation	Reactive integration - of customers and pilot customers
Reactive integration - of customers and users; direct and indirect - consultants - sales and service personnel with customer contact	- internal support units and experts - sales - top management	Reactive integration - suppliers/ service providers - internal units and support units - local units - top management	- internal experts - sales representatives
Passive integration - of competitors; direct and indirect			

Figure 2. Aggregated modes of stakeholder integration in the different stages.

4.1.1 Stakeholder integration in idea screening and ideation

The early phase of the innovation process with the highest level of stakeholder integration: internal units and colleagues are integrated in the mode of mutual co-creation for idea screening and -generation. Majorly in workshops, internal work groups brainstorm together on behalf of input such as customer feedback, strategic guidelines and the motivation to improve business by joint ideation. Internal units are integrated foremost to align knowledge about market developments, customer input and technical know-how. Extraordinary is the example of RFS, who organise a yearly retreat for mutual co-creation across the organisational divisions, to align expertise across disciplines and units:

It’s already something like a tradition to sit together in a hotel on a weekend or somewhere else, once a year, to brainstorm and throw ideas together. This was we identify new breeding grounds for innovation that gets more and more interesting by its concretization. (RFS – PM)

The majority of stakeholder integration happens in the mode of reactive integration, though. The most prominent stakeholder group for reactive and passive integration in idea screening is “customers and users”. In formal and informal processes, customers are being observed, interviewed, asked for feedback and asked for input in informal conversations. Customers were given a strong role for triggering the initiation of new services or consultancy activities at the supplying organisation: the interviewees report about active pull by the customers for the solutions of their problems, as e.g. interviewee EMS - HSS formulates it.

It’s a lot from the customer. We have an enormous amount of machines in maintenance, a lot of customer contact. So our customer comes and says ‘there is that service person that does these smaller motors here. That’s a simpler quality test than the ones you do. Couldn’t you do the service for these motors as well?’ This is one of the projects that we are looking at, currently. (EMS –HSS)

Customer integration and the integration of internal sales and customer contact personnel during the stage of ideation go often hand in hand in the cases examined. Interviewee LSC – PM stresses how colleagues in service and consulting gain access to customer needs and forward them to the product managers:

Service is important since they talk to customers, on everyday basis. They see where problems and potential for improvement lies. [...] We also have consultants in the field who administer projects at the clients’ location and spend several days with them. They really get a feeling for what is needed and bring that back. (LSC – PM)

The active approaching of customers to find out about needs and behaviors is prominent in the cases that deal with service innovation in IT - LSC, EMS and OSP. Regarding the cases in manufacturing, the customer integration has a stronger character of detecting and collecting customer needs when already in interaction with the customer, because of another project or sales process. These are occasions when customer contact employees ask their customers about their needs and observe their behavior.

The integration of sales and other internal units is characterized by the mode of reactive integration, being rather a provision of feedback and answers to questions than solving problems and thinking together. Reasons for integration are, above all, access to their knowledge about customers and the market. Further, project managers aim to create a stake in service innovation projects from early on or to integrate the expertise of other units for unique offerings.

To give employees at all organizational units and levels the possibility to engage in product and service innovation to all employees, in three of the case companies, RFS, EMS and LSC, all employees are engaged to provide their ideas in a pool for idea and future trend screening. This happens online at LSC, via e-mail at RFS and in a post box at EMS. All three cases have in common that they gave the impression of a strong innovation culture.

A third point in the fuzzy front-end is the passive integration of competitors or “the market”. It was reported as common practice amongst all case companies to screen and watch competitors’ offerings. This passive integration is happening by the product managers themselves and additionally by innovation management working in parallel at LSC and ESC.

4.1.2 Stakeholder integration for idea evaluation

After a concept for a service innovation project has been established, internal stakeholders, customer contact employees and, less pronounced, customers are being integrated reactively. The evaluation of innovation initiatives is foremost accomplished after receiving a first assessment, feedback and opinions from internal stakeholders that are asked for their “go” that the idea can become a project. In the majority of cases, these internal stakeholders are top management, internal units with a link to the idea, e.g. marketing and IT, and sales. This reactive integration for idea evaluation can be formal in weekly or monthly board meetings or informal.

In one case, at BSN, sales representatives are external agents. They are integrated reactively in the idea generation phase as well. *“You talk about these things with the sales agents and they say ‘this and that would be important, too’. It’s interplay between the development team and sales.”* (BSN – SM).

Either directly or through sales representatives, customers are being integrated in a reactive mode, to give feedback. This is in many cases happening in a rather informal way, building upon trusted relationships.

Parallel to informal conversations, case company LSC has an established customer board that meets twice a year and is getting informed and reactively integrated on new ideas and ongoing development projects. But even ESC reported about integrating customers in special sessions: *“We tried it for the customer online cockpit for the first time. We asked two, three larger customers to our table, separately. We presented the basic structure and asked them questions about it. It’s not the usual way, that was the first time.”* (ECS – MSS) Another scenario for reactive customer integration is presented by RFS who invites customers for an “open house day” to present latest developments and give the possibility for open exchange and feedback conversations.

4.1.3 Stakeholder integration during development

During development, internal stakeholders are the predominant stakeholder group. The project manager integrates IT resources, experts and product related units in the innovation process to define the future service in depth and to solve problems as they occur. Top management and boards as well as local units are reactively integrated to stay informed about the progress and to maintain a stake for the support of the project.

Interviewee ESC – MSE summarizes the need for the early integration of internal units as follows:

All units should be participating from the beginning, of the project, this is important. Because, if a department is not informed but needs to participate in some sort of production process... and they realize we cannot do it that way – then we are in trouble. From the beginning you need to have everyone on board who is affected by the project. (ESC – MSE)

In this stage of the service innovation process, external service providers are integrated in a reactive mode for the reason of resource gaps to fill. These might be human resources, like engineering or programming resources or required equipment in cases at hand. The suppliers for services might be engineering offices, software agencies and rarely innovation management consultants. In three cases universities and students were found to be integrated stakeholders to support the organization with specific equipment, tools and know-how or time.

4.1.4 Stakeholder integration for the testing of services

For the testing of new services, stakeholder integration is enabled in a reactive way throughout all observed cases and projects. It can be derived from the data that internal experts and sales representatives are the first to be integrated for feedback and adjustments of the offering as well as for strategic reasons.

The software development cases made strong use of pilot customers, implementing several formal and informal feedback loops, using surveys, usability tests on one hand and direct conversations on the other hand. Unlike the manufacturing cases who offer a service as a rather individual service in the beginning and maintain feedback from the direct interaction and presence at the customer.

Even though the impact is much stronger in IT related cases, test run with customers are not restricted to IT development projects: RFS’s innovation manager reported about a test run with internal pilot users for an internal service, for two years. At the cases for software development, reactive customer integration in testing can be conducted by product management but also by the IT developers in parallel.

4.2 Further insights from the exploratory study

Benefiting from the exploratory set-up of this multiple case study, further insights about stakeholder integration could be derived. It is found that (1) managing and balancing internal and external stakeholders is the task of the product manager, next to the product management job. For internal stakeholder management informal stakeholder integration (2) and the continuous integration of top management (3) was found. For external stakeholders the practice of indirect integration (4) was identified. Last but not least it was revealed that organisations are getting integrated by their customers at the same time as they are operating as stakeholder integrators (5).

(1) Data revealed that in five of the six researched case companies, **service innovation is managed by product management**, next to their regular duties. Only at EMS there is a team called Sales, Service and Maintenance that is in charge of service innovation. Accordingly, product managers report that their service innovation projects are standing in competition for resources in the everyday business. Even in the cases where there is an innovation management responsible to support service innovation activities, **managing and balancing internal and external stakeholders** is the task of the product manager.

(2) Next to formal and project management processes, there are a number of **informal and parallel processes** observed, **for the integration of internal stakeholders** like top management, but also customer contact employees, other units or rarely customers. This can be a question for feedback about ongoing testing activities, sensing of support for ideas with the top management during lunch or informal incidental meetings with customer contact employees.

(3) Summarizing over all cases and the **integration of internal stakeholders in all stages**, the empirical data shows that there are regular milestones meetings, where project managers report their service innovation project progress to a board of other units and /or **top management**, even in those cases where there is no articulated service innovation process or strategy. The character of integration of top management and internal units here is foremost reactive but can develop into discussion and problem solving meetings that develop to the degree of mutual co-creation, intended or not.

(4) For the integration of external stakeholders, a phenomenon emerging from the data analysis is that the **integration of customers** in the very beginning and in the very end of the innovation process is **indirect**, majorly implemented by sales personnel. In the studied case companies, project managers generate knowledge and triggers for service innovation from the results of the contact between sales and service personnel and the customers.

We first diagnose what does the market need, what input do we get from our local offices, from our employees or even directly from the customer. That is, we do not have the direct contact here in our headquarter. Most of the times it runs via our sales employees out there. From that we derive our requirements for innovation, prioritize them and develop our two to three big projects per year. (EMS – MSS)

In a majority of cases it was also found that the integration of customers for testing new services is not turned into action by the project manager but by a third party. In the example of ESC and BSN testing is realized through sales representatives. *“We had our first inspection and approval from the technician. Then we, no, our service responsables, asked our best customers to participate in a three month trial.”* (ESC – MSE) Even at LSC and OSP the testing with customers is carried out by software developers, who forward their feedback to the service innovation project manager.

(5) Finally, the analysis of the present empirical data showed that manufacturers like RFS, ESC and BSN and also the software developer OSP **are getting integrated by their customers**. The more know-how is demanded, the more co-creative and trustful is the mode of collaboration. This can trigger innovation projects or ad-hoc development of a new service for an individual customer demand.

The majority, 80-90%, of what we developed and even our current innovation topics are based on suggestions or wishes from the customer. What the customer says decides – we develop it this way and maybe a tick more to that. This is why our development is so strongly linked to the teams that deal with customers every day, who know about their needs and pains. (OSP – CE)

5 Discussion

This study was designed to give better insight into the practice of stakeholder integration non-core service organisations. With an exploratory research approach, the authors aimed to illuminate which stakeholders are getting integrated in which mode in the different stages of the service innovation process, and why. The study showed that “mutual co-creation”, the highest degree of stakeholder integration, is realized with the members of the organisation only, with an emphasis on the early phase of service innovation. Employees are seen as one of the key sources for idea generation and are integrated throughout the innovation process because of their knowledge about processes and customer needs, because of their expertise and technical know-how and also to maintain a stake in the project (strategic and political considerations).

This study shows that the idea generation with internal stakeholders is strongly dependent on the integration of customer contact employees as the major source for information about customer needs, problems and behaviours. Still, customer contact employees, just like customers themselves, are integrated in a reactive mode, with few exceptions. Scholars like Edvardsson et al. (2013), Matthing et al. (2006) and Gustafsson et al. (2012) have discussed that reactive stakeholder integration might only skin the surface of customer needs in the context of service organisations. The access

to sticky knowledge and latent needs is a central topic in service research and SDL (Edvardsson et al., 2013; Gustafsson, Kristensson, & Witell, 2012) which can presumably only be accessed in bidirectional communication processes (Gustafsson et al., 2012) and is difficult to process and translate into the organisation (Mention & Asikainen, 2012). In the present context of non-core service organisations, it is only trusted customers that are integrated, with the omnipresent notion of relationship development with the customer for the future of business.

This empirical study also revealed that customer integration in practice is not implemented by the decision making service innovation project manager but by customer contact employees that forward information. This confirms findings from a case study in service industries by Smith and Fischbacher (2005) that gave first evidence that the needs and interests of stakeholders are channelled through other stakeholders. Given these practices, this paper identifies that customer contact employees should be consciously given the role of “translators of information” (Gottfridsson, 2012) and be integrated intensively to “make the voice of the customer heard” in the organisation (Smith & Fischbacher, 2005, 1042). The in-depth knowledge of customer processes, necessary for service innovation in non-core service context of manufacturing, and high levels of detail with an immersion in the context of customers are found to be beneficial factors for service innovation in service organisations (Gustafsson et al., 2012; Melton & Hartline, 2010) and should be considered as a motivation for direct, yet more resource intensive, customer integration.

The management of internal and external stakeholders for service innovation is, especially in the manufacturing cases ESC, BSN and EMS a task that comes next to the project managers’ core business. This indicates that the integration of external stakeholders is competing for resources with the integration and management of internal stakeholders as research by Perks and Riihela (2004) has shown also for service organisations. The findings of this study contribute to current research that in non-core service organisations, the service innovation project itself is additionally conflicting with every day product business.

6 Conclusions

From the perspective that service innovation is a multi-dimensional process, depending on and effecting internal and external stakeholders bi-directionally (Schleimer & Shulman, 2001), it is crucial for the management of service innovation projects to know about the roles, modes and timing of stakeholder integration.

This empirical study in business-to-business services in manufacturing and software development shows that stakeholder integration is rarely implemented in the mode of mutual co-creation. From a SDL viewpoint, the co-development of future value propositions, especially with customers, is a key issue. Mutual co-creation could be identified with internal stakeholders for idea generation, only.

This study shows that trusted customers are integrated reactively in the very early and the late stages of service innovation. The fact that this integration is, in frequent cases, realized as indirect integration through customer contact employees leads to the question if this practice can really provide decision making project managers with deep insights on customer needs and behaviour. As Matthing et al. (2006) state, this might only “skim the surface” of potential insights – but in non-core service innovations, long-term customer relationships are omnipresent and affecting the integration of customers.

The study illustrates that top management and other internal units are integrated reactively throughout the service innovation process, to create a stake and to include “affected stakeholders” (Edvardsson et al., 2013) early. Here, future research could analyse the bidirectional effects in service systems on more detail and depth.

The interdependency of stakeholder integration is highlighted in this paper. The formal and informal integration of stakeholders can affect other stakeholders, the resource allocation in different projects of the organisation as well as the future relationship with the stakeholder. More research is needed to deepen our understanding of these interdependencies. It would be interesting to learn more about the effects that changes in service innovation strategy or the tools to be used for stakeholder integration have on the organisational context, processes and outcome of service innovation activities.

Finally, this explorative research gave evidence that stakeholder integration and being integrated as a stakeholder can be happening simultaneously. Future work could examine this further and make the interplay between different service systems more explicit in models and definitions.

Social investments: A social innovation approach and the importance of active ownership

Robert Jonsson, Erik Jansson

Linköping University

This paper is about social investment funds as a tool for directing financial means for welfare services supplied by local authorities. The empirical context is a municipality in Sweden. Through the fund social welfare agencies can get investment loans through which innovations in welfare services may be developed and integrated into the organizational practices. The aim of the paper is to contribute with an understanding of significant organizational conditions for the development of multiplier effect of social investment in a municipal context. The result highlights the importance of (1) a project manager with a focus on method development, (2) learning and transformation of method development into multiplier effects, and (3) management that direct attention toward the creation of multiplier effects.

1 Introduction – Social investments and the goal to create multiplier effects

The basic purpose of public organizations in Sweden is realization of societal interests via decisions in democratic assemblies. The implication is that activities of public organizations often have several different overall mission and goals (Lind; Ivarsson-Westberg, 2011). The Swedish municipalities of today have four main assignments: democracy, supplier of service, authority and being a society actor (Montin, 1997; Jonsson et al.,2002).

Infrastructure investments, business establishments and employment issues, as well as tourism and the establishment of training programs, housing for the elderly and mentally ill have become important parts of being a society actor. Particularly in the light of structural problems and setbacks related to the traditional financial governance (Jonsson, 2013). But the achievements of municipalities do not only have concrete effects, it also has more implicit consequences as it influence attitudes in society. This is something that happens both consciously and unconsciously (Jonsson et al.,2002). One important tool in this is the use of social investments and more particularly the establishment of social investment funds.

A social investment fund gives monetary resources to projects to enable them to invent new and more efficient practices and organizations for welfare services. These can in turn be institutionalized in the regular operations without increasing costs. In the paper, the terms method development and social innovation are in a sense used synonymous for that kind of progress. The argument is that both method development and social innovations in a social investment context aims at creating multiplier effects, i.e. effects that are formed and developed, value added and leveraged from a specific project to continuous operation. Whether it is merely refinements of existing methods - method development - or development of a new method or knowledge - social innovation - the organization need an ability to convert these to multiplier effects. Hence, it does not happen automatically. It requires a well thought out organization and management for this to be possible (Jonsson et al.,2014).

Method development, social innovation and multiplier effects are things that earlier have been of subordinate importance in the municipal context (Larsson, 2008). But with the introduction of social investment funds as a new resource allocation system this has started to change. To handle this, as well as the method development, an ability to “walk on two legs” is required. First, the individuals in the project need to have the ability to act action-oriented and secondly, they must have an ability to reflect. The latter is a prerequisite to problematize and consequently developing new methods and social innovations (Larsson, 2008).

For method development and social innovation to be translated into regular operations it requires that individuals learn something. However, it is not enough that individuals learn something theoretically; it also requires that individuals are able to apply the lessons learned and to allow them to it (Ellström, 2009). An individualized learning in development contexts is no guarantee of long-term effects. To convert method development to multiplier effects it requires individual learning in theory and practice, but it also requires an organizational learning (Burlin; Svensson, 2011).

We are well aware that the concept of social innovation sprawl, but in recent years there has been studies to homogenize the use of social innovations. The basis of what we today call social innovations is based on Joseph Schumpeter’s research. He broadened the concept of innovation to not only include technology development (Rønning et al.,2013). Cajaiba-Santana (2013) has through literature studies from two previously dominant perspective, actor and structure, developed a conceptualization with focus on social investment as a process. Bonificacio (2013) also clarifies the concept of social innovation by arguing that it includes an organizational process. In this paper, we take note of the Cajaiba-Santana claims – that it is important that we continue to study social innovation from a process perspective. Social change takes time and consists of social processes is important.

Research has also shown that we know little regarding the creation of method development and social innovations that lead to multiplier effects. According to Cajaiba-Santana (2013) and Rønning et al.,(2013), we need to increase

understanding of social innovation from a procedural point of view. What we know is mainly related to the large EU project (Svensson et al., 2013). We know far less about this in relation to social investment funds in a municipal context – for obvious reasons because it is a new resource allocation system.

Finally, it needs to be highlighted that capability of handling both action and reflection is a key success factor in carrying out development work in project form (Löfström, 2010a, 2010b). But that does not seem to be enough to create multiplier effects. Brulin and Svensson (2011, 25) argues that the development-oriented learning that takes place in the form of projects need to be regarded in an organizational context with an emphasis on active ownership. With active ownership they mean “that there are strong players who can create the conditions for a project driven forward and taking responsibility for the results taken care of and will be a long lasting impact”. The active ownership is a complex phenomenon in a municipal context because it is based on different logics (Jonsson; Arnell, 2006; Jonsson, 2008) and domains (Adolfsson; Solli, 2009). Hence, this paper argues that we need better understanding of the interplay between social investment and the active owners in a municipal context. The paper aims to contribute with an understanding of such significant organizational conditions for the development of multiplier effects of social investment in a municipal context.

The rest of the paper is organized as follows. The next section presents the what and why of social investment funds in a Swedish local government context. After that the methodological approach is highlighted. The fourth section contains a theoretical presentation on project management, learning evaluation, and active ownership. In the fifth section the empirical data is presented, focusing on a particular investment fund and one of its projects. In the sixth and final section the paper concludes with reflections regarding significant organizational conditions for the development of multiplier effects on social investment in a municipal context.

2 The what and why of social investment funds

As indicated, social investments is about using early interventions, often organised as projects, to decrease the risk of people ending up in an unwanted situation, e.g. dropping out of school, ending up unemployed, committing criminal acts, using drugs etcetera. It is mainly about developing a more efficient service that in turn creates opportunities for individuals to improve their lives, e.g. through increased school attendance, self-esteem, enhanced CV or improved family situation. In Sweden, the municipality of Norrköping started its own fund for social investments in 2010. The purpose of it is described as follows (Norrköping, 2014):

The purpose of the fund is to find preventive practices in Norrköping that break negative events at an early stage. The starting point is thus to find the local residents who are more at risk of being socially excluded and give them the right help to avoid falling off.

For the municipality, the financial benefits might involve reduced need for resources, such fewer placements of children and young people, reduced inputs from the overall student health or fewer investigations of the school psychologist.

For the individual the benefits are about a future with education, a job an own income. Simply, a better life.

When the effects of these investments are beginning to appear, when the municipal costs are reduced as a result of the investment, the units' financial space shall be reduced by the same amount. The surplus should then be highlighted in the annual accounts and earmarked to be used for future social investments. Because of that, the fund will be continuously replenished and new social investments can be made.

Both the financial and social benefits should be assessed for all investments. When an investment generates financial and social benefits, it might be time to implement the developed method in ordinary activities.

The assumption is that social investments, i.e. early interventions, are more financially advantageous than trying to “save” people at a later stage (Nilsson; Wadeskog, 2008). Hence, social investments are important from a social and financial perspective, as well as for the municipality and the nation as a whole (SKL, 2014). With that said, it is also important to note that funding for social investments is still a very small part of the total investments in a municipality; investments in fixed assets dominates.

From the beginning of the 2010's, we can see that there are a number of municipalities in Sweden that have or want to implement some kind of social investment fund. One reason is that it gives an opportunity to increase the ability to handle welfare resources both within and between time periods. Hence, this new resource allocation system helps municipalities to act as a more conscious community stakeholder and to provide more efficient service through method development and multiplier effects.

So how does a social investment fund work from a financial perspective? The Swedish municipalities are used to allocate financial resources to plan and administer annual recurring activities, and monitor and report what has been done (Knutson et al., 2006; Brorström et al., 2014). Municipalities in Sweden have been inspired by the traditional investment budgets when trying to streamline the management of welfare resources both within and between time periods. The social investment fund could be seen as an answer to the continuous cuts in budgets for welfare services while the demand increases.

As mentioned, a social investment fund provides financial resources to projects. In some municipalities this is done via a loan. Hence, the project is required to generate a return so they can pay it back. An example of this is provided above (the quotation from Norrköping). In other cases the project is given a donation without any restriction of repayment. This in turn means that the financial resources in the fund decreases with time, which is not the idea in the loan-based fund.

The municipalities that were first with resource allocation based on social investments met opposition. The arguments against social investments is that it is not possible to take up a welfare investment in an asset register, which is quite possible in areas such as school buildings, streets and bridges. There is a material uncertainty regarding the asset's value, which is one of several reasons for social investments not yet being included in the balance sheet in Swedish municipalities. It is, however, important to note that although there is uncertainty associated with social investment, the traditional budget process also contains uncertainty. Primarily they tend to focus too much on the next time period, which provides obstacles and uncertainty regarding long-term consequences.

Traditional budgeting combined with social investment means that the focus moves from being just about the costs of operations for a period, to also include discussions regarding the consequences. Also, social investments put method development and learning in forefront. Bengtsson (2013) argue that a key motivation behind the state and local government involvement in activities and investments is a pursuit of financial efficiency. Swedish municipal budgets and annual reports reveal that this is not always the case. In operating budgets, as well as investment budgets, there are municipal financial calculations that provided the principal base for the financial action plans. An explanation for this is that the municipality is regarded as an organization focused on results and balance sheet. A municipal calculation tells you what the social investment is expected to result in relation to the municipality's financial statements. A socio-economic calculation on the other hand provides answers to what the social investment will mean financially in the short and long term for the society (Eklund, 2012). The latter ones is, however, not that common.

3 Methodology

The theoretical approach in the paper combines theories from institutional organization, project research and evaluation studies with focus on learning evaluation. The literature review has contributed to the conceptual and theoretical framework needed for the analysis in our study. However, the study is based on an abductive process (Alvesson; Sköldbberg, 2008) and the collection of the empirical data has therefore had substantial influence on the theoretical framework (and the other way around).

Empirically we have chosen the social investment fund of Norrköping, i.e. the first social investment fund in a Swedish municipality. The reason is based on the approach to study social investments from a process perspective. That requires a fund that has been running for as long as possible, making the social investment fund in Norrköping the obvious choice. At the mid of 2014, six projects had received financial resources. We chose to focus on one of these, and more specifically the only one that had reached the point where money were about to be transferred back to the fund. The project is called "Every child should be in school". Hence, the study's contribution is primarily applicable in the context of municipal context, but the reader should be able to see a larger and more general use than that.

A mix of sources has been used to collect the empirical data. One is publically available documents regarding the social investment fund as a whole as well as the particular project in focus. Primary data have been derived through (1) taking part in local conferences and group discussions among politicians, civil servants and professionals in the different sectors of welfare services, and (2) via interviews with people working with the social investment fund as well as people within the project.

In a summation of the epistemological beliefs and methodological approach it becomes clear that the study contributes to the understanding of important organizational conditions for the development of multiplier effects on social investment in a municipal context. Worth mentioning is also that the study is part of a larger study funded by the Swedish Association of Local Authorities and Regions. It focuses on organization and management of social investment funds in a municipal context.

4 A theoretical approach – The project management and the importance of active ownership

The lack of active ownership related to development work, often in the form of projects, is a common explanation for why development work does not lead to sustainable efficiency. Previous research has shown that there is a lack of management work related to long-term actions. Management teams have acted as reference groups that have been focused on short-term results and an overall focus on here and now. Henceforth, Brulin and Svensson (2011) sought active owner who demands and at the same time try to decrease the vertical uncertainty between owners, management team and projects. Carlström (2005) uses the concept of collaborative ability to pay attention to the attitude demanded by the collaboration. Collaborative capacity is an ability to listen to the views of others while there is an ability to convey messages based on different logics and perspectives to interact in a fruitful way.

According to Svensson et al (2013) it is important that the management team act professionally towards the projects management and teams, with a focus on a close dialogue and learning. If the interaction between the political leadership

and the management of social investment is based on a quest for results, methodology and multiplier effects there are good conditions for learning in the projects and in the organization (Jonsson et al., 2014).

The active ownership means that, both during and after the project time, taking interest in the results and the learning that is generated in the projects. Besides that the active ownership is about taking responsibility for learning, methodological developments and creating of multiplier effects (Ellström, 2009).

How the management of a social investment fund is designed is a matter for each individual municipality. Regardless, it is important that the management team has the opportunity to disseminate information between investment projects and to the organization. It is important that the management team in the form of active owners creates opportunities to, when necessary, define the projects and link projects with base organization. Löfström (2010a, 2010b) uses the concept of boundaries, both structural and conceptual to deepen reflection about creation and termination of projects. Dealing with limits and uncertainties associated with development projects is important for the management team, but also for the project and the political leadership.

To know if the development is on track, the expected results are achieved and to continuously have a focus on learning, Svensson et al (2013) recommends a process-based learning evaluation. By including a learning evaluator early in the process, the focus can be set on how to measure the results and effects. A learning evaluator contributes to methodological development and helps to focus on how development can be translated into regular operations (Burlin; Svensson, 2011).

Through the literature review, a number of important organizational conditions for the development of multiplier effects in relation to social investment in a municipal context have been identified. The various organizational conditions that the literature has shown are important to facilitate the development of multiplier effects in a municipal context. A good project team with a collaborative ability and a good project manager is the basis for method development to take place. For it to be formed and increased, value added and leveraged it is also required that the project team is interested in spreading lessons, a learning evaluation and active ownership.

Learning evaluation in social investments is a prerequisite for monitoring the results, facilitate method development and contribute to the understanding of how multiplier effects can be created. To facilitate the work of the learning evaluation, it is advantageous that there is a forward elaborate evaluation plan. The plan is the basis, but because it is about development flexibility is important, which means that learning is the focus. To manage the complexity inherent in municipalities it is important that the active ownership reduces vertical uncertainty and thus makes it easier for project manager to highlight methodological development.

5 Empirical results - the project team and the owner of the project are responsible for creating multiplier effects

In this section we focus on the social investment fund in the municipality of Norrköping, and more specifically the project "Every child should be in school". We start of by describing the context in which the fund was established. The project is than describe based on the summation of the previous section, i.e. in turn it will cover the social investment project, the learning evaluation and the active ownership.

Norrköping was seen in the early 2010's as a vibrant cultural centre, including a symphony orchestra, a regional theatre, unique petroglyphs and a football team playing in the top Swedish league. The proximity of the archipelago and that Kolmården Zoo is located within the municipality of Norrköping was something that was emphasized. On the website (www.norrkoping.se) the municipality was presented as a supplier of services, an authority and as a society actor that supports work, business, culture and sport.

Norrköping has undergone great trials. Most prominent during the 1900s, industry restructuring as the textile industry in central Norrköping was driven out. The old industrial properties, which are centrally located along the River, constituted a unique cultural heritage. Today several of the old industrial buildings are used by Linköping University and local companies. The structural change meant that Norrköping no longer only was regarded as an industrial city. Norrköping was instead described as a city with many small companies within many different fields. In the end of 2013 Norrköping was the seventh largest city in Sweden with its more than 130 000 inhabitants. The structural transformation has meant that the municipality has more structural underlying problems compared with other major municipalities in Sweden.

Norrköping was a few years into the 2010's, organized based on assignments. This way of organizing the municipality's management had been in use for about 10 years when the social investment fund became a reality. The underlying idea of the organizational model was to provide an equivalent service in the entire municipality – based on assignments. During the 1990s and a few years into the 2000s, Norrköping was instead organized in smaller parts based on geography.

At the beginning of 2011, Norrköping began to work with the social investment fund. At the start the fund had a total of SEK 40 million available. In the mid of 2014, about 80% of that amount was actively used in the six projects. One project was reaching its end and repayment to the fund from the responsible authorities has begun to take place. As described earlier in the paper, the social investment fund is based on a reversal model - when the budgeted results have been achieved, there is a repayment to the fund. If a situation arises where social investment project does not achieve the goals and a refund cannot be done, there is a direct write down of the social investment. If that happens, the city

council have to decide whether the fund will be reduced by that amount, or if financial means will be added to the fund to keep it at a 40 million level.

It is the council who is ultimately responsible for the social investment fund, but the management of the social investment fund have the operational ownership. It is the management team who accepts proposals for investment and follows the various projects in relation to effects. Since 2014 they also focus on methods development in relation to multiplier effects.

5.1 The social investment project – Every child should be in school

The social investment project “Every child should be in school” is a collaborative project between two of the organizational units within the municipality: the Education office and the Social services. The target group is the children in the municipal elementary schools. However, children in schools that perform teaching on behalf of the municipality, a minority, are not included. In the mid of 2014 the project was in its final phase.

The objectives of the project were split into three levels: individual, group (school) and organization (municipality). At the individual level, the goal was mainly through increased self-esteem reduce exclusion. Absenteeism at the end of the project was expected to be zero. At the group level, the goal was to increase the knowledge of school absences and successful practices and methods to reduce school absenteeism. At the organizational level, the goal was to find ways for better synergy realisation between organizational units.

At the start of autumn 2012, the project was structured on the basis of five teams. The teams were directed to different geographical areas in the municipality. Each team had its own manager and the teams consisted of social workers and educators. After more than half a year the problems with the teams working in different ways were highlighted. Particularly there was no one with a holistic view of the project that could coordinate the work. In light of this setback, it was decided to appoint a project manager working half-time. After the project manager was in place, another important change was made. Instead of working towards geographical areas the team were organized from different missions (remember – the municipality as a whole was organized around assignments). The teams’ various missions became outreach- and attendance promotion, support for early intervention and treatment provision. This generated a more focused use of the resources.

5.2 Learning evaluation – Discoveries during the project

When the project started, it contained guidelines regarding follow-up. They were mainly focused on the objectives with the use of questionnaires as the main method for gathering data. Besides that, medical records and registration of school attendance was used. The latter was documented via an IT support system named Dexter. This was a completely new system, and therefore there was uncertainty among the schools on how the system should be handled. The project has therefore put a lot of effort on increasing the use of it. A high level of use means better data to analyse patters in absenteeism; a prerequisite to be able to find all students that needs support. Data from the project shows that the registration in Dexter is increasing and all schools are expected to use it fully at the end of 2014.

As the project progressed the project manager and the management team of the social investment fund acclaimed a need for an ongoing learning evaluation of the project. It was thought that such an evaluation would give better insights about the consequences of the processes within the project. Two experts from the two participating office’s (the Education office and the Social services) was asked to follow the project in more detail and present progress reports for the fund’s management team. The interim reports were official and was also presented at the municipality’s website. The follow-up in relation to the objectives show that the project is successful. Attendance has improved during the project and the invalid absenteeism has decreased. Despite this, it is interesting to note that the first reports highlighted performance monitoring, but with time the evaluations got more focused on how the method development would be put into the regular organization after the project ends.

There are several examples of the work to create a transition from project the regular organisation. Most of them have its base in concrete routines for the schools to work by to be able to handle the problems on their own. Hence, the creation of routines is a way for the project to facilitate the creation of multiplier effects. Since this facilitation has been considered important it has consumed a considerable amount of the resources in the project. For example, one person has had these routines as the main task since the internal reorganization of the project, and a lot of meetings and discussions around these have been conducted.

One concrete routine that has been highlighted is the need for an appointed person in every school responsible for the children’s attendance. A lot of schools have already chosen to follow this recommendation. Project members have also conducted meetings with these to inform them on their ongoing work as well as the routines that they have establish based on the experience from the project. The later consist, among other things, of routines for establishment of (1) a plan to deal with the absence of a specific child, (2) three part conversations between the child, parents and Social services, and (3) a better collaboration and information exchange between the school and Social services.

Another example of the work to ease the creation of multiplier effects is the full-day conference that was arrange in the spring of 2014. It had the theme "All children in school" and focused the learning that has come out of the project. The project has had an experimental approach since an established method was lacking. During the conference the

conclusions from the project was therefore discussed. Several of them were in the form of concrete recommendation (with related tools) to the schools.

As mentioned, the learning evaluation has contributed to the focus on the transition from project to the schools. But the evaluations have also shown that the one important lesson on the group level (schools) is that there are many causes of absenteeism, and that they in turn often are complex. The project teams' conclusion from this was that each child's situation must be explored and that it is important with a large amount of flexibility in the daily operation, i.e. the activities must be adapted so that they fit the individual child. Another lesson is the importance of asking for the child's experiences; they give a lot of useful information that can be used to tailor the support. For this knowledge to be used as a base for action in the schools after the project, i.e. to implement the methodology development, the project management highlighted that there needs to be staff in the schools that understand and use the developed processes to manage school attendance and absenteeism. Giving a person at each school the responsibility of overlooking the attendance of the children is one important part in this, but other roles are important as well.

5.3 The active ownership – Continuous feedback and focus on results

In Norrköping, the management team of the social investment fund consist of the managing director of each office as well as two officials who work with the social investment fund. The management team also includes a few appointed politicians. This is considered important for the continuous dialogue between the politicians and the officials. The management team is chaired by the municipal financial manager. One important reason for this is to signal the importance of the fund. Another is the fact that he was the one that developed the model on which the fund is based. The model's structure is similar to how municipalities in Sweden manage investments in fixed assets. In the latter case an investment is made and when it is in place the concerned part is charged with a capital cost (interest and depreciation). Social investments works in the same way but with an important difference: social investments are not charged with any internal interest.

When the social investment fund had just been created, the management team followed the projects with a focused on performance monitoring; are they reaching the objectives? With time they noted that this was not enough; they felt that they needed more information on the progress, especially when one of the projects reached its finalization. Among other things they needed information on the transition between project and ordinary operation, i.e. how the projects are preparing for multiplier effects. The need for a continuous learning evaluation for every project grew stronger, and the usage of it right from the start in new projects. This was sought to create the attention of the projects towards results, methodology development and conditions for multiplier effects.

In relation to the project "Every child should be in school", the implementation of a learning evaluation came as a result of a dialogue both between and internally in the management team for the fund and project respectively. The management of the fund, both officials and politicians, have also shown an active interest in the project's continuous results. The manager of the Education office and the Social services respectively (the two involved offices in the project) have come to take a particularly active role in this; requesting information from the project, being there as active support and showing that they care about the results. With a learning evaluation as the base this has meant a focus on the development of method and structures that can be used after the project. One concrete consequence of this is the full-day conference mentioned in the previous section. The conference was not an event organized by the project; it was set up as a collaboration between the project and the management team. This shows that the management team finds the project important and want to create the best opportunities possible for multiplier effects.

6 Conclusions – Multiplier effects and the importance of an active ownership

As mentioned earlier, several Swedish municipalities have drawn inspiration from traditional investment budgets to increase the ability to handle welfare resources both within and between time periods. This has created a new resource allocation system; the social investment fund. The idea is that the fund should lead to methodology development and social innovation, but the fund per se could also be considered a social innovation. That innovation is an important organizational tool when searching for method development and multiplier effects. But a social investment fund in itself is no guarantee for success; a well thought out organization and management is necessary for that to happen (Jonsson et al.,2014).

Given that a social investment fund is a new resource allocation system for the Swedish municipalities, there is reason to research its construction and how it is used. Therefor the aim of this papers aim is to contribute with an understanding of significant organizational conditions for the development of multiplier effect of social investment in a municipal context.

The organizational conditions that have been put forward in earlier research, as well as in our study, are important to understand and to handle. These conditions are summarized below.

- Social investment project: it is important with a project manager with a clear focus on method development.
- Learning evaluation: transformation of method development to multiplier effects is a necessity for long-term success, and learning is in important enabler in that.
- Active ownership: the management needs to manage the process and direct attention toward the creation of multiplier effects.

A good project team included a collaborative ability, and a good project manager constitutes an important base for method development to take place within the framework of social investments. For method development to be formed and developed, value added and leveraged it is also required that the project team is interested in spreading lessons, are using a learning evaluation and have an active ownership.

Previous studies (Ellström, 2009) and the reported results in this paper have shown that a project that can handle action and reflection is an important organizational condition for the development of new or improved methods. Carlström (2005) has shown that collaborative capacity of participants in projects is important. The case of “Every child should be in school” shows that via (1) the large amount of internal discussions that have taken place within the project, and (2) the dialogues between the project and representatives from the schools. But for method development to have lasting impact it requires more than that.

Learning evaluation is an important approach if development is to be realized in the organization. The learning evaluation is focused on results and how the method development can be converted to multiplier effects (see also Svensson et al., 2013). The paper, and specifically the case, draws attention to the importance of organizing for learning evaluation in the planning phase of a social investment project. This was not done in the case project – but the actors learned the “hard way” that this is important.

The single most important organizational condition, however, is the active ownership. Previous research by Brulin and Svensson (2011) shows that we know little about the active ownership. And we know even less related to the municipality context and social investment. The paper has shown that the active ownership in a municipal context is complex. It involves different ideologies (Arnell; Jonsson, 2006; Jonsson, 2008) and different domains (Adolfsson; Solli, 2009). Also, the active ownership consists of several players - players who over time are replaced and act upon different logics. Regardless of the underlying complexity of the active ownership in a municipal context, it is the active owners which have the greatest impact on the process to multiplier effects. The other conditions are important, but the active owners are those in charge of the process. They have the possibility to create good prerequisites for the other conditions and actors that are involved. In the particular case this is done via an active support, showing that good results as well as concrete work to convert the developed method to the ordinary organization are important. The support communicates that the work is material. Without that it does not matter if a fantastic work is being done within the project; if the politicians and top managers do not care, changes in the ordinary organisations will never happen.

Even if the paper has drawn attention to important conditions for creating multiplier effects, especially active ownership, we need to know more about the active ownership in a municipality context and particularly in relation to social investments. We need longitudinal studies of social investments, active ownership and multiplier effects.

A new approach for building the optimal free-to-play game offering

Henna Järvi¹, Mikko Pynnönen², Jukka Hallikas¹

¹*School of business, Lappeenranta University of Technology*

²*School of Industrial Engineering and Management, Lappeenranta University of Technology*

This study examines mobile gaming industry and in specific what is the optimal free-to-play game design. We utilize business model and customer oriented service design literature and introduce a novel method, Design of Experiment (DOE). We conducted two workshops with gaming experts and interviewed mobile game developers to identify the optimal free-to-play game design. As a result we present a framework for optimal game design, evaluated by the gaming experts. With this research we are contributing to both service design theory and introducing a novel customer oriented methodology.

1 Introduction

Since the launch of smart phones and tablets, the way we see games and playing has changed dramatically. Mobile games and the revenues they bring have created a lot of opportunities for companies. Inside mobile game industry the focus is shifting from the so called premium games (purchase and play) to free-to-play games.

The problem with today's service management in general and also in gaming industry is that service offerings do not meet the customer's requirements and therefore lead to their low usage and lower willingness to pay for them. In order to produce service offerings that customer will use, a systematic customer-oriented service design process needs to be established. (Aurich et al., 2010, 138) The problem with the shift in gaming industry is the optimal structure of the game design to be able to attract the customers not only to download the game but also to purchase the game items.

In this study, we utilize a novel technique, Design of Experiment (DOE) (Montgomery, 2012) to structure the game offering in the optimal way to meet the customer requirements. Ideally designed service design would provide most customer value and thus result in business success for companies operating in the game industry (Howden; Pressey, 2008; Hu et al., 2009). Since the focus is shifting from premium games to F2P games there is clearly a need to study how free-to-play offering and customer requirements meet and how the offering should be modified. Therefore the research question of this paper is: *What is the optimal service design of free-to-play service model?*

After the introduction we present the theories used in this study. Second, we present the methods used in this study and illustrate the results of our study. After results, we move to discussions and conclusions.

2 Literature review

2.1 Business models

Business models emphasize a holistic, system-level approach in explaining how companies "do business" (Zott et al., 2011, 1019). Business models are trying to explain in a simplified manor the mechanisms which companies utilize to create value. The main three components of a business model are: 1) value proposition, 2) architecture of value creation and 3) benefit model. Value proposition defines the benefits customer or another partner of the company will achieve. Architecture of value creation defines the benefits achieved by the company. The necessary internal and external units and different transformation processes are described. Benefit model describes the mix of benefit sources and kinds of benefit. (Aurich et al., 2010, 140)

When focusing on technology and innovation management, the main purpose of a company's business model is to understand how technology is converted into market outcomes. In order to influence the market outcomes, companies need to focus on finding technology's connection with customers and understanding different players and their roles in the operating network. When business model is the correct one it will facilitate value creation with the technology, dynamics in innovation network and creating an infrastructure of relationships. (Zott et al., 2011, 1036)

2.1.1 Business models in mobile gaming

Mobile game developers can be seen as companies which are utilizing a certain technology or innovation in creating new products and services. In mobile gaming industry, four different business models are present at the moment: premium, freemium, ad supported and hybrid. Their characteristics are discussed next.

Premium game is defined as a game that costs more than \$0.99. It has been the predominant model in the early phases of application stores and is used by some of the biggest names in the market, such as Cut the Rope and Angry Birds. When thinking what games should be offered as premium games, the rule of thumb is that if there is no natural or obvious way to integrate consumable items to the game or app, the right business model would be premium. (Morel, 2012) Once a premium game is launched to the market the content of the game cannot be changed. Thorough

prescreening of the game is needed and game houses invest in focus groups that pretest the game multiple times before it is launched.

Free-to-play (F2P) business model is the most represented model in Apple’s App Store. It means that the game is free to download, however players purchase items inside the game. (Park; Lee, 2011) Free-to-play game items can be categorized into three groups; 1) items connected to game personalization, 2) durable items which provide long-term benefit and 3) consumable items which provide instant benefit during the game (Špikić, Čudanov; Štavljanin, 2013). The rule of thumb when considering freemium as the right business model is that, if you have thought of game items in the game development phase, offer it as a free-to-play game (Morel, 2012).

The percentage of how many players are purchasing in-game items is called conversion rate (Principles of Mobile Game Design, 2013). Statistics show that only 2-6% of free-to-play game players purchase items inside the game (Morel, 2012; Tyni et al., 2011, 24). Hence there are over 90% of users who are playing but not purchasing in-game items. If 5% of the players are purchasing in-game items, it is considered high. Another important characteristic is ARPU (Average Revenue Per User) which is usually measured per month. If ARPU is greater than \$4 the game is doing well. If the conversion rate is 5% and ARPU \$4, the average paying player is spending \$80 on the game. (Principles of Mobile Game Design, 2013)

When only 2-6% of players are purchasing in-game items, it creates a risk for game developers when designing and later on launching games since the majority of the players are not producing revenue. The design of the game needs to be so exciting and fun to play that it attracts people to play and also pay in order to secure the revenue stream for the company.

Free-to-play game differs from premium in price and additionally in developing style. Since it is free the game can be altered after it has been launched. Game developers should pay a close attention to application store ratings, blogs and forums to find out the possible problems in the game and fix them (Morel, 2012).

Ad-supported games can be freemium or premium by nature, nevertheless the main source of revenues is different advertisements inside the game. Some of the most common types of advertisement are banner advertisement, video, offer walls and interstitials. Finally, there can be different hybrid models. The two most common hybrid models are: freemium with ad-supported and premium with in-app purchases. (Morel, 2012)

Choosing the right business model is naturally the most important step and it has to be chosen before the game has been developed. In the industry there are two main criteria for choosing the right business model; 1) content first, then money and 2) decide your business model early in the development process. (Morel, 2012) For example if the main monetizing method is advertisement, then the game developers need to leave room for them in the game.

2.2 Key factors in games

Sweetser and Wyeth (2005, 5-6) have identified 7 step criteria for a game which is enjoyable and causes player to experience the “flow” moment as presented in table 1. Games must keep player’s concentration through a high workload but the tasks need to be sufficiently challenging to be enjoyable. An enjoyable game in the best scenarios helps player forget the track of time and lose the awareness of the surrounding world. (Sweetser; Wyeth, 2005, 4)

Table 1. Criteria for game flow.

Element	Criteria
Concentration	Game should require player to concentrate and he/she should be able to concentrate on the game. Game should grab player’s attention from the start. They should not be overburdened with tasks they do not see important. The games should have a high workload while still being appropriate for player’s skills.
Challenge	Games should be challenging enough and match player’s skill levels. Games should be able to provide different challenge levels for different players. The level of challenge should increase when the player proceeds in the game.
Player skills	Game needs to support development and mastery of player’s skills. Starting the game should be easy and no previous specific skills should be required from the player. Learning the tricks in the game should not be boring. Tutorials in the beginning of the game should be provided and they need to feel like the player is already playing. Game interfaces and mechanisms should be easy to master.
Control	Players should experience the feeling of control over the actions in the game. Especially they should feel they are controlling the character. They should be able to feel that what is happening in the game world has some meaning and players have the power to shape the game world.
Clear goal	Game should have clear goals which are presented at appropriate times and are easy for the player to understand.

Element	Criteria
Feedback	Player needs to receive relevant feedback at appropriate times. Player should always know the status and score.
Immersion	Player should experience deep but effortless involvement in the game. They should become less aware of their surroundings and they should experience an altered sense of time. They should feel emotionally connected to the game.

2.3 Service design

Service design has been described as the outside-in perspective on service development (Holmlid; Evenson, 2008, 341). Service design focuses on understanding users and their context, service providers, social practices and converting this understanding into development of evidence and service systems interactions (Patricio et al., 2011, 181). Service design systematically applies design methodologies and principles to the design of services. It assumes customer as the starting point and models how service can be performed keeping the customer the center of all actions.) Service design brings unique methods and perspectives to service innovation (Holmlid; Evenson, 2008, 341-342).

A customer-oriented service design approach begins with the customer. The whole process is iterative and the target is to create services that are useful, desirable, usable, efficient and effective. To fully understand the service experience it is crucial to walk through the service as the customer would. Understanding what he/she might find difficult or desirable are key points when crafting services. (Holmlid; Evenson, 2008, 342) In different phases of the service offering development process, different feedback tools and methods can be used. For example, customer surveys or feedback reports can be used to identify customer requirements. (Aurich et al., 2010, 139) Since free-to-play games are not locked with their design once they are launched, game developers should follow different feedback channels to identify possible mistakes and problems and improve the game.

3 Methodology

The empirical research in this study consists of the two consequential stages: 1) The voice-of-the-customer analysis and 2) service design optimization

In the first stage, we identify the voice-of-the-customer in the game context. This will include the identification of customer requirements for free-to-play game environment. We also connect these requirements into critical game service design factors that may have important role in terms of the customer value creation. In order to find out the relevant design factors of the service for the customer we have to analyze the interconnections of the service functions and customer requirements. We use Quality Function Deployment (QFD) framework to analyze the high level offering design before we approach further. QFD is an analytical tool that is designed to convert high-level business objectives into processes (Clegg; Tan, 2007). It is a method that is used for converting customer demands into quality characteristics, and developing product design by systematically deploying the relationships between these demands and the product characteristics (Lee; Ko, 2000). At this stage we utilized two workshops with gaming experts to understand the customer needs and to map the initial offering concept of a free –to-play game. The role of this first phase was to ensure the fit of the offering to the customer purchase process which also represents the company sales process quite well.

In the second stage of the research process, we will conduct an experiment for investigating the optimal design for free-to-play game. By utilizing the Design for Experiment (DOE) method, the example free-to-play game design is optimized for both maximizing the downloading of the game in the first place and for optimizing the in-game purchases afterwards.

The design of experiment (DOE) method was applied in the pre-study of factors affecting to the attractiveness of game playing environment. In DOE method the designs are changed systematically and data is collected accordingly on each changed designs (runs). We have selected a two-level factor design for the study. In the two level design, two alternative design options are identified for each identified factor. The levels are often presented as -1 and +1. Blackett-Burman L 12 design matrix was used in the DOE study. The Blackett-Burman matrix details can be found e.g. in Ledolter and Swersey (1997). The DOE matrixes provide determined order for factor levels under study. In other words, it specifies the combination of factors for each run. An advantage of the DOE is that only fractional number of combinations have to be studied still providing reliable results. This reduces significantly the time and resources needed for conducting studies. Another advantage of DOE is that when the combination of factors are studied simultaneously, the interaction of these factors can be analyzed. Two lead-user customers were used as a data source in a pre-study.

4 Results

4.1 Voice-of-customer analysis

Based on workshops within gaming experts, we identified four phases of customer gaming process that are: 1) interest to download the game, 2) Interest to purchase the game, 3) committing to the game and 4) sharing the experience of playing.

For the successful gaming experience, all of these phases have to work smoothly. The game features have to support these phases. Also based on a workshop with gaming experts, we identified general design factors of a free-to-play game. The design factors are: 1) playing time, 2) character of the game, 3) purchase type, 4) payment type, 5) changing game, 6) game identity, 7) social and 8) multiplayer. The design factors are explained in detail in table 2.

Table 2. Design factors.

Factor	Description
Playing time	Playing time can be either restricted or unrestricted. Restricted playing time means that there are some limits to playing time; energy, task, help from others etc. When playing time is unrestricted there are no limitations how much the player can play.
Character of game	Game's character can be either ad hoc or the plot is continuous. In ad hoc games the plot changes due to player's actions or due to the game itself; for example the player unlocks new levels or a new item is released by the game developer. A continuous plot refers to games which do not have for example visible levels but the game is going on without the player realizing he/she has earned enough points.
Purchase type	There are two options in purchasing type: purchase the game and purchase in game. Purchasing the game means that player downloads the game for his/her application store and pays for the game; this is known as a premium game. Purchasing in game means a free-to-play game, meaning the game is free to download but it has different items for sale. In some games in-game purchases are mandatory.
Payment type	Payment type can be either transaction or monthly payment. When the payment is transaction products and money are exchanged once. A monthly payment means that consumer pays some fee in a month in return for limitless or limited products.
Changing game	There are two possibilities in changes inside game: no and random. An example of no changes in game option is Packman. In Packman the player is always repeating the same steps, collecting the points and running away from the killers. When the changes are random, it means that the game changes and the player cannot affect to that; for example different enemies emerge and there are different steps to complete.
Game identity	Game's identity can be either standard or personalized. In so called standard games the player cannot affect to what the character looks like. In personalized games the player can for example, name the character, change hair color and outfits for free or purchase items for the character.
Social media	Social media factor means that the game has either connection to social media (for example Facebook, Twitter) or then not. Through social media players can post their scores and exchange items with other players.
Multi-player	Multi-player factors means that the player is either paying alone (option no) or then in interaction with other players (option yes) (Prototyping a mobile game, 2013).

We applied the QFD matrix to see how these design factors are connected and how they support to the phases of customer gaming process (see Figure 1). The Importance of these needs/wants was rated from the company perspective, the question being how important the phase is in the selling process of the game. The analysis reveals that all factors have fairly good fit to all of the elements of customer gaming process and therefore there is no need to drop any factor out of the further analysis. Also the analysis shows that none of the customer process phases lacks support from the design, so there is no need to add functions to the design.

Relationship Key: Strong Medium Weak Weight 9 3 1				Product/Service Requirements & CTQs								Importance (1-Low, 5-High)	Total
				Playing time	Character of game	Purchase type	Payment type	Changing game	Game identity	Social media	Multiplayer		
Customers' Needs/Wants													
Interest to download				1	3				1	3	9	4,0	68
Interest to purchase				9	9	9	9	3	3	3	9	5,0	270
Immersion				9	9	9	9	9	9	3	9	4,0	264
Social interaction				3	3	3	3	3	9	9	9	3,0	126
													0
													0
CTQ Priority				94	102	90	90	60	82	66	144	728	
% Importance				13	14	12	12	8	11	9	20	100	
Priority rank				3	2	4	4	8	6	7	1		

Figure 1. The Quality Function Deployment Matrix to find the key design elements.

The most important factor is Multiplayer option with importance rate of 20%. However, all the functions are relatively close to each other CTQ priority scores. The only customer “want” that the offering does not support as well as others is Downloading, but it is still on acceptable level. Based on these results we decided to keep all the design factors in the further analysis.

4.2 Service design optimization

For conducting the DOE study, we first identified the critical service design factors affecting to the choice of the game with the expert group. The results of the factors and their levels (two level design) is illustrated in Table 3. 8 different factors represent important design elements for developing game service structure which appeal potential customers.

Table 3. Design of experiment factors and their levels

Factors	-1	1
Playing time	Restricted	Unrestricted
Character of game	Ad-hoc	Continuous plot
Purchase type	Purchase game	Purchase in game
Payment type	Transaction	Monthly payment
Changing game	No	Random
Game identity	Standard	Personalized
Social media	Yes	No
Multi-player	Yes	No

Based on the identified factors and their levels, the Blackett-Burman matrix design was adopted with one replication (12*2). It follows that the study design contains 24 runs (rows) where each row presents combination of designs which is measured by using 1-10 scale for service attractiveness (1= least attractive; 10= very highly attractive). The used datasheet for the used L12 matrix is presented in table 4.

Table 4. Datasheet for L12 DOE study.

Playing time	Characted of Game	Purchase type	Payment type	Changing game	Game identity	Social media	Multi-player	Attractiveness
Unrestricted	Continuous plot	Purchase game	Monthly payment	Random	Standard	No	Yes	4
Unrestricted	Continuous plot	Purchase in game	Transaction	Random	Personalized	Yes	No	8
Unrestricted	Ad hoc	Purchase in game	Transaction	No	Standard	No	No	7
Unrestricted	Continuous plot	Purchase game	Monthly payment	No	Standard	Yes	No	6
Restricted	Ad hoc	Purchase game	Monthly payment	Random	Personalized	Yes	No	2
Restricted	Ad hoc	Purchase game	Transaction	No	Standard	Yes	Yes	2
Restricted	Continuous plot	Purchase in game	Monthly payment	No	Personalized	No	Yes	2
Unrestricted	Ad hoc	Purchase game	Transaction	Random	Personalized	No	Yes	5
Restricted	Ad hoc	Purchase in game	Monthly payment	Random	Standard	No	No	1
Restricted	Continuous plot	Purchase game	Transaction	No	Personalized	No	No	3
Restricted	Continuous plot	Purchase in game	Transaction	Random	Standard	Yes	Yes	8
Unrestricted	Ad hoc	Purchase in game	Monthly payment	No	Personalized	Yes	Yes	3
Unrestricted	Continuous plot	Purchase game	Monthly payment	Random	Standard	No	Yes	7
Restricted	Ad hoc	Purchase game	Monthly payment	Random	Personalized	Yes	No	1
Unrestricted	Ad hoc	Purchase in game	Monthly payment	No	Personalized	Yes	Yes	10
Restricted	Continuous plot	Purchase in game	Transaction	Random	Standard	Yes	Yes	5
Restricted	Ad hoc	Purchase in game	Monthly payment	Random	Standard	No	No	1
Restricted	Continuous plot	Purchase in game	Monthly payment	No	Personalized	No	Yes	2
Unrestricted	Continuous plot	Purchase game	Monthly payment	No	Standard	Yes	No	1
Unrestricted	Ad hoc	Purchase game	Transaction	Random	Personalized	No	Yes	5
Unrestricted	Continuous plot	Purchase in game	Transaction	Random	Personalized	Yes	No	5
Restricted	Ad hoc	Purchase game	Transaction	No	Standard	Yes	Yes	4
Restricted	Continuous plot	Purchase game	Transaction	No	Personalized	No	No	10

The analysis is done after the data collection with the Minitab software. The software allows us to provide both numerical and graphical information about the studied design. In this case we investigate the effect of the design change of each selected factor for the game customer attractiveness. As shown in the main effect plots in figure 2, payment type, playing time, and character of game present most significant effect on attractiveness. Therefore, these factors seem to be most important in terms of game design choice.

Figure 2. Main effect plot for game attractiveness.

Based on the DOE study, the optimal design for the free-to-play game service is presented in Table 3. An optimal design is calculated with Minitab software based on the main effects of individual plots and their interaction with each other. As shown, only in Payment type factor the -1 (transaction) is provided for optimal design. The analysis shows that when the optimal design is adopted, the predicted attractiveness of the service model is 6,833 out of 10 as maximum. It is thus expected that this combination is most attractive design for the customers.

Table 5. The optimal design.

Factor	Outcome of DOE	Meaning
Playing time	1	(Unrestricted)
Character of game	1	(Continuous plot)
Purchase type	1	(Purchase in game)
Payment type	-1	(Transaction)
Changing game	1	(Random)
Game identity	1	(Personalized)
Social media	1	(No)
Multi-player	1	(No)
Predicted responses Attractiveness	6,833	

5 Discussion

In this study we wanted to investigate the optimal way to design a free-to-play offering. The changing nature of the industry and growing demands of the customers force game developers to develop games their customers really want to play. When only 2-6% of players of a particular game are producing revenue to the developer, the game developers need to think carefully what kind of games should be created and what aspects they should include.

We used two different methods to optimize the design for the customer and the firm. First we used voice-of-customer based QFD process, where the initial check of the design factor relevance was tested. Since the focus was on generally in playing the participants put impact on issues that might have an effect to the different phases of customer gaming process. For example multi-player option was the most important factor in voice-of-customer and the reason behind this could be ability to play with friends or friends are already playing and you feel the social pressure to play.

After voice-of-customer analysis was completed, we used DOE process where we asked the game experts to evaluate the attractiveness of different offering combinations and then used the Minitab to analyze the attractiveness of single factors in the design. In Design of Experiment phase the participants were asked to think about a specific game and how they would value each aspect. In voice-of-customer analysis multiplayer was the most important factor, however in DOE it was not seen important at all. This can be explained by the different level of analysis. In DOE model the participants were thinking of a specific game and to these specific participants, multiplayer option was not important.

The optimal free-to-play design according to this research is a game where playing time is not restricted, the plot keeps evolving, it is free to download and purchasing happens inside the game, payment is transaction, the game changes randomly, character of the game can be personalized and there is no connection to social media and you are playing solo. Unrestricted playing time and continuous plot were the most important things for the participants.

The result of this research is the above mentioned optimal free-to-play design but what needs to be remembered is that not all consumers are willing to play similar games. In mobile games two different market segmentations should take place. Naturally consumers want to play different kinds of games, for example war games or puzzle games. This is the first level of segmentation. A second level of segmentation should happen on a level of individual game. Some consumers want to purchase in-game items in a continuous changing game world, other players value free playing or purchasing the game as it was before. Since the statistics show that only 2-6% of players purchase in-game items the game developers should offer options for those consumers who wish to play mobile games but are not willing to purchase in-game items.

6 Conclusion

This research focuses on identifying the optimal free-to-play design hence the contribution is both theoretical and methodological. This study contributes to the service design literature (e.g. Holmlid; Evenson, 2008; Aurich et al., 2010) by introducing a systematic methodology for customer driven service design in service companies. Additionally a novel method, Design of Experiment was introduced alongside with voice-of-customer. With this way the consumers can be take part into game developing process by clearly stating what kind of games they are willing to pay, in addition when they are willing to purchase games or in-game items.

This study could be improved in different ways. The methodology in hand has not been used in this kind of research before, hence it needs some more runs. The study focus was in testing the methodology and process and therefore we did not use large customer samples for the voice-of-customer part, but instead used the company experts in evaluation. It would be beneficial to use larger customer study in the first phase of the process. Additionally the workshops should be repeated with higher number of participants in order to see the incremental issues. Games are highly related to

experiences and different people experience them differently and therefore value different issues. In the attractiveness evaluation in with DOE the different customer segments should be recognized and the population should represent all relevant segments. Increasing the number of participants and possibly conducting qualitative interviews we could identify different important aspects.

Viability template – a practical tool for assessing viability of transformative service innovations in health care context

Valtteri Kaartemo, Marikka Heikkilä, Jouni Saarni, Aki Koponen

University of Turku

The paper develops and showcases the viability template which is designed to assess the innovation potential of transformative service ideas. Based on the transformative service research and innovation literature, we highlight the importance of novel simplifying technology, supporting value networks, cost-effective business models, and regulatory environment which enable renewal of the prevailing market practices. We operationalize the template as a set of questions and assess the innovation potential of three pilot cases on new transformative services. The pilot cases present technologies that aim to develop and spread the usage of user-friendly electronic health care services in Finland.

1 Introduction

Transformative service research (TSR) combines transformative consumer research with service research in order to inform how to improve the consumer and societal well-being. So far, the emerging field has not paid particular interest in transformative service innovations, which we define as the evolutionary process whereby organizations or individuals transform new, useful knowledge, in order to advance well-being in the service ecosystem. In fact, most of the empirical studies on innovation in health care focus on idea generation rather than dissemination (Lämsäsalmi, Kivimäki, Aalto, & Ruoranen, 2006). There is a dearth of research in innovation in public health services that discusses the role of institutions in dispersion of service idea to service innovation. This stands in contrast with strong focus on practices and existing institutions that otherwise characterize the industry. Often the overall improvements in health care services are based on an intertwined set of different types of innovation: product, process, organizational and market innovations (Windrum & García-Goñi, 2008). The consumer well-being is usually most apparent in product innovations in e.g. new medical technologies. The direct well-being effects of the other innovation types are more vaguely observed. Due to many interconnections and needs for proof of concept, transformative service innovations in health care are challenging to implement.

We acknowledge that there is an abundance of seemingly good ideas that suggest how technology or process reconfigurations could be employed to increase well-being in health care context. Nevertheless, before these ideas can be referred as transformative service innovations, they need to be accepted and adopted in parallel by multiple stakeholders, such as service provider's management and employees, service purchasers, authorities and service users, or consumers. And then they need to be diffused through market practices by institutionally embedded actors. These practices may be in line with the original plan for value proposition or stemming from unforeseen stakeholder activities.

The objective of this study is to increase understanding on institutionalization in transformative service innovation processes in the context of health care. Furthermore, the study aims at building up a template for analyzing the different extents of viability of transformative service innovations. By viability we refer to the transformative service innovation which 1) includes a novel idea that can be deployed into practices that increase well-being in service ecosystem, 2) is accepted and adopted by different stakeholders and 3) has suitable features to attract diffusion in its innovation and stakeholder networks. We build on TSR, innovation literature and institutionalization processes to understand how disruptive ideas spread to advance consumer and societal well-being. We operationalize a viability template that can be employed to assess the viability of potential transformative service innovations. In the empirical part, we showcase the developed viability template by assessing three potential innovations in health care context that aim at improving well-being through increased efficiency and empowerment of patients. In addition to showing how the template was used in evaluating the viability of these cases, we discuss how the template could be developed further.

2 Theoretical background

2.1 Transformative service research

Anderson et al. (2011, p. 3) define TSR as “the integration of consumer and service research that centers on creating uplifting changes and improvements in the well-being of consumer entities: individuals (consumers and employees), communities and the ecosystem.” TSR focuses on the socially oriented contexts such as health care and education, in which the nature of service speaks to consumer's and society's well-being. Instead of focusing merely on customer satisfaction and loyalty, this emerging area pays attention to the effects on well-being of multiple stakeholders.

Research on consumer behavior has paid attention to health for long. For instance, Neergaard and Irvine (1989) conducted a study on underlying motivations, factors, and processes involved in family management of well-being. Since then, the health care-related consumer studies have expanded to cover, for instance, electronic word-of-mouth on health social networking sites (Liang & Scammon, 2011), men's behavior as health consumers (Buckley & Tuama,

2010), and the choice of non-conventional treatments (Rajamma & Pelton, 2010). Despite health care consumption has been approached from various directions, there is surprisingly little research on health care innovations in consumer research. As a notable exception, Caldwell and Kleppe (2010) studied the role of early adopters in the diffusion of health care innovations. They underscore that public demonstration by early adopters reduces consumer resistance to HIV/AIDS public health innovations.

Similarly, service research has mostly neglected health care innovations. However the readiness of both health service providers (Okazaki & Castañeda, 2013) and patients (Lanseng & Andreassen, 2007) in adopting new technologies have been taken into account. Lanseng and Andreassen (2007) focus on early adopters and their expectations of the technology. Similarly, Okazaki et al. (2013) focus on perceptions of the technology as well as personal characteristics of the physicians. Heikkilä et al. (2014), in turn, analyse the feasibility of a health service innovation and its business model from both the provider network's and pilot customer's point of view, and Nikayn et al. (2014) discuss its social implications. Although these studies increase our understanding of the behavior of pioneers in adapting health care innovations, they are limited in terms of raising awareness of the institutionalization of health care innovations into market practices.

The importance of institutionalization is particularly discussed within the service ecosystems approach (Vargo & Akaka, 2012; Vargo & Lusch, 2011). In service ecosystems approach, actors are perceived as being embedded in social context in which they integrate resources to increase their own well-being. In other words, value is always co-created with multiple stakeholders in context. As actors are embedded in social structures, it is perceived that institutions both enable and constrain value creation and the adoption of new practices. Although health care practices have been studied with service ecosystems approach (McColl-Kennedy, Vargo, Dagger, Sweeney, & Kasteren, 2012), it remains unknown how institutionalization of these practices occurs. Particularly, this is an important question in the health care innovation setting that introduces new or changed practices.

2.2 Innovation

Innovation is considered as a multi-stage process whereby organizations transform ideas into new/improved products, service or processes (Thompson, 1965), in order to advance, compete and differentiate themselves successfully in their marketplace (Baregheh et al., 2009). Conventionally, innovation is defined as "the process of bringing new products and services to market" (Hauser, Tellis, & Griffin, 2006, p. 687). In other words, innovation is expected to substitute existing solutions.

A recent view in marketing perceives markets as institutions (Araujo, 2007). As a result, it is understood that innovation is not only about new or improved products and services but something that is different in the market, i.e. institutional framework. Marketing can enable the maintenance of the institutional framework or destabilize it, for instance through introduction of innovations. Therefore, it is important to understand "when are markets ready for disruptive innovations" (Klenner, Hüsigg, & Dowling, 2013). Disruptive innovations were typically conceptualized as lower quality solutions that eventually gain market share from established companies (Christensen, 1997). In brief, the solution needs to be affordable, simple, and substitutive. In addition, the market leader's solution needs to be more than good enough, and the disruptor needs to be able to design a novel business model (Christensen, Johnson and Rigby, 2002). The other type of disruptive innovation, "new-market disruption", takes place when the (existing) solution in one market can be brought to a new market and serve customers' needs not served by the existing incumbents. Again this requires that the business logic around the existing technological solution is redesigned to fit the new market.

There is a rich literature on innovation diffusion. Following Rogers (2003) innovation diffusion process comprehends the adoption processes across several individuals over time. But, in many instances, also in health care, adoption and diffusion occur among organizations shaped by their structures and hierarchies. Slow diffusion of innovations is acknowledged in health care. Diffusion of innovations in healthcare in particular require credible evidence base, observability, strong leadership and trust (Berwick 2003) and it also requires strong social interactions between professional groups and suitable organizational contexts (Fitzgerald, Ferlie, Wood, & Hawkins, 2002).

The review of empirical studies on the assimilation of technologies in health care by Robert, Greenhalgh, MacFarlane and Peacock (2010) points out the importance of understanding how routines emerge and are shaped through the production and reproduction of patterns of activity, how actors are influenced by pre-existing social structures in their technology adoption, and how we need a holistic model to understand socio-technological networks in diffusion of health care innovations. In brief, it is seen that it is not enough to have a simplifying technology that is new and unique to potential customers. Instead, developers of health care innovations need to take into account routines, social structures and regulations in order to understand whether a novel idea has potential to become market practice. Also in public health care which is often organized as quasi-markets (Bartlett & Le Grand 1993), it should be noticed that the adoption of innovations requires acceptance from both by purchasers and producers of the services.

And last, taking the service ecosystems approach to innovations, we need to expand our view to cover the ecosystem or the value net that is involved in institutionalizing the innovation: the service providers and patients (consumer research) and wider social context (service research). We acknowledge that the view on consumer response needs to be widened to several actors in the market. These actors form the innovation networks, i.e. "the configurations of strategic entrepreneurial nets aimed at improving the effectiveness of innovation performance" (Corsaro, Ramos, Henneberg, &

Naudé, 2012, p. 54). In this view, health care innovation is seen more holistically through multiple actors in the network.

2.3 Synthesis and the development of viability template

The study by Caldwell and Kleppe (2010) hints that consumer research sees institutionalization as an important step in the diffusion of health care innovations. However, this question as well as discussion on health care innovations in general has been missing in consumer research. However, dispersed studies in the field of TSR have guided us to focus on certain characteristics that may be used to assess the innovation potential *ex ante*. The innovation needs to be

- novel compared to substitutes
- fit with existing practices (legal and regulation)
- beneficial to users and cost-effective for providers
- beneficial to the value network

Christensen et al.'s (2009) framework synthesizes the views presented above. Their model consists of enabling elements of disruptive innovation: 1) Sophisticated technology that simplifies, 2) Low-cost, innovative business models, 3) Economically coherent value network and 4) Regulations and standards that facilitate change.

Figure 1. Elements of disruptive innovation by Christensen et al. (2009).

As the model above lacks operationalization, we synthesize the elements of disruptive innovation in the template that can be used in analyzing the viability of health care value propositions. As a practical tool, the viability template may be used to assess the innovation potential of transformative service ideas at least in two scenarios. First, it may be used for funding decisions to cherry-pick which projects have the most diffusion potential. Second, it may be used for business development by increasing understanding on the potential barriers for diffusion in the wider institutional setting.

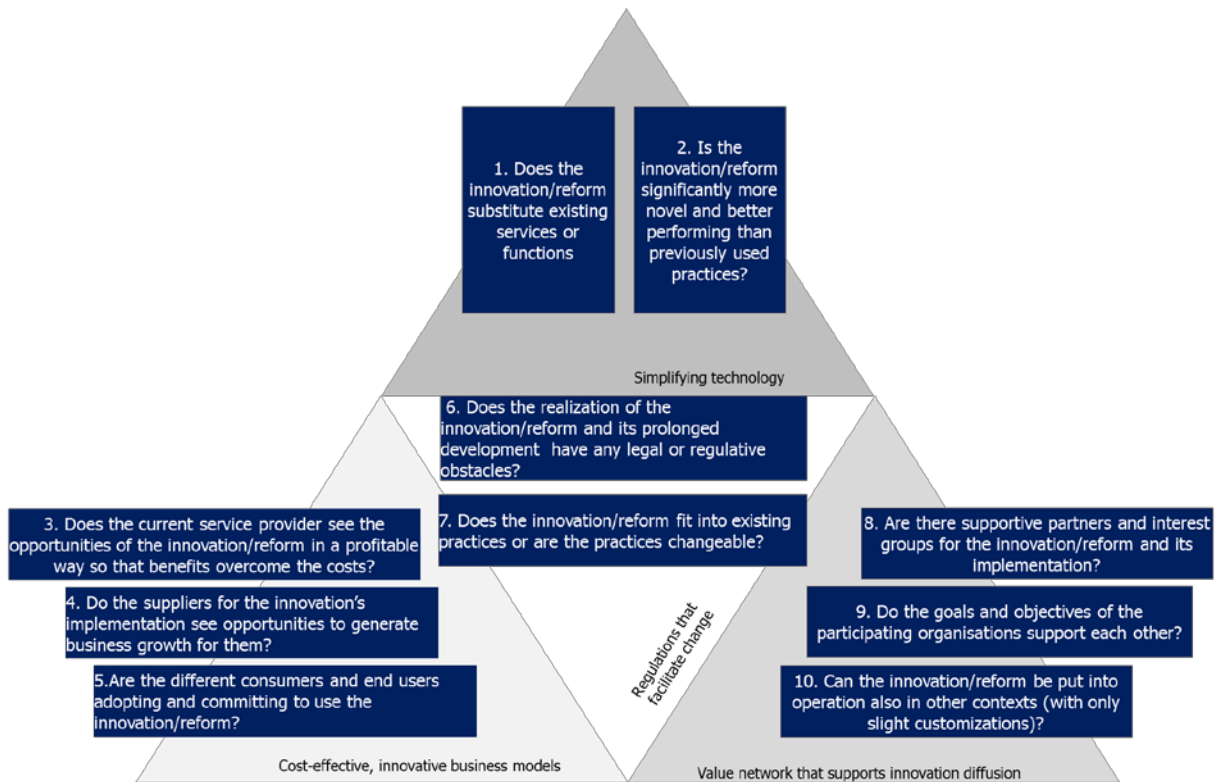

Figure 2. Viability template of transformative service innovations.

Viability template is based on Christensen et al.'s (2009) elements of disruptive innovation. The uppermost triangle represents technological solutions, which enable some processes to be carried out in a simpler or more effective way. For its assessment following questions were derived that focus on value-in-use-in context (Vargo & Lusch, 2008):

- 1) Does the reform substitute existing services or functions?
- 2) Is the reform significantly more novel and better performing than previously used practices?

New technology enables value creation either by reaching a new performance level in some respect, or by simplifying previously used methods. When renewing health care services the substitution is very important feature. If the reform does not replace any older functions, its adoption would only increase the service system's size unless it enables very novel and radical value increase. Overlapping information systems and double bookkeeping of health information entries is a typical example of uncompleted substitution.

In the lower left corner, the service provider's need to have functional business models when using the reform so that consumers will value and use the provided service. We extend the business model view as to what are the incentives of different stakeholders to change their behavior in accordance with the reform. Thus, we extend the view to wider value co-creation opportunities.

- 3) Does the current service provider see the opportunities of the reform in a profitable way so that benefits overcome the costs?
- 4) Do the suppliers for the reform's implementation see opportunities to generate business growth for them?
- 5) Are the different consumers and end users adopting and committing to use the reform?

Willingness of these key stakeholders to adopt the use of reform is crucial for its viability. Decision-making becomes often monetized, requiring calculations and proof of concept that reform's adoption will lead into a positive surplus compared to existing situation. However, even if there are incentives to adopt the reform, two more elements affect its rate of success. Regulation and standards are located in the center and determine what kinds of changes are allowed and what not. Thus, the viability template takes into account not only various stakeholders but the influence of institutions enabling and constraining value co-creation and the diffusion of market practices (Akaka, Vargo, & Lusch, 2013).

- 6) Does the realization of the reform and its prolonged development have any legal or regulative obstacles?
- 7) Does the reform fit into existing practices or are the practices changeable?

Rules, standards and legislation are society's formal means to ensure fair, safe and ethical courses of action. And naturally they are drawn up only afterwards of any innovation emergences. Informal routines and practices are rooted in organizations' culture, and changing of them requires recurrent communication and demonstrations.

Then the rightmost triangle describes the value network that affects the reform's diffusion. If the reform doesn't diffuse to other organizations, it easily can be seen only as an experiment and it will not reach its full coverage. Here, it is emphasized that support for the reform's diffusion can only be expected when multiple stakeholders experience mutually beneficial outcomes (Maglio & Spohrer, 2013)

- 8) Are there supportive partners and interest groups for the reform and its implementation?
- 9) Do the goals and objectives of the participating organisations support each other?
- 10) Can the reform be put into operation also in other contexts (with only slight customizations)?

Viable innovation requires that there are no major conflicts in interests of different stakeholders around the innovation. Mutual understanding of the goals and motives of each partner helps innovation adoption and diffusion considerably. Low need for modifications and customization implies for a greater simplicity of innovation and therefore greater chances for diffusion. The questions may be developed further but as such it synthesizes important themes raised in transformative service research, innovation literature, as well as institutional theories. In the following, we present three cases which are all assessed by using the viability template.

3 Research Design

The empirical study is built on the analysis of three pilot cases on transformative service innovations. These pilots were sponsored by a national innovation fund institute promoting projects aiming for sustainable well-being in Finland. One of its divisions aims to contribute to the development of user-friendly electronic services for health promotion and create conditions for Finland to become a pioneer in electronic welfare. The division has executed its mission by sponsoring research in the theme, influencing opinions and launching and funding experiment projects where new innovative ideas are put into practice and evaluated.

After running several pilot projects in health and wellbeing area, the institute commissioned the researchers to help analyzing the viability of their on-going and future pilots. The aim was to have a practical tool, a template that the funding institute can apply to estimate the potential viability of a reform (its strengths and weaknesses) and to focus their efforts in advancing its diffusion.

3.1 Cases

In our study in collaboration with the institute three pilot services were selected as interesting examples of potential transformative health care reforms: 1) electronic maternity card, 2) electronic tool for assessing the need for medical care for birth control, eating disorder and tooth crack and 3) electronic service to motivate senior citizens to do physical exercises. We do not claim that these transformative service ideas are necessarily truly transformative but they represent cases in which the service provider aimed at transformative service innovation.

An electronic maternity card currently piloted in one city region in Finland, involves replacing the traditional paper-based information storage procedures with an electronic health record service that allows expectant mothers to access all information relating to their pregnancy online. The objective of the electronic maternity card is to improve the exchange of information between maternity clinics, expectant mothers and hospitals, to reduce the likelihood of mistakes, to improve customer service, and to make monitoring high-risk pregnancies more efficient. Besides self-monitoring their health expectant mothers can use the electronic service to share information from their pregnancy with their family and friends if so willing.

In the second service pilot concerning assessment of need for medical care the service provider management had a strong vision to speed up the triage determination process by replacing phone interview with an electronic form in selected patient groups. This freed nurse resources for other tasks and encouraged some customers to seek care which would not otherwise have done that. It was demonstrated that carefully planned electronic procedure can be created but traditional phone interview was still required in some situations.

The third pilot focusing on senior services showed that a tablet computer is a suitable and engaging platform also for elderly people to receive health related information and instructions if suitable contents are upheld. Technological execution was considered to be simple but the contents and user guidance are the areas which need most of the development efforts.

3.2 Data collection

Our assessment of the cases is based on 12 semi-structured interviews of the service providers, system providers and responsible project leaders at the funding institute. Each interview lasted from 1 hour to 2.5 hours. In addition, we collected secondary material from the funding institute (contracts, minutes of board meeting, and final reports when available) to justify our assessment.

Table 1. List of interviewees.

CASE	STAKEHOLDER	INTERVIEWEES BY POSITION
Electronic maternity card	Service provider	Head Nurse, Maternity Clinic
		Executive Medical Director, Maternity Clinic
		Coordinator, IT Management of City T
	System provider	Chief Executive Officer, IT Company A
		Project Manager, IT Company A
Medical care need assessment	Funding Insitute	Senior Lead
	Service provider	Director of Development, Medical Care Organization
Senior tablet computer service	System provider	Project Manager, IT Company B
	Service provider	Director of Development, City J
	System provider	Project Manager, University
		Researcher, University
	Funding Insitute	Specialist, Systems

Our interview data is solely based on the viewpoints of service and system providers. However, to overcome the absence of end-customer view, we had access to consumer satisfaction survey results conducted in two of the cases, and tested all services by ourselves as well. As a result, the template may not cover all aspects in the assessment. Nevertheless, the data indicates the usability of the template.

4 Empirical findings

We applied the viability template presented in this article to assess the successfulness of the pilots. The results are presented in the Figure 3 using green, yellow and red colors to describe our interpretation of the status of the pilot regarding viability questions. Green means that the pilot is seen not to have problems regarding the specific item, whereas yellow points out some problems and red serious problems.

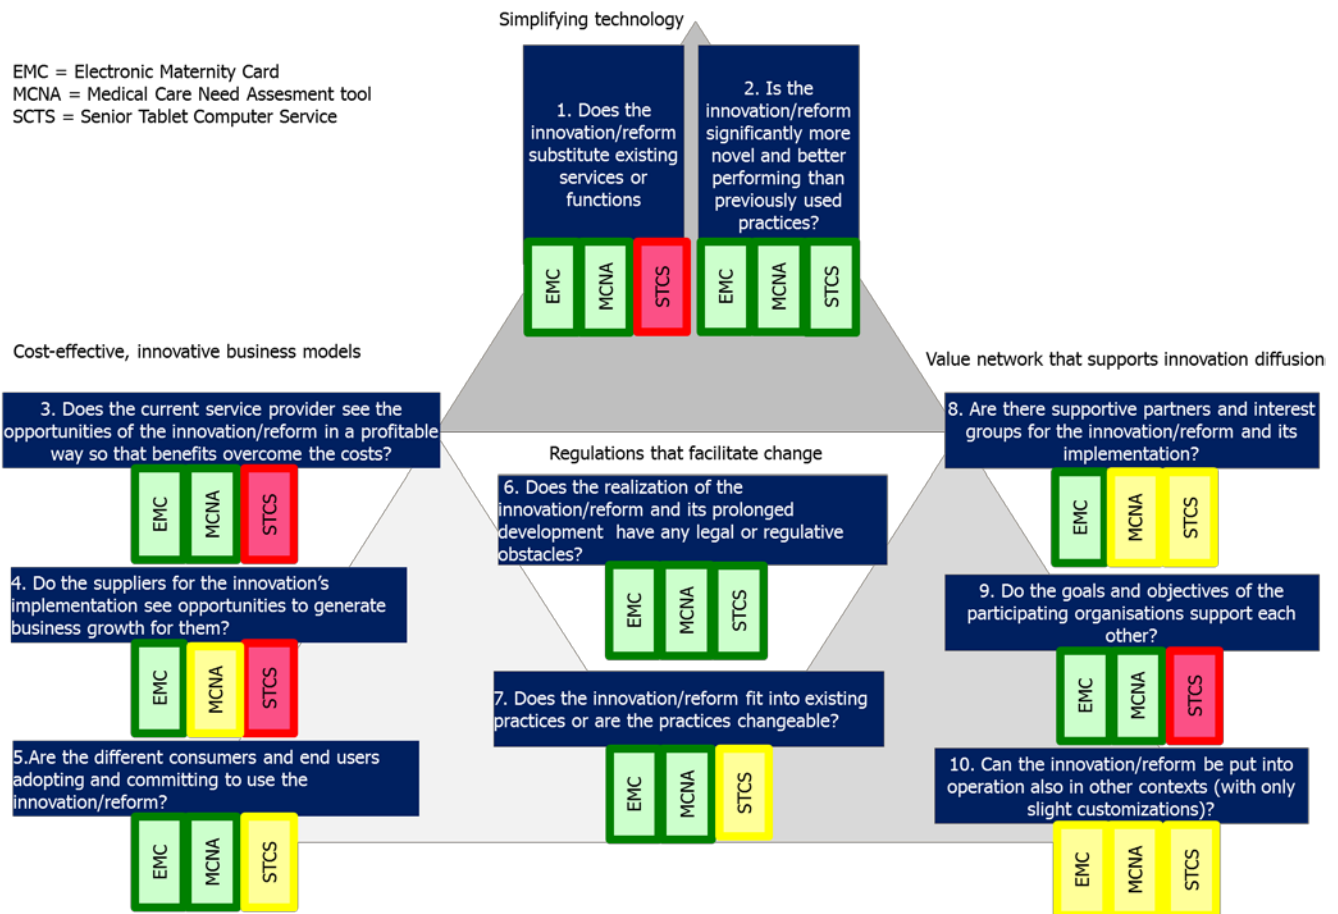

Figure 3. Three pilot cases assessed with the viability template.

According to our analysis two of the pilots performed well in majority of viability issues. The first pilot (electronic maternity card, EMC) passed all questions with green colours, except for one yellow grading concerning adaptability of the reform in other context with differing information systems and interoperability requirements. The reform may require heavy investments in electronic patient records and can thus face challenges in wider diffusion at the time when public health care is looking for ways to cut spending instead of investing more.

Similarly, the expansion of the second reform (medical care need assessment, MCNA) to new contexts requires integration and tailoring. Furthermore, the system provider of case 2 needs to put more effort if it desires to expand the adoption of the reform. The new practice has been accepted within its current special clientele. However, more efforts are expected if the innovation is expected to have wider societal consequences.

The third pilot (senior tablet computer services, STCS) had many severe issues to tackle, predicting failure of the reform. Especially the business model of the reform was not successful and the parties did not see prospects for profitability or business growth. These challenges are crucial when the reform is not substituting existing services. The participating organizations are not committed to the wider diffusion of innovation, as they lack mutual goals. Also current funding system is not supporting the idea becoming a market practice as public and private partners are not interested in investing in preventive health care technology.

5 Discussion

This study mostly focuses on representing the practical tool for assessing potential transformative service innovations in the health care context. The assessment of the cases indicates how the viability template can be employed to understand the rich institutional context of new technology. The template combines together important issues that need to be considered in assessing the innovation's diffusion potential. The template is thus helpful in making funding decisions and in pivoting transformative service ideas.

The practical tool enabled us to focus on most crucial questions on the institutional setting surrounding the potential innovation. Thus, we were able to provide the funding institute important information that remains often overlooked in decision making and ex post analysis.

It should be emphasized that the red light indicating problems in the institutional setting does not simply translate as "no go". Instead, these lights indicate the action points that require further attention. In case, new simplifying technology does not benefit from wide support, it is possible to influence other stakeholders in various ways. For instance, a demonstration can be developed to showcase the benefits of new technology. Second, opinions of authorities

and other key stakeholders can be changed with active lobbying. Third, stakeholders may become more committed to the innovation diffusion if they participate in the development process. Also cases implicated that in the regulated markets or quasi-markets of health care, procurement practices typically neglect to value propositions that promote diffusion or R&D of the service.

As a scientific contribution, we continue the discussion on assessing the role of institutional setting in the diffusion of innovations. Our study can be considered as an approach to operationalize “disruptive susceptibility” (Klenner et al., 2013), which focuses on the readiness of innovation networks to adopt new solutions. Similar to the study by Klenner et al. (2013), we extend the view from the service providers, customers and competitors to more general market characteristics. Readiness for change is important, as institutions strongly affect not only private market characteristics but public service innovations. For instance, non-profit organizations always engage in maintenance or transformation of dominant institutional logic depending on whether it fits the actor’s aims or not. In line with Coule and Patmore (2013) we conclude that in order to engage in deinstitutionalization or transformation of existing institutions, the service provider needs to have a value proposition that resonates with aims of potential network partners.

It is unquestionable that the practical development and scientific approval of the developed template require further evidence. There is a need for a theoretically valid set of questions. The questions represented in this paper are selected intuitively by consulting the related literature. Before the viability template is adopted in wider use, there is a need to ensure that all important questions are asked. Despite these remaining shortcomings, we believe that our study advances the assessment of the institutional setting that is still often overlooked in the general innovation literature.

Particularly, our study takes a strong position in emphasizing the role of networks and institutions in health care context. The context is characterized by separation of buyers (or financiers) and users of innovations. This is an important notice that should be taken into account in assessing the generalizability of the template in other contexts. Therefore, we invite other scholars to test the tool not only in the context of health care but in institutional settings that represent more traditional business markets. On the other hand, we also invite better understanding of the quasi-market context in health care.

6 Conclusions

In the institutionalization process of transformative service innovations we identify the importance of novel technology that outperforms existing solutions, value network that supports innovation diffusion, innovative business models that are cost-effective, and operative environment that supports renewal of the prevailing practices. We propose that in order to transcend from service ideas to transformative service innovations, all or most of these elements need to be aligned during the innovation process.

We contribute to the transformative service research by empirically explicating how to assess institutionalization potential in innovation process. In addition, we inform service innovation literature by conceptualizing service ecosystems approach to analyze the diffusion of innovative market practices. Particularly, we highlight the importance of environmental fit, or technology-market interplay, in the service innovation process. For practitioners (funding agencies and business developers), we provide a set of concrete questions that may be addressed in assessing and enhancing transformative service ideas. Last, we acknowledge that the development work of the practical template remains in its early stages. Therefore, we invite other scholars and practitioners to advance our understanding on how to assess the influence of institutional setting on the viability of transformative service innovations.

Value co-destruction in transformative service practices: Information and knowledge processes in public health care

Valtteri Kaartemo¹, Helena Känsäkoski²

¹University of Turku, ²University of Oulu

The paper discusses how the information and knowledge processes in the public health care context obstruct the value co-creation by patients, their families, and the health care organisations. The empirical research focuses on the childhood obesity care. The results indicate how involvement of patients and their families in the process does not always enhance value creation in the patient's well-being. Particularly, some families deny the problem and some have needs that are not taken into account by the health care professionals. By identifying barriers in information and knowledge processes, we provide practical recommendations and contribute to the emerging transformative service research.

1 Introduction

Value creation in health care is a billion dollar question that requires increasing scholarly attention from multiple scientific fields. Particularly, transformative service research (TSR) has recently emerged to tackle this issue. Anderson et al. (2011, p. 3) define TSR as “the integration of consumer and service research that centers on creating uplifting changes and improvements in the well-being of consumer entities: individuals (consumers and employees), communities and the ecosystem.” TSR focuses on the socially oriented contexts such as health care and education, in which the nature of service speaks to the consumer's or society's well-being. “Although these service contexts are examined in terms of customer satisfaction and loyalty, arguably even more important is exploring their effects on well-being outcomes.” (Anderson et al., 2013, p. 1203) TSR focuses on how the interaction between service providers and the consumers (incl. families or communities) influences the well-being outcomes of both actors (Anderson et al., 2013). Despite having an interest in transformative outcomes, emerging TSR literature has not yet paid particular interest in either the role of patients or service providers in the co-creation of well-being (Rosenbaum et al., 2011). In this paper, we tackle this question in the context of childhood obesity care and prevention.

Support to lifestyle changes have been found crucial in the treatment of childhood obesity (Luttikhuis & Baur, 2009). Therefore, the available studies on childhood obesity typically encourage the involvement of families in the treatment. In fact, the research findings of Golan, Kaufman and Shahar (2006) suggest that children should be even omitted from active participation in lifestyle counselling, and the health care professionals should focus on parents to fight childhood obesity.

Instead of limiting the study to individual patients, this study therefore extends the view on value co-creation to the requested collective level of consumer entities, or ‘third parties’ (Anderson et al., 2013; Hardyman, Daunt, & Kitchener, 2014), i.e., families of child patients. Furthermore, whereas the study by (McColl-Kennedy, Vargo, Dagger, Sweeney, & Kasteren, 2012) focused on customer value co-creation practices, we extend the view to the organizational practices of service providers as requested by (Rosenbaum et al., 2011), i.e., institutions and norms surrounding the healthcare professionals.

We build on multidisciplinary theory basis by incorporating service research with information studies. The empirical part consists of a qualitative case study in the context of Integrated Care Pathways (ICPs) of two Finnish University Hospital districts. The empirical data, collected between 2009 and 2012, consists of semi-structured interviews of health professionals in primary and special health care, of children and their mothers, a family questionnaire, and care path instructions and memos of an ICP work group.

2 Theoretical background

2.1 Value co-creation (and co-destruction) in social context

Porter (2010, p. 2477) defines value in health care as “the patient health outcomes achieved per dollar spent”. In service research value has been understood as a much richer concept that involves experience beyond physical changes and monetary measures. In service research, value is perceived as a phenomenological and contextual construct. This means that value is always determined by an actor in his or her own context (Vargo & Lusch, 2008). Particularly, this has been emphasized in S-D logic that has shifted the focus from value-in-exchange to value-in-use and further to value-in-context. Value-in-context has been defined as “an improvement in system well-being and we can measure value in terms of a system's adaptiveness or ability to fit in its environment.” (Vargo, Maglio, & Akaka, 2008, p. 149)

By emphasizing the context in value creation and determination, it has become evident that customer's service ecosystems are important in value co-creation. Customers are not perceived as isolated actors but as parts of wider

communities within which they interact and integrate resources. This insight has resulted in studies that underscore the importance of multiple actors (Arantola-Hattab, 2013; Fyrberg Yngfalk, 2013), such as families as value co-creators.

Particularly, health care typically involves multiple interactions with different health professionals. Fyrberg Yngfalk (2013) emphasizes that these multiple actors may have a differing view on the value creation process, and some of the interactions may even be contradictory from the perspective of the patient's value creation. In other words, actors are not always creating value by integrating resources. In fact, studies indicate that customers may "misbehave" (Echeverri, Salomonson, & Aberg, 2012) and the service exchange process may end up in value co-destruction (Cova, Dalli, & Zwick, 2011; Echeverri & Skålén, 2011)). In order to avoid value co-destruction, the service provider should be able to spot the misbehavior and guide the customer accordingly. In addition, the literature indicates that value may be co-destructed as a result of destructive behavior of both customers and service providers.

Zainuddin, Previte and Russell-Bennett (2011) have studied health services' outcome in the context of preventive public health care. In the study, they identified themes that explain value determination, namely convenience, control, peace of mind, behavior as reinforcement for beliefs, identification of self as an influencer, and benefit of behavior to others. In this sense, it is understandable that improved health is not the only type of benefit that is provided by the preventive health care. Also, this underscores that service providers and the patients have probably different viewpoint on value and its measurement, depending on their social context.

McColl-Kennedy et al. (2012) have studied value creation practices in the health care context. They show how patients contribute to their own value creation by managing their health care. In their approach, they describe activities of patients positively affecting their quality of life. However, Berry and Bendapudi (2007) have highlighted that patients may be reluctant to participate in the coproduction process, as healthcare service is something they need but not necessarily want. Olsson (2014) has, in turn, noted that the reluctance to participate in the process may stem from lack of information or wrong type of information. Therefore, in this study we take a closer look at information and knowledge processes in order to identify the barriers for value co-creation in health care.

2.2 Information and knowledge processes

The terms knowledge and information are used in knowledge management literature sometimes interchangeably. In this paper, the term information is used when discussing information transfer of explicit documents or messages through some media or in human interaction. Knowledge sharing (van den Hooff & Huysman, 2009) is, in turn, an activity in which knowledge is made available to another or others in personal interaction and can result in construction of common meanings and creation of new knowledge; that is building understanding and learning.

Treatment of patients requires care decisions which are based on patient information (Gorman, 1995) professional medical knowing, information about guidelines and practises, work experiences, and ethical principles of care. In the course of the treatment, patient information is typically documented in the electronic patient records (EPRs). These entries form an information and knowledge reserve for other professionals in the health care organisation.

According to the idea of value creation by Normann and Ramirez (1994), knowledge processes require interaction in the value network between the stakeholders. Implicitly this outlook thus emphasises the importance of knowledge sharing. Knowledge sharing involves an individual who guides another individual through using his own thinking or insights to help them see their own situation better. Successful knowledge sharing requires awareness of the receiver's knowledge needs or gaps, use and purposes (McDermott, 1999).

Riege (2005) identifies barriers to knowledge sharing at the individual, organisational and technology levels. At the individual level these include structural, cultural and personal barriers, and at the organisational level mostly structural and managerial problems. Furthermore, technology must support the activities of the organisation. Riege emphasises the role of management to support, motivate, and encourage individuals to transfer and disseminate both existing knowledge and to apply newly generated knowledge.

As noted by Riege (2005), structure of the social network and especially temporal and spatial proximity influence the opportunities to share knowledge (Keating, Ayanian, Cleary, & Marsden, 2007). Hasgall and Shoham (2008) claim that hierarchical organisations do not enhance effective use of personal knowledge. Furthermore, lack of time can hinder knowledge sharing (Riege, 2005).

Regarding the social context, it is also important to acknowledge that organisations are not homogenous cultures. There can exist several subcultures, which all have their own norms and practices (Ipe, 2003). In these subcultures, different professions and their jurisdictions can inhibit knowledge sharing (Currie, Finn, & Martin, 2007). Keating et al. (2007) perceived that primary health care physicians rely often on colleagues for new information and advice about the care of their patients. Physical proximity, for example working in the same clinic affects knowledge sharing and physicians seek out those colleagues who have the most experience and are likely to give the needed information. Fattore, Frosini, Salvatore and Tozzi (2009) claim that social influence creates similar behaviours among doctors.

2.3 The research objective

The current research on service practices emphasize that value is co-created (or destructed) by socially embedded actors. It is understood that these actors integrate resources, particularly knowledge and skills, for the benefit of themselves and others. This assumes that knowledge and information flows freely from an actor to another, and that the

integration of knowledge resources benefits the actor. Nevertheless, studies on value co-destruction indicate that value is not always co-created in these processes. Thus, the focus shifts toward the prevailing structures that hinder information and knowledge processes.

We are particularly interested in the information and knowledge processes in public health care, and in the involvement of patients and their families in these processes. We take a closer look at the phenomenon through a research setting in multiprofessional Integrated Care Pathways (ICPs) of childhood obesity in Finnish public health care. The main research question is formulated as follows: How do the information and knowledge processes in the ICP obstruct the value co-creation by the patients and the health care organisations?

3 Research design

The qualitative case study involves the Integrated Care Pathways (ICPs) of two Finnish University Hospital districts. An ICP is a practise between primary health care and special health care. An ICP ensures the use of available resources in primary health care and specialised care as efficiently as possible.

The empirical data, collected between 2009 and 2012, consists of semi-structured interviews of 30 health professionals in primary and special health care, and of three children and their mothers, a family questionnaire (N=13), health care organization's care path instructions and memos of an ICP work group. The choice of method is validated by (Hardyman et al., 2014) who note that value co-creation in the health care contexts requires more ethnographic touch and a range of methods (i.e., observation, interviews, and documentary analysis) to understand how value is created by patients and the health care professionals.

The interviews of the health care professionals of both embedded units of analysis and the interviews of the patients and their families were digitally recorded and transcribed verbatim by the researcher. The interview quotations were translated from Finnish by the researcher. The quotations were marked with letters and numbers. The code UA1 refers to the first unit of analysis and UA2 to the second unit. Letters Sp refer to health care professionals in special health care, letters Pr to health care professionals in primary health care, and letter M to the mothers of the patients and Ch for the children.

To protect the anonymity of the interviewees in health care their professions are not mentioned although this information would be interesting. Since there are only one or two actors in each professional group full anonymity could not be guaranteed if the professions are mentioned in the quotations. Quotations from the open-ended questions in the family questionnaire in UA2 are marked with letter F and a number.

The analysis of the embedded units was performed separately at first and then the findings of the two units were combined. The findings of the embedded units of analysis were combined because they proved to be similar for the most part, as presupposed. The similarities are due the firm regulation of Finnish health care and moreover, the care practises in both university hospital districts are based on national Current Care (Käypä hoito) guidelines. However, analysing the embedded units of analysis separately allows comparison of the possibly emerging differences in the two units.

In addition to the interviews, the document material: the care path instructions of the four municipalities' health care centres, the care path protocol of the second university hospital, the document of the regional care pathway for obese children in the first university hospital, and the memos and agendas of the first unit of analysis ICP's work group meetings between 2009 and 2012 were content analysed. The themes which emerged in the documents were categorized and counted. Due to the nature of the survey including its size (N=13), the data were analysed quantitatively only through standard deviations. The data of the open-ended questions were analysed through content analysis.

The research was conducted according to the Finnish law and decree of medical research. The World Medical Association Declaration of Helsinki (WMA, 2009) requires that subjects are protected from any discomfort and harm that may be psychological, emotional or economic. This research involved a minimal risk for the subjects that participated in the interviews. The findings are presented so that they cannot be used against the children's, parents' or health professionals' interests. Ethical rules of scientific research were followed by ensuring that the data and analysis were accurate and the findings were presented honestly.

4 Empirical findings

4.1 Interaction between health care professionals, the patients and their families

In our study, we find out that parents are not ready to actively participate in practices that would be required for positive health outcomes for their children. In brief, parents are unmotivated and incapable to undertake required lifestyle changes. According to our study, parents have enough information to understand that lifestyle changes are needed. However, the changes require efforts and resources which are a challenge for the families. In other words, the problem is not the amount of information but that the type of information and knowledge that is provided to the patients and their families. The information is not able to motivate or to empower the parents enough.

Lifestyle changes require determination and motivation. The patient and family interviews in UA1 indicated that the most important motivating factor for weight management was health in a lifelong perspective: "It is of course that you

do not get any diseases at older age”(UA1M1). Physical and mental welfare were also important issues: “The child should feel good now and in adulthood both physically and mentally and have good self-esteem” (UA1M3).

From the families’ point of view, information value is related with their conceptions about the health risks of childhood obesity. This, in turn, is related with their motivation to change lifestyle towards healthier nutrition and to more active living habits. If the family does not recognise the child’s obesity as a problem which should be treated, they can find health information patronising and irritating. From the perspective of health care professionals, the main challenges for lifestyle counselling appeared to be firstly the sensitive nature of obesity and overweight and secondly the children’s and families’ lack of motivation to make lifestyle changes in order to lose or to manage weight.

About one-third of the interviewed health professionals thought that health and prevention of diseases are not motivating factors for children or for their families. “Of course there are some children and families which are not at all motivated. They find it difficult to come here, they are not interested, and we shift those patients away.”(UA1Sp3). Health care professionals simply consider that knowledge and information is not the problem but lack of motivation. “I know that they do know. It is not about that. It is about how they can realise it. There should be some other way. I do not believe that our way is so good. I do not believe”(UA1Pr5). One family’s answer in the UA2 patient survey is in accordance with the health care professionals’ opinion: “It is not about lack of knowledge. We parents have gone to many weight management courses. Everyday life is sometimes rough and when you are tired weight management does not succeed.”(F1). As families perceive receiving enough information from primary and secondary health care, they do not search for additional information sources. “...quite many people say that yes, I have got knowledge, I know what should be done. But how do I realise it?” (UA2Pr8).

Thus, our research indicates that the information and knowledge given could be of wrong type for these families. For instance, families expect practical tips how to solve some of the challenges that lifestyle changes bring to the family. For instance, in one family parents aim that the obese child would not feel somehow different than the other children in the family. Restricting one child’s portion sizes and denying extra portions is a challenge in a big family.

In general, the patient and family interviews in UA1 indicated that lifestyle changes are not easy although the families find the counselling good. “I am sure that the adolescents and parents know in theory what should be made and they have heard all these lifestyle and nutrition instructions many times but they are so frustrated with that repetition and they do not have a trick how to do it.”(UA1Sp2).

The findings of the interviews in UA1 and of the family survey in UA2 indicate that every family has its own challenges in weight management. For some families the challenges are with changes in nutrition: “...he does not like all foods. Some salads and root vegetables—he does not want to eat them. So that we have not been able to realise all the instructions because I cannot get him to eat them.” (UA1M1). Nine families reported that increasing fruits and vegetables into the diet and avoidance of sweet or salty treats was a challenge for them. The portion sizes were a problem for eight families but the frequency of meals did not seem to cause so many difficulties. Four of the thirteen families found it difficult to restrict portion sizes, especially when the child complains of hunger after the meal.

For other families adding exercise to everyday life was difficult: “It depends on [child’s name] also, I cannot make him exercise by force.” (UA1M2). Seven families could not find time to exercise. Two families answered: “to combine the long school days and exercise”(F2), and “the school days with the traveling lasts from 7a.m. to 4 p.m. Then there is no energy left”(F12). Eight families found it difficult to restrict the child’s or adolescent’s television or computer time. As a result, the families would like to have more practical advice, support and encouragement. Club activities for children and family exercise were also wished for. On the other hand, the parents did not seem eager to discuss issues about weight problems either face-to-face or online with other similar families. Perhaps the families do not want to be labelled as “families with obese children” by joining discussion boards or clubs with peers.

Health care professionals thought that the most prominent costs or sacrifices of lifestyle changes for the families are to carry responsibility for the child’s eating: “With these weight issues it is mainly about setting boundaries for the child and if this is a problem it is a big challenge for the parents” (UA1Pr4). The question remains whether this is an issue of being incapable of setting boundaries or denying the problem. Of course, setting boundaries may be challenging when there is lack of motivation on the child’s part. One parent describes the challenging situation at home as follows: “The child has a difficult and rough puberty. Lack of social relationships led to the computer and to game addiction. When the mother remarked about the eating habits it led to resistance. The child eats the treats, snacks, and chips in secrecy and the wrappers are found here and there. (F7).

It is also common that the family denies the problem. The issues of overweight and obesity raise strong emotions which can appear as the child’s or parents’ resistance, denial or even anger towards the health care professionals. Especially if the parents also have weight problems it can be difficult to bring up the issues of weight management because the parent can find this insulting: “For some families it is a sensitive issue, especially if they all have overweight. They do not necessarily want - some can even refuse. They do not want to discuss these issues so that the child can hear them, they do not want to bring them up.”(UA1Pr4). All 18 primary health nurses and doctors reported that they had sometimes encountered resistance and denial from parents when interfering with the child’s overweight. Some families apparently perceive lifestyle and eating habits as private and personal issues so they want to maintain their boundaries: “For example I have seen such situations that the parent has called saying this letter has hurt him/her or that the letter stigmatises children even if that is not the purpose. I cannot know what kind of dynamics there are in the family and why it is like that. So parents do not understand why we interfere.”(UA2Pr2).

If the family does not find that the child is overweight or obese, lifestyle guidance is not perceived relevant for them. “I think that it often arouses negative feelings and that the parents do not even necessarily understand that the child is obese; they think that the child is quite normal. And when the public health nurse interferes, well, I have a feeling that it is not so pleasant.”(UA1Sp1). Denial may be even more common when the whole family suffers from obesity: “There are of course those people who say that we eat like this and we do not want to make any changes.” (UA1Pr2) As parents deny the problem the health care professionals feel powerless. “Many parents do not react at all. The child can be very chubby and my follow-up are as good as nothing because I only talk with the child and I cannot reach the parents.”(UA2Pr2). In addition, the problem may not be only limited to the parents but wider social context that may resist lifestyle changes: “...a grandparent can live nearby and older people have different perceptions about healthy children and how they should look. A chubby child is a healthy child...” (UA1Sp2). The child’s life is affected by so many people that if they do not think in the same way, the situation can be very challenging.

Although the families say that health and well-being is a value and motivating factor for them, this does not show in the results of weight loss or weight management. In other words, health professionals do not think that health and facts of risks of obesity are valuable information for the families. “Definitely I think that the child or adolescent is not worried if we say that when you are in your fifties you have arthritis or when you are forty you can get type 2 diabetes. It is unimportant for them when they are so young.” (UA1Sp2). The associated health problems seem too distant for children or adolescents. In these cases it can be assumed that the information value of the families’ differs from the information value of health care professionals. Therefore, it is worth taking a look at the structures in health care that influence the information provided by the health care professionals.

4.2 Structures in health care influencing information and knowledge processes

Counselling is perceived as the mean to help patients to achieve the goals of health and well-being. Particularly, in the context of childhood obesity the counselling should focus on enabling lifestyle changes. However, our study identifies barriers for effective service provision. As a result, health care professionals tend to focus on medical issues rather than lifestyle counselling. This stems also from other underlying structures which are problematic for knowledge and information sharing and other information and knowledge processes. We identify the important boundary between primary and special health care, between the municipalities, between permanent and temporary workforce, and between different professional groups.

Firstly, a clear boundary between primary and special health care can be identified in the interviews of the health professionals. Thus, primary healthcare and special health care are two separate institutions. From the primary health care’s perspective, special health care is an unknown entity; the practises and actions are not familiar to primary health care professionals: “We have made a referral to special health care very seldom, but when we have done so I have a feeling that we do not get any feedback. Somehow it is a bit ambiguous, the patients disappear somewhere...” (UA1Pr3). In special health care the referrals from primary health care are the principle sources of patient information alongside laboratory results and growth charts. In general, the contents of the referrals vary. It is not always clear, what kind of care is needed in special health care: “In some cases it remains an open question that when the referral arrives, you do not exactly know what it is about”(UA1Sp3).

The health care professionals do not often know the actors and the practises in other organisations. This was evident in both units of analysis: “I always think what the content of those appointments is. Is it so that the child goes there for weighing or are some public health nurses able to take the parents? I don’t know.”(UA2Sp1). In special health care many professionals were concerned about possible contradictions or overlap in counselling because they did not know what kind of information the child and the family have already received in primary health care and from other personnel in special health care. “I have thought that it would be interesting to know what different professionals have said to a patient. We have this care protocol as a document but does it come true like that? Are there some gaps regarding some family, which nobody has mentioned? Or are there overlapping issues and do they confirm the message or are they frustrating? How much contradictory information do we provide?”(UA2Sp2)

Secondly, each municipal health care centre which belongs to the regional ICP is a separate actor in the ecosystem. The practises and actions even of the neighbourhood municipality are not always familiar in other health care centres although some collaboration can take place: “In [name of the municipality] they have their own system but I do not know how well it works”(UA2Pr2). In patient care, health care professionals must be familiar with the previous medical history of the patient and also be aware of the family’s medical history in order to evaluate risks and hereditary tendencies for medical problems. However, the EPRs of neighbourhood municipalities’ health care centres do not communicate with each other, which does not enhance collaboration. For example, one health centre in UA2 recently became part of a larger community which provides social and health services for four municipalities’ inhabitants and technological problems cause difficulties in collaboration: “...we are in the same organisation as [municipality’s name],[municipality’s name] and [municipality’s name] and it just came up in a meeting that [municipality’s name] and [municipality’s name] do not have access to the intranet where we have information for every employee and forms and everything else that we need in our work.”(UA2Pr5).

Moreover, the patient documents must be requested from the other organisation with the permission of the patient. The boundary between health centres is thus actually structural due to different EPRs. Furthermore, the practise of transferring patient documents is defined by the law (MSAH 1994): “We get the papers of the child welfare clinic quite

well, but we do not get any other papers. We also do not have permission to send the epicrisis of the [name of the hospital] forward.”(UA1Pr2).

Thirdly, long work relationships establish collaboration and trust and the network ties become stronger. Colleagues and co-workers are perceived as insiders: “We have good telephone connections. We know each other and it is easy to call a colleague and to talk about work issues” (UA2Pr9). Trust in these relationships is based both on affective and cognitive aspects. For example the public health nurses who have been working with the same doctor in the child welfare clinic or at a school form an “insider” dyad: “In this other school we have had the same doctor for years and with him collaboration goes well since we have known each other for a long time” (UA1Pr4). Cognitive trust in these dyads is based on the health care norm to respect co-workers’ competencies and also on the dominance of medical knowledge and the knowing of doctors. Collaboration and communication with a familiar co-worker is easy and builds up affective trust. However, the doctors in training remain as outsiders. This is partly due to the practises in university hospitals where doctors in training change after their fairly short (from three to six months) training period and they do not have time to internalise the practises and norms of the institution. “And the specialising doctor is always the weakest link, because he/she is new and this work differs from other medical work.” (UA2Sp2).

Constantly changing work partners hinder true collaboration and trust. There is not enough time to build up trust and to learn to collaborate. This seemed to be a problem especially in primary health care because understaffing had led to changing substitute personnel. “Formerly when we had a regular doctor at the secondary school, it felt that it was so much easier to work with a person you were used to working with and whom you were able to trust. But now, we have these visitors. During that time when I worked at the other secondary school there were at least ten different doctors. Continuity in the collaboration between the public health nurse and the doctor would be so important.”(UA1Pr3). Attitudes towards newcomers and their knowing came up in the interviews of more experienced health professionals. “It can well be that someone has been let’s say six months working here and then suddenly realises that we have these weight path instructions.”(UA2Pr4).

Fourthly, the norms also seem to keep up the boundaries between different professional groups. Sharing of information, knowledge and knowing is more common within one’s own professional group. This may be due to common language and use of terms and similar education, and thus also a similar basis of knowing and competence. Thus, sharing of knowledge and information seems to be not only more common but easier within one’s own professional groups. In some cases there are clear boundaries even in the same health centre: “Maybe it is that the child health clinic functions as the child health clinic and the doctors work as doctors and the nurses work as nurses. We have only two floors here in between us but sometimes I have a feeling that information transfer does not function well.”(UA2Pr6).

For example, in both university hospitals the special health care doctors attended the doctors’ meetings regularly but the weight clinic team meetings in the UA2 hospital were not so significant for them. “I myself think that the meeting on Wednesday mornings concentrates on the medical aspects because the doctors are there—we do not talk about such things as does the child get enough exercise—we focus on the medical problems such as high blood sugar levels and how to handle those problems. It is for me a meeting where I can see the medical aspects and the meeting in the afternoon is more of nursing.”(UA2Sp). In addition, the doctor-focused information sharing causes problems with the epicrisis or care feedbacks from special health care to primary health care, as the message about the electronic epicrisis goes to the doctor who has written the referral. All the public health nurses mentioned this as a concern. “The epicrisis comes from the doctor and it is available in [name of the EPR system]. But if you have not written the referral yourself, you cannot keep up when the epicrisis from special health care arrives. If I am not active myself, I do not see the epicrisis.”(UA1Pr3).

The implications of the social structures can be identified in the focus on biomedical knowledge. The prevalence of biomedicine reflects in the attitudes of health care professionals. This, in turn, appears in lifestyle counselling which has so far been very factual and clinical: “It is more or less talking about facts: what it is about...” (UA1Sp2). However, one professional recognises this as a problem — obesity is a multifaceted and complicated problem and the treatment is not simple: “Maybe it was all over Finland and maybe even worldwide that the approach to obesity treatment was factual. Health care professionals must give the families instructions and some advice, but it is not at all like that.”(UA2Sp2). Childhood obesity is also a sensitive issue for many families. The parents may feel guilt or shame and these emotional aspects should be taken into account in counselling.

The dominance of biomedical knowledge is visible in the doctors’ role as decision-makers both in primary and in special health care. For example, the main tie between primary and special health care is managed by the doctors through the referral-epicrisis system. “For example, only a qualified doctor is allowed to diagnose a disease. Care decisions should be based upon diagnosis. In this work I handle the referrals and I take a look at these patients. I think that the most important thing is to make differential diagnosis, to pick those patients who clearly have a disease and those who have risks for complications such as disturbances in sugar metabolism or in fat metabolism or have high blood pressure and other things.” (UA2Sp).

In special health care the role of the doctors seems to be more dominating than in primary health care. In primary health care the public health nurses work very independently in the prevention of childhood obesity and they consult the doctor only when needed. The primary care doctor decides if some further medical examinations or procedures are needed. However, for the families the doctor’s opinion can be more significant than the public health nurse’s intervention: “The school doctor is there then when the child is really overweight. The idea is that the doctor is there to

give some authority and to influence the families to do some changes”(UA2Pr7). The focus on biomedical information and minimum lifestyle counselling is an easy but inadequate solution to the complex problem. “To provide information is easy, but how to motivate people and how to support the motivation, that is the real challenge.”(UA1Sp3). Division of work tasks and responsibilities is at the same time a social norm, a practise, and an issue which is strictly ruled by the laws (MSAH 1994). The individual care path instructions are parallel to the national Current Care guidelines. Division of work tasks of different professional groups can be perceived as a norm: “The public health nurses play a key role here. They meet the families and children and adolescents and ask them for follow-up visits and give guidance and that is actually all you can do”(UA2Pr4).

Health care professionals follow care path instructions that contain elements of medical knowledge about the subject matter, organisational routines and practises, and about the justification of health care to interfere with the problem. All the instructions contain recommendations of weight (and growth) controls for follow-ups and they define what laboratory tests should be taken for the purposes of health risk evaluation and differential diagnosis. Furthermore, the care path instructions take a stand on the issues which should be brought up in counselling. In all the instructions these are rhythm of everyday life and meals, exercise habits, constitution of the diet, snacks, and drinks. However, there are not detailed instructions about the content of counselling.

Different professionals meet the patient mostly separately and thus every professional hears a slightly different patient narrative and constructs the conception of the patient and his/her problem from their own professional point of view. These different conceptions may even lead to conflicts in collaborative care. “Sometimes when I read the doctor’s texts I think how he has been able to make the status and ask for the anamnesis of the family and to give instructions in twenty minutes. The child has been severely obese for ten years and the instructions are that ‘daily exercise is recommended and eating of treats should be minimised’. Yes, that is the solution!” (UA2Sp2)

The most important factor which hinders interpersonal communication during the work day is lack of time and lacking opportunities to meet colleagues and coworkers due to busy schedules in both primary and special health care. Personal interaction requires time from all the participants. Furthermore, structure of the social network, physical distance and lacking opportunities to meet colleagues and co-workers make sharing of knowledge and knowing challenging. Lack of time also influences the quality of entries in EPRs. The notes must be accurate and careful recording can take a long time: “Yes, it takes time. Of course we public health nurses have personalities so that one can write very accurately her texts and the other less” (UA2Pr12). Even in hasty situations the entries have to be made: “We try quickly to write into the care plan what we have been talking about” (UA1Sp4). Moreover, reading the previous texts requires time: “I think that it has enabled better transfer of information, if you only have got time to open the files and read them”(UA2Pr5).

For health care professionals negative weight management results cause frustration and lead toward idea that childhood obesity is not even worth investing time. “...in my experience obesity treatment is extremely frustrating...I do not know what could help in it. I am quite desperate about it...Of course, you can try and it is worth to try...”(UA1Sp2). In the end, it should be remembered that it is not only about the practices in health care that cause frustration. “Maybe it is more about parental attitudes. I do not know. Somehow I feel that they do not want to do anything about it, they do not want a change. Because in order to make changes they should completely change their lifestyle and they are not ready to do it.”(UA2Pr4).

Above, we have identified several practices in health care, and discussed how these influence the information and knowledge processes as well as focus on biomedical medicine. This results in counselling that is not supporting the value co-creation of the families of obese children.

5 Conclusions

Knowledge and skills are required for value co-creation. In healthcare environment, knowledge is integrated by patients and their families to improve the wellbeing of the patient. In some situations the role of patients own activities are crucial, particularly in lifestyle related preventive healthcare. But surprisingly, we often witness cases where a patient is reluctant to participate in the coproduction process, as healthcare service is something he needs but not necessarily wants (Berry & Bendapudi, 2007). In the long run, this can be value destructive not only for the patient but to the society. In this study, we find that the issue is not that there would not be enough information available but organizational practices and information and knowledge processes may guide toward provision of wrong type of information. We found both families that deny the problem of childhood obesity and families that admit the problem but expect more practical advice, support and encouragement from the public health care. The problems stem from the information and knowledge processes and structures which are deeply embedded in the health care system.

Our study reveals that the health care professionals do not often know what is required by the patient families or how to deliver information that would be useful for them. Although ICPs have been designed to standardize the role of each actor in the pathway, the knowledge is not flowing smoothly to benefit the patient. As a result, the childhood obesity treatment is in danger of not supporting lifestyle changes in the families of obese children. In the study, we identify the barriers in information and knowledge processes that lead to these challenges, namely focus on biomedical knowledge, norms of following instructions, and lack of time and resources to act differently. As a result, we make explicit the problems behind the childhood obesity care that leaves families unmotivated and incapable of undertaking

necessary life style changes. Wrong type of counselling is wasting scarce resources in a society, and therefore the service provider's activities should support the required lifestyle changes.

Theoretically, we contribute to TSR literature by highlighting that agency and interaction in transformative service may also have negative effect on well-being of actors (Anderson et al., 2013). Instead of limiting the study to individual patients, this study extends the view to the requested collective level of consumer entities, or 'third parties' (Anderson et al., 2013; Hardyman et al., 2014), i.e., families of child patients and their social contexts. Furthermore, whereas the study by (McColl-Kennedy et al., 2012) focused on customer value co-creation practices, we extend the view to the practices of service providers (Rosenbaum et al., 2011), i.e., institutions and norms surrounding the healthcare professionals. As a result, this study contributes to the TSR literature by answering to the call to identify potential barriers for value co-creation in health care (Hardyman et al., 2014).

We are limited in having a look at traditional health care system. Hardyman et al. (2014) highlights the role of service interaction to understand patient engagement. These interactions are not limited to the face-to-face-meetings with general practitioners but are extended to pre-consultation phase and encounters with friends, family members and even online forums. Recently, Loane, Webster and D'Alessandro (2014) discussed the role of virtual health communities in value co-creation in greater detail. They built on the exchange of social support, as the mechanisms for providing opportunities to create and experience value. They emphasized that value co-creation in health care covers more than traditional medical solutions. By changing the focus from patients to families, we contribute to better understanding of the role of social context in value co-creation (and co-destruction) in transformative service research. However, the data from families is limited and further research is called for understanding transformative service practices in the patient's family.

Constructing user understanding for technological innovation in service and manufacturing companies: expert insights

Laura Kanto

Aalto University

It has been widely acknowledged, that the user knowledge is important source of innovation. However the practices and challenges of user knowledge management in service and manufacturing companies have not been studied sufficiently. This study is based on a qualitative empirical inquiry among 14 experts representing 8 services and 6 manufacturing organizations in Switzerland, Germany and Finland. The findings highlight that while knowledge from the actual use context is crucial in all parts of an innovation process, the key challenges making use of customer knowledge include that the user knowledge is collected by persons that are not involved in the innovation project teams.

1 Introduction

Through user knowledge companies can obtain new ideas and respond to changes in the market more rapidly compared with in-house innovation (Rajala et al., 2013). Yet, making use of user knowledge is considered to be challenging (Bogers et al., 2010), as the knowledge held by users is often tacit by nature and difficult to share (Bonner, 2010). In manufacturing companies operating in business-to-business (b-to-b) context, users have hardly been considered the center of attention in an innovation process (Roto et al., 2013) – the companies have been either product-centric or customer-centric (Galbraith, 2002). On the contrary in service companies operating in business-to-consumer (b-to-c) context is the user, which is most often the consumer, has naturally been the center of attention.

Today, many of the manufacturing companies have added some services to their offering portfolio due to the globalization and low margins on products (Kinnunen & Turunen, 2012). This phenomenon is called as servitization. Although there are challenges in servitization, it brings opportunities with it too. One of them is the grown ability to gain user knowledge. This is because the service process includes always the user (Edvardsson & Olsson, 1996). Traditional manufacturing companies are considered to have a product-oriented culture (Bowen et al., 1989). Services are seen as “add-ons” or as unprofitable necessities to sell products (Oliva & Kallenberg, 2003). To overcome this, Grönroos (2008) has argued, that companies should not concentrate to their offering but rather on their customers and users among others. Even though, research on how to methodically integrate the customer and user understanding in service development process is scarce (Edvardsson et al., 2012).

The participation of organizations has been increasing for a long period, but the decisions about major innovations have resisted increased participation. There is still a small group of individuals within the organization that have the privilege to make the decision, also about the user knowledge. Employee-driven innovation (EDI) refers to the generation and implementation of significant new ideas, products, and processes originating from a single employee or the joint efforts of two or more employees who are not assigned to this task (Kesling & Ulhøi, 2010). Front-line employees are potential interpreters of user needs (Hasu, Saari & Mattelmäki, 2012) and thus may be a valuable source of user knowledge.

In this paper my aim is to identify user knowledge practices that are used to construct user understanding for technological innovation in IT-driven service companies and in manufacturing companies. I also aim to identify user knowledge practices that support or may benefit from EDI activity in organizations. This paper is organized as follows. First, the theoretical background of the study is established by reviewing the literature on user knowledge management and its linkage to employee-driven innovation. Then, research design, case selection, and data collection is described. Thereafter, the findings from the expert interviews are reported. Finally, I explain my contributions to the theory and practice of user knowledge management for effective user-focusing innovation.

2 Theoretical background

Previous studies have defined users as firms or individual consumers that expect to benefit from using a product or a service (e.g. von Hippel, 2005). In business-to-business (b-to-b) environment, the concept of “user” is considered more complex compared with b-to-c markets. Particularly in industrial business, users are often organizational actors. They may not be the same individuals and even not necessarily in the same organization as the vendors’ primary customers. Also, there is swapping of information between users about vendor products and implementation experiences (Fincham et al., 1994). This can make user knowledge a property of the users’ organization or community.

2.1 User knowledge management for technological innovation

Research on how to methodically integrate the customer and user understanding in service development process is scarce (Edvardsson et al., 2012). Although users are seen as important part of innovation process, previous studies have

not paid sufficient attention to the types of customer and user involvement in different innovation process activities (Coviello; Joseph, 2012). The changing role of users has been investigated and some reasons why users would help facilitate the development and further diffusion of the vendors' offerings have been suggested by Pollock and Hyysalo (2014). The reasons include that users' may want to ensure continued take-up of vendor products and that specific needs can be catered for within and between domain competition. It has been argued that firms need a special competence on the organizational level to systematically integrate customers and users into the innovation process (Lettl, 2007). Moreover the intensity of customer and user interaction varies for different stages of the innovation process (Gruner; Homburg, 2000). And at the same time, companies that have invested in open innovation activities have faced risks and barriers that hinder them from profiting from their open innovation initiatives (Enkel et al., 2009).

Edvardsson et al. (2012) point out that in order to integrate users' context-specific knowledge and situational experiences in the innovation process, there should be interaction between the innovators and the users throughout the different phases of the innovation process. To address this need, Edvardsson et al. (ibid.) propose a framework for customer integration connecting situational information on the use context though the methods of service development. In order to support the innovation process, innovators need efficient cross-functional collaboration (e.g. De Luca et al., 2010) and interaction among integrated business departments (Schindlholzer et al., 2011) to have the relevant knowledge when and where it is needed.

There are several innovation methods that highlight the need of user knowledge. One of them is design thinking, which is a set of practices for creating innovations. Innovation by design thinking is meeting people's needs and desires in a technologically feasible and strategically viable way (Brown, 2008). The design thinking also brings together the innovation team and the user.

2.2 Utilizing user-knowledge management to foster employee-driven innovation and vice versa

The core assumption on employee-driven innovation (later: EDI) is that, in traditional organizations, ordinary employees tend to be permanently excluded from decisions made about innovations (Kesting; Ulhoi, 2010). In this research field, organizational members that have been assigned formal authority to make decisions about innovations are called managers and those who have not been assigned are called employees. One of the core information that the managers need, to be able to make good decisions on innovation, is the knowledge of users. This knowledge is not easy to acquire and it takes time and requires analytical skills to interpret and understand the information (Kesting; Ulhoi, 2010).

Employee-driven innovation research suggests that radical innovations are not user driven, but employee-driven. Users just need to adopt and buy those innovations. This viewpoint has also been argued in the marketing literature (e.g. Atuahene-Gima, 1996; Im; Workman, 2004; Renko; Carsrud; Brännback, 2004), although opposite arguments has also been presented. Especially in high-technology companies, a market orientation needs no to be added to R&D in the innovation process, but it needs to blend with it (De Luca *et al.*, 2010).

The concept of "practice" refers to a type of activity that consists of several elements: bodily movement, mental activities, objects and their use, contextual understanding, normative understanding and emotion (Reckwitz, 2002). In everyday practices, learning takes place in the flow of experience, with or without our awareness of it (Gherardi, 2000). In innovation context practice would refer to the shared understanding of corporate life (in this case: understanding of customer and user knowledge) and the "corporate kind of creativity" and praxis would include ways of presenting, commenting, refining and evaluating ideas (in this case: knowledge about customers and users) (Lempiälä, 2011). One suggestion would be that the front-line employees are taken to be part of the innovation process more tightly to bring the user knowledge with them.

As presented in previous chapter, the user knowledge is most often intangible. It is hold in the heads of key account managers (or similar), maintenance persons, customer support service persons and other organizational members working with the users. It is rarely the innovation managers how knows the users well (Kanto et al., 2014), but it is the front-line employees that are potential interpreters of user needs (Hasu et al., 2012) and thus may be a valuable source of user knowledge in decision making process.

3 Research design

The research was conducted as a qualitative explorative study. The research followed an abductive process (Dubois and Gadde, 2002), combining theoretical knowledge and empirical insight systematically. Thus, the research process comprised both inductive and deductive phases. The inductive case study approach makes it possible to gain novel insight from the empirical world (Yin, 1994). This methodological approach analyses the empirical data gathered from the cases in light of the existing theoretical explanations, extending them if necessary. The researchers examine the literature relevant to the problem area, and employ the empirical data, filling in its gaps and revealing its flaws. In this vein, the research elaborates the meaning and extends the coverage of the prevailing theories.

The data of this study consists of 14 in-depth expert interviews. All the experts presented the senior management level in their organizations. Six (6) experts in Finland, Switzerland and Germany were interviewed in six different well-established industrial manufacturing companies operating in b-to-b environment. Similarly eight (8) experts in

Switzerland and Germany were interviewed in eight different well-established IT-driven service companies operating both b-to b and in b-to-c environment. The list of interviewees is presented in Table 1.

The semi-structured interviews lasted on average one hour, and were arranged during January-March 2014. All interviews were recorded, transcribed and coded by exploring the commonalities and differences.

Table 1. List of interviewees.

Service companies, both b-to-b and b-to-c			
	Position	Department	Industrial sector
1	Senior manager	Design	Banking
2	Senior manager	Design	Telecommunication
3	Senior manager	IT	Software
4	Senior manager	IT	Banking
5	Director	IT	Banking
6	Director	IT	Insurance
7	Senior manager	IT	Banking
8	Senior manager	Sales&Marketing	Banking
Manufacturing companies, b-to-b			
	Position	Department	Industrial sector
9	Director	IT	Chemicals
10	Senior Manager	Development	Metals
11	Director	Marketing & Sales	Pharmaceuticals
12	Manager	Desing	Marine
13	Manager	R&D	Chemicals
14	Director	R&D	Pulp and paper

4 Findings

As described above, the experts that were interviewed are members of companies operating both in traditional industrial sectors and also in IT-driven service sector. The companies operating in traditional manufacturing companies were facing the paradigm shift of offering – from purely manufacturing centric to more service oriented company. Even though the interviewees considered their companies still very much as manufacturing centric organizations: “I was wondering if we have any service, just service. I suppose all of our services are tied to the products” (Expert number 9) and “Think in the past our company has been very much product- or technology-driven... and we learned that this is not the approach for the future. We are now trying to change to be more human-centered.” (Expert number 13)

The findings from the expert interviews were similar in every country, but differences were found between manufacturing and service companies. The main findings are listed in table 2.

4.1 User knowledge practices

There is a difference between service and manufacturing companies in the utilization of user knowledge. The user knowledge that is utilized, in the innovation process of manufacturing companies, is the knowledge from the problem cases, user wishes in some extend and market trends. The user knowledge is quite narrow, because for manufacturing companies it is easier to talk with the customers than it is with the users: “Our product is more like a raw material, so it’s hard to discuss with the user” (Expert number 14). The service companies have more varieties in the sources of user knowledge. Most of them user either friends & family testing, special interest groups or extreme users: “We have a special interest group... we invite these people three to four times a year and ask how they use the services, what they need and so on” (Expert number 7).

There is a shift of attitude and culture going on in manufacturing companies: “We call it a client innovation center where we bring our lab expert and our key account managers together. And they go together to meet to users, arrange workshops whatever. This center started in half a year ago” (Expert number 13). Half of the experts working for service companies described a similar kind of “attitude change” which happened already 5-6 years ago: “We change our organizational set up from a technology-centric approach to a more human-centered approach in 2008.” (Expert number 2) and “We started this [design thinking] approach with heavy user-involvement in 2009” (Expert number 1).

The experts described several practices that were used in their organizations to collect user knowledge: “We need to talk with people along the whole consumption chain. Not only the value chain of the manufacturing.” (Expert number 13) and “We have set up a customer interface -programme, because we want to have an ultimate experience for every contact between our company and customer... And the customer is almost always the user” (Expert number 4). However the way the users are met in service companies has more varieties than in manufacturing companies: “We encourage the team to connect with the users... Go to have lunch with them, watch them, talk to them... doing that, they get the chance to create emotional bond with the user...” (Expert number 1) and “Prototyping is very important. It’s much easier to understand what the service is going to be like, if you have something that you can try” (Expert number 7). In addition the service companies use storytelling, ethnographic research and living labs: “We have set up a testing laboratory to which we can invite our clients [=users] to test our new offering” (Expert number 7). The company, in which the expert number 14 works, has also done experiments with the 3D-printing methodology and has found it a potential way to make intangible matters to tangible ones.

4.2 User knowledge practices that support or may benefit from EDI activity in organizations

The common problem noticed by each expert is the fact that only the sales persons meet usually the customer (which may or may not be the user) in a meeting room or in conferences. However there is also willingness in sales support and design to contact the users directly. At the moment this activity is not supported by top management, although every visit at user or customer site has been valuable for the sales support and design managers & specialists: “The visits were useful. I got to know what they expect from our products and also got to see how big their facilities are” (Expert number 12). There were also individuals in the case company that had started to change the practices by their own:

“I have been travelling around [the customer sites] and I have took the younger colleagues with me... there is a lot of knowledge which is not written any were, and you can better understand the meaning from gestures than from written words” (Expert number 12).

The personal meetings with user and development team members are important, because only that way the employees are able to create a emotional bond with the users: “One of the major shifts was to really make sure that a product manager gets in contact with the real customers... this kind of empathy is the key to corporate customers as well” (Expert number 2). And these personal meetings are important also, because the intangible nature of user knowledge: “Unfortunately in most ways it [user knowledge] stays with people... it’s very difficult to really transfer this kind of knowledge” (Expert number 2).

A challenge in this user approach, mentioned by almost each expert is that the frontline employees needs to give space for innovation teams: “Key account managers need to be convinced that especially product managers need access to customer to really understand them and to be able to develop tailor-made products” (Expert number 2). Only expert number 14 told that also the employees in innovation teams can meet the users whenever needed. On the other hand the maintenance persons in the manufacturing companies meet the users in their work or at least in their work space: “The maintenance persons are our best contact to users. They get the best knowledge from the live situations.” But the maintenance persons are involved in innovation process only occasionally.

The traditional “Upstairs, Downstairs” separation of employees and managers is still clearly seen in each company, because the innovation board is an upper management level activity. However there is some good action coming also from the top management which may benefit the EDI activity, or at least the connection with users: “The head of the residential business was very much fond of this kind of approach [human-centered approach].” (Expert number 2) and “The [design thinking] approach came from the senior management. CEO pushed it a lot here and that helped enormously. It motivates managers to go for it” (Expert number 3). Moreover, expert number 7 told that they show their appreciation to the employees by not having suggestion boxes.

“No, we do not have suggestion boxes. It would be full every day and if someone brings in an idea, we should give him feedback about it... no time to give feedback for hundreds of employees... Instead, if you bring an idea for the innovation team, it is evaluated and most often... 7 out of 10 ideas get funding and also support for getting a team around the idea.” (Expert number 7)

Table 2. Main findings from the 14 interviews.

	Service companies	Manufacturing companies
User knowledge: sources	Friends&Family testing, special interest groups, extreme users, personal meetings, workshops, storytelling, ethnographic research, living labs, prototyping	Customer and user meetings, maintenance events, conferences (rarely), some workshops, only rarely some prototyping
User knowledge: who meets the user	Relationship managers, innovation managers (if possible)	Sales (second-hand information), Technical customer service, Customers' customer (if asked by R&D), Maintenance (if asked by R&D)
User knowledge: challenges	Relationship managers do not want to give access to meet client (=user), relationship managers are not heard through innovation process	Lack of user knowledge in general, lack of capability to utilize user knowledge, lack of cross-functional development teams

5 Conclusions

The paper contributes to the understanding of how user knowledge is collected in service and industrial organizations. The findings reveal the main challenges in making effective use of user knowledge in the studied settings. The user knowledge is found easy to use in business-to-consumer settings, but in business-to-business environment it is difficult to find the user of the offering. Different kind of user knowledge practices were found from service organizations, but there lack of user knowledge methods in manufacturing organizations

The findings are of primary interest to theory development and business practice, as the experts represent both service and industrial manufacturing companies operating in technology- and resource-intensive industries. The major challenges in the traditional in-house innovation experienced in the case organizations include that the individuals who are in charge of the innovation processes find it difficult to understand the meanings of user-related information and they cannot grasp the value of user knowledge. The findings suggest that taking the individuals to be part of the construction of user understanding it would benefit the company from the viewpoints of user-driven innovation and employee-driven innovation. Difficulties in accessing user knowledge may be overcome through increasing participation of front-line employees in innovation.

Social and Individual Factors Influencing User Participation in Facebook-based Brand Communities

Puneet Kaur

School of Science, Aalto University, Finland

A survey was taken of adolescents to understand the role of various social and individual factors in users' formulation of attitudes towards using commenting as a mode of participation in Facebook-based brand communities. Also, the relationship between a users' attitudes, continuation intentions, and activity levels are explored. The findings reveal that self-efficacy, hedonic motivation, reciprocal benefit, and social influence have a positive impact on the user's attitude. Among these, self-efficacy is found to have the strongest influence. On the other hand, external influence, social presence, and habit do not play any role in determining users' attitudes. Furthermore, attitude, continuation intention, and activity levels are significantly related. The findings have implications for organizations intending to use social network service-based brand communities to practice user-centric service innovation.

1 Introduction

Social networking services (SNS) have brought a change in the way humans communicate and keep in contact with their social circle. Most recently of all, SNS have also begun to exert their influence on the operations of organizations (Cvijikj; Michahelles, 2013; Muk; Chung, 2014). Some examples include: advertising about organizations' achievements, mission, and current tasks; practicing innovation processes; and involving and engaging customers. As the majority of people use some form of SNS, organizations are establishing their pages on various SNS to get easy access to their customers (Jung et al., 2014). These brand pages attract users who are either dedicated to specific brands, or are interested in the future offerings of the underlying brand. Brand communities in the network space can be defined as a "specialized, non-geographically bound community, and based on a structured set of social relations among admirers of a brand" (Muniz; O'Guinn, 2001). Hence, the established brand pages on SNS can be referred to as SNS-based brand communities. For example, on Facebook (FB), users can become members of FB-based brand communities by clicking the "Like" button on brand pages.

Organizations have recognized the importance of involving users in innovation processes (Buur; Matthews, 2008; Fuller et al., 2008, Von Hippel, 2005). In this context, relatively recent research has suggested that organizations are trying to establish closer bonds with their customers and involve them in the innovation processes by getting to know customers' opinions regarding existing and future services through SNS-based brand communities (Ding et al., 2014; Richter et al., 2011; Bolotaeva; Cata, 2010; Palmer; Koeing-Lewis, 2009; Park; Kim, 2014). The SNS-based brand communities empower customers by providing them up to date information about the company's new and existing offerings, connecting them with other existing and new customers, and most importantly, by giving them voice (e.g. enabling them to comment, express, or give feedback about a company's offerings). The participation of the user can be done at the following levels: (i) idea generation, (ii) evaluation of the potential of the new ideas while making decisions regarding future products and services, (iii) development of existing ideas with users and manufacturing, (iv) acquisition of feedback about the organization's existing products and services. Therefore, SNS-based brand communities are potential platforms to practice user-centric service innovation. However, user-centric innovation can only be practiced in SNS-based communities if their members are sufficiently engaged.

As the brand communities established on various social media platforms have experienced a rise in popularity, they have received less attention from researchers (Habibi et al., 2014). Enabling and retaining active user participation has been recognized as a potential challenge faced by SNS-based brand communities (Ding et al., 2014; Habibi et al., 2014; Deloitte, 2009). Based on research of about 400 companies, Deloitte's study (2009) reports that around 30% of companies are facing problems getting people engaged in SNS communities. At the same time, around 20% of organizations are facing issues retaining the existing members of their communities. About 35% of organizations have less than 100 fans (Deloitte study, 2009). Similarly, Sysomos's study (2009) of 600,000 FB pages also reports that only 23% of the pages have more than 1000 fans, while only 0.047% have more than 1 million fans.

In SNS-based brand communities, user participation can be affected by various factors. Some examples are: different SNS features enabling user participation, feedback from the brand and other members of the community, content type, number of members, and interaction patterns. To the best of our knowledge, the phenomenon of user participation in SNS-based brand communities via SNS-specific features has not yet been explored. Hence, in this study, the user participation phenomenon is explored through the lens of the commenting feature of FB-based brand communities. The FB commenting feature is appropriate, as it enables content generation by the users, which is crucial for practicing user-centric innovation. The present study investigates the role of individual factors (hedonic experience, habit and self-efficacy), and social factors (social influence, reciprocal benefit, external influence and social presence)

in formulating user's attitudes towards using the commenting feature as a mode of user participation on FB-based brand communities. Also, the impacts of attitude and continuation intentions on users' continuation intentions and their levels of activity are explored. The present study will contribute to facilitating and enhancing user-centric service innovation through SNS-based brand communities.

2 Background

In a recent study, Habibi et al. (2014) conducted an extensive literature review of brand communities, and summarized the work done in this field. It was found that brand communities have been explored from the following perspectives: characteristics, antecedents, and outcomes, from the perspectives of firms and consumers. On the other hand, Cvijikj and Michahelles (2013) found that SNS have been researched based on user types, usage patterns, impression management, motivational aspects, privacy and security issues, and network structure, in addition to their usage in differing domains like education and politics. Furthermore, it was found that there is a lack of research on the use of SNS in the organizational context (Cvijikj; Michahelles, 2013).

Social media has brought about a noticeable change in user behaviour in the online environment (Habibi et al., 2014, Zaglia, 2013). Zaglia (2013) states that social media has made people more open and expressive. On the same note, Habibi et al. (2014) state that people have now began to use real identities instead of pseudonyms for expressing themselves in the online environment. Furthermore, Habibi et al. (2014) report that social media-based brand communities are different from the traditional brand communities from the following perspectives: (i) social context, (ii) absence of any kind of structure, (iii) varied sizes, with abilities to accommodate up to millions of members, (iv) variation in storytelling, as it involves features such as: liking, commenting, and sharing, and (v) the possibility to associate with other affiliated brand communities. Hence, the findings from research on traditional communities might not be applicable to the nature and implications of social media-based brand communities. Furthermore, we argue that it would be worthwhile to investigate whether there are differences between brand communities established on different social media platforms. For example, content generated on FB is visible to the friends of the user through the ticker feature, while this is not the case on YouTube. This kind of setting makes social influence and peer pressure more influential on FB than on YouTube. In this regard, this paper examines SNS-based brand communities with a specific focus on FB-based brand communities.

2.1 SNS based brand communities

The majority of the research on social media brand-based communities addresses SNS (Zaglia, 2013; Habibi et al., 2014; Jung et al., 2014; Wallace et al., 2014; Ding et al., 2014; Muk; Chung, 2014). Zaglia (2013) recognizes the presence of brand communities on FB by comparing FB pages and groups to the three markers of brand communities: consciousness of kind, shared rituals and traditions, and moral responsibility (Muniz; O'Guinn, 2001). From the organization's perspective, the following dimensions of SNS-based brand communities have been researched: (i) brand trust (Habibi et al., 2014; Jung et al., 2014), consumer engagement (Cvijikj; Michahelles, 2013), continuation intention (Jung et al., 2014; Lin; Lu, 2011), joining intention (Muk; Chung, 2014), brand love (Wallace et al., 2014), role of marketer- and user-generated content on user participation (Ding et al., 2014), intention to word of mouth (Wallace et al., 2014) and user participation motivations (Zaglia, 2013).

2.2 FB-based brand communities

Facebook is one of the most popular and largest SNS with international acceptance. Facebook has 1.32 billion monthly active users, and 829 million daily active users as of June 2014 (Facebook newsroom, 2014). Hubspot (2011) reports that organizations consider FB to be one of the most influential social media channels for business-to-consumer businesses. Furthermore, about 80% of businesses are active on FB (Infographics, 2012). Also, about 20 million people become fans of pages on FB each day (Infographics, 2010). The two top brands are: Coca-Cola (with 52.7 million fans) and Disney with 38.6 million fans (Infographics, 2012).

Facebook-based brand communities can take two forms: fan pages and groups. In this paper, we specifically focus on FB fan pages. They were introduced in 2007 to enable organizations and influential personalities to connect with their fans (Sysomos, 2009). As mentioned previously, Zaglia (2013) has categorized FB pages as brand communities.

The domain of user participation in brand communities has been explored from two theoretical perspectives: the social capital theory (SCT) and social identity theory (SIT) (Habibi et al., 2014). The SCT states that utilitarian motives govern consumer's participation in brand communities (McAlexander et al., 2002; Schau et al., 2009; Zaglia, 2013), while the SIT posits that consumers participate in brand communities for the hedonic purpose of satisfying their need for identification (McAlexander et al., 2002; Zaglia, 2013; Muniz; Schau, 2007). In the context of FB, users have different motivations for participating in FB fan pages and groups, including: (i) seeking user-tailored information, (ii) skill improvement, (iii) passion sharing, (iv) social enhancement, (v) entertainment, (vi) enjoyment, (vii) retention and formation of relationships, and (viii) expression of their concerns (Zaglia, 2013). She found slight differences in terms of user motivations to participate in FB fan pages and groups. For example, social enhancement acts as a stronger

motivator on FB fan pages than in groups, while information seeking is a more prominent motivator in groups than on fan pages.

3 Study Methodology

The following section discusses the underlying research questions, research model, measures, and data collection procedure.

3.1 Research Question

In FB-based communities, content generation can take the forms of commenting and individual posts created by consumers. In this paper, we are specifically focusing on the commenting feature of FB-based brand communities. While researching consumer engagement in FB brand pages, Cvijikj and Michahelles (2013) found commenting to be an indicator of consumer engagement. Furthermore, Wallace et al. (2014) suggest that it would be worthwhile to investigate the commenting feature on FB as a proxy for consumer engagement. About 3.2 billion people use the like and comment feature of FB each day (Infographics, 2012). A Deloitte study (2009) of about 400 companies states that around 30% consider the frequency of the posts and comments by the people to be an indicator of the success of their community. Organizations can use the commenting feature to generate new ideas for possible future products and services, improve existing ideas for possible services, and gather feedback to improve existing products and services. Therefore, the present study asks the following research questions:

- RQ1. How do social (social influence, reciprocal benefit, external influence and social presence) and individual factors (self-efficacy, habit, hedonic motivation) impact users' attitudes towards using commenting as a mode of participation in FB-based brand communities?
- RQ2. How do users' attitudes impact their intention to continue using commenting as a mode of participation in FB-based brand communities?
- RQ3. How do users' attitudes towards commenting impact users' activity levels in FB-based brand communities?
- RQ4. How do users' continuation intentions regarding commenting impact users' activity levels in FB-based brand communities?

3.2 Research Model

The research model is based on the theory of reasoned action (TRA). This theory explains the phenomenon behind human actions. The TRA posits that a user's attitude influences their behavioural intention, which in turn impacts their usage behaviour. In our case, continuation intentions represent a user's behavioural intention and a user's activity level reflects their usage behaviour. The factors influencing user attitude have been selected based on the study context. The justification for using the selected constructs has been explained in the following text.

Social Influence (SI): refers to the importance of others' (e.g. family, relatives, friends, peers, neighbours and colleagues) opinions in users' decision-making processes in regard to technology usage (Venkatesh et al., 2012; Hsieh et al., 2008; Irani et al., 2009). A study by de Valck et al., (2009) found that the social network of the user has an influence on their behaviour. For instance, the existing literature has shown that SI has a significant impact on formulation of perceptions regarding technology use (Venkatesh et al., 2003; Anandarajan et al., 2002; Sapio et al., 2010; Zhou et al., 2010) and adoption (Venkatesh et al., 2003; Brown; Venkatesh, 2005; Fulk; Boyd, 1991; Hsieh et al., 2008). Wallace et al. (2014) found that consumers get associated with the brand and related activities for the sake of impression management. Consumers aim to express their social and inner self to others by getting associated with the brand and participating in their activities even if those brands have nothing to do their real life. Muk and Chung (2014) found that the recommendation of important referents influences the user's intention to join brand pages. Furthermore, it is also important for adolescents to verify their choices with peers (Muk; Chung, 2014). Based on the above discussion, we believe that SI can impact users' participation behaviours in FB-based brand communities as well. This leads to the following hypothesis:

H1: *Social Influence* positively influences user attitudes towards using the commenting feature to participate in FB-based brand communities.

Reciprocal Benefit (RB): can be defined as user perceptions regarding the attainment of mutual benefits for their performed actions. In the context of SNS-based brand communities, RB addresses the social and general usefulness of user participation in them (Preece, 2001; Hamari et al., 2013). For example, the existing literature has revealed that users' tendencies to gain recognition and seek information play an influential role in driving user participation in brand communities (Dholakia et al., 2004; Raacke; Bonds-Raacke, 2008; Ridings; Gefen, 2004; Habibi et al., 2014; Hsu; Lin, 2008). With regard to SNS-based brand communities, users sharing their knowledge through commenting on members or moderator posts might seek recognition, or help when needed, in lieu of their contribution. We believe that the

phenomenon of mutual reciprocity is also influential in the FB-based brand communities. The above justification leads to the following hypothesis:

H2: *Reciprocal Benefit* positively influences user attitudes towards using the commenting feature to participate in FB-based brand communities.

External Influence (EI): refers to the extent of the importance of the external entities (e.g. expert opinions, advertisements in the offline and online environment, promotional offers and mass media reports) on the users' behaviours and decision-making (Bhattacharjee, 2000). The EI plays a dominant role in the initial adoption and acceptance of new technologies and information systems (Lee et al., 2003). For example: advertising through different mass media channels is found to have positive influence on technology adoption intentions (Lee, 2003; Mahajan et al., 1990). Furthermore, Muk and Chung (2014) have found that advertising on social media impacts users' intentions to join brand pages on FB through the means of attitude and subjective norms. Moreover, SNS-based brand communities are relatively new to users. Therefore, it is relevant to examine the impact of EI on user participation in FB-based brand communities. The above discussion leads to the following hypothesis:

H3: *External Influence* positively influences user attitudes towards using the commenting feature to participate in FB-based brand communities.

Social Presence (SP): can be defined as the "user's perception of personal, sociable and sensitive human contact in the medium" (Gefen and Straub, 2004). The SNS have been classified as platforms having a medium level of SP (Kaplan; Haenlein, 2010). Also, SNS-based brand communities are better in terms of SP than traditional communities. This is due to the possibility to use various forms of media (e.g. videos and pictures) along with the text. Koh et al. (2007) state that SP is a significant factor enabling effective communication in social contexts. Additionally, they have also empirically shown that the enhancing the level of SP in virtual communities has a positive influence on the posting activity of the members. Similarly in the domain of web advertising, Fortin and Dholakia (2005) report that SP has a strong influence on user involvement and arousal. The above discussion leads to the following hypothesis:

H4: *Social Presence* positively influences user attitudes towards using the commenting feature to participate in FB-based brand communities.

Self-efficacy (SE): can be defined as a user's self-confidence of his/her abilities to accomplish the desired behaviour (Bandura, 1977). Bandura (1977) states that SE influences users' decisions to perform actions. Self-efficacy is found to have a positive influence on technology adoption (Vijayasathy, 2004; Hernandez et al., 2009). Users with high SE are more motivated, and make great effort to accomplish intended tasks (Schunk, 1990 and Bandura, 1977). Based on review of the existing literature on online community user participation, Zhou et al. (2011) report that SE is critical for user participation. This paper believes that SE can also play an influential role in driving user participation on FB-based brand communities. In the context of FB-based brand communities, to enable participation, users' self-confidence using the FB features, together with the content generated through their participation are needed. The above discussion leads to the following hypothesis:

H5: *Self-efficacy* positively influences user attitudes towards using the commenting feature to participate in FB-based brand communities.

Habit (H): can be defined as a user behaviour that has attained a state of automaticity through self-learning (Kim et al., 2005; Limayem et al., 2007). Habit is found to have an influence on technology use (Davis; Venkatesh, 2004; Kim; Malhotra; 2005; Kim et al. 2005; Limayem et al. 2007, Venkatesh et al. 2012). The authors of this study are of the belief that those users who have a habit of participating in FB activities using commenting are more likely utilize it in FB-based brand communities as well. Hence, habitual behaviour is relevant to user participation in SNS-based brand communities. This discussion leads to the following hypothesis:

H6: *Habit* positively influences user attitudes towards using the commenting feature in SNS-based brand communities.

Hedonic Motivation (HM): refers to the user's determination to perform actions based on the elements of fun, enjoyment, and entertainment derived from the technology or service usage (Sledgianowski; Kulviwat, 2009; Lu et al. 2009; Van der Heijden 2004; Igarria et al. 1995; Venkatesh et. al 2012). In consumer behavioural research, HM is found to play a significant role in influencing users' behaviours towards IT adoption and usage (Brown; Venkatesh 2005; van der Heijden 2004). In the context of SNS, pleasure oriented characteristics motivate users to continue their usage (Kang; Lee, 2010; Sledgianowski; Kulviwat, 2009; Raacke; Bonds-Raacke, 2008). Furthermore, entertainment is found to have a positive impact on user engagement in brand communities (Muntinga et al., 2011; Raacke; Bonds-Raacke, 2008). Hence, HM can also lead to user engagement in SNS-based brand communities. The above discussion leads to the following hypothesis:

H7: *Hedonic Motivation* positively influences user attitudes towards using the commenting feature to participate in FB-based brand communities.

Attitude: can be defined as the “individual’s evaluations of an object” (Jung et al. 2014). The SNS-based brand communities are relatively new forms of brand communities (Muk; Chung, 2014). Consequently, users might not have any prior experience participating in these communities. Additionally, Peter and Olson (2010) state that attitude is an important determinant of human behaviour. Therefore, it is relevant to investigate the different factors influencing the users’ attitude formation process in the context of FB-based brand communities. Based on existing research, we hypothesize that attitude can positively influence users’ continuation intentions and their activity levels. The continuation intentions address the human tendency to continue using the commenting function as a mode of participation in FB-based brand communities. For example, attitude is found to have impact on the revisit intentions of the users (Jung et al., 2014; Um et al., 2006; Huang; Hsu, 2009). On the contrary, the users’ activity level deals with their tendency to become more active members and generate more content as a result of receiving more comments on their previous activity.

H8: *Attitude* positively influences users’ intentions to continue using the commenting feature to participate in FB-based brand communities.

H9: Attitude positively influences users’ activity levels in FB-based brand communities.

H10: Users’ intentions to continue using the commenting feature to participate positively influence users’ activity levels in FB-based brand communities.

3.3 Measures

The respondents were asked to evaluate individual and social factors, attitude, continuation intention, and activity level using five point Likert scales ranging from never ‘1’ to always ‘5’ (see Table 1).

3.4 Data Collection

The data was collected from 728 Indian adolescents (aged 13 to 18 years) who were active FB users, using a pen-and-paper survey. The students were recruited from eight senior and junior high schools in four different cities in the Northern part of India during December 2013. Permission to conduct the study was granted by the schools’ managements. They were clearly informed about the study objectives, time requirements and expected outcomes. Student participation was voluntary, and completely anonymous as they were clearly informed not to mention any identification information (e.g. name or roll number). After attaining permission, the study was advertised on school notice boards. The advertisement informed students about the study details i.e. objectives, participation requirements, date, place, and time. Before conducting the study, the students were again informed about the study background, and objectives in detail. Furthermore, before beginning the study, it was made sure that students had experience on FB and using FB-based brand communities. The students were given freedom to leave the study whenever they wanted.

4 Statistical Analysis

The statistical analysis in the present study was performed using IBM SPSS 22.0 and AMOS 21.0. First, the exploratory factor analysis (EFA) was performed using the empirical data in order to examine the factor structure of the study constructs. Later, the factorial solution was re-confirmed using confirmatory factor analysis (CFA). Finally the CFA was utilized to examine various construct validities and reliabilities.

4.1 Exploratory Factor Analysis (EFA)

Before performing EFA, two popular statistical tests, namely the Kaiser-Meyer-Olkin measure of sampling adequacy (KMO) and Bartlett’s test of sphericity were utilized. The data returned a KMO value of 0,929 and a significant Bartlett’s test of sphericity ($p < 0.0001$), which indicate the fitness of the data for EFA. The minimum threshold for the factor loadings was 0.45; factor loadings below the threshold value of 0.45 were not allowed. Cross-loadings and parallel loadings were also not allowed. The process of item removal was repeated until a stable set of factor loadings were obtained. The EFA returned total of seven factors (see Table 1).

Table 1. EFA constructs, construct items, factor loadings and Cronbach's alpha.

Sub-constructs (Source)	Items	Factor Loadings	Cronbach alpha
Social Influence (Adapted from Ajzen, 1991)	People who are important to me think that I should post comments.	0.69	0.81
	My friends think posting comments is a good idea.	0.61	
	People who influence my behavior think that I should comment.	0.66	
	People whose opinion I value think I should comment.	0.60	
Reciprocal Benefit (Adapted from Hsu; Lin, 2008 ; Hamari; Koivisto. 2013)	Commenting can be mutually helpful.	0.56	0.83
	Commenting can be advantageous to be me and other people.	0.69	
	Commenting improves my motivation to participate.	0.56	
	FB community encourages me to comment.	0.45	
External Influence (Adapted from Bhattacharjee, 2000)	I feel pressure from media and commercial to use commenting.	0.75	0.87
	I feel encouraged by media and commercial to use commenting.	0.74	
	I feel persuaded by media and commercial to use commenting.	0.74	
Social Presence (Adapted from Gefen; Straub, 2004)	There is a sense of human contact in commenting.	0.76	0.86
	There is a sense of sociability in commenting.	0.78	
	There is a sense of human warmth in commenting.	0.66	
Self-efficacy (Adapted from Venkatesh et al., 2012)	I feel confident using comment function.	0.77	0.91
	I feel confident in utilizing comment function.	0.79	
	I feel comfortable using comment function on my own.	0.79	
	I can easily operate comment function on my own.	0.71	
	I feel comfortable using comment function even if there is no one around me to tell how to use it.	0.55	
Habit (Adapted from Venkatesh et al., 2012)	The use of commenting has become a habit for me.	0.71	0.90
	I am addicted to use commenting.	0.79	
	I must use commenting.	0.75	
	Commenting has become natural to me.	0.54	
Hedonic Motivation (Adapted from Venkatesh et al., 2012)	Commenting is fun.	0.73	0.90
	Commenting is enjoyable.	0.87	
	Commenting is very entertaining.	0.74	

4.2 Confirmatory Factor Analysis (CFA)

The CFA of the seven-factor model returned a good model fit (cmin/df = 1.883; CFI = 0.976; GFI = 0.94; AGFI = 0.923; RMSEA = 0.035; pclose = 1.000). The goodness of the model fit fulfilled the cut-off criteria suggested by previous literature (Kline, 2011; Browne; Cudeck, 1993; Hu; Bentler, 1999).

4.3 Validity and Reliability

In the present study, various types of construct validities and reliabilities are examined. These include: i) *Content validity*: It was ensured by drawing and adapting the items for measuring the different constructs from the existing

literature. The undertaken items have been previously validated to measure the underlying construct by several researchers. Therefore, content validity is guaranteed. ii) *Face validity*: Conducting a pilot study with 20 users representing the target group ensured the face validity of the study. The pilot study was conducted to determine if any items or words were confusing or hard to comprehend by the adolescent users. The feedback from the pilot study was incorporated into the survey before conducting the final study. iii) *Convergent validity*: The convergent validity was ensured using the following three metrics: (i) the average variance extracted (AVE) value for all constructs was greater than 0.5 (Fornell; Larcker, 1981), (ii) the composite reliability (CR) value for all constructs was greater than 0.70 (Fornell and Larcker, 1981), (iii) Cronbach's alpha value for all constructs was greater than 0.70 (Hair et al., 2006) (see Table 1; Table 2). This shows that the present study has met the criteria for convergent validity. iv) *Discriminant validity*: The discriminant validity was assessed using the following metrics: (i) the square root of the AVE for a construct was greater than the correlations of the underlying construct with other constructs (Fornell; Larcker, 1981; Chin, 1998), (ii) the inter-correlations between the different constructs were not greater than 0.9 (Palvou et al., 2007); and (iii) The average-variance explained (AVE) of the construct was greater than the variance between that construct and other measures (Barclay et al., 1995) (see Table 2). Therefore, the present study constructs fulfil the criteria of discriminant analysis.

Table 2. Convergent and discriminant validity of the study constructs (A = Attitude).

4.4 Hypothesis Testing

The research model explains 58% of the variance in the users' attitudes towards using the commenting function to participate in FB-based brand communities. Self-efficacy is found to have the strongest influence on user's attitude. It is followed by hedonic experience, reciprocal benefit, and social influence respectively. However, external influence; social presence; and habit have no impact on users' attitudes. The research model accounts for 31% of variance in the intention to continue using the commenting feature in FB-based brand communities. Also, the model explains 41% of variance in the users' activity levels due to feedback in the form of commenting on their prior activity. Hence, it can be seen that hypothesis H1, H2, H5, H7, H8, H9, H10 stand accepted.

Figure 1. Research Model.

5 Discussion

This paper investigates user participation phenomena in FB-based brand communities with regard to the commenting feature. The impact of individual and social factors on users' attitudes towards using the commenting feature as a mode of participation in FB-based brand communities is explored. Also, the influence of attitude is examined on the users' intentions to continue using the commenting feature, and users' activity levels. Finally, the relation between continued use intentions and user activity levels is also examined. The findings of the study provide information to the practitioners and researchers about factors that influence user behaviours related to formulating positive attitudes towards participation in SNS-based brand communities. Furthermore, it also indirectly predicts which factors encourage higher activity among users in addition to retaining these additional activity levels.

The study findings validate the established relationship between attitude, behavioural intention, and usage behaviour in the context of FB-based brand communities (Ajzen, 1991). This also proves that the retrieved research model correctly explains user behaviour in FB-based brand communities. It was found that high positive attitude leads to higher user activity and continuation intentions in FB-based brand communities. On the other hand, the increase in the users' activity levels can also be credited to higher continuation intentions of the users. However, it has also been found that attitude has a stronger influence on user's activity level than behavioural intention.

The study findings reveal that users' self-confidence is quite important in predicting their participation behaviour. It is found that users with high self-efficacy have a favourable attitude towards commenting. In relation to FB-based brand communities, self-efficacy addresses users' confidence in using commenting, in addition to the content generated through the use of the commenting feature. As the users become experienced in using FB, the self-efficacy associated with content generation will need more attention. Furthermore, anecdotal evidences suggest that users' fear of criticism, relevance, and accuracy of their generated content is one of the major concerns of the users influencing their participation. The influence of self-efficacy on feature enabling participation and content should be examined independently in future studies. Additionally, the study shows that undergoing high hedonic experience by using commenting also leads to formulation of positive user attitudes. The existing literature reports that adolescent users seek enjoyment, fun, and entertainment (Leung; Wei, 1998). Hence, the provision of such an experience by FB-based brand communities makes the user's attitude favourable.

Attainment of high reciprocal benefits leads to development of a supportive attitude among users. In SNS-based brand communities; users can get the following reciprocal benefits in lieu of their participation via commenting: recognition, enhancement of their existing level of learning, and help in resolving their problems. For example, users can enhance their learning through the feedback and criticism that they get from fellow community members or a community moderator. Also, getting feedback on their comments can also provide them recognition, which is one of source of pleasure for adolescents in the online world. Additionally, the presence of social influence also positively

influences users' attitudes towards commenting. For example, in FB the comment given by the user becomes visible to their social network via the ticker function. This supports the impression management needs of the users by giving them a sense of achievement, and by revealing their association with the underlying brand.

The study found no influence of external influences, social presence, or habit on the users' attitudes towards commenting. Muk and Chung (2014) report a positive influence of advertising on users' intentions to join brand pages. However, the present study findings suggest that media and commercials can motivate users to join brand pages, but cannot influence their participation behaviour e.g. content generation via the commenting feature. So, external influences alone are not sufficient to instigate user participation. The impact of other elements of FB-based communities (e.g. content type, communication pattern, or content frequency) on users' attitudes could be reasons behind this that require further exploration. Regarding social presence, users did not find any social presence in the commenting feature, as it might lead to harsh comments and unpleasantness. It can be that the target user group, i.e. adolescents, might not be mature enough to understand the concepts of human warmth and sociability, so they misinterpret them. Furthermore, it might also be possible that the concept of human warmth, sociability, and human touch are irrelevant in relation to users' attitudes in FB-based brand communities. However, this would require further research intervention for validation. Finally, contrary to the usual belief, the habit of commenting does not affect users' attitudes. The study participants are experienced users of FB, so commenting should be a part of their habitual behaviour. But as discussed previously, the possibility of conflict arousal or unpleasantness due to commenting might be acting as a restricting factor. Furthermore, the nature of the SNS-based brand communities (e.g. environment, level of interaction) might also influence users' habitual behaviours.

6 Managerial Implications

The study findings have managerial implications for organizations intending to practice user-centric service innovation via SNS-based brand communities. The study findings provide insight to organizations and brand community managers for managing FB-based brand communities. For example, FB-based brand communities should focus on enhancing users' self-confidence. It can be done by keeping interaction, tasks, and content on FB-based brand communities balanced with the skill set of the users. Users' self-confidence can also be boosted by paying attention to the content they generate. Brand community managers can do this by providing positive feedback to the users and mentioning their names while doing so. Apart from raising their self-confidence, this can also cater to their impression management needs by giving them recognition among their social network. This is possible in the case of FB; as such activities will become visible to the user's social network through the FB ticker. All of the aforementioned actions will also provide entertaining and enjoyable experiences to the users. This will, in turn, encourage and motivate users to continue their commenting participation, and to become more active members; thereby escalating content generation on FB-based brand communities. Efficient management of content generation activities in FB-based brand communities can lead to the generation of valuable information for the organizations. Such information reflecting users' opinions can guide organizational decision-making regarding the provision of future products and services.

7 Limitations and Future Work

The present study also suffers from certain limitations. The study context has some limitations that also offer possible future research directions. The data has been collected from Indian adolescents, which leads to contextual contributions that also restrict the applicability of the findings. In the future, similar research should be conducted on users from different age groups, and also from other regions having different cultural backgrounds. Furthermore, the data has been collected from users self-reporting that they are members of brand communities. In future, the research should be conducted on the users of some specific brand communities. As mentioned earlier, we believe that there might be differences in user behaviour on different social media platforms. However, this argument needs further investigation. Hence, it would be relevant to study the user behaviour on various social media platforms for validating or disproving this hypothesis.

Regional Innovation Factories: Towards participatory and agile incubation processes

Mika Kautonen¹, Rhiannon Pugh², Mika Raunio¹

¹University of Tampere, Finland, ²University of Lancaster, UK

Abstract. *So far, most innovation policies have been targeted to a narrow “elite” and rather isolated group of economic actors with high technological capabilities. National and local governments have made significant investments in physical and financial innovation infrastructure, devoting less attention to potential innovators and individual-level incentives. Along with an increasing interest in grand challenges and social innovation, participation in innovation activities has recently expanded to include new kinds of actors, demanding an increased focus on the individual level. The main argument here is that an emerging mode of agile innovation platforms (regional innovation factories) can be conceived that is focused on the individuals and providing the right incentives that support their innovative behavior as opposed to the substantial investments in traditional innovation infrastructure. We will present two case studies that provide a good contrast between the two types of policies, namely the Technium program of Wales and the New Factory platforms of Finland.*

1 Introduction

1.1 Cathedrals to communities

Policy-makers all over the world have come to realize that regional policies for research and innovation are “absolutely necessary in the current international economic scenario” (Piccaluga 2006, p. 273). A particular focus of regional innovation policy is the interface between academia and industry; universities are seen as key drivers of regional economic development in the knowledge-based economy (Gibbons et. al., 1994; Etzkowitz & Leydesdorff, 1997; Feldman & Desrochers, 2003; Drucker & Goldstein, 2007, etc.).

There are countless examples from around Europe, and indeed beyond, of policies that aim to foster the birth and growth of innovative knowledge-based firms, often focusing on the knowledge and IPR generated at the interface between universities and industry. Particularly popular have been policies that develop a physical infrastructure to enable collaboration, in particular science parks and incubators (Etzkowitz et. al., 2005; Massey et al., 1992; Phan et. al., 2005; Vedovello, 1997). Studies have found a variable success of these strategies; some science parks and incubators are held up as examples of successful innovation interventions (Casper & Karamanos, 2003; Longhi, 1999; Etzkowitz et. al., 2005). Cooke & Morgan are more critical of the proliferation of these approaches across Europe, describing the physical presence of science parks and incubators in weaker regions as “cathedrals in the desert” (Morgan, 1997). An interesting research question arises from this body of work around why some approaches are successful and others are not. This paper is premised on the notion that if we can better understand what leads to more effective innovation policy, regional governments could better channel their efforts and resources and enjoy economic growth outcomes for their citizens. To borrow Nauwelaers & Wintjes’ point of departure from their own innovation policy study (2003, p.194): “*Innovation is a good thing, at the level of the firm and the region, and there is a call for public intervention to get more of it.*”

In this article we suggest that a great deal of those policies have been created in a top-down fashion, imitating good practices from the outside without carefully considering the context at hand (c.f. Melancon & Doloreux 2013), taking a “one-size-fits-all” approach (Tödting & Tripl, 2005; Martin & Sunley, 2003). Often they fail to consider the concrete practices and incentives for participants that would make those policies functional. We claim that a majority of policies related to a creation of science parks, incubators, and knowledge transfer schemes represent a somewhat traditional top-down approach of regional and local innovation policies. We suggest, however, that a new perspective should be adopted for regional innovation policies, instead, that would target at creating such local innovation environments that incentivize their potential participants to innovate by creating excitement and providing support not only through public or private service infrastructures but also by fostering community-like elements. While these kinds of environments should provide somewhat predictable institutional conditions, they should nevertheless leave room for individuals and teams to not suppress their zest and creative energy. In other words, instead of traditional science parks and incubators we will call forth what we term as regional innovation factories; a new generation of regional innovation platforms that put focus on individuals and teams, their ambitions and motivation, and creation of like-minded communities with a sense of belonging and mutual support, among other things. This would parallel with an increased impetus on social innovations and on efforts to deal with the “grand challenges” for which a wider circle of stakeholders can participate into (c.f. European Commission, 2010).

To illustrate our point, we will present two case studies that provide a good contrast between the two types of policies that have been implemented in European regions (Stake, 1995; Yin, 2009). The large and ambitious, yet not

particularly successful, Technium program of Wales highlights many of the problems related to the traditional top-down regional innovation policies. New Factory platforms of Finland show some evidence of those features of the new perspective. In the former case, the triple helix approach has been successfully put into practice in the form of an ambitious program, but it has proved insufficient as an approach to foster growth. The latter case provides us some insights what 'extra' might be needed to make such policies 'tick'. By contrasting these two cases, we aim to provide insights to wider innovation policy studies by identifying the critical elements that could help policies in this domain to succeed.

1.2 Established foundations

In this section, we will outline the main approaches of the recent decades upon which regional innovation policies are often built. These include the regional innovation system approach, the triple helix approach and the regional cluster approach, at least. Following on from these existing approaches and theories we will introduce a more recent development; the regional innovation platform. Firstly, the important pre-existing theoretical approaches are briefly outlined here, with the pertinent insights to policymaking highlighted, upon which regional innovation policies in Europe (and indeed beyond) have recently been built.

As already explained, there has been a strong interest in the role of universities as innovation drivers. Often the empirical studies extolling the virtues of universities as regional economic drivers focus on a small set of exceptional examples; leading US examples include MIT and Stanford, and in Europe the examples of Cambridge, Grenoble, Oulu, and Linköping (Cooke, 2004). Theories are provided by academics to explain the importance of universities in regional economic development, and the increasingly entrepreneurial and varied roles ascribed to universities (Godin & Gingras, 2000; Olssen & Peters, 2005; Vorley & Nelles, 2010); two prominent concepts in the academic theory that have infiltrated policy practice are the modes of knowledge production thesis (Gibbons et. al., 2004) and the triple helix (Etzkowitz & Leydesdorff, 1997). Triple helix approach has focused on a certain type of regional setting in which dynamic interaction between government, industry and universities have generated knowledge-based economic growth (Etzkowitz & Leydesdorff 1997, 2000; Etzkowitz & Ranga 2010). Within the approach, sometimes also a 'quadruple helix' of other active participants has been acknowledged (Carayannis & Campbell, 2009).

Looking beyond the university sphere, a group of theories have been proposed that take a more systemic view of innovation, exploring the interlinkages between various actors partaking in innovation activities, and conceptualizing innovation as a non-linear and context dependent phenomenon (Lundvall, Edquist etc). Of the different variants on systems thinking, the regional innovation systems (RIS) approach is most applicable to the regional innovation policy context within which this paper is situated. RIS conceptualizes the regional interaction between producers and users, as well as between "the knowledge generating sub-system and knowledge exploiting sub-system" (Autio, 1998; Cooke, 2004). Appreciating the increasing globalization of innovation activities, the dual concept of "local buzz and global pipelines" (Bathelt et al., 2004) has been introduced, to put more emphasis not only on local formal and informal spillovers but on extra-regional linkages and knowledge flows. The approach has contributed to an increased understanding of institutional underpinnings and evolutionary development paths that play crucial roles.

Closely linked to the systems approach is the regional economic cluster approach (Porter 1998, 2008; Maskell & Malmberg, 2005 etc.), which has recently put more emphasis on innovation and knowledge-driven dynamics within studies of clustering that have for a long time been conceived in terms of traditional agglomeration economies. These knowledge dynamics include unique regional competences and supporting institutions as competitive assets. Recently, the importance of extra-regional, global linkages have been more often stressed (e.g. Wolfe & Gertler, 2004).

However, these approaches lack a firm grip of the more micro-level dynamics; they do not convincingly outline how these dynamics begin to work in favor of knowledge-driven regional development. Increasingly more focus has been put on more individual-level dynamics (Saxenian 1994; Bunnell & Coe, 2001); for example on trans-national entrepreneurship or mobility of individuals energizing innovative behavior in a certain location. Networks and entrepreneurship literature have contributed by studying individuals' attitudes and behavior towards processes of discovering and exploiting new opportunities, and those contexts where these may take place (Down, 2006; Sarasvathy and Venkatraman, 2011). Florida's creative class thesis (2002) has put emphasis on individuals but has done so by restricting population to a rather narrow elite class of innovators and creative professionals that is relevant and by leaving out a majority of people who do not belong to this class. His focus was neither on those micro-level mechanisms that may further enable those potential innovators to unleash their creativity.

In summary, there are plenty of studies that focus on "the region" but not so much about the people within the region. And those that do are very "elite-focused" looking at scientists, researchers, venture capitalists etc. Thus, there is not much focus on the "normal" residents of a region (especially a weaker and peripheral region) and how they can have an access to innovate. There seems to be a need to ensure this in many regions facing structural and societal problems or in cases where, for example, there are educated and competent people who could potentially participate in finding solutions into "grand challenges" with greater access to innovation support and activities, and better entrepreneurial opportunities.

In terms of the policies and interventions put in place to address these issues, this paper suggests that regional innovation policies are not analyzed much except by describing some successful, often unique or extreme cases (such as Silicon Valley) whereas analyses of policy failures is lacking to a great extent. Nevertheless, there are important

contributions that concentrate on, for example, innovation platforms or issues such as incentives and encouraging milieus favorable for innovation, to which the following section turns.

1.3 New perspectives?

This section includes a short literature review on contributions revolved around an emerging concept of innovation platform and the various ways in which it has been defined and treated. In the end, we will present our own conceptualization which emphasizes a bottom-up perspective, instead of a more policy-led conceptualization of, for example, Cooke & de Laurentis (2010), Cooke (2012) and Asheim et al. (2011). Harmaakorpi and his colleagues (Harmaakorpi 2006; Uotila et al. 2012), on the other hand, have approached platforms as kind of a method to solve practical problems in innovative ways but under a guidance of researchers or other specialists.

So far, innovation policies have benefitted from academic research in terms of, for example, outlining some of the key elements and institutions and interactions between them necessary for innovations to occur. However, theoretical models and approaches deployed have been of rather top-down fashion, despite all of their merits. Due to these characteristics, not enough attention has been paid on micro- and individual-level drivers and motivations –it has been generally assumed that, given all key elements are at place, inside the black box of innovation platforms (clusters, science parks, technology transfer schemes etc.) innovation processes would take place seamlessly. Only recently, some of the new approaches have paid attention to the core issue: what motivates people to innovate? Innovation activities are not “business as usual” but needs people who become inspired (Castells 2000; Moulaert et al., 2007).

Traditionally, a motivation for an innovator has to a great extent been seen to be financial; e.g. in science parks, techno-entrepreneurs have innovated in order to reap the financial benefits later if their businesses will success. Von Hippel (1998, 2010), for example, has noted that some users of a certain technology or product have been active in developing those because of other motivations (usability, new functions etc.). Within the open source software movement (Raymond, 1999), a grassroots engagement has taken place in a large number of specialists around the world, often as unpaid, voluntary inputs to generate code. Open innovation concept, introduced by Chesbrough (2003), was originally about large corporations and their management of innovation although the concept has become popular outside its original context and transformed to consist of other type of actors, too (e.g. Perkman & Walsh, 2007). Crowd-funding introduces an interesting perspective on individuals becoming investors of innovations (Ordanini et al., 2011).

In cases where former industrialized cities have faced economic downturn, people may become motivated to innovate to secure their jobs or to invent them new jobs by innovating, not primarily to become rich. We term this the “inclusive innovation” perspective. Here, we may learn from the entrepreneurship literature that deals with “necessity entrepreneurship” (Block & Wagner 2010). However, this has a somewhat negative tone depicting innovators struggling whereas there is also evidence (Reynolds 2002) of people fulfilling themselves by innovating new solutions, products and applications. Of course, both perspectives are relevant.

Thus, those conducting innovative activities used to be people working in R&D units whereas innovation activities have recently become more usual for a much bigger number of people in a much more varied contexts than it used to be (see e.g. Grimm et al., 2013). It seems to be also politically viable to enable people to innovate, to increase their ability to navigate in increasingly insecure labor markets or to facilitate their efforts to generate new forms of services (Needham, 2007), among other things.

All this means that a rationale of the regional innovation policy needs rethinking. We argue that the innovation platform approach is useful for this as it puts emphasis on the actual micro-level context mostly from the bottom-up perspective. Nevertheless, it has so far been somewhat fuzzy concept (c.f. Markusen, 2003) without a strictly defined content and thus insufficient to advise policy-making. As an interesting emerging form of innovation platform, we will here introduce a concept of a regional innovation factory (RIF, see also Raunio & Kautonen 2014 and Kautonen & Raunio 2014). It can be seen as a more agile, informal, DUI- and community-based model of an innovation platform than, for example, a traditional science park model.

Regional innovation factories are fuelled by individuals’ and small informal groups’ innovativeness and strong motivation to excel. University students, other individuals such as unemployed experts, and their teams are gaining more importance as actors nurturing innovation processes (Raunio et al., 2013). Whereas firms and research laboratories tend to follow their long-term strategies and cut out projects that are not in their core interests, RIFs provide seedbeds for numerous short-term innovation projects to flourish. In a spirit of democratizing, inclusive and open innovation models, phases from idea generation to innovation commercialization may take place in different places and organizations or outside formal organizations. Examples of this can be IPR generated by a firm transferred to a student group to develop it into a demonstration to determine its business value or leftover ideas developed into businesses by specialists who have been laid out from large corporative R&D labs.

We outline the key functions of regional innovation factories to be a) business generation (e.g. new incubator and start-up practices); b) hands-on training of future innovators often in the global environment; c) attracting innovators and investors also from abroad; and d) supporting the emergence of regionally rooted innovation communities. For RIFs, two features essentially make them distinctive from more traditional innovation platforms such as science parks, incubators, and cluster programs: first, community-like dimension and, second, broader and more heterogeneous group of stakeholders and innovators.

The concept of an innovation community has recently become more relevant than before because innovation processes often tend to involve several actors with incentives other than financial ones being the most important. The innovation community may be formed of a group of actors essential to or supportive for an innovation process. Communities may occur within or across organizational boundaries, they may be of different sizes regarding the number of their participants and they may range from local to global. For example, the following definitions and types of communities or networks discussed in the literature may help to define an innovation community:

- A hacker community or other web-based communities, such as open-source software developer networks (Himanen 2004) with their emphasis on mutual help, common goals, and reciprocity;
- A community of practice (Lave and Wenger 1991; Wenger 2000) has some features similar to an innovation community, referring especially to the learning of a group of actors who share the same interest in solving a certain (temporary) problem, yet CoP refers to a more static setting while innovation communities deal with a changing phenomenon;
- Open innovation, networked and user-driven innovation refer to a similar kind of phenomenon, i.e. the need to link more actors to the innovation process in order to create new knowledge or a new product, or to commercialize a new product. West and Lakhani (2008) have attempted to come up with a concept of an innovation community from the open innovation perspective.
- A global innovation network (GIN) connecting distant actors to the same innovation process (Barnard and Chaminade 2011), however, usually focusing on an organizational level, not team or individual level as in the conceptualization in this paper.

In the context of innovation-driven regional development, it has also been suggested that innovation communities (e.g. networks of government-supported agencies, university-based groups, business executive groups, NGOs) could create a “community of communities to support the learning enhancing the regional economic development as well as development of innovation communities themselves” (Lippitz et al. 2013, 63–65). We share the view that a “community of communities” could enhance the innovation-based development and there is a need for a regionally oriented home base for this purpose. Innovation communities are also relevant due to a community-building approach that emphasizes the mutual support among the members. Helping and supporting others without expecting financial reward (not at all or not immediately or directly) are stressed.

1.4 Goal, research questions and structure

The paper intends to conceptualize a new perspective on regional innovation policies, i.e. regional innovation factory (RIF), based on an international scholarly discussion on regional innovation platforms. In order to do that, the paper scrutinizes two contrasting cases to empirically illustrate its main points. The idea is that such RIFs seem to hold a potential to make, among some other measures, regional innovation policies to ‘tick’ due to their ability to provide individual-level incentives that are often non-existent or are not thought of in designing and conducting policies.

Through the empirical outcomes and theoretical elaboration, we aim at contributing to a discussion on value-adding policy development in the field of regional innovation policies. The key questions we aim to answer to are the following: 1) If we accept the view that there is a tendency towards an expansion of participation into innovation activities (see also the literature review), then what does this mean in terms of regional innovation policy-making? 2) Can we identify some of those factors that would make regional innovation policy measures more attractive for a large number of individuals in order to incentivize them to innovate and to engage in entrepreneurship, and what would be some of those institutional preconditions to foster those developments?

This paper examines two case studies and conducts an analysis based on a comparison between them. Firstly, the methodology and methods behind the research will be explained. This is followed by an introduction to the two cases in question both in terms of the regional settings and the specific programmes being examined. Then the cross-case analysis is presented, which looks at the similarities and differences between the two programmes and why these exist. The final section presents conclusions and policy lessons for both of the cases in question but also of wider relevance to policymakers and researchers in the field of regional innovation policy.

2 Methodology and data

The paper will deploy a case study methodology in a form of two cases that gives us a good contrast and allows us to empirically investigate the debates about the applicability and replicability of prominent modes of regional innovation policy in different peripheral contexts. The two programmes selected have similar underpinning rationales and motivations, but have been designed and implemented in quite different manners, and have experienced different trajectories and results. This makes for an interesting study of why one approach has been arguably successful, and the other less so.

We argue that the Technium program of Wales highlights many of those problems related to the traditional regional innovation policies, whereas the New Factory platform of Finland shows some evidence of those features of the ‘new school’ of regional innovation policies. This article presents its findings in a fairly tentative manner, and we cannot assert with total confidence an analysis of the success or failure of the programmes because both are still underway.

This investigation draws on various sources of qualitative data to build up a comparative case study of two different interventions, in two different regional contexts. Innovation is a geographically and historically determined phenomenon (Mackinnon et. al., 2007; Storper et. al., 2011), and so a methodological approach that takes account of these factors was deemed necessary. The case study approach was chosen because it allows us to draw comparisons across different studies and draw out some interesting lessons about theory and policy that could be of use to academics and policymakers in different regional settings (Stake, 1995; Yin, 2009): “*Case study research... offers policy makers opportunities to increase their understanding of complex social settings and programmes in order to inform the policy judgements they need to make.*” (Simons, 2009, p.107).

As such, through the empirical outcomes and theoretical elaboration, we aim at contributing to a discussion on value-adding policy development in the field of regional innovation policies. Two policy interventions were identified with similar underpinning approach and logic, and are considered prime candidates for a comparative case study of innovation interventions to shed some light on why certain interventions in certain places work and others do not.

To elaborate on the specific methods employed and data collected: both empirical case studies were conducted in a similar manner, which allows for comparison and triangulation to take place, both of which are central elements of the case study methodology (Stake, 2005, p.454, and Yin, 2009, p.18). The timescales of the two case studies are different, because the programs under consideration were not implemented at the same time: the Technium program in Wales was launched in 2001 and continues to run, but the New Factory in Finland was implemented from 2008 onwards. Before the analysis of the two cases is provided, some background context about the two studies is provided with further details about the empirical research undertaken in each case.

2.1 Wales

Wales is one of the four “home nations” of the UK, alongside Scotland, England, and Northern Ireland. It has a degree of self-governance; innovation and economic development is addressed by the Welsh Government and Assembly (as opposed to the central UK government and Parliament) and so provides an interesting case of a semi-autonomous region within the EU taking its own approach to innovation. It is important to recognize Wales as a weaker region, with half of the country receiving the highest level of Structural Funds from Europe, and sitting at the bottom of UK regional competitiveness tables (Huggins & Thompson, 2010). The Welsh approach to innovation policy and programs over the last fifteen years has been studied at length, and there is one particular program that has emerged as central to the innovation agenda: the Technium program.

The case study of Wales combines policy analysis and stakeholder interviews to provide a comprehensive evaluation and discussion of Welsh innovation policy. The time range of the case study is from 2001 to the present day. The policy analysis was triangulated with 57 anonymized, semi-structured interviews were conducted with key stakeholders from the business, government and academic spheres in Wales. The purpose of these interviews was to gain the perspectives of the different stakeholders involved either in the formation, delivery, or “use” of innovation policy on how it has evolved and their evaluations of the specific action taken.

2.2 Finland

Finland, on the other hand, has gained a reputation for its national innovation system and yet, after Nokia’s crisis, the country has seemed somewhat vulnerable for global economic restructuring (see e.g. Financial Times, September 7/8, 2013, 5). Much hope has been attached to a large cohort of small, knowledge-based growth-oriented companies that have emerged in a wake of Nokia. However, it is too early to say how the national economy will cope with its recent challenges.

The case of Finland similarly combines policy analysis and stakeholder interviews to provide a comprehensive evaluation and discussion of a Finnish innovation policy especially regarding one of its most successful ongoing activity at the regional level (New Factory). The time range of the case study is from 2007 to the present day. The policy analysis is based on 12 semi-structured interviews with key stakeholders from the business, government and academic spheres in Tampere, the main location of activities (Tampere is the second largest city-region in Finland as well as the second centre of R&D of the country). The policy analysis is partly based also on a participatory action research of longitudinal character. This includes, among other things, one of the authors to participate into the steering group of one of the New Factory sub-programs from 2010 until 2013. Active participation has enabled a researcher to gain material and insights as well as to lead discussions that have accumulated information otherwise difficult to gather. However, there is also much formal data on program performance (results and impacts etc.) available that helps to objectively evaluate the success of the policy.

2.3 Contrasting Wales and Finland

These two regional settings provide us with an extremely interesting comparative case study. Both regions are peripheral in the European sense, with small populations (approximately 5.4 in Finland and three million in Wales) and a combination of city and rural settings (see Table 1). Whilst there is some difference in the relative economic strength of Finland compared to Wales, and this leads to interesting discussions about regional innovation policy and economic

development in divergent economic contexts. The selection of these two case studies was primarily based on the interesting comparisons that can be made between the two programmes, which have a similar foundation of stimulating innovation through variations of the incubator approach but have somewhat divergent experiences. The following section presents the two case studies, explaining the two programmes that have been implemented to create a foundation upon which the discussion and analysis can be built.

Table 1. Comparative data for Wales and Finland.

	Wales	Finland
1. Number of inhabitants, million (2011/2012)	3,06	5,4
2. GDP (PPP) per capita, USD	30,5	36,4
3. Key industries (%; employed person by industry)*	Services 74,5 Manufacturing 10,1	Services 74,6 Manufacturing 14,2
4. Employment rate** (2010/2012)	67	69
5. Level of education, tertiary level (% by population aged 15)	10 have not achieved 5 GCSEs or equivalent	28,2
6. R&D expenditure (% of GVA/GDP)	1,2	3,6
7. Innovation activity (% innov. active of all enterprises)	40,6	56,2
8. Internet users (%; used within last three months)	76	90

*Services (ISIC classification: G–S), Manufacturing (ISIC classification: C) **by persons of working age (15–64) Statistical sources for Wales: 3) National Assembly for Wales; 5) Welsh Government; 6. Office of National Statistics; 7. Community Innovation Survey via UK Government; 8. Stats Wales, Welsh Government Statistical source for Finland: Statistical Yearbook of Finland 2013, Official Statistics of Finland, Statistics Finland: Helsinki.

3 Technium and New Factory

This section presents the two cases that lay an empirical foundation for the analysis. Table 2 shows the main characteristics of the two innovation policy instruments, Techniums in Wales and New Factory in Tampere, Finland. It can be noticed that both instruments have broadly similar characteristics and they aim at nurturing new knowledge-intensive businesses in their respective regions.

Table 2. Main Characteristics of the Two Programmes.

	Techniums	New Factory
Main functions	Support and office space for high tech firms	Services, support and premises for innovation projects and start-ups
Goals	To support (university spin off) high tech firms to commercialize research for economic growth in Wales	To boost innovation culture and entrepreneurship in Tampere Region
Organizational setting	Triple Helix: WDA, Welsh universities, new technology-based firms	Triple Helix: Hermia Group, City of Tampere, Tampere-based universities, heterogeneous group of new and mature firms
Time period	2001, ongoing	2008/2010, ongoing, expansion (international network of units)
Financial resources/budget	£93.4m (appr. 114 M€ total development cost), 89% public	€5.9m; 60.3% public
Notable outcomes	Technium in Swansea originally a success that led to a creation of other sites	98 new firms, 238 participating firms, 3600 students as participants, 600 new jobs
Important to note	In decline (reduction of location from 10 to 4)	Continues to grow and expand to other locations also abroad

3.1 Techniums

One of the most high profile innovation interventions over the last decade in Wales is the Technium programme, which features in all of the economic strategies and represents a significant infrastructural investment. The Techniums provide

office space and support for high-tech firms to commercialise research and turn this into economic growth; it is especially aimed at university spin-offs and high-tech firms, and began its life as an alliance between the universities and the government. The rationale behind the programme was that the universities have expertise in IP, and the Welsh Government in physical property and business support; it was designed as a combination of these elements. The Technium programme is concerned with building the appropriate high-tech infrastructure to create a knowledge-based economy in Wales and aims to address some of the fundamental problems in the Welsh innovation infrastructure, such as the lack of broadband in several areas.

In its original design, the Technium concept encompassed business support, networking activities, and advisory services to make it more than simply a physical incubator space. As the discussion of the New Factory will illustrate, there are common elements between both programmes, which aim to be more than incubators. However, a key difference between the two is whether these extra elements were delivered. In the roll-out and delivery of the programme across Wales these were lost, reducing the Techniums to straightforward physical incubators. The initial Technium in Swansea was opened in 2001, and in 2002 a new regional innovation strategy was launched with a nationwide Technium network at its heart. At the programme's peak, there were 10 Techniums across Wales, but this has recently been cut down to 4 because of high costs and low occupancy rates. Morgan (2012, p.16) expresses his surprise that there has been no public inquest into the "failure of an experiment that cost around £111 million. Through considering both the formal evaluations that have been carried out by other researchers and the insights gained from the interviews with key stakeholders this section provides some explanations as to why the Technium programme has not proved to be successful in Wales.

The most obvious problem with the programme was the loss of the extra innovation elements, in particular the advisory services and management assistance, which led to the replication of traditional incubator approaches (Cooke & Clifton, 2006). Cooke (2003, p.19) does not see the Techniums as innovative, and are simply properties leasing space; a design flaw in the concept is that it replicated old approaches and failed to prioritise management assistance through, for example, allocating part time space to venture capital, legal advice, and management accountancy. As one economic policy-maker put it: "[Techniums] weren't all proper innovation centres".

Another issue was the over-ambitious nature of the scheme and the fact it was rapidly expanded to ten centres across Wales based on the success of the first Technium in Swansea. Little rationale has been found for the roll out of the scheme (DTZ, 2010), and stakeholders highlighted the problems with trying to replicate the success of one case across the whole of Wales: "We've had tendency in Wales if something works well once then it will work ten times better if we have ten times as many, and it appears unfortunately that wasn't the case" (Innovation Policy-maker).

Furthermore, the centres could not be located in the most appropriate locations where the business demand already existed because of the restrictions on where the European Structural Funds could be spent; the Convergence areas of Wales are the poor and rural areas to the North and West. Had the Techniums been located in the economically stronger city areas (such as the capital- Cardiff) it is likely they would have met more business demand from high-tech firms and start-ups located in those areas: "I think that model was flawed in so much as it was necessarily tagged to European funding, which is necessarily tagged to particular areas of Wales... There was no critical networks around it in some areas, I don't believe in some areas there has ever been a business case. There have never been businesses to populate that." (Business Representative)

The scheme was overambitious because it assumed that over 400 incubator spaces could be filled, which turned out not to be the case (Cooke & Clifton, 2006). As a result, occupancy rates were very low, only 4% in the Pembrokeshire Technium (DTZ, 2010): "The 'Emptiums'... there was nobody there. The place was empty." (Professor of Business Studies).

This resulted in very high costs per job of £190, 000 (DTZ, 2010); however Bristow et. al. (2007, p.25) point out that these tended to be graduate, R&D based positions, which form the basis for more high value-added growth in the future.

So, overall the scheme has not been considered a success, and there are a number of specific problems highlighted by evaluators and stakeholders interviewed. More general problems such as a lack of specific objectives and rationales, and the lack of evaluation and monitoring of the programme have also been underlined (DTZ, 2010). One of the founders of the programme, explained that "poor leadership and failure by universities to buy into the scheme stymied its chances", and universities were more interested in creating IP than exploiting it. From the governmental perspective, the former Economic Development Minister blamed failings by senior civil servants in his department; "the concept was sound...the management and roll- out was deficient", and insists despite their claims otherwise, that civil servants did not keep ministers informed on the performance of the programme and major decisions being taken (Davies, 2012). The following interview quotes reasonably summarises the opinions expressed about the programme: "We have seen largely that it has been... Discredited is a bit harsh. But largely it has not been a roaring success" (Business Representative); or: "I think the Technium network is not one of the greatest examples of what we have to show to the world" (Professor of Enterprise).

On a more positive note, Bristow et. al. (2007, p.25) suggest that the Techniums facilitate university-business knowledge transfer thus "laying the basis for a new knowledge economy" (2007, p.25). They also explain that although the cost per job seems very high, the jobs tend to be graduate, R&D based positions, and form the basis for more high value added growth in the future (Bristow et. al. 2007). Although four Techniums do remain, the future of the remaining Techniums is somewhat uncertain. It remains to be seen what the fate of the remaining Techniums will be, and whether

they will be more successful now that the surplus supply of space has been cut. In summary, the Welsh Government's most significant innovation project since its birth in 1999 has been reviewed by researchers and key stakeholders in the innovation system as unsuccessful, and is widely seen to have been a waste of money that can hardly be afforded in a weaker region such as Wales. Whilst the underlying concept was reasonably sound, there were a number of fundamental problems in the delivery and roll-out of the programme which led to it being little more than a traditional incubator approach, providing physical space for innovative firms, which were not filled. However, as one interviewee was at pains to point out, this experience is far from specific to the Wales case study: "Wales is not alone in this. If you go around Europe there are many of these examples of effectively white elephants" (Professor of Economic Geography).

It is important at this point to highlight the divergence in the performance of the different Techniums. Whilst the majority have not been particularly successful, there are two centres that are broadly seen to have been a success and look set to continue to exist in the near future. The first is the Swansea Technium, the original Technium, which is thriving in its location at Swansea University. The second is the St. Asaph Technium, which is focused on the strong Opto-Electronics sector in the area and has strong links to Glyndŵr University in the north of Wales. Of the eight centres, these are the only two that Welsh stakeholders consider to really have been a success.

3.2 New Factory

Tampere city-region is the second largest by population in Finland, and also the second after the capital city-region Helsinki as a node of Research and Development by its three universities, large R&D units of the private sector (e.g. largest R&D facilities of Nokia Group world-wide) and resources (e.g. financial inputs for and personnel in R&D). However, as all industrial centres of Finland, the region has faced pressures of globalization and industrial decline for decades. On the other hand, the region headed by the City of Tampere has explored and experienced regional innovation policies already from the beginning of 1990s with many policy successes as well as failures (Sotarauta & Kautonen, 2007; Kostiaainen & Sotarauta 2003; Valorinta et al. 2010). After a construction and long-term operations with science parks, "traditional" incubators, university-industry technology transfer schemes and cluster programs, some of the policy-makers in Tampere came up with a policy model that has become widely recognized as a good practice. Representing both private and public organizations, these policy-makers had gained a considerable experience of innovation policy and they wanted to combine these lessons with their aspiration to create a more "agile" and inspiring instrument in a fashion of open innovation.

The New Factory is a combination of several "engine rooms" (*Demola*, *Protomo*, *Suuntaamo* and *Accelerator*), which have their own functions but work towards the same goal of creating new businesses through and from open innovation processes. Demola is an environment in which to generate prototypes and demonstrations from ideas coming typically from private firms, developed in projects by multidisciplinary student teams. Protomo functions in a somewhat similar way, but instead of students as its "workers", it employs self-employed entrepreneurs and experts often in a phase of career transition. Suuntaamo is a kind of open test laboratory for new products and processes, itself already a privatized spin-out of New Factory. The newest engine, Accelerator, provides new businesses with various business service resources and competencies, including help to find matching venture capital. In addition, a new First Customer initiative helps young firms to identify and approach their very first business-to-business customers and partners. Common to each engine is an attempt to operate on principles characterized as "customer focused, down-to-earth, agile, cost-efficient and effective". So far, the most long-standing and also most visible engine of the New Factory is Demola. A typical collaboration scenario in Demola is the following:

- A firm that has a concept or idea that is subject to high levels of uncertainty decides to outsource the development process for Demola to come up with a prototype or demonstration through further development and testing;
- The concept is evaluated and formalized into a project design by Demola;
- A multidisciplinary student team is built around the concept, gathering student candidates from the universities and polytechnics, and a project contract is signed by the stakeholders (the firm and the team) including issues related to IPR and the timetable;
- Concept development starts, lasting 3–8 months, with sparring and support by Demola and the firm, and including a concept or prototype testing conducted with the users; and
- Demonstration of the concept or prototype is carried out by the student team, followed by project evaluation and the finalization of license agreements.

The benefits of Demola are not limited to a single firm, since the student team also has a chance to utilize the created immaterial asset by setting up a start-up company in the case in which a firm does not acquire a license for the IPR. Students may also be recognized for their talent, leading to employment. All the IPR generated during the project belongs to the student team. At the end of the project, the partner firm can acquire a license for the results and reward the students for their work according to the performance criteria agreed earlier. The method is notably effective, due to the well-defined IPR framework (avoiding the contractual costs of collaboration), the focus on the concepts preselected by firms and the diverse set of skills and ideas of the students working on it.

Behind the New Factory, there are several key actors of the regional innovation policy, including Hermia Ltd. (a semi-public local innovation agency) and the three universities located in the city. The essential characteristics of the New Factory are openness and many community-like features that make it stand out from the traditional innovation platforms.

New Factory was established in the spring 2010 following the convincing experiences received from the two initiatives of Demola and Protomo established in 2008. NF is a key part of a new local innovation program, Open Tampere, which was launched first as a pilot in 2010 and then as a large-scale program from 2012 onwards, scheduled to last until 2018. This program aims at fostering new growth of firms and international businesses and at promoting a continuous innovation-based transformation of the traditional industries. It also involves stakeholders such as students, other citizens and heterogeneous local communities in participation in many ways.

In less than four years, New Factory has succeeded in generating 583 demonstration and prototyping projects with 238 partner companies; helping to generate 98 startups and 600 new knowledge-intensive jobs; and attracting 18 million euros of funding for startups and innovators (Matikainen 2013). Costs of the New Factory are about 5,9 million euros for a period from 2008 until the end of 2013.

The Assembly of European Regions announced New Factory as winner of the European Innovation Award in 2010. In addition, Demola received the Baltic Sea Region Innovation Award in 2012. New Factory is well recognized also on a national level and used as one of the key national examples of new open innovation paradigm by the Finnish Ministry of Employment and the Economy. NF is located in “Kuusivooninkinen” (six floors), an old cotton factory building constructed in 1837, by then the tallest factory in the Nordic countries. Virtually no funding at all is spent on the premises except for the rents.

These open innovation platforms are environments for product and service development and for new market creation. Their processes, from idea generation to real business, are guided by clear, explicit procedures that have made operations easy and have left space for creativity. However, a fundamental idea behind the obvious success of New Factory is that its engines have attempted to create a ‘community spirit’ among the participant individuals and are, at best, fuelled by participant individuals’ real, genuine motivation.

Advantages of Demola’s and Protomo’s platform concepts have been recognized elsewhere. Consequently, the Demola network, for instance, has already spread to eight other European cities and is about to extend to other continents, too (Demolas abroad, at present, in Norrköping, Linköping, Malmö, Lund, Vilnius, Budapest, Riga, and Maribor). Protomo network has diffused rapidly to several other cities (8) in Finland.

However, there are some challenges for the New Factory: Mostly based on project-funding (of which 60% from public sources), continuation in the future is to some extent open even if Demola, Tampere, was able to recently come to an agreement with the three local universities and the city on a long-term funding principles. Another future issue of NF is how to achieve a big regional economic impact. Although the numbers of participant firms and people are impressive, there are also a considerable regional economic structural change taking place which sets a lot of future expectations for the whole programme.

3.3 Cross-case analysis and conclusions

In this section the two cases of Technium and New Factory are compared and contrasted to draw some lessons about innovation programmes that follow a broadly conceived incubator approach to economic development (see Table 3). There must be some caution exercised when drawing these conclusions due to the heterogeneous nature of the two regional case studies. The situation is not so simple to be able to say that one approach is successful and another is not, and the two programmes are functioning in different geographical, political, and historical contexts. This paper appreciates that a number of different factors impact upon the success of a programme or implementation and that it would be overly simplistic to pinpoint particular elements and suggest causality of success or failure. Instead, this paper considers firstly the similarities and then the differences between the two approaches in order to draw out some lessons about how incubator approaches can be better employed to achieve increased levels of innovation at the regional level.

The similarities between the two programmes are as important as the differences because they underpin the logic behind comparing the two approaches. Both programmes are underpinned by the same principle of providing the space and support for innovation activities to take place, as per the rationale presented in the first section of driving regional economic growth through innovation supports. Both approaches are premised on the assumption that encouraging indigenous innovation, as opposed to importing or transplanting innovation from elsewhere along the lines of inward investment, can help drive economic growth at the regional level and is an appropriate strategy for peripheral regions of Europe. Another similarity is the focus on universities as sources of ideas, knowledge and human capital; both programmes were designed to have strong links with regional institutions. They both build on a long tradition of incubation and science park approaches in Europe and beyond. However, despite these fundamentally similar underpinnings, the two programmes have some important differences that are important to examine in order to draw out further lessons about the usefulness and best-practice regarding incubator style approaches in the peripheral region setting.

Table 3. Main differences between Techniums and New Factory.

Techniums	New Factory
Top down	Bottom-up
No focus on incentives	Incentives for key stakeholder groups important
Participation: limited to few groups of stakeholders (“innovation elite”)	Participation: widely distributed including new groups of participants (“democratized”, inclusive)
Much focus on physical space	Much focus on activities and practices
Organization-oriented	Individual- and team-oriented (community aspects)
Building new incubators from scratch	Re-generating old buildings into new uses
High capital investment	Lower capital investment
Quickly rolled out to ten different locations	Smaller scale, yet two successful sub-programmes rolled out to new domestic and foreign locations but without top-down control and guidance

Perhaps the main difference between the programmes is the top-down nature of the Technium programme, compared to the more bottom-up approach taken by the New Factory, which is much more community premised. Whilst the original Technium in Swansea developed in a bottom-up manner, arising from local needs and the impetus of Swansea University, as the programme was rolled-out across Wales it became increasingly top-down and prescriptive. The Welsh Government attempted to emulate the successes of the Swansea centre in ten different locations across Wales, and as the discussion above illustrates, this was largely unsuccessful. The connection between local needs and supply of infrastructure and services become disconnected, and the rationale for implementing the programme across Wales was lost. The New Factory, in contrast, takes a more locally-based approach to economic development, concentrating more on the grass roots level. It is important that the New Factory programme retains this local connection, and that its successes at the local level do not lead to a replication as was the case with the Technium.

The conceptualization of the nature and process of innovation that both programmes take is somewhat different. For New Factory, the key starting point is innovation project work whereas in Techniums, physical spaces were first set up and only then followed by activities targeted to get innovation activities to go on, which is quite typical for the traditional approach of science parks. New Factory would not exist without the innovation projects, there is all the time a big flow of projects beginning and ending (with more than 90 per cent license buy-in from the participating companies in Demola, for example). In stimulating innovation activities from the ground-up, the New Factory avoided the problems encountered by the Technium programme of there being a lack of business demand for innovation services in the area. Having already pump-primed innovators in the local area, the New Factory ensured a lively and fruitful environment within which to situate an incubator; the “local buzz” was already created. The New Factory programme has shown a greater appreciation of innovation a participatory and interactive process that can come from anywhere, whereas the Technium was quite linearly focused on spin-outs and university based innovation.

Another key difference between the two approaches is how far beyond the traditional incubator approach they go. The traditional incubator approach is premised on providing the space for innovative high-growth companies to set up, usually in association with a university or research institution of some sort. However, these programmes were both premised and established along the lines of an incubator-plus approach, to incorporate wider networking, business services, and supportive activities. A major problem with the Technium programme in Wales is that these elements got lost as the programme progressed; the management and innovation support elements did not materialize, and the centres descended into purely physical manifestations. In contrast, the New Factory has successfully established a supportive network-based environment where the people are more important than the physical property. There are many measures taken to ensure the programme retains its status as a more-than-incubator including networking events, training, showcases et cetera. These other activities also existed at the outset of the Technium programme, providing a lesson as to how priorities can change and elements of a programme can get lost as it gets bigger and bigger. It is important that the New Factory retains its extra features that ground it in the participatory and bottom-up mode of innovation.

Table 3 shows the differing cost between the two approaches; this is partly to do with the scale and length of the programmes because the Technium was running already for several years before the inception of New Factories, and at its peak totaled ten centres across Wales. Indeed, the scale of the programme was one of its core problems as the interview quotes provided above illustrate. Another reason for the difference in cost was the manner in which the New Factory regenerated existing physical property, whereas the Technium programme built new centres at great cost to the public purse. Wider benefits stem from economic regeneration, and the New Factory programme is breathing life back into the ex-industrial buildings that dominate the Tampere skyline. This is adding to the wider feeling of local buzz and excitement around innovation activities, and is bringing wider benefits to the residents of the locality beyond the purely economically derived benefits to the individuals and companies there. In the Technium case, the centres were often built on “green-field” land in locations beyond the towns and cities. Whilst many of the buildings look impressive, they are

not contributing to improving the local urban environment or providing any services or access to local people. They are very much “cathedrals in the desert”.

The difference in resources could be an important factor behind the progression of the two programmes: due to the Convergence funding available in Wales, there was a large financial resource available to develop the programme. This is in contrast to the New Factory, which was necessarily much more constrained. Perhaps, paradoxically the constrained resources of the New Factory may have led to it being a more bottom-up and community-focused intervention. To elaborate, the New Factory involved a small local network with representatives from international business and regional development agency and universities, with rather scant funding resources were forced to focus on content. This differs greatly from abundantly funded government and EU program in Wales, which was delivered by the central funding agency on a much larger scale with relatively little local impact. While the biggest problems in Welsh case were related to extension phase of the program, and while the original Technium in Swansea was successful, also in the case of New Factory the expansion phase may be considered as critical. The expansion has taken place thus far through Demola and Protomo activities, but both in very different modes, seems to have avoided some of the problems of replicating approaches in different contexts by maintaining the demand-based and bottom-up approach.

4 Traditional model to regional innovation factories

4.1 Discussion and lessons learned

In this section, we provide a discussion based on the comparison of the two cases presented above. From this discussion a number of policy lessons emerge (see Table 4). Lessons emerge for policymakers in the two regional settings under examination (Finland and Wales) but also for those in other regional settings considering or attempting to implement similar incubator-based approaches. There is also an interest to researchers examining regional innovation policies in programmes, who may see parallels and lessons from their experiences elsewhere.

Table 4. Points of interest between the traditional and the new approach to broadly conceived incubation processes.

Approach	
Traditional	Participatory (Regional innovation factory)
Organizations: university top research, science-based firms	Individuals and teams: university students, freelance experts, young entrepreneurs
Knowledge: R&D, IPR	Capabilities: training/mentoring, practices
Science to market, STI	Interactive, problem-driven, DUI, with STI
Closed innovation, exclusive practices	Open innovation, many potential stakeholders
Formal collaboration and legal contracts	Community-based ideals with some formal contracts backing up
Organized activities with occasional “cafeteria effects”	Organized chaos
Business from science and technology	Innovations with creative experimentation
Top-down; “innovation infrastructure first”	Bottom-up; “innovation projects first”
Participation: limited to few groups of stakeholders (“innovation elite”)	Participation: widely distributed including new groups of participants (“democratized”)

By examining the successful cases within both the Technium and New Factory examples there is a tentative conclusion to be drawn about the geographical setting of incubatory approaches, and questions about the relevance of the approach in more rural settings. If we examine the first Technium, in Swansea, began in quite a local-focused manner, meeting the needs of the city by providing a physical space and the support for new high-growth firms and spin-outs, many of which were associated with the local university. The concept worked well in this setting; Swansea is a city of 230, 300 people with two universities (and other further education institutions) and is the second centre of Wales outside of the capital, Cardiff. It compares almost directly with Tampere, a city of 213, 217, which also has two universities and other higher education institutions. Whilst more similar cases would be required to test this hypothesis further it does seem that a network based incubator approach can work well in a smaller city setting with strong interlinkages between universities, businesses, and local residents, and clear governance that can steer a programme in the right direction for the city. In a smaller urban setting like these, the networks are tight and lines of communication between decision makers, planners, entrepreneurs, academics etc. are likely to be good, allowing the different stakeholders to come together in a manner that is constructive and honest. Experience of conducting research in both the Welsh and Finnish setting proves that networks are well integrated and the bottom-up approach is relatively easy to implement.

However, as the Technium case shows, it is a very problematic approach in more rural and sparsely populated areas where the network and demands for such services simply do not exist. The problems in the Technium programme

emerged when it was rolled-out across Wales based on the success of the first centre; whilst the original Swansea centre is still thriving the Techniums in other parts of Wales did not fare so well. The experience of the Technium suggests that these incubator-style approaches may be inappropriate in more rural and peripheral areas with lower population and less businesses to populate the centres; it also seems that having a university located nearby is essential to the success of the centre. We suggest that an important lesson for the Finnish policymakers going forwards is not to attempt the replication of the New Factory in rural settings if the demand is not already there and the networks are not already in place. Instead, if the approach is going to be attempted in such locations, a different conceptualization may be necessary, in close collaboration with local stakeholders and actors to design a variant of the approach that is appropriate to the context, needs, and existing resources.

The “people centred” elements of the New Factory have found to be an important and unique aspect of its success to date. As explained above, the approach to innovation being taken is one that is very much participatory, democratic and community focused. It goes beyond the linear understanding of innovation that it is driven mainly by IPR and R&D often situated within universities, to one that is interactive and evolutionary. We suggest that this people focused approach is much more in line with thinking at the European policy level about “Grand Challenges” and solving big problems through innovation in a more participatory and bottom-up fashion (EC refs). Especially in regions that are suffering from issues of unemployment and slow growth we suggest that this mode could be especially useful. In Wales, this has been an important priority for many years, in light of the de-industrialization of the coal and steel industries thirty years ago. In Finland, it could be increasingly important going forwards, especially in the Tampere region where the strength of the regional economy was driven by, though not completely dependent, on the success of Nokia. This point has a much further relevance to other regions struggling with these issues. A mode of innovation policy that is more entrepreneurial and bottom-up in focus can allow regional policymakers to work with what they already have in their regions, empowering local populations to innovate and take control of their economic futures. We suggest the New Factory model as a means of instilling this approach at the regional level, as part of a broader approach to innovation and economic development. The lesson of the Technium serves to remind us of the importance of retaining the “people” and “community” elements of a programme because when these became lost, the programme began to fall apart.

An important lesson that the New Factory teaches us is one that is very visible to any interested observer of the Tampere region and this is the benefits of a regeneration based approach to incubators, rather than a construction based approach. Of course this insight is very much context dependent, and assumes that there is available and appropriate ex-industrial building stock to be developed, but the wider benefits of this approach, beyond that of saving money, is clearly visible. As well as providing the economic benefits to the companies, entrepreneurs, and researchers involved in the New Factory, the programme is providing a wider service to the city and its residents by re-generating and injecting “local buzz” into the area. Having asserted that a major problem with the Technium programme is that it became too property rather than people focused, it will not do to over-emphasize this point, but it is important to recognize the wider benefit that well designed property approaches can bring to the region rather than creating these “Cathedrals in the Desert” which suck in huge amounts of money and provide little benefit to the local populations.

4.2 Conclusions

If it is assumed, as we do in this paper based on a theory and the two illustrative empirical European cases, first, that participation into innovation activities is expanding at least in many European regions, and second, that instead of overinvestments in heavy innovation infrastructure, economic growth and well-being in mature knowledge economy might be often generated by many non-financial incentives for individuals to use their creativity and skills. It should be considered whether we should broaden the idea of a human from ‘homo economicus’ towards ‘homo ludens’ (Huizinga 1949) when incentives and environments to support the economically feasible use of intellectual capital is promoted. Consequently, we also have to reframe the policy approach, as well as the research agenda of the innovation studies.

What policies, incentives and institutions could be appropriate? What is a sufficient innovation infrastructure? To some extent these questions already have some preliminary answers. For example, several contributions emphasizing the fact that “one size fits all” should not be applied refers that more the same is likely to fail also in building of innovation infrastructure. Further, content of policies, at the level of individuals rather than of macro-structures and groups of institutions should be more carefully designed. This requires more understanding of the local needs, as well as capabilities to apply very specific policy tools in specific contexts. The role of national policy has to give room for the more regionalized and even local approaches.

Alongside the specific lessons and suggestion we can make based on these two examples, there are some wider insights about the nature of innovation policymaking practice and the benefits of cross-region analysis. We argue strongly in favour of this mode of research, and also policymaking, and this paper has illustrated how regions can learn from each other’s experiences in both the positive and negative.

According to Clifton & Diaz Fuentes (2014), for example, OECD’s policy advice and transfer initiatives are not sufficiently funded and followed. Further, policy advices are often on a too general and abstract level or they are even kind of “umbrella” policies rather than detailed examinations of functional and non-functional solutions in certain socio-economic conditions. The detailed benchmarking and case studies may provide at least a partial solution for this dilemma, and ease the search of functional performances with the goal of improving the practices of other organisations (Niosi, 2002).

Whilst the Technium programme has not proved as popular as the Innovation Factory has proved to be, there are a number of useful and important insights that can be drawn from both cases equally. We can learn as much from each other's mistakes as we can from each other's successes. Welsh policymakers were trying to do something new and different in the early part of the new millennium, and it was not overly successful; however, we should praise their vision and effort. They are far from alone in trying to replicate successful incubator approaches across Europe and worldwide, and were following advice from leading regions in doing so. The Finnish case is illustrative of how this best practice from elsewhere can be combined with local capabilities and made relevant to the local context; the combination of borrowing good ideas from elsewhere whilst also taking a "bottom-up" approach to policymaking is recognized as the ideal. It remains to be seen how successful this programme proves to be as it progresses and grows, and the reader is reminded of the Technium's early successes and the later problems it encountered as it expanded.

The regional innovation factory approach is suggested as a more-than-incubator approach to regional economic development and is certainly looking to be a promising and positive style of innovation programme. However, we are not suggesting that it be transplanted wholesale in a one-size-fits-all manner to other regional locations. Indeed, the positive aspects of the approach – its bottom-up nature and community-focus – are unique and totally context dependent.

Expectations on social innovations by citizen participation in Japan

Kazuhiko Kawasaki

Tokai University

Japan has entered the era of “shin-shimin” (new citizens) since around 1990.

This paper aims at identifying some “demand pull” factors as well as “supply push” factors for this transition.

A case of “EbetsuShift Forum” illustrates even university students are becoming active “shin-shimin” (new citizens).

1 The era of shin-shimin (new citizens)

1.1 The era of shin-shimin (new citizens)

Simon Andrew Avenell categorizes phases of civic thought and activism in postwar Japan as, nascent, formative, elaborative and transformative followed by the era of shin-shimin (new citizens) from around 1990.

Table 1. Phases of civic activism in postwar Japan.

Phase	Movement	Identities
Nascent	Cultural circle activism Ca 1945-55	The people
Formative	The Anpo struggle 1958-60	Shimin
Elaborative	Beiheiren 1965-74	Shimin as Japanese and Asians
Elaborative	Antipollution and Antidevelopment Protest (ca 1964-75)	Shimin as jumin (local residents)
Elaborative	The movement for citizen participation (ca 1963-75)	Shimin as kokumin (Japanese nationals)
Transformative	The new civic movements (ca 1975-89)	Shimin as seikatsusha (inhabitants of daily life)
?	The rise of civil society (ca 1990-present)	Shimin as shin-shimin (new citizens)

(source: p. 241, Avenell, S.A (2010): Making Japanese Citizens –Civil Society and the Mythology of the Shimin in Postwar Japan. University of California Press)

The shin-shimin is regarded as a self-reflexive, self-responsible subject open to collaboration and engagement with traditional opponents, all in the name of fundamental social change. (Avenell, S.A 2010, 251)

1.2 Seven factors for the rise of shin-shimin

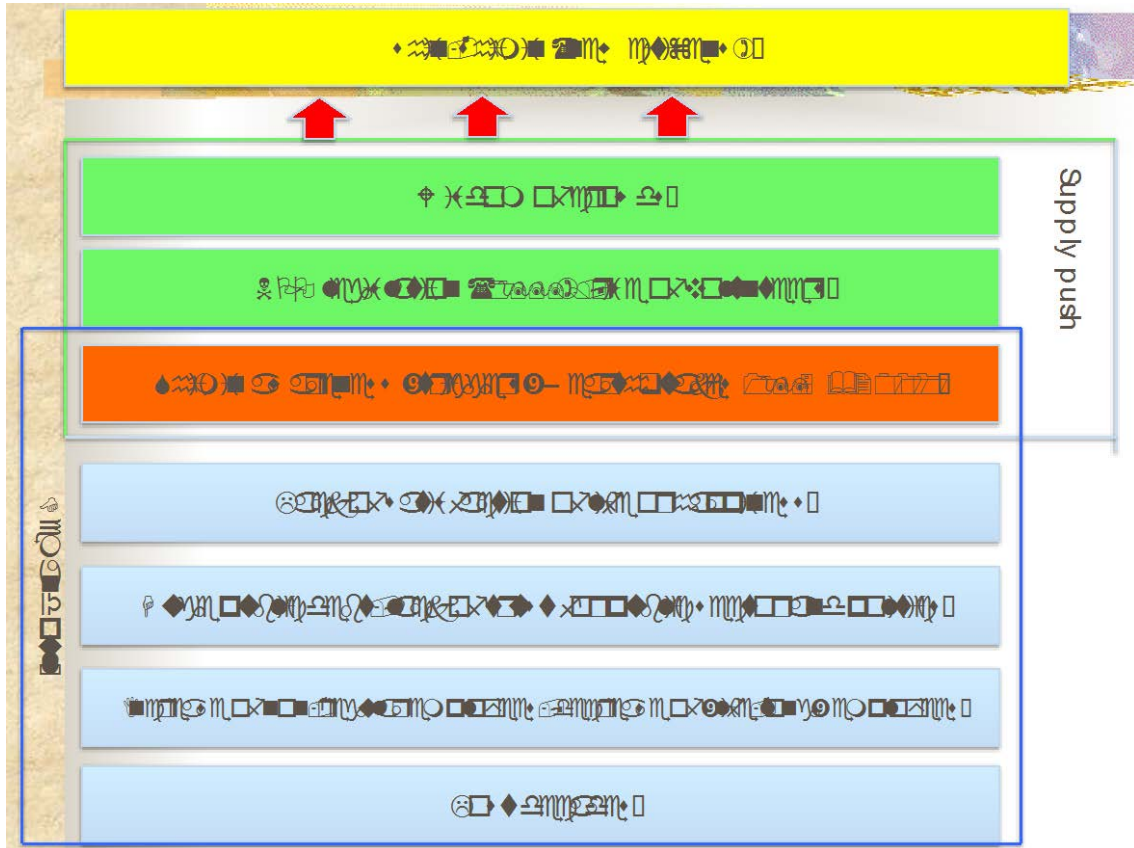

Below is a trial to analyze and identify 7 factors for the rise of shin-shimin from demand-pull and supply-push sides.

1. Japan’s “lost decades“
2. Increase of non-regular employees, decrease of “life-long employed“
3. Huge public debt, lack of trust for public sectors and politics
4. Decreasing satisfaction of life or happiness

5. Shin-shimin awareness “triggers” - the earthquakes in Kobe (1995) and in East Japan (2011)
6. NPO legislation (1999) and boom of volunteers
7. “Wisdom of crowds”

1–5 can be regarded as “demand pull” factors while 5–7 can be seen as “supply push” factors for the rise of the civil society or shin-shimin (new citizens)

Exhibit 1. Demand-pull and supply push factors for shin-shimin.

1.2.1 The lost decades in the Japanese economy

The Japanese economy since the beginning of 1990’s is often described as “The lost decades“. There are many evidences for this description.

GDP per capita in Japan was one of the highest in the world at the beginning of 1990’s but was down to the 18th to 19th in 2006-2008, and 25th in 2013. (World Bank online)

Japan’s share of world’s total GDP was 17.7% at the peak (1995) , which is now down to 8%(2007) and 5.4% (2013).

IMD’s world competitiveness yearbook’s rankings of Japan showed a steady decline from No. 1(1991-2) to 24th(2007), 22nd (2008) ,17th(2009), 27th(2010) and 21st(2014).

Exhibit 2. Annual GDP growth 1999–2011.

source: OECD Factbook 2014

Exhibit 3. Real GDP growth in OECD countries 2000–02, 2010–12.

Source: OECD Factbook 2014

1.2.2 increase of non-regular employees, decrease of "life-long employed"

Japanese labor market became well-known with "life-long employment" after the World War II.

This structure is however changing rapidly during the last decades and the share of "non-regular" employees are increasing as the exhibit shows.

Exhibit 4. Share of non-regular employees in Japan 2002–2013 (%).

1.2.3 huge public debt, lack of trust for public sectors and politics

Public debt of the general government in Japan as compared to GDP is by far the highest among the OECD countries.

Situations are similar even for local municipalities. Not to mention Yubari, a city on Hokkaido, most northern part of Japan that went bankrupt in 2007, most municipalities and governments have less possibilities for policy measures than before.

Exhibit 5. General government debt/GDP 2011.

1.2.4 decreasing satisfaction of life or happiness

Easterlin paradox or paradox of happiness is applicable even in Japan as the figure shows. (Easterlin, 1974)

In recent international comparisons by OECD (How's Life?) or World Happiness Report, rankings of Japan are around 20th. or 43rd.

Exhibit 6. The degree of life satisfaction does not increase in Japan.

There are active ongoing debates on happiness in Japan.

Major points of discussions are that it is not money or material things that make people happy but rather 1) feeling good, 2) engaging fully, and 3) doing good as positive psychology points out. (Siegel R, 2011)

Many feel good and happier for example by engaging or volunteering fully for others and for the society.

1.2.5 Shimin awareness "triggers" - the earthquakes in Kobe (1995) and in East Japan (2011)

The Great Hanshin Earthquake (January 17, 1995) took more than 6,000 people's life.

The Great East Japan Earthquake (March 11, 2011) with tsunami caused loss of nearly 16,000 people and the meltdowns of the nuclear power stations in Fukushima

These earthquakes and disasters are regarded as triggers for shimin awareness by many researchers. They offered concrete realities to act and help the victims. Many companies and universities offered possibilities to take off for volunteer works to help the victims.

Persons who took part in volunteer work in the areas affected by the disasters increased to 4.3 millions in 2011, three times more than in 2006. (Ministry of Internal Affairs and Communications)

1.2.6 NPO legislation (1999) and boom of volunteers

After the Great Hanshin Earthquake, NPO (non-profit organization) legislation was introduced in Japan in December, 1999 and the number of registered NPOs has been increasing as the exhibit 7 below.

Areas of volunteers activities cover on health, for the aged, for the handicapped, for children, on sports, culture, art and science, for regional development, for safety promotion, for sustainability, disaster related activities and so on. (Cabinet Office of Japan, 2014)

Volunteers and NPOs are surely some symbolic indicators of civic society, citizen participation and democracy.

However, Japan has much to catch up with compared to the many nations in the West. For example, Sweden which has only 7% of population in Japan, has some 200,000 NPOs and 86% of all citizens between 16 and 84 years old are members of NPOs. (SCB, Undersökningarna av levnadsförhållanden, 2008) Nearly half population (16-74 years old) has taken part in volunteer work during the last 12 months in 2009. (Svedberg L., 2010)

Pro bono (being, involving, or doing professional and especially legal work donated especially for the public good), social entrepreneur, parallel career, "Altruism driven economics" (Tateoka, 2006) are some key words that attract especially younger Japanese workers.

Exhibit 7. Number of NPOs in Japan 1999–2014.

1.2.7 “Wisdom of crowds“

There are increasing numbers of citizens who take part in different public discussions in Japan.

One reason might be the trust for “Wisdom of crowds“ (Surowiecki 2005), instead for “wisdom of experts or specialists“ (Nishigaki, 2013). Especially after the meltdowns of nuclear power stations in Fukushima, trust of Japanese for experts or specialists has decreased radically. Their argument is that experts are good when the problem is identified, while much of the current problem handles about to find out and identify the problem. Then “wisdom of crowds“ must take part in.

Most of municipalities invite citizens to take part in policy discussions actively.

Seminars and workshops on facilitations or coaching to make it easier for citizen participations are very popular and attract many.

2 EbetsuShift Forum - a case of students’ initiative

Activities of shin-shimin (new citizens) are rising in many areas of life and policies as mentioned before.

This part takes up a concrete case by university students to illustrate movements of shin-shimin are affecting even students.

On Sunday, March 13th, 2011, an event named EbetsuShift Forum (<http://ebetsushift.jimdo.com/>) was held in Ebetsu, a adjoining city to Sapporo in Northern Japan. It was only 2 days after the Great East Japan Earthquake with tsunami and the meltdowns of the nuclear power stations in Fukushima.

EbetsuShift Forum’s main guest was Prof. Akira Suzuki, Nobel prize lauriate in chemistry and was organized by some 50 students from Sapporo region.

I had a course at a Rakuno Gakuen University in Ebetsu in 2010/11 semester on regional development and then the news came in that prof. Suzuki, resident in Ebetsu will receive the Nobel prize.

The students wanted to organize a seminar with prof. Suzuki as a main guest to discuss on regional development and vitalization of Ebetsu City.

It was not so easy though. Among others prof. Suzuki became a super star in Japan and was much occupied with speeches and other engagements. He did not have time simply.

The strategy of the students was then to invite the Swedish ambassador in Tokyo also that might give some pressure to prof. Suzuki.

This strategy worked out and prof. Suzuki promised to join the forum with the Swedish ambassador Stefan Norén.

Ebetsu city has a population of 120,000 and has a character of an “academic” town with not less than 6 universities and colleges with 12,000 students totally.

More than 45 students from 7 universities in the Sapporo region formed an organizing committee for “EbetsuShift Forum”.

The forum got much attention from the media and was carried out successfully with a total of more than 200 participants.

The program consisted of 2 parts.

Part 1: presentations by students followed by a “world café” on regional development in Ebetsu

Part 2: Discussion on future of education with among others prof. Suzuki.

According to an evaluation survey of the participants, they were much impressed by the initiatives and achievements of students and satisfied with the conference. Many participants looked forward to the continued session to come. Even if it was the dark period directly after the disaster, many saw the light in the future by the power of young students.

Below is an example of voice of a participant.

-Much impressed by the power of students. Want to continue to discuss more. I can see the future of Japan more positively now.

Impressions by the students are below.

“I have never been so much excited as this event before in my whole life. Very nice to know that participants could value our efforts. EbetsuShift Forum became an unforgettable experience for me.” Kazuki Yamada, chairperson of the organizing committee.

“It was not so easy to organize and lead nearly 50 students. But the positive evaluations by the participants gave tears in my eyes and I am much satisfied with the results we could attain.” Rina Noguchi, vice chairperson of the organizing committee.

I was also much impressed by creative powers of the students and am confident that the efforts and the experience gave them self-efficacy.

Exhibit 8. presentation by students.

Visualization of services - Closing expectations gaps and increasing service quality

Jana Koers, Vanessa Lellek, Prof. Dr. Torben Bernhold, Lamis Youssef

University of Applied Sciences Münster

The Paper presents a solution to eliminate any possible expectation deficits on the client side within the delivery of services by using visualization methods. The existing options for services are screened within a literature review in service management and, afterwards, reflected with experts from the Facility Management sector. In referring to these results, a method will be presented which supports a continuous exchange of information within services and hybrid bundles of services in specific. Using the example of the planning process of real estates as hybrid value creation, a service visualisation which makes the planning process more transparent to the customer and the other stakeholders is presented.

1 Introduction

Service industries play a progressively essential part in our overall economy (Kellogg & Nie, 1995). However, the wealth of visualization and planning methodologies and tools available in manufacturing industries is not as abundant in the service sector. Many new services fail to realize their objectives, which could result in customer dissatisfaction with potential long-term consequences (Smith, 2007), due to the fact that important dimensions of service processes are often missing or, at best, only vaguely implied (Kellogg & Nie, 1995). Furthermore, as numerous researchers have indicated, direct application of concepts and methods developed from the manufacturing arena to the service sector is inadequate. Service production encompasses all processes necessary to deliver a service, including customer interaction, management activities and service production operation (Fließ & Kleinaltenkamp, 2004). Therefore, the use of product-based models and language to define and manage service businesses confines thinking in a way that limits innovative management approaches. In addition, layout issues are more complex than in the job shop of the manufacturing arena as one must also examine the customers' movement and contribution in the service process (Kellogg & Nie, 1995).

In addition to this, the procurement of services entails uncertainty for customers due to the heterogeneity and immateriality of services, which are intangible activities designed to achieve a certain range of desired outcomes (e.g., technical, informative, and knowledge-related activities). It is not obvious to the customers what they will receive for their money before the service purchases (Bernhold, 2010; Meyer, 1991; Lasshof, 2006). Likewise, there is a difficulty for the service provider to market their services without the possibility of presenting the final product. The intangibility surrounding a service makes it hard to set standards (Lim, Kim, Hong, & Park, 2012) and complicates the conventional management tasks of designing, constructing, conducting and controlling the performances which go into creating a service (Kingman-Brundage, 1989). In addition, because of the intangibility of many results, perceptions and potential gaps between perception and reality are more significant issues in services than they are in products (Lim, Kim, Hong, & Park, 2012). Expectations are complex and dynamic notions that are affected by an array of aspects. Initial expectations set the thresholds that will determine whether disappointment, satisfaction or delight results from an encounter. Research shows that when assessing quality of process and result, customers have a 'zone of tolerance' between their expectations and what they perceive they are receiving. The zone of tolerance is very narrow after initial service failure (Harvey, 1998). Since customer satisfaction is measured inversely by the gap between expectations and perceptions, attracting customers with lofty prospects that cannot be met, will result in disappointed customers, frustrated servers, and negative word-of-mouth that will repel prospective customers (Harvey, 1998). Additionally, customer satisfaction has a substantial effect on follow-up services, or possible long-term partnerships, which can have advantages for both parties. Thus, clear communication and close cooperation between marketing and operations is pivotal to success (Harvey, 1998). One possibility to avoid the disconfirmation of satisfaction is to integrate the customer into the service process very early on, or to show them the service configuration before its procurement. At the same time, the presentation of service results is needed at the beginning of the delivery process. Therefore, it is important to reduce information asymmetries associated with the service procurement to reduce uncertainties in service procurement for both sides. It should be obvious to the service provider that the customer is an important and active element in the value chain and that their needs and expectations also have influence on the service result (Lasshof, 2006; Chase et al., 1983).

In this paper, the described problem is examined more closely using Facility Management (FM), an innovative service sector, as an example. Property-related services, as a form of hybrid value creation products, include the realization of individual customer requirements and solutions within the planning, building, and operation of real estates. In this context, a broad variety of stakeholders are involved (planners, architects, engineers, client, users) and should be integrated in a life-cycle-wide planning process to ensure that the potential of hybrid value creation can be implemented during subsequent lifecycle phases. Due to the complexity of such product-services combinations and the integration of different stakeholders, the transparency of the building planning process is insufficient and optimization

potentials are not apparent. According to this, there is a need for simulation tools that make the processes and outcomes more transparent for the participants. Therefore, the following paper contains a literature review of prospective solutions for the given problems and a critical reflection of these findings within the Facility Management domain. As a result, different approaches for service visualization are regarded and one is explained in more detail which is also used as a basis for developing an information-system-based reference model.

2 Theoretical Background

2.1 Facility Management

Facility Management (FM) is a management discipline which focuses on the economic use of facilities and real estates. Therefore, related services for meeting the company's needs in the working environment are in the scope of FM, which contains the management of support processes to enable the company's core activities. In doing so, worker's environmental needs are satisfied by simplifying their tasks, whilst the return on investments in facilities and real estates is increased throughout the real estate lifecycle time. Therefore, FM includes permanent analysis and optimization of cost-based activities related to technical facilities, buildings, and internal processes that are not related to the core activities of the company (GEFMA 100-1, 2004). In its European standard, FM is considered as the combination of multiple processes within a company into services that allow companies to more efficiently improve their primary activities:

In general, all organizations, whether public or private, use buildings, assets and services (facility services) to support their primary activities. By coordinating these assets and services, using management skills and handling many changes in the organisation's environment, Facility Management influences its ability to act proactively and meet all its requirements. This is also done to optimize the costs and performance of assets and services (DIN EN 15221-1, 2007).

The German Facility Management Association differentiates nine real estate lifecycle phases; each of these phases contains different facility services. Figure 1 gives an example of some facility services.

Figure 1. Life cycle phases in FM (GEFMA 100-1, 2004).

What is special in FM is the economic analysis of property from the aspect of lifecycle costs. In this context, the FM-focused planning plays an important role, since the life cycle costs, of which the usage costs account for the largest part can be minimized by user-based planning. FM-focused planning, therefore, pursues low construction costs in combination with high quality and a reduction of the life cycle costs. In order to accomplish this, numerous stakeholders have to be involved in the planning process and responsibilities and competences have to be determined for a controlled process.

2.2 Hybrid Value Creation in FM

Hybrid products represent complex problem solutions which consist of material products and immaterial performances by integrating goods and services. The target solution determines the contingent goods and services which have to be used and matched (DIN PAS 1094 2009). Hybrid products require the integration of the external factor, in this case the customer, in a high degree. In Facility Management benefits in kinds and services are inseparably interconnected. In order to achieve competitive advantages, planning, construction and operation of buildings cannot be carried out isolated from each other. Products and services are adhesive in consideration of information demand. For instance, planning documents are needed for the planning and control of the maintenance process. On the other hand, experience made in operation of current used constructions and systems as to maintenance intensity or fault liability of the product can be integrated in the planning (Bernhold, Nitzsche, Rosenkranz 2008). The potentials of hybrid value added are particularly used in mechanical engineering. Along the lifecycle of benefits in kind numerous services are provided for customized problem solving's, e.g.: Phase before using: funding, engineering and consulting; utilization: maintenance and operation; subsequent use: disposal, remarketing and recycling (McAloone 2006; Spath, Demuß 2006, Sturm, Bading 2007; Aurich et al. 2007; Leimeister, Glauner 2008).

Hybrid value added in Facility Management hold the challenge to involve multifaceted stakeholders along the whole lifecycle of a building: architects, professional planner, constructor, craftsmen, owner and Facility Manager (Schäfermeyer, Rosenkranz 2008; Pfnür 2011). It is a challenge to integrate all these players in such a way that an external factor, here the customer, can follow the process. Oftentimes, agreement and transparency of what information from which player has to be exchanged do not exist. However, the broad integration of all stakeholders is the requirement for the realization of complex and innovative service offers.

2.3 Customer Satisfaction and Service Quality in Service Delivery

In order to achieve high service quality and to find a customer-orientated problem solution, it is important to focus on customers and their satisfaction with the service experience and the final service result. Therefore, customer satisfaction can be defined from different viewpoints which highlight either the process or the service outcome (Hahn, 2002).

One of the most prevalent models for the evaluation of customer satisfaction is the customer satisfaction / dissatisfaction (CS/D) model which defines customer satisfaction as the “outcome of a complex information processing process” (Herrmann et. al., 1997). According to this model, customers evaluate their satisfaction by comparing the subjectively perceived performance of the product or service with the performance they expected before the product or service was bought (Vavra, 1997; Gerson, 1994). Therefore, the expected result can be either confirmed or disconfirmed by the perceived result. In the case of disconfirmation, the perceived result can be either better than the expected result (positive disconfirmation) or worse (negative disconfirmation). The latter leads to customer dissatisfaction, whereas the confirmation of expected results and positive disconfirmation generate satisfaction (see Figure 2).

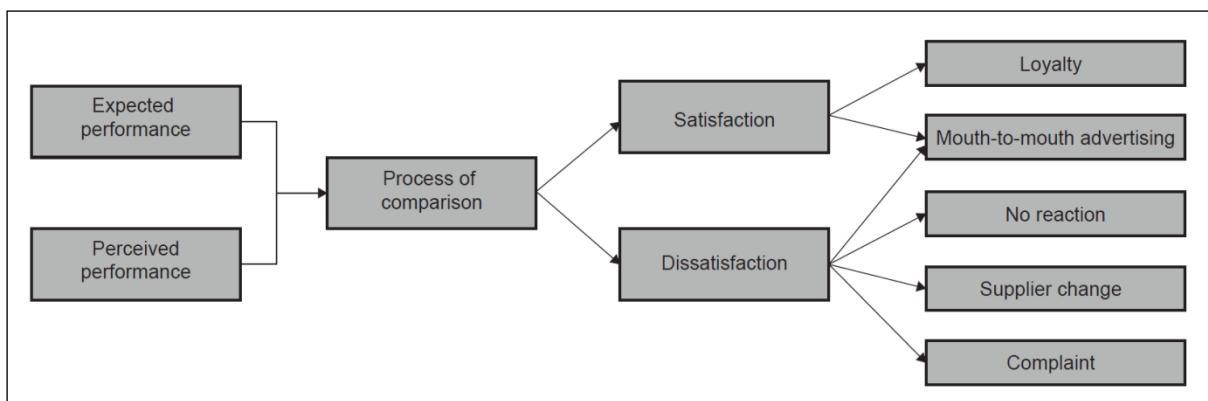

Figure 2. Customer satisfaction / dissatisfaction (CS/D) model (compare Homburg/ Stock, 2003; Hahn, 2002).

Different consequences from satisfaction or dissatisfaction can be derived. For example, loyalty from satisfied customers who tend to repurchase a product or service, or word-of-mouth advertising in the case of recommendations to potential buyers. Conversely, dissatisfied customers may also have a negative impact on word-of-mouth advertising, become inclined to change suppliers, or express their dissatisfaction in the form of complaints (Hahn, 2002).

Pertaining to services and the intangibility of their results, it is difficult to align the service quality and the consistency of services with respect to customer requirements (Meyer, 1991). This is a challenging task for service providers because services are sold before their delivery. That means customers face uncertainty about what to expect from service results. Service providers are also confronted with the insecurity of not knowing how to satisfy customers' needs and expectations in a sufficient way. To some extent, customers do not even know what they are expecting or what they really need for solving their particular problem or rectifying their individual needs. This can also lead to

dissatisfaction with the delivered service although it was carried out thoroughly. Several studies have shown that quality plays a large role in achieving customer satisfaction (Zeithaml et. al., 1988; Bolton & Drew, 1991). The SERVQUAL model, also referred to as the GAP Model, by Parasuraman et al. (1988), for example, identifies five different service gaps which are related to the concept of service quality and factors affecting it (Parasuraman et al., 1985). With regard to the customer perspective in service delivery, there is, for example, a discrepancy between the executive perception of the service provider and the consumer perception, whereas the service provider may not always understand what their customers are expecting. In addition, even if the specifications meet customers' requirements, there may be another gap between the service specifications and actual service performance, because it is not of high certainty due to the human factor in delivery (for more see Parasuraman et al., 1985). The expectations of customers are also dependent on their former experiences or what advertising or communication they receive. Therefore, Parasuraman et al. state that service quality is the result of the consumer's comparison of expected service and actual perceived service (see Figure 3).

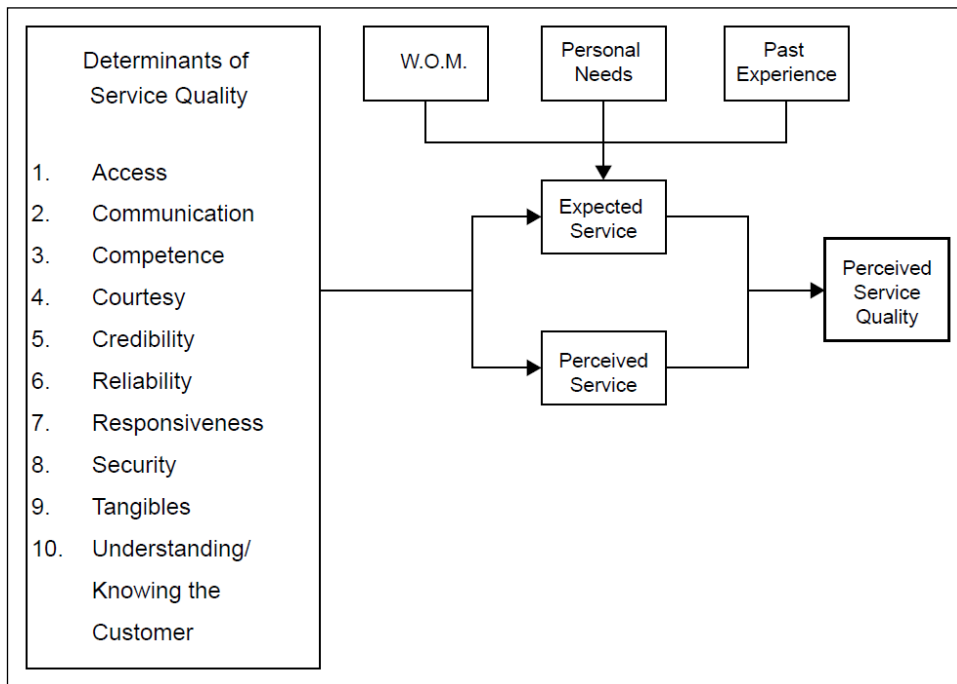

Figure 3. Determinants of perceived service quality (Parasuraman et al., 1985).

With regard to the importance of customers' expectations and its linkage to customer satisfaction or perceived service quality, it is necessary to be aware of what customers expect. It is also of high relevance to manage those expectations in order to raise customer satisfaction and customer perceived quality to accomplish opportunities of economic success. Customer expectations can be influenced, for example, by understanding the customers' point of view or identifying their needs, by coordinating corporate communication strategies, or by increasing transparency of service processes so that expected results match the actual service results (Bidmon, 2004; Richter, 2005).

3 Methodological Approach

The scope of the investigation is to identify potentials for increasing the transparency of service results with respect to FM-focused planning which results from hybrid value creation in the planning process and its challenges. With respect to an extensive cooperative planning, the coordination work should be reduced and it has to create transparency between different stakeholders by means of visualization approaches. The study aims to identify visualization options for service processes especially to customers. In line with this, the definition of "visualization" was analyzed in more detail and available implementation options for creating transparency in services were investigated. Next, information and processes that must be provided to the customer at the beginning of services were outlined using the case of FM-focused planning. The aim was to show new perspectives for hybrid value creation with regard to service processes in construction planning and Facility Management. Consequently, potentials for service visualization were initially investigated in practice in order to identify the research gap in more detail and to gain insights in practical service business. This was realized by conducting interviews with experts from the Facility Management sector with the objective of defining the status quo regarding their experiences. The interviews also served to investigate how to deal with customer expectations and service providers and to determine whether there are already management tools in use in practice.

Secondly, a literature review of selected documents was carried out. By means of qualitative content analysis, the various theories, methodologies, and definitions of service visualization were identified and categorized. Conceptual constructs were then refined in an attempt to explain interactions between the categories. By critically noting the

explicit or correlational linkages between individual concepts, and the multiple instances they are supported in the data, inferential statements were created. This enabled the drawing of conclusions and the development of implications to the Facility Management sector. Based on these findings a method has been developed for the visualization of services in a FM-based planning process which is divided into three levels with different detailing depths and scopes of visualizations. The following table summarizes the research process briefly.

Table 1. Research design.

Research steps	Used methods	Purpose and justification of used methods
Definition of research question	Problem focused interviews	<ul style="list-style-type: none"> • Specification of the research topic
Identification of state of the art	Literature review	<ul style="list-style-type: none"> • Examination of status quo • Identification of potentials for service visualization • Definitions of relevant terms • Understanding of customer experiences and related terms • Identification of methods used for the management of customer experience
Problem solution	Method development	<ul style="list-style-type: none"> • Problem focused solution • Management approach for customer experience through service visualization (e.g. service blueprinting) • Method development for visualization of services

4 Results/ Findings

4.1 Perception

As already mentioned, the customers’ experience of a service is elementary for their satisfaction. Therefore, interviews with experts from the Facility Management domain were arranged to acquire an idea of how to gain experience before a performance is provided. Based on the assimilated requirements of the interview partners, a definition of “previous experience” was developed. Generally, an experience is something that happened in the past. Past experiences can be used for designing and upgrading future processes. In building planning phases, the experience of the results is gained in form of plans (drawings) and communication. An absolute experience of a building and the services in it is only given in the operating phase after the building is constructed. This is because the building can be experienced with all senses; namely, seeing, smelling, hearing, feeling. The experience grows with the lifecycle of a building. Moreover, experience is subjective and every stakeholder in a project has a different view. To minimize the subjectivity, communication and the exchange information are fundamental.

In summary, experience is the feasibility of gathering data and information and processing them in the brain. Data acquisition and processing are influenced by various environmental conditions. For this reason, experience is always partially subjective. The more complex a process is, the more important the feasibility of experience is to reduce the subjectivity. Hence, an easy solution is needed to bring all stakeholders to the same level of experience as much as possible. In the next step, one potentiality in the form of visualization processes is given.

4.2 Visualization

“Every problem solving effort must begin with creating a representation for the problem” (Simon, 1996; Lim, Kim, Hong, & Park, 2012). Visualization assists humans in competently building and using their mental model. Visualizing a complex yet invisible system helps people comprehend and analyze it (Lim, Kim, Hong, & Park, 2012). A visual representation provides an insight of the various strategic choices available (Kellogg & Nie, 1995). In addition, it can facilitate ‘tangibilizing’ and conceptualizing the aspects of a service and how they relate to the service as perceived by consumers.

As well, it can provide a valuable mode of communication and coordination throughout the service delivery process (Smith, 2007). This can considerably enhance dialogues between the people involved in discussion, allowing them to achieve mutual understanding more efficiently and effectively (Lim, Kim, Hong, & Park, 2012). Establishing a generic visualization facilitates an augmented and shared understanding by clearly communicating the interfaces, leadership and organization challenges. It enables a joint and shared holistic understanding of complex, support contracts. Thereby, it encourages co-creation of improved value between providers and clients (Mills, Parry, & Purchase, 2011). The design

of a service should, therefore, integrate the instrumentation of tangible evidence; that is: everything the consumer uses to verify the service's effectiveness (Shostack, 1984).

Visualization presents systematic means to help those who design services ensure that they meet customers' requirements. Every service system and service action has to be devised both in terms of satisfying technical quality and the perception of quality by customers. Service visualization helps to translate the dimensions of quality into service specifications and standards (Harvey, 1998).

For all the subjectivity and immateriality of services, service design and services operations necessitate discipline, procedures, standards and attention to details in order to function effectually and efficiently (Harvey, 1998). However, the development of a new service is typically defined by trial and error. Developers interpret a subjective description of a need into an operational model that may bear only a distant similarity to the original idea. This leaves ample opportunity for conflict, inefficiencies and poor decision making (Smith, 2007). In the absence of a detailed design, there is no way of guaranteeing quality or conformity (Shostack, 1984).

Better service design affords the key to market success, and more importantly, to growth (Shostack, 1984). This is because it highlights main decision points, important criteria and the demand for active control measures in the service design. What is more, it provides a foundation for continuous improvement and service re-design, thereby providing a platform for future new services and opening opportunities for repositioning and overall strategic development such as diversification, new market entry etc. (Smith, 2007). Thus, if a way can be found to illustrate the service system concretely, the service management task is not only simplified but important elements of control are gained as well (Kingman-Brundage, 1989).

4.3 Service System Blueprint

The most prevalent service-specific representation is service blueprinting (Mills, Parry, & Purchase, 2011). Created by Shostack and developed further by Kingman-Brundage to visualize service processes (Fließ & Kleinaltenkamp, 2004), service blueprinting derives its technique from systems approach and industrial engineering. In the simplest terms, a service system blueprint is a picture of a service system (Kingman-Brundage, 1989). Thereby, it is more exact than non-visual descriptions and less prone to misinterpretation as it is quantifiable and non-subjective (Shostack, 1984) (Smith, 2007).

4.3.1 Applications of Service Blueprinting

Service system blueprints have become a keystone of the studies on service design, evaluation, development, and operation (Lim, Kim, Hong, & Park, 2012). As a heuristic method for analyzing and planning service processes (Fließ & Kleinaltenkamp, 2004), it offers managers and system designers with a reliable, practical tool for simplifying the most complex service systems by displaying the operation of existing systems (Kingman-Brundage, 1989). The main applications of this visualization have been in the consumer markets of hospitality, retail and banking (Mills, Parry, & Purchase, 2011).

Service blueprints can be used as either a design tool or a coordination tool (Fließ & Kleinaltenkamp, 2004). In addition to helping designers and managers recognize potential glitches, it is a great communications instrument to clarify contingency plans (Harvey, 1998). By relating particulars of a service in a way that is intelligible and effectual, the different parties concerned in the service system are able to understand and deal with it objectively regardless of their roles or individual point of view (Kingman-Brundage, 1989; Fließ & Kleinaltenkamp, 2004).

The advantages of service system blueprinting lie in the method's aptitude in disclosing what is currently implicit. In that way, it can be used as a basis for development of consumer resources geared to reveal the "invisible actions" (i.e., those performed backstage or even in support areas) taken on the consumer's behalf to ensure service quality (Kingman-Brundage, 1989).

4.3.2 The Framework of a Service Blueprint

A service system blueprint illustrates the details of service delivery by answering this question: Who Does What, To Whom, How Often, and Under What Conditions? (Kingman-Brundage, 1989). Essentially, it depicts the process and structure of a service system by utilizing the horizontal and vertical dimensions of a flat surface. Process is shown from left to right on the horizontal axis as a series of actions (rectangles) plotted chronologically. A flow line represents the service path by connecting discrete actions carried out by the customer and the service provider. Service structure is represented on the vertical axis as structural layers. The vertical axis distinguishes between different areas of actions (Kingman-Brundage, 1989; Harvey, 1998; Fließ & Kleinaltenkamp, 2004).

The primary structural strata, or action areas, are common to all services: consumer interaction, support functions, and management. Within these three primary sections, finer distinctions can be made (Kingman-Brundage, 1989). They are separated by four horizontal lines:

1. *Line of Interaction* which separates the customer action area from the supplier action area representing the direct interactions between customer and supplier. Above the line are the activities, choices and interactions performed by the customer. Actions performed by contact personnel are located below the line.

2. *Line of Visibility* differentiates between actions visible to the customer (onstage) and invisible to the customer (backstage). Onstage (front office) actions often represent the tip of the service iceberg.
3. *Line of Internal Interaction* distinguishes between front office and back office activities, separating support functions from the backstage, contact stratum. Support processes, which are necessary to provide front office employees in delivering the service, are carried out beneath the line.
4. *Line of Implementation* separates planning, managing and controlling functions (management zone) from the “doing” activities (support zone). Activities in the management area also take place while the service operations are conducted.
(Smith, 2007; Fließ & Kleinaltenkamp, 2004; Kingman-Brundage, 1989)

4.3.3 Limitations of Service Blueprinting

Performance is the unit of analysis in a blueprint and is defined as the series of activities, or tasks, undertaken in rendering a service understood to be an instrumental interaction. In this manner, service blueprints are task-oriented; they focus on observable actions or events. While this is greatly beneficial in facilitating the customer’s understanding of the service delivery process, it is incapable of portraying to the customer the actual result of the service system in the form of a finished product.

Furthermore, although the customer is granted an overview of the process, they are unable to verify the outcome of the individual steps. As an example, if it had been agreed that the roof of the building is to be blue but due to an error in communication or implementation it was painted green instead, there is no way for the customer to repair this error before the end of the service and the delivery of the final product.

Moreover, due to the complexity of the real-estate life cycle process and the numerous participants, the ‘clean’ lines of separation will be difficult to maintain. Unlike in other service system, the interactions between the various stakeholders are non-linear. Hence, the two-dimensional format of the service blueprint is insufficient in adequately representing the multifaceted interactions and processes of the Facility Management services.

4.4 Cooperation Experience Model

Hence, a new framework was created that adequately addresses the complex requirements of service system visualization; in particular, in hybrid value creation processes such as Facilities Management. The development of this visualization model is based on the results of the project “FlexNet” (2011–2013) promoted by BMBF (Federal Government Department for education and research, Germany). The FlexNet projection is a tool for identifying and documenting flows of information during the planning and operation of buildings (Bräuer, Knackstedt, Matzner 2013; Averbeck et al. 2013). In the current project “Cooperation Experience”, this projection is developed further. The initial results are applied in the following solution for the effective visualization of service processes. For modelling the cooperation and information interfaces, several levels are needed which have different detailing depths (Figure 4).

Figure 4. Method framework of the Cooperation Experience Model..

The first level gives a quick overview of processes, while the second level describes the activities between the cooperation partners, and in the third level, the processes are completed with detailed information.

In the first level (Figure 5), the processes needed for the whole service process to generate a performance are described. The focus is on gaining a quick understanding of the gross process without specific knowledge. The involved partners are related to the chronologically arranged process steps. This framework should be discussed in the first project meeting and the first meeting with the customer to assign responsibilities. The whole process has to be captured from the beginning to the end. Neither weak points nor room for improvement are pictured in the first level.

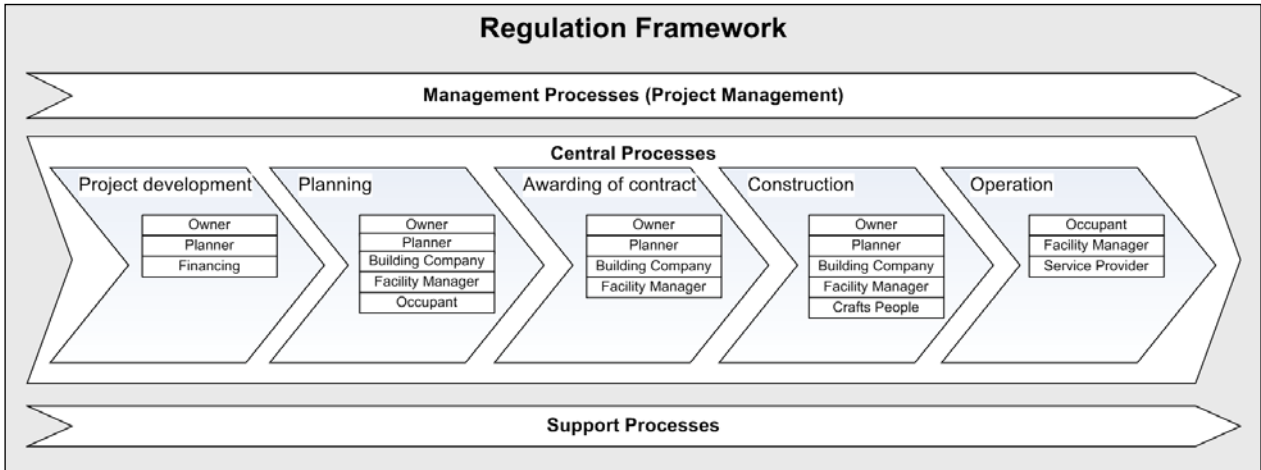

Figure 5. Regulation Framework.

The second level (figure 6) represents a “cooperation-arena” which contains the processes identified in the first level with their activities. Many arenas exist in this model such as process steps in the regulation framework of the first level. Hence, every process step of the first level is a framework for one cooperation arena. In the arena, every process relevant to the stakeholder is presented. Moreover, information objects which need to be interchanged between the players for the process are described.

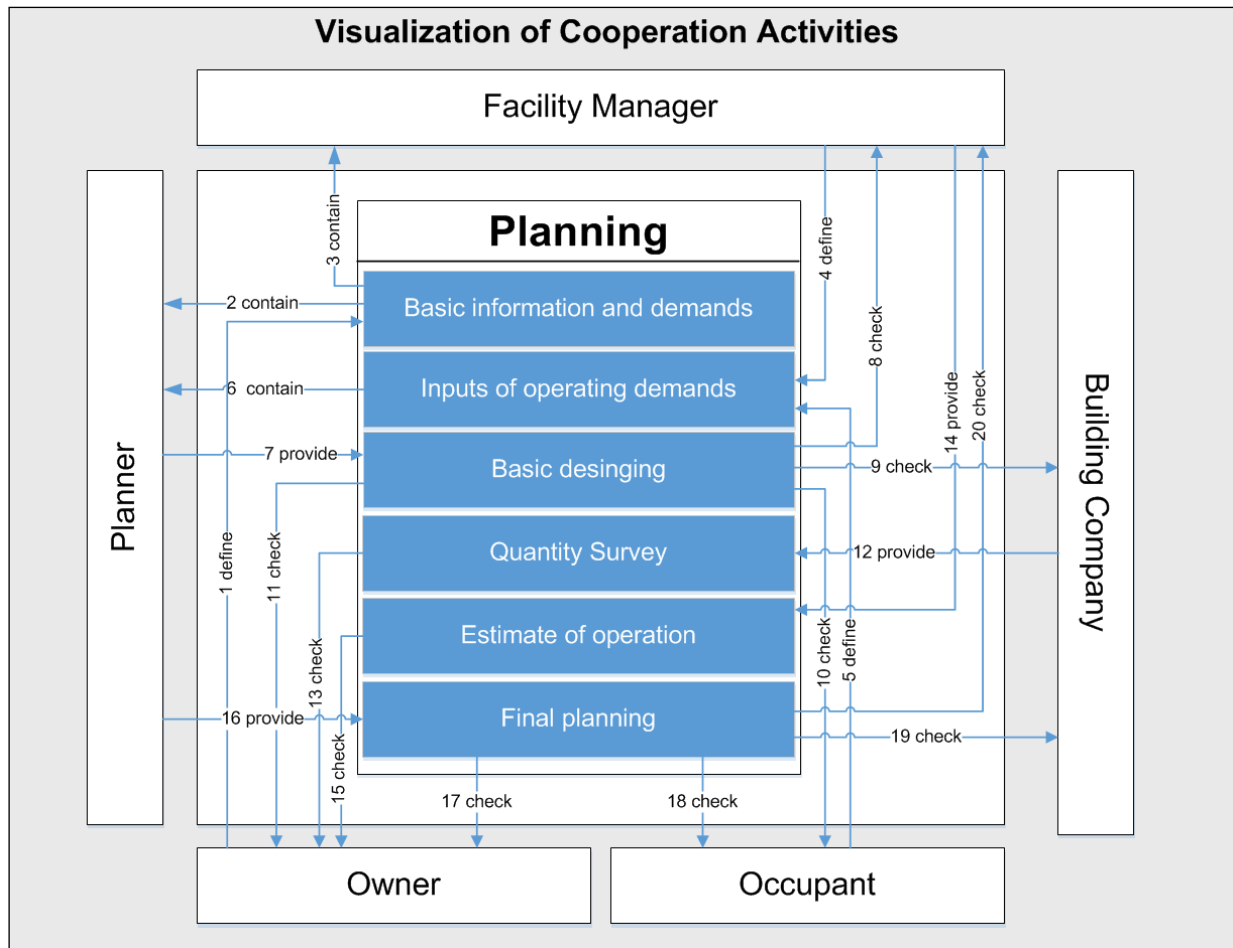

Figure 6. Visualization of Cooperation Activities.

The stakeholders are arranged around the arena and are connected with arrows. For the customer (owner), the cooperation activities are obvious in terms of who the emitter is and who the addressee is. The customer is part of the arena and they have an overview of with whom they have to cooperate. The order of interactions is numerically marked. In addition to the numbers, verbs on the arrows describe what happens with the information. In the middle of the arena, the information objects are located which are part of the process steps. They are ordered chronologically among each

other. The customer is able to spot at a glance who is responsible for which information and, therefore, who their contact person is. To create the arena, the following questions have to be answered: Who initiates which activity? Which stakeholder is involved in this activity? And which information has to be sent to these stakeholders?

In the third level (figure 7), the processes described in the second level are detailed. The purpose of this level is to support the processes of the second level with more detailed information. With the help of the choreography diagram, potential loop lines and branches can be pictured. A choreography diagram always displays exclusive processes with two or more player. Customers can see in detail which stakeholders work together, at what time and which information objects are exchanged. They are informed of when they can count on results and information. Simultaneously, the documentation of every single process is ensured so that traceability and transparency can be achieved. Hence, customers can plan when they want to compare their expectations with the intermediate results to intervene if the expectation gap is too big. Moreover, they know when the other stakeholders need their input. This reduces failures of coordination and optimizes the process flow and the intermediate results and, therefore, the final result.

Figure 7. Choreography Diagram.

With the help of this model customers feel integrated in the process. They can follow the whole process, have opportunities to intervene, and can actively influence the results. The feeling of being able to participate in the results leads to higher customer satisfaction.

5 Conclusion

Coherent visualization of service processes is essential to the prosperity and effective management of service businesses. Clear customer understanding of the service system can lead to the closing of expectation gaps, the active participation of the customer in service operations, enhanced coordination of diverse activities, and improved communication between stakeholders among numerous other benefits. However, due to the complex and intangible nature of service delivery systems this can be difficult to achieve.

The Cooperation Experience model developed in this paper is recommended for use in the visualization of multifaceted service systems such as hybrid value creation in Facilities Management. The model offers a comprehensive knowledge of the entire system, the various stakeholders and participants, and their roles in the detailed system procedure and flow of information.

Further advancement can be made to the model by implementing additional information and indicators. Specifically, ratings of the process or performance, customer satisfaction indices, and completion time assessment can enhance the rigorousness and expediency of this visualization approach.

Transcending the division of 'economic' and 'social' innovation

Kaisa Koskela-Huotari¹, Jaakko Siltaloppi², Stephen L. Vargo³

¹VTT Technical Research Centre of Finland, Oulu, Finland, ²Aalto University, Helsinki, Finland, ³University of Hawaii at Manoa, Honolulu, USA

This paper aims to transcend the division of 'economic' and 'social' innovations by drawing from the emerging service ecosystem perspective. This view has three fundamental implications on innovation. First, it offers unifying basis for considering all human collaboration as value co-creation through direct and indirect service exchange. Second, it portrays innovation not as a novel output, but as an institutional change in how value is co-created. Third, it conceptualized value co-creation simultaneously framed by multiple nested 'levels' of institutional context which bridges the micro and meso level analysis more common to 'economic' innovation with the macro level of 'social' innovation and provides the conceptual grounds for leveraging valuable insights from both domains to build a more unifying theoretical basis for innovation.

1 Introduction

Conventional literature on 'economic' innovations builds heavily on assumptions and models characterized by technical emphasis, manufacturer-centricity, transactional nature of exchange, and profit maximization (see e.g. Godin, 2006; Howaldt; Schwarz, 2010). The literature on 'social' innovation, i.e. new solutions for societal challenges, on the other hand, highlights the importance of a systemic view on innovation, the centrality of collaboration, and the underlying institutional processes (see e.g. Howaldt; Schwarz, 2010; Pol; Ville, 2009). Hence, 'social' innovations are often seen as something very different from 'economic' innovations (Mulgan et al., 2007). In this paper we argue that, while this juxtaposing may offer some insights, it is more constraining than enabling for the development of a unifying theoretical basis for innovation studies. Hence, this paper aims to transcend the division of 'economic' and 'social' innovations by drawing from the emerging service ecosystems perspective (Vargo; Lusch, 2011; Lusch; Vargo, 2014) grounded in service-dominant (S-D) logic (Vargo; Lusch, 2004, 2008).

Central to S-D logic is the transcending concept of "service" that shifts the focus of value creation and exchange from outputs (e.g., goods and services) to a process of actors applying their competences and other available resources for the other's benefit (Vargo; Lusch, 2004). That is, service is exchanged for service, either directly or indirectly (e.g., through a good or money). Reframing the foundational basis of exchange this way provides a unified lens for considering all human collaboration, whether it would be characterized as 'economic' or 'social' in traditional terms, aiming at improving wellbeing, that is, value co-creation through service-for-service exchange. This unification roots in the systemic view of value co-creation inherent to S-D logic that sees all actors as fundamentally similar resource integrators. Hence, this view conceives society as a web of interconnected resource integrating, service providing and value co-creating actors forming dynamically evolving and complex service ecosystems (Vargo; Lusch, 2011). The emerging service ecosystems perspective highlights the importance of institutions – socially shared 'rules of the game' – in value co-creation (Vargo; Akaka, 2012). In other words, institutions provide the enabling and constraining structure of service ecosystems, that shape the ways in which actors co-create value by integrating their competences and other available resources, for the benefit of others and themselves (Lusch; Vargo, 2014).

The service ecosystems perspective has several fundamental implications on how innovation is viewed. In this paper, we focus on three key implications that reframe the goal, nature and scope of innovation. First, by emphasizing the co-created nature of value and the transcending notion of 'service' as the basis of exchange, the service ecosystem perspective offers a unifying basis for framing all innovation, whether traditionally seen as 'economic' or 'social', as aiming toward value co-creation through direct and indirect service exchange. Second, it portrays innovation not as a novel output produced by a firm, but as change in the institutionalized ways of co-creating value by integrating resources through service exchange in a service ecosystem (Vargo et al., forthcoming). Third, the service ecosystems are conceptualized as having multiple nested 'levels' of contexts that simultaneously frame value co-creation practices (Chandler; Vargo, 2011). This implies that innovation is always systemic by nature, unfolding in the nexus of dynamic interactions among fundamentally similar resource integrating actors, socio-technical systems, and reproduced institutions (e.g. Geels, 2004; Lusch; Vargo, 2014). Service ecosystems can, hence, be seen as interinstitutional systems characterized by the interplay of partially conflicting institutional logics enabling change and innovation (cf. Friedland; Alford, 1991; Thornton et al., 2012). This perspective bridges the micro level analysis more common in research focusing on the manufacturer-driven 'economic' innovations, technological innovations in particular, with the macro level emphasis of 'social' innovation research aiming, for example, at policy-level implications. Building on these premises, the service ecosystems perspective provides the conceptual grounds for moving beyond the distinction between 'social' and 'economic' innovation, leveraging valuable insights from both domains towards a unifying theory of innovation.

The paper is structured so that, first, we give a brief description of the prevailing dichotomy between ‘economic’ innovation and ‘social’ innovation. Second, we introduce the emerging service ecosystems perspective and its three key implications on innovation studies. We then discuss how the implications of the service ecosystems perspective reframe the goal, nature, and scope of innovation and enable transcending the ‘economic’ and ‘social’ innovation dichotomy. We conclude the article with a discussion of the implications of our transcending view on innovation research.

2 Division of ‘economic’ and ‘social’ innovation

Seminal work on innovation studies dates back to Schumpeter’s (1934, 1950) analysis on the circular flow in economic life and disruptive character of development. Though Schumpeter noted that the economic life goes on in an ever changing social and natural environment and that these changes often condition industrial change, his focus on innovation was strictly limited to a producer-centric activity: “It is, however, the producer who, as a rule, initiates economic change, and consumers are educated by him if necessary; they are, as it were, taught to want new things, or things differ in some respect or other from those which they have been in habit of using” (1950: 65). Hence, Schumpeter took an extreme position assuming that the demand side would simply adjust to the supply side (Lundvall, 2010) and giving innovation research its prevailing manufacturer-centric focus.

The one directional view on innovation provided grounds for the development of the linear model of innovation that postulates innovation starting with basic research, continuing with applied research and development, and ending with production and diffusion (Godin, 2006). Hence, the linear model describes innovation as a rational process that can be decomposed into discrete stages or components each of which can then be planned, programmed and managed (Cooper, 2001) the same way as other, more routine activities (Price; Bass, 1969). It also narrowed the notion of innovation mainly as technical change emphasizing the material and tangible aspects of the phenomenon, and directed the focus of innovation at the advancements in the natural sciences and mechanical engineering to create new products and processes (Howaldt; Schwarz, 2010).

Due to these developments, the conventional literature on innovation is based on assumptions and models characterized by manufacturer-centricity, technical emphasis, transactional nature of exchange, and profit maximization (see e.g. Godin, 2006; Howaldt; Schwarz, 2010). Over time, this so called ‘*economic*’ (or business or industrial) *innovation* frame has been found problematic and restrictive. Hence, several different conceptualizations of additional ‘forms’ of innovation, for example user innovation (von Hippel, 2005) and open innovation (Chesbrough, 2006), have emerged, exposing the boundaries of the ‘economic’ innovation and extending the scope of innovation research.

One of these alternative forms is ‘*social*’ *innovation* (Mulgan, 2007; Howald; Schwarz, 2010). Although mostly ignored by the ‘mainstream’ innovation research, social innovation has experienced a surge in social sciences over the past twenty years (Pol; Ville, 2009; Howald; Schwarz, 2010). Although considerable amount of effort has been made to identify social innovation as a distinct type of an innovation, the concept still remains quite unclear with regard to terminology, concept and content (Pol; Ville, 2009; Howald; Schwarz, 2010). One way of distinguishing social innovations from other kinds of innovations relates to their goals. For example, Mulgan (2007: 8) defines social innovation as “innovative activities and services that are motivated by the goal of meeting a social need”. In other words, social innovations are seen as new concepts applied to overcome societal challenges such as population aging and environmental problems and oriented toward objects that are not primarily economically motivated (Dees, 2007; Howald; Schwarz, 2010). Hence, social innovation often focuses on human needs that are ‘not yet’ or ‘no longer’ perceived as important by either the market or the state (Howald; Schwarz, 2010).

According to Howald and Schwarz (2010), substantive distinction between social and economic innovations can also be found in their immaterial structure. In social innovation, change does not occur in the medium of technical artifact but at the level of social practice. Hence, a social innovation is seen as a new combination and/or new configuration of social practices in certain areas of action or social contexts. Therefore, the focus of social innovation research has been directed at the complexity and systemic character of the process of innovation (Fagerberg et al., 2005), one of its key characteristics being the widening identification of the variety and heterogeneity of the actors, organizations and institutions that are involved in the process of innovation (Howald; Schwarz, 2010). Social innovations are still, however, seen as predominantly developed and diffused through organizations whose primary purposes are social (Mulgan, 2007).

In our view, several problems stem from the juxtaposition of ‘economic’ and ‘social’ innovations, and portraying them as distinct forms of innovation. First, defining social innovation as separate from, or opposite to, economic innovation is problematic because the outputs of innovation processes taking place within, or initiated by, ‘economic’ actors, such as new technological artifacts, production or service processes, organizational forms and new markets (Schumpeter, 1934), can and do contribute to solving social needs and meeting social challenges (Howald; Schwarz, 2010). Second, new social practices that contribute to solving social problems can also influence the outputs of economic actors’ innovation processes, in particular technologies, in novel ways by developing new uses and meanings for them in the value creating processes (Orlikowski, 1992). With this view, it is obvious that social and economic benefits are often overlapping and mutually reinforcing; the economic benefit for the developer does not exclude social benefits for the users as sometimes implied in the social innovation literature. Hence, it may be beneficial for both economic and social innovation studies to elaborate further on the shared basis and mutual interconnections between social and economic innovations.

3 Transcending nature of the service ecosystem perspective

Service is exchanged for service – it is this simple idea that constitutes the starting point and the core of service-dominant (S-D) logic (Vargo; Lusch, 2004; 2008; 2011, Lusch; Vargo, 2006; 2014). S-D logic is an alternative worldview originally aimed at overcoming the products versus services (or tangible versus intangible output) -divide characterizing much of marketing as well as other business literatures (Vargo; Lusch, 2004; 2008). This was done by introducing the transcending notion of *service* that focuses on the process of serving rather than on the form of output. In S-D logic, service is defined as the application of resources (such as knowledge and skills) for the benefit of another (Vargo; Lusch, 2004). In other words, service is exchanged for service when actors apply their competences to provide service for others and reciprocally receive similar kind of service (others' applied competences) in return. Conceptualized this way, service becomes the fundamental basis of all exchange, providing a common framework for understanding both 'economic' and 'social' exchange.

Thus, S-D logic is based on an understanding of the interwoven fabric of individuals and organizations, brought together into networks and societies, specializing in and exchanging service (applied competences) to create value at the context of their everyday lives (Lusch et al. 2007; Chandler; Vargo, 2011). Hence, S-D logic views value as contextual and co-created through service-for-service exchanges among multiple actors (Lusch; Vargo, 2014; Vargo; Lusch, 2004). This opposes the traditional, goods-dominant (G-D) logic view on value creation and exchange that emphasizes firms as the (sole) value creators through the production of value-embodied goods that are exchanged through market transactions with value destroying consumers.

Thus, S-D logic can be seen as a part of the more general move away from a mechanistic to a systemic worldview (Capra; Luisi, 2014) as it highlights the dynamic and complex nature of value co-creation by arguing that actors constantly apply their competences and integrate available resources from multiple sources for value creation (Vargo; Lusch, 2011). This systemic view is encapsulated in the concept of service ecosystems, defined as “relatively self-contained, self-adjusting system[s] of resource-integrating actors connected by shared institutional logics and mutual value creation through service exchange” (Lusch; Vargo, 2014: 161). The service ecosystems perspective emphasizes the co-created nature of value, the dynamic integration of resources, and the importance of institutions – shared rules, norms, values and beliefs, as well as shared language and technologies – as constitutive elements of service ecosystems.

The three following sections introduce three key insights of the service ecosystems perspective on innovation that provide a conceptual basis for transcending the prevailing division of 'economic' and 'social' innovations by reframing the goal, nature and scope of innovation.

3.1 Value is co-created through service exchange

S-D logic and its service ecosystems perspective (Vargo; Lusch, 2004; 2011; Lusch; Vargo, 2014) build upon the notion of value as co-created by multiple actors (cf. Prahalad; Ramaswamy, 2004), rather than being created by a single actor. Central to this perspective is the idea that value emerges and unfolds over extended periods of time, and is not tied to the discrete, production-consumption events (Vargo, 2009). This provides an alternative approach to the goods-logical view in which value is seen as created by firms (i.e., “producers”) in the form of offerings, that is, outcomes of the firm's R&D and production process. Moving the locus of value creation from exchange to use transforms the notion value from one based on units of firm output to one based on processes of integrating resources (Vargo et al., 2008). Hence, value unfolds as resources from multiple sources are combined in the context of an individual's life. Thus, value is co-created, that is, driven by the integration, exchange and application of resources as the joint effort of various actors (Vargo; Lusch, 2008; 2011), and contextual, that is, uniquely derived and determined by each actor in their respective social contexts (Chandler; Vargo, 2011; Vargo et al., 2008).

Value co-creation in service ecosystems is enabled through service-for-service exchange (Vargo; Lusch, 2004; 2011). From the service ecosystems perspective, the fundamental purpose of any actor or collective of actors is therefore to “serve itself by serving others” (Lusch; Vargo, 2014: 17). Conceptualized this way, value co-creation becomes the fundamental basis of all activity in service ecosystems, leading to a definition of value as an improvement in system's wellbeing, that is, co-viability, which can be evaluated in terms of system's ability survive and prosper in its environment (Vargo et al., 2008; Vargo; Lusch 2014). In other words, by highlighting the co-created, systemic and contextual nature of value, S-D logic broadens the process of value creation beyond a firm's operational activities to include the active and essential participation of all actors in value co-creation.

Furthermore, the service ecosystem perspective suggests that all actors are fundamentally similar resource integrators that co-create value by integrate resources from multiple sources through reciprocal service exchange (Vargo; Lusch, 2011). The reason why the fundamental role of service in exchange is so difficult to see in the modern world is that in the efforts to improve our wellbeing, human kind has come up with several ways to co-create value more effectively by exchanging service indirectly. This means that the notion of service in S-D logic is not tied to the distinct moments of direct physical interaction among people. Instead, service can be provided indirectly, for example, in the form of a product or money. Hence, the emphasis on service as the fundamental basis of exchange in the service ecosystems does not mean that products and money are ignored. On the contrary, they are seen as important facilitators of service exchange: products are considered as vehicles for service provision (Lusch et al., 2007) and money as a 'right' for service (Lusch; Vargo, 2014). Through the different forms of indirect service exchange, both physical and

time related constraints of direct service exchange are being bent and value co-creation made more effective. Thus, the service focus is more general and transcending by its nature, since it covers exchange situations involving different types of goods as well as situations in which there are no intermediate products (Lusch; Vargo, 2014).

Value is co-created through the exchange, integration and use of resources from private, market-facing and public sources (Lusch; Vargo, 2014). Resources in S-D logic are viewed as anything (tangible and intangible) an actor can draw on for support (Vargo; Lusch, 2004). Resources can be roughly divided into two categories; operand resources that are usually tangible and static such as natural resources, and operant resources that are often intangible and dynamic such as knowledge and skills. This view suggests that innovation primarily involves the integration of operant resources – those that are capable of acting on other resources to create value (Vargo; Lusch, 2011). It is important to note that in addition to intangible resources, such as knowledge and skills, also technology, when viewed as potentially useful knowledge (e.g. Mokyr, 2004), can be seen as an operant resource (Akaka & Vargo 2013). This implies that technology is always an integral part of service provision (beneficially applied useful knowledge) and thus, always also foundational to value co-creation (Vargo et al., forthcoming).

Thus, the service ecosystems perspective offers a view on innovation that is based on service, understood the application of competences for the benefit of another. Actors engage in reciprocal service exchange in order to co-create value, that is, to improve the wellbeing of themselves as well as the system of which they are part of. Furthermore, the service ecosystems perspective emphasizes that value is co-created by integrating various resources from multiple sources through direct and indirect service exchange, making no distinction between ‘economic’ and ‘social’ exchange. Hence, the service ecosystems perspective portrays innovation as a complex and systemic activity aimed at mutual value creation in which no actor participates alone, but contributes to the emergence of new solutions together with other actors. The service ecosystems perspective also proposes a broader conceptualization of technology and views it as useful knowledge, as opposed to mere technical artifacts, making technology always foundational to value co-creation.

3.2 Innovation is institutional change in value co-creation

By shifting the focus of value co-creation and exchange from outputs to the process of serving, service ecosystem approach highlights the fact that all actors are fundamentally similar resource integrators interacting with each other through service exchange (Vargo; Lusch, 2011). When looked through this actor-to-actor perspective, the fallacy of the linear and sequential conceptualization of value creation, flow, and destruction characterizing much of the economic, marketing and innovation literature is revealed (Lusch; Vargo, 2014). Therefore, the service ecosystems perspective steers attention towards the existence of much more complex and dynamic exchange systems and points to a systemic view of generic actors embedded within an institutional structure (ibid).

The service ecosystems perspective reframes the human society as a web of interconnected value co-creating actors forming dynamically evolving and complex service ecosystems, in which value co-creation is facilitated by shared institutions (Vargo; Lusch, 2011). Institutions are the humanly devised schemas, norms, and regulations that enable and constrain the behavior of social actors and make social life predictable and meaningful (North, 1990; Powell; DiMaggio, 1991; Scott, 2014). Institutions, as ‘the rules of the game’, provide the structure for value co-creation and resource integration in service ecosystems by shaping the ways in which actors apply their competences and other available resources for the benefit of others (Vargo; Akaka, 2012; Lusch; Vargo, 2014).

Ultimately, this view suggests that innovation is driven by the collaborative efforts of various actors to find or develop new ways to co-create value within service ecosystems through changing the institutions that enable and constrain their actions (Vargo et al., forthcoming). Hence the nature of innovation changes drastically from the production of novel outputs by a firm to the process of institutionalizing new value co-creation practices by multiple actors in a service ecosystem. Compared to the traditional views on innovation, service-ecosystems approach not only removes the distinction between “producers” and “consumers” in value co-creation (Vargo; Lusch, 2011), but also the distinction between “innovators” and “adopters”, and argues that all actors participate in innovation with a fundamentally similar way by creating, maintaining and disrupting institutions (Vargo et al., forthcoming).

3.3 Multilevel institutional context frames value co-creation

The notion of service ecosystems is fundamental to value co-creation because it acknowledges how large-scale social structures and institutions evolve relative to the resource integration and service provision activities performed by individual actors within different contexts (Chandler; Vargo, 2011). The service ecosystems perspective allows zooming both in and out to see actors as well as collectives of actors, not in isolation, but in all of their dependencies and interdependencies generated by the web of service-for-service exchange relationships (Lusch; Vargo, 2014). Service ecosystems, resulting from these reciprocal service exchanges, are characterized by complexity. This means that building on top of an individual actor are structures composed of multiple individuals, such as families, firms, industries and nations, themselves composed of many parts and, in turn, parts of still larger structures (Ostrom, 2005: 11). What is a whole system at one level is a part of a system at another level.

Hence, service ecosystems are viewed as having multiple nested ‘levels’ of contexts that frame resource integration, service exchange and value co-creation (Chandler; Vargo, 2011). These different levels or frames can be conceptualize

as different institutional orders, such as family, religion, state, market, profession, corporation (cf. Thornton et al., 2012). Each institutional order has a central logic comprising a set of material and symbolic practices and organizing principles that provide logics of actions for individuals and organizations (Friedland; Alford, 1991; Jarzabkowski et al., 2009). A mechanism by which institutional logics exert their effects on individuals and organizations is when they identify with the collective identity of a social group related to an institutional order (Thornton; Ocasio, 2008). Individuals are simultaneously members of multiple social groups. Service ecosystems can be seen as interinstitutional systems characterized by various nested institutional logics (cf. Friedland; Alford, 1991). The macro level systems emerge from the micro level service-for-service exchanges (Lusch; Vargo, 2014) and provide the context by which the micro level exchanges are framed (Chandler; Vargo, 2011). The multiple levels of institutional arrangements simultaneously manifest themselves in the actions of individual actors in value co-creation and as the actors connect with one another through their service-for-service exchanges, they ultimately join their partially different and partially shared institutional constellations together (cf. Chandler; Vargo, 2011). In other words, the multidimensional context composes of reciprocal links among actors connecting their partially shared institutional logics that guide the actions and interactions of individual actors. This constitutes the unique context of a specific exchange.

As a result, value co-creation is framed by complex and multidimensional institutional contexts that bring forth the diversity of institutional logics. The consequence of the diversity is that actors often encounter situations in which many institutional logics offer contradicting and conflicting interpretations and prescriptions for action (Friedland; Alford, 1991; Thornton et al., 2012). The intersecting and overlapping institutional logics can, for example, create conflicting views on what value is, and how resources should be integrated for value co-creation (Vargo et al., forthcoming). These conflicts and contradictions in institutional logics are the sources of choice, synthesis and change that follows (Friedland; Alford, 1991; Seo; Creed, 2002; Thornton et al., 2012) and can be seen as prerequisites of innovation.

Viewing service ecosystems as interinstitutional systems enables to see how value co-creation through service exchange is always simultaneously framed by multiple nested 'levels' of unique institutional contexts which bridge the micro level interactions (e.g., between companies and customers) emphasized in 'economic' innovation research, with the macro level emphasis (e.g., changes in norms or policies) prevailing in studies focusing on 'social' innovation. This is well aligned with the views that innovation is always systemic by nature, unfolding in the nexus of dynamic interactions among human actors, socio-technical systems, and reproduced institutions (e.g. Geels, 2004).

4 Discussion

In the current innovation literature a distinction is often made between 'social' and 'economic' forms of innovation. In this paper, we argue that while this juxtaposing may offer some insights, it is more constraining than enabling for the development of a unifying theoretical basis for innovation studies. In order to transcend the division of 'economic' and 'social' innovation, we draw from the emerging service ecosystems perspective and argue that it provides the conceptual grounds for transcending the above stated dichotomy and enables leveraging valuable insights from both domains while moving toward a unifying theory of innovation. The three key implications of the service ecosystems perspective are presented in Table 1. They reframe the goal, nature and scope of innovation.

Table 1. Transcending the division of 'economic' and 'social' innovation with the service ecosystems perspective.

	Economic innovation	Social innovation	Service ecosystems perspective
Goal of innovation	Maximizing profits for the firm by selling outputs	Creating 'public' good by overcoming societal challenges	Improving systemic wellbeing by co-creating value through service exchange (serving itself by serving others)
Nature of innovation	Change in technical artifacts / outputs	Change in social practices and settings	Institutional change in value co-creation practices
Scope of the innovation	Process: Linear, one-directional manufacturer-centric process from research to diffusion Focal actor: Firm (single)	Process: Complex and systemic process on the level of social behavioral patterns. Focal actors: Non-profit organizations (multiple)	Process: Complex and systemic process of creating, maintaining and disrupting institutional logics framing value co-creation in multiple nested 'levels' of context Focal actors: Generic actors (all)

The first implication of the service ecosystems perspective transcends the division of ‘economic’ and ‘social’ innovation by broadening the goal of innovation. The manufacturer-driven ‘economic’ innovation literature emphasizes the profit maximization of the innovator – firm – and highlights gaining a competitive advantage over competitors in the market as the goal of innovation. ‘Social’ innovation, on the other hand, takes as its goal to overcome societal challenges, taking the perspective of public and non-monetary ‘good’, as opposed to the benefit of an individual private corporation. Finally, the service ecosystems perspective provides a more general notion of value co-creation i.e. increasing one’s wellbeing by serving others and being served in return. The systemic nature of value co-creation also implies that the prerequisite for individual wellbeing or viability is the viability of the more general system of which the actor is a part. To capture this idea Vargo and Lusch (2014) have recently introduced the notion of co-viability.

The second implication relates to the nature of innovation. The ‘economic’ innovation literature usually focuses on the new technological artifact as the output of the innovation process, although recent research has expanded the notion of innovation by also considering other outputs, such as services, as well. ‘Social’ innovation, like economic, focuses on the output of the innovation process, but expands the notion of innovation to cover also the overall processes and practices that allow actors to address specific social problems. While this is very welcome development, it often leads to a situation in which the importance of the ‘social’ elements is emphasized to the extent that the influence of economic processes and technology is forgotten altogether. The service ecosystems perspective views innovation as an overarching change in ongoing value co-creation practices among multiple actors. As value co-creation in service ecosystems is enabled and constrained by institutions, the way value co-creation practices can change is through the change in the institutional logics that guides them. Hence, all actors in service ecosystems are perceived as fundamentally similar resource integrators that engage in institutional work, that is, in creating, maintaining and disrupting institutions.

The third implication of the service ecosystems perspective draws attention to the scope of innovation and the innovation process. In the manufacturer-centric ‘economic’ conceptualizations, innovation is perceived as a linear and one-directional process driven by the single actor (usually a firm) from the early research stages through to launch and, possibly, to the diffusion of the technology. Social innovation, on the contrary, takes a more systemic view on the phenomenon according to which many stakeholders participate in the process of shaping new solutions to social problems. The social innovation research, however, tends to focus on non-profit organizations to distinguish itself from the for-profit focus in economic innovation. The service ecosystems perspective encapsulates both for- and non-profit actors, and all other actors, within its systemic view of value co-creation, according to which innovation is a complex and systemic process driven by many actors contributing their resources and visions to shaping the solutions and promoting their adoption. Furthermore, it acknowledges the influence of the surrounding institutions in relation to the individual service efforts among actors. In other words, the service ecosystems perspective conceptualizes value co-creation simultaneously framed by multiple nested ‘levels’ of institutional contexts. This context continuously evolves and changes through the service-for-service exchanges linking different actors together. For individual actors, the resulting view is one in which they frequently encounter situations in which many institutional logics offer contradicting and conflicting interpretations and prescriptions for action. This causes uncertainty, confusion and stress, but is also the basis for choice, synthesis and change, that is, the prerequisites for innovation.

Through these three transcending implications, both social and economic innovation can be understood as special cases of the service ecosystems-based notion of innovation. In the context of goals, improvement in wellbeing does not discriminate between the generation of financial profit for one actor (firm) and the generation of public good (often defined by a few actors for the whole community). In terms of the nature of innovation, the service ecosystems view accommodates both tangible ‘vehicles’ of service provision and exchange, and the broader processes that make use of various tangible artifacts as well as competences in the process of solving specific problems. The perspective also (re)conceptualizes technology as useful knowledge and makes it fundamental in value co-creation. Finally, our complex and systemic view lends itself to both actor-centered studies of innovation processes, as well as to studies focusing on systems of specific types of actors seeking to develop new value co-creation practices by changing social structures.

Thus, our framework offers a more generic conceptual framework within which different ‘types’ of innovations can be studied. For the ‘economic’ innovation research our approach offers insights that extend beyond the firm-centered development and production of novel artifacts, allowing analysts to understand the purpose of these artifacts and how the financial performance of the firm depends on the ability of the new artifact to enable new and better forms of co-creating value in the ecosystems level. Furthermore, it helps expand the firm-centered viewpoints to surrounding networks which contribute to the emergence of novel artifacts.

For social innovation research, the service ecosystems perspective offers a fundamentally similar yet more generic conceptualization of innovation in which the researcher is not limited to specific types of organizations or outputs. In this sense, our view separates the systemic dimension from the social benefit often entangled in social innovation research, establishing the basis for systemic studies of innovation in all contexts. For social innovation research, our emphasis on the institutionalization of new solutions suggests that more attention could be paid to the contested and political processes that often surround the development of solutions to social problems, not the least because they often entail the involvement of the public sector with political decision-making and bureaucratic resource allocation. Furthermore, as literature around social enterprises and social movements illustrate, the change processes themselves involve reconciliation among multiple institutional logics advocated by different stakeholder groups with differing

abilities to impose new solutions, or protect the old, over others (e.g., Battilana; Lee, 2014; Benford; Snow, 2000). Innovation studies have a lot to learn from these discussions.

5 Conclusions

S-D logic (Vargo; Lusch, 2004; Lusch; Vargo, 2014) provides a lens to look at the human society in a different light. According to it the billions of human actors and millions of organizations are part of many complex and evolving service ecosystems. By reframing all human action as value co-creation in service ecosystems by fundamentally similar kinds of actors integrating, applying and providing resources for each other through service-for-service exchange, S-D logic provides a broader framework to make sense of the underlying complex phenomena such as innovation.

In this paper, we argue that this service ecosystems perspective on innovation provides the conceptual grounds for moving beyond the distinction between ‘economic’ and ‘social’ innovation. It does this by reframing the goal, nature and scope of innovation in a transcending manner which allows seeing both ‘social’ and ‘economic’ innovation as special cases of the service ecosystems-based notion of innovation and enables leveraging valuable insights from both domains in order to build a more unifying theory of innovation.

Reflecting Rural Supply Regarding Demographic Change in Germany: A Qualitative Analysis of Requirements and Acceptance to Preserve Quality of Live in Rural Areas

Susann Kuerbis, Bettina Hofmann, Stephanie Schmitt-Rueth

Fraunhofer Center for Applied Research on Supply Chain Services SCS

Demographic change in Germany is characterised by low birth rates and increasing life expectancy. Especially rural areas suffer from this trend. Furthermore, this fact results in lower quality of life due to gradual reduction of infrastructure. However, there is a rising need for supply because of ageing population. The objective of this paper is to analyse which requirements citizens have regarding local food and medical supply concepts and what kind of solutions are possible. The aim is to identify critical requirements and acceptance factors that should be considered when establishing local supply concepts in rural areas in Germany.

1 Impact of demographic change on the basic supply with goods and commercial services in rural areas

1.1 Demographic change and rural areas

Demographic change in Germany is characterised by low birth rates and increasing life expectancy. Until 2060 the population is expected to decline from 80.5 million to 65-70 million people. Simultaneously, the proportion of higher-aged population groups will increase, e.g. people aged 80 years and older will triple until 2060 (Statistisches Bundesamt, 2009). Especially rural areas are affected by these trends. Rural areas make up to 96 percent of Germany's territory and 71 percent of the German population. According to the OECD (2007), rural areas are divided into three categories: predominantly rural, semi-rural, predominantly urban. The rural areas are characterized, among others, by a lower population density (less than 150 inhabitants per square kilometre), an ageing population and a minimally equipped infrastructure and basic services. Whereas populated areas record an increasing number of inhabitants (OECD, 2007), rural areas suffer from a declining population.

1.2 Challenges of rural areas in demographic change

The decreasing population results in lower quality of life due to gradual reduction of infrastructure. However, there is a rising need for rural supply because of ageing population. In the future, the group of over 65 year olds will gain importance in many areas of life. But these people do not represent a homogenous group. Hence a generalization of the characteristics and needs of the elderly is impossible. However, seniors differ especially due to ageing compared to younger generations and thus have special requirements towards their environment. A particular challenge of demographic change deals with a quantitatively and qualitatively adequate supply of the population with services and infrastructure. Especially in sparsely populated rural and structurally weak areas where younger people leave and mainly the elderly remain there could be supply deficits through vacancy of buildings, lack of economic resources and financial constraints on local authorities. This in turn entails the dismantling of infrastructure, such as the setting of bus services, the closure of schools and post offices. Looking at the forecast of the next few decades, an increase of these trends in some regions is foreseeable.

1.3 Local supply in rural areas in danger

Local supply in rural areas is determined by different interacting factors, e.g. food, health care, social interaction and political systems. Services of general interest comprise services that offer a special public interest (Einig, 2008, 17). These are goods and services that are necessary for human existence and aspects of the welfare state principle. The EU Commission defines services of general interest as market and non-market services that are provided in the public interest and therefore linked by the authorities with specific public service obligations (KOM 2000, 42).

Services of general interest are technical facilities (as to say water supply, sewerage and waste management, communications and transport infrastructure), social services (e.g. education including child care, cultural institutions, health and elderly care) as well as emergency services, fire and disaster control. In particular, ensuring high quality of public health is one of the central tasks of the German welfare state. Local supply is often not directly taken into account as it is mainly provided by private service providers. However, local supply is a basic need that must be guaranteed in terms of welfare. Especially inside the residence, local supply has to satisfy primarily short-term and medium-term demand for goods that are required every day. Altogether, local supply is an important part of social

participation and part of constitutionally required equally securing of living conditions (see Article 72 (2), Constitution of the Federal Republic of Germany).

2 Securing the future and viability of the rural areas - but how?

2.1 Need for conceptual strategies for new supply solutions

For the purposes of equal living conditions, for all sections of the population and for effectively securing the future and viability of rural areas despite of demographic change, it is inevitable to develop basic conceptual strategies for new supply solutions. Due to the ageing of the population, local supply requirements increase. Furthermore experience shows that people aged 65 years and older visit general practitioners most often. The paper therefore focuses onto these two specific but highly relevant areas of medical supply and local supply.

2.2 Local food and medical supply as study focus

Structural changes in retail food supply: There is a significant decline in sales points in Germany - from 150,000 in 1966 to about 55,000 in 2002 (Kuhlicke, 2005). In particular, smaller, neighbourhood-oriented retail outlets are affected by closures. Furthermore, a clear structural change regarding forms of offering can be observed - from independent retailers to supermarkets, hypermarkets and discount stores. The locations of food retailers are increasingly oriented to the accessibility by car and have increasing requirements (e.g. sales area of at least 700 square metres). Demographic change will exacerbate this situation because a higher proportion of population is affected by these problems. Especially less mobile population groups are affected by the deterioration of local supply. About 8 percent of Germany's population are people with disabilities. Especially so-called corner shops are threatened by the ongoing rural development. These corner shops are retail stores that offer food and other everyday items. The business is often so small that only one person, often the shopkeeper him-/herself, works there. In Germany, the common speech calls these shopkeepers "Aunt Emma".

Threatening outpatient medical care in many rural areas: In the next few years, many doctors will retire: this is a consequence of the unfavourable ageing structure of active medical professionals in Germany. From 1999 to 2009, the average age of contract doctors increased by three years to 52.1 years (Adler, 2011). It will be difficult to find successors for all practices - especially in rural areas. One reason why re-occupation of physician practices is so difficult in rural areas is the lack of attractiveness, especially for young professionals. Many doctors complain about unfavourable conditions. High workload with decreasing profitability as well as negative factors such as the lack of cultural events or long distances to educational institutions and schools for children discourage many young doctors.

2.3 Objectives

The objective of this paper is to analyse which requirements citizens in rural areas have regarding supply concepts and what kind of solution is possible. The aim is to identify critical requirements and acceptance factors that should be considered when establishing local supply concepts in rural areas in Germany. Especially the following questions will be responded:

1. What kind of local structure is needed to provide a basic supply of goods and services in rural areas?
2. What kind of solutions is needed in outpatient medical supply to meet the necessities of a rising number of consumers in rural areas?

3 Requirements and acceptance of the population as key criteria for new concepts

3.1 Identification of requirements and acceptance factors based on Kollmann (1998, 2000)

In order to examine predictable factors related to requirements and acceptance of citizens regarding new concepts in supplying rural areas, a specific model is chosen to identify these critical factors: the dynamic acceptance model of Kollmann (1998). Within this model, acceptance is viewed as a process with three phases (see Figure 1):

Figure 1. Phases of the dynamic acceptance model of Kollmann (1998) (own illustration based on theory of Kollmann 1998).

The attitude phase consists of awareness, interest and expectation. Here the expectations and attitudes of potential users that lead to a positive buying decision or excludes a possible purchase are examined and highlighted. The process results in so-called attitude acceptance. During the adoption phase, potential consumers run through different processes, which are divided into testing/experience, purchasing/acquisition and implementation. As a result, a new acceptance value (adoption acceptance) is created. If a purchase decision is positive, the actual use and acceptance of an innovation can be observed (use phase). At the end of this phase, a first reliable result in terms of overall acceptance of a product, service or concept can be observed. In this paper we focus on the attitude phase, examining awareness, interests and expectations.

In order to identify the factors that influence the requirements and acceptance regarding local and medical supply solutions, this paper uses Kollmann's (2000) classification of determinants that affect acceptance directly:

- **Product-related determinants:** these are typical characteristics that are necessary to assess an innovation, such as relative advantage, complexity, compatibility, divisibility, communicability, uncertainty and use of readiness. Use of readiness refers to the ability of innovations to enable an individual and problem-oriented use.
- **Adopter-related determinants:** these contain socio-economic criteria such as age or social status as well as psychographic criteria. To these belong e.g. lifestyle, personality, perception, motives, attitude and expectations. Furthermore these determinants include the observed buying behaviour and actual usage behaviour. The observable buying behaviour refers e.g. to product choice and price behaviour. Regarding actual usage, a relationship between frequency of use, usage patterns and use of acceptance is generated.
- **Company-related determinants:** these describe organization-specific variables such as firm size, location, economic situation, organizational structure and industry. They could also include buying-centre-specific variables such as decision makers, influencers, users and buyers. Furthermore, there are decision maker specific variables such as socio-economic variables, psychographic variables, professional motivation, risk-taking, position in the company and buying-/utilization-related variables.

There are also **environment-related determinants** that form the overall framework and thus influence the process in general. This entails the technological environment (e.g. norms, standards, technical development), the macro-economic environment (e.g. market structure, economic situation, funding sources, market growth expectations), the political and legal environment (e.g. data protection act, interest groups, competition law, market access restrictions) as well as the socio-cultural environment (e.g. public opinion, social norms, user groups, communication habits).

Against this background, it is possible to define the evaluation grid for the respective creative workshops and to create the workshop concept in order to get answers to these acceptance determinants (see Figure 2).

Figure 2. Evaluation grid of requirements and acceptance factors of supply concepts in rural areas (own illustration based on theory of Kollmann 1998, 2000).

3.2 Direct integration of people into the study based on the life situation approach

In order to develop new sustainable concepts, it is important to understand that people act and behave in different living situations and have to deal with different external circumstances. These are often not comparable from person to person. Life of a person includes a variety of dimensions such as income, employment and occupation, wealth. But also social life, social care and network resources. The inclusion of individual perception and orientation is a necessary condition in order to understand people decisions, expectations, hopes and fears. Empirical studies of innovation research show the importance of users as active participants in successful innovation development (von Hippel, 1998; 2001). The interaction with users in the design phase of new concepts, be it products or services, allows a greater orientation towards needs regarding innovation and the early response to problems of acceptance by later-users, which consequently leads to an improvement in quality of innovations. Thus, in order to develop sustainable concepts for solving social and economic problems, it requires a participatory process with inclusion of citizens in every workshop setting and topic.

4 Methodology

There were methodological problems answering these research questions because everyday life of citizens is highly complex but has to be displayed within their complexity. That is why, a qualitative research approach was chosen. Regarding on both supply topics “medical supply” and “local supply”, specifically developed workshop concepts were designed so that citizens are involved as experts in the development and evaluation of practical, implementable and sustainable solutions.

4.1 Setting

In between November 2013 and July 2014, a total of five creativity workshops in different German cities (Nuremberg, Regensburg, Coburg, Augsburg and Wuerzburg) were performed with a mean number of 10 participants. Since critical requirements for medical and local supply services should be generated from a use perspective, a user-centered design of workshops was chosen. This approach guaranteed that the user took over an active role in the generation and assessment of new services (Edvardsson et al. 2010). It was observed that most of the participants were over 60 years old, native speaker and they were often socially committed. Through their registration, the participants agreed in taking part in the workshops voluntarily and free of charge. The implementation of both workshop topics “Aunt Emma Is Dead! - Long Live Aunt Emma! - New concepts in the local supply” (workshop theme 1) and “Rural Areas In Transition - Prospects of Future Health Care” (workshop theme 2) was hosted within the so-called “Regional conferences for more social participation (RegiKon)”. The aim of these regional conferences was to identify novel concepts and potentials of information and communication technologies and to network. There should be an exchange of experiences and the creation of a platform to provide information in the context of social participation, civic engagement and neighbourhood (for further information: <http://www.geronto.uni-erlangen.de/forschung/regikon.shtml>).

4.2 Special workshop concept - Focus groups und personas

In the context of the workshop concept based on appropriate creative activities, the participants are guided and encouraged to reflect which requirement and acceptance factors of the examined solutions can be listed. In addition to

their personal opinion, the participants are dealing with the personas method in order to put themselves in the position of different groups of people and their needs.

Focus group interviews were chosen due to the fact that usually six to ten respondents can be interviewed at the same time, a recording by audio or video and a natural speech situation are possible. Disadvantage focusses the lack of structure of the responses, so coding is difficult, as well as the fact that not every participant can answer each question on his own including that there is little information about each participant him-/herself (Kuß, 2012; Mayerhofer, 2009). The content and order of the temporal sequences are usually well defined (Blank, 2011). Each participant was free to select his preferred workshop topic at the conference. Thus, it could be assumed that each participant has a concern or at least interest in the subject that was chosen. Furthermore, by choosing the form of "managed creative group", a sub-form of group discussion, the performance of the group could be increased playfully in combination with a variety of creative techniques (Kuß, 2012).

Personas as special kind of projective tools were used. A uniform definition of personas does not exist. However, there is consensus in literature that personas are fictional archetypical characters that represent distinct groupings of behaviour, goals and motivations (Chen et al., 2011). They "represent groups of users" (Chapman et al., 2008) and represent persons that are representative for the investigated context (Nielsen, 2013). In our workshop, personas were used to enable the participants to place themselves into the situation of specific groups in order to identify irregularities or work out suggestions for improvement or advantages and disadvantages and different customer needs or benefits.

4.3 Approach

The workshop concept was applied methodically to both workshop topics, local supply and medical supply, and was carried out in three parts within 90 minutes. Up to three moderators supported the implementation of each workshop.

In the first part, the participants were welcomed and introduced to the topic. In the second phase of the workshop, participants were divided into three groups and each group was led by one moderator. First, participants were asked to approach the object of investigation in a playfully manner. For this, each participant had the opportunity to tinker with his own "Aunt Emma" or his own "Country Doctor" according to their own ideas with paper dolls. The participants had the choice between different torsos, heads and various clothes. Upon completion, the participants presented their specially designed dolls orally in their group and explained what memories, ideas or associations they had according to their customized doll. The dolls were then pinned on a board that was clearly visible.

Afterwards (second part), the participants were set in a story about an imaginary village with various situations. For this purpose, the moderators asked the participants to put themselves in the situation of residents in this village. In the first workshop topic (local supply) there existed a village shop on site and the residents were asked about their own ideas and needs. The second workshop topic (medical supply) used a negative scenario in which a recognized doctor retires and leaves with no successor to his practice. All participants had the opportunity to concretely address the issue of rural supply, as they are personally affected and had to search for their own solution proposals. After that, all participants were asked – despite their "I"-perspective – to put themselves into the perspective and position of other two personas in each group (see Table 1).

Table 1. Personas used per workshop topic per groups (own illustration).

	Personas in workshop topic 1: Local Supply	Persona in workshop topic 2: Medical Supply
Group 1	mother, 35 years (single parent, two children, unemployed)	old lady, 87 years (no car, walking aid, children living in the city)
	pensioner, 81 years (widowed, three adult children limited mobile)	
Group 2	grandmother, 67 years (married, five grandchildren, former secretary)	
	teenager, 18 years (single, no children, trainee)	
Group 3	family man, 52 years (married, one child, enterprise employee)	
	hairdresser, 40 years (in a relationship, one child, self-employed)	

Regarding workshop concept 2 (medical supply), besides own ideas for new health care concepts various existing or potentially useful supply concepts for health services were presented in the group work in order to derive statements of what is needed and accepted (see Table 2). Health care in rural areas in Germany is discussed to be designed in the future especially by combining services in central locations (medical center), mobile care services as mobile medical practices, the use of telemedicine, temporarily occupied practices, pick-up and delivery services and community nurses. The participants of the workshops had the opportunity to discuss the advantages and disadvantages of each concept

from the “I”-perspective and the particular perspective of the used personas (due to the discussion of six medical supply concepts only one persona was presented in each group in workshop topic 2) and to bring suggestions for improvement.

Finally, in the third part, respective group results were presented all participants in a plenary by the moderators. In an open discussion, participants once again had the opportunity to deal more intensively with the topic by discussing. All statements within these workshops were recorded by voice recorders and evaluated with content analysis (e.g. Kassirjian 1977). In the content evaluation, based on the acceptance model of Kollmann (1998), aggregated categories were formed for all workshops which in addition to the requirement criteria allow insight into the spontaneous reactions and motivations of the participants, such as enthusiasm, desire, rejection etc.

Table 2. Medical supply concepts regarding workshop concept 2 (own illustration).

	Medical Supply Concepts	Description
Group 1	telemedicine	...means that health data are digitally recorded and transmitted to healthcare workers. So there is a constant medical care across spatial distances.
	community nurse	...is a specially trained nurse who makes house calls to patients once or twice a week. She is responsible for care and follow-up care in home settings, but does not determine types of therapy.
Group 2	mobile medical practice	...are special converted vehicles, in which treatments are carried out once or twice a week. Check-ups and services such as vaccinations and dressing changes can be covered.
	pick-up and delivery services	...ensure permanent transfer to the next town or a home supply. The patient can visit a doctor or is provided with medicines, etc. at home.
Group 3	temporarily occupied practice	...is a second practice of a general practitioner. Patients can visit a doctor during consultation hours that are offered once or twice a week.
	medical center in a neighboring village	...is a permanent institution with numerous doctors. Many therapeutic and diagnostic options are offered. However, the patient is responsible for the transport himself.

5 Findings

Based on the qualitative content analysis, the findings of this paper are profiles of requirements for sustainable models of rural supply and give recommendations for their design. These should lead to a higher efficiency regarding the implementation process of sustainable models for local supply in rural areas regarding basic supply of goods and services as well as outpatient medical supply.

5.1 Local structure for providing basic supply of goods and services in rural areas

Findings towards the first research question, what kind of local structure is needed to provide a basic supply of goods and services in rural areas, all answers point into the same direction: “Aunt Emma” is not dead, it must rather be revived. For all workshop participants, a corner shop represents an irreplaceable opportunity to provide them with food and demands of daily life. Based on the evaluation grid of this paper (see chapter 3.2), in the following, requirements and acceptance factors are explained and illustrated which were identified in the context of the content analysis and summarized in Figure 3. Since the statements that were found regarding personas show no differences - except for the product-related determinants - they were evaluated together with the “I”-perspective.

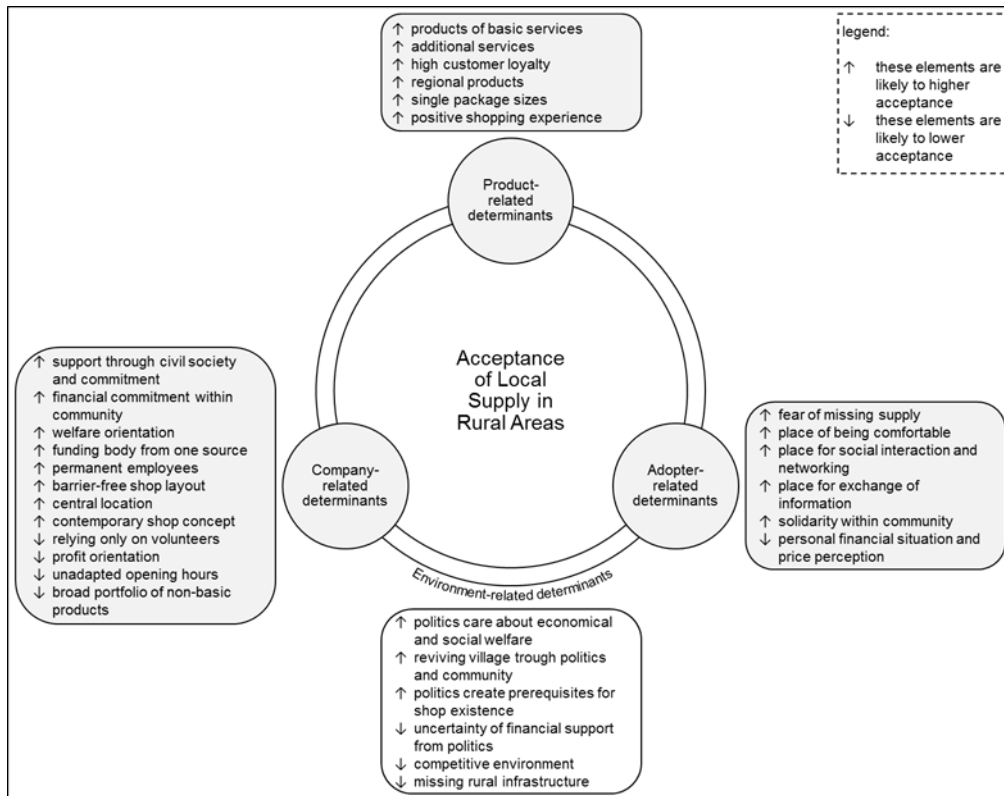

Figure 3. Detailed evaluation grid of requirements and acceptance factors of local supply concepts in rural areas.

Product-related determinants: In a corner shop food products are expected in the first place from the “I”-perspective as well as all personas: from basic foodstuffs (such as pasta, bread, eggs, milk, sugar and salt, butter, meat and cheese, fruit and vegetables) over (alcoholic) beverages to luxury consumables (e.g. candy, tobacco). Furthermore, a small refrigerated counter with frozen products (e.g. pizza) and a shelf with canned food should be available. But even a basic need for drugstore, sanitation and office requisites (such as toiletries, paper handkerchiefs, toilet paper and laundry soap, magazines, greeting cards or stamps) should be supported. But there are some expectations that are persona specific: just the persona of the teenager could ask for contraceptives, the hairdresser with her child on the other hand baby products such as diapers. From the perspective of the grandmother also tickets for the bus (much more personal than a ticket terminal), flowers, knitting/sewing accessories, animal food and small gifts for her grandchildren would have to be re-purchasable. The size of the products should be usable for all households; food that is not packaged is preferred. Inferior goods are excluded. Electrical appliances, clothing, shoes, fashion jewelry, home improvement articles should not be sold. Also non-prescription pharmacy products were mentioned especially for elderly people as well as personas with children. A pharmacy itself, however, consistently was excluded due to legal issues. But as a special service of the corner shop, a pharmacy pick-up and delivery service could be offered within the corner shop. It would also be useful if the shop includes a post office, information corner about and products from farmers of the region and a coffee machine. Offering additional services could higher the attractiveness of the corner shop attractive for many people, e.g. through home delivery of products in the form of pick-up and delivery services or bringing people to the store via bus connections. Especially people without a car or limited mobility can benefit from this. Furthermore, the possibilities of the internet can be integrated: orders can be made over the internet (as well as on the phone) to avoid a high stock of goods and orders can be picked up upon arrival. Also transmitting events of the store could be possible. Especially for people with levels of care, this would be a way to maintain contact in the world outside. There is a need for different actions inhabitants can actively get involved. For example, pre-Christmas cookie baking, baking in general and reading evenings were named. Also, the possibility of using a secondary space for events and courses within the shop was mentioned.

The aspect of the regionality of the products was very significant for every participant: the offering of products from the specific region could represent a differentiation character (e.g. homemade jams and cakes, farmer products from the surrounding area). But it was criticized that having everything in one appears difficult to implement. Focusing on the supply of products of daily use is significant. Especially from the persona perspective of the father, it is useful to buy basic items he forgot to buy in large supermarkets.

Adopter-related determinants: Not only food supply and services play a role: the participants in the majority agreed that the corner shops are perceived as a center of communication, a place of well-being with an atmosphere of trust and personal encouragement. Anonymity should not exist there. Rather, it is a place that brings people together and is kind of a village center. The already existing concepts of baker busses or butcher cars are important, but they would

not fulfill the aspect of informing, sharing and communicating and that is why they do not contribute to a vibrant village life. The opportunity to interact communicatively and socially through a kind of small coffee and pastry corner with seating is very attractive, especially for older residents. Also, the presence of a notice board, as for flea markets, neighborhood help, sharing and event information is considered significant: only a strong village community is viewed as a prerequisite for the success of such a store. The desire for longevity of the store is particularly pronounced: the fear of missing supply is profoundly. The workshop participants would avoid a store, when it is much more expensive than discounters. It was feared that due to the small size of such a corner shop each product would be very expensive, due to minimum order quantities. The individual financial situation is important, too: no citizen should ever be excluded by the prices from “Aunt Emma”.

Company-related determinants: Regarding company-related determinants, the most important aspects mentioned were: ownership, human factors and shop design. From a business perspective there was skepticism among workshop participants regarding a realization of the ownership. From a financial point of view, Cooperatives are very interesting. The aim of such a concept has to be viable on its own: without profit it is not worth it. There was generally agreement that there must be a person who assumes managerial character and exaggerates the concept: whether public or private. A person that takes over initiative. At the same time one has to find the balance between profit and human factors: such a store concept only exists by taking into account the common welfare of all inhabitants. The inclusion of the entire village community is essential – and can secure the business survives in the long term. People can make their contribution to the store offering their different skills: such as marketing knowledge or artisan activities. This is an excellent work with volunteers. Without volunteers it will not be feasible. But the concept should not be based only on voluntary work. It takes at least one permanent employee resistant in case of losing (all) volunteers. In addition, hourly time sharing models can be used. Mothers, socially disadvantaged, young people and families - each person can be included. In this way, intergenerational work can be realized which is indispensable for a vibrant village community. Even official honors of the local municipalities are to be considered. The accessibility of the store must be ensured, i.e. suitable for walker-rollers and prams. A central location in the village is preferred, so that everyone has short paths. However, a viable operation of the store is only possible if the respective place has a certain size in order to ensure a customer base. The opening hours of the corner shop have to be adapted to the peculiarities of the villagers: during the week 7-13 o'clock and 15:30 to 20 o'clock to accommodate the returnees to the village. Saturdays the store should be open from 7 to 13:30 o'clock and on Sundays after church.

Environment-related determinants: Based on the environmental point of view, the important role of community or even the local administration was mentioned. Special financial support and funding for village renewal and recovery could be a way to receive the concept of corner shops. It could also be operated by community itself which also has the responsibility to secure and expand infrastructure. A official recognition by communities for the involvement in corner shops is of particular importance (e.g. in the form of certificates or appreciation). A kind of store management is conceivable, which is suspended in the administration of the municipality itself. From a market perspective, corner stores cannot compete with the big supermarkets. But they do not need to do this, if they can prove their own perceived values and benefits: they are more than a supermarket: they are vibrant village centers with an important social factor.

Summary: A corner shop is very suitable as a local structure to provide a basic supply of goods and services in rural areas. But to do this, it is necessary to develop itself from a pure product provider to a service provider. The concept of “Aunt Emma” should not have a too narrow perspective – that was the major demand of workshop participants. The corner shop has to be used as a starting point of further developments in services and products. Furthermore, setting up such structures of the village centers is not easy. Experts are needed who have the appropriate expertise for designing, developing and implementing local and internal structures of such a supply concept. It would be, for example, advantageous to have a focal point which bundles these activities such as district offices. The required knowledge is very comprehensive and special: tax, accounting, labor legislation, liability and insurances as well as health certificates just to name a few. This is the reason why development of practical guidelines is necessary: e.g. a kind of checklist, which includes the essential aspects to be observed. It should be noted that such a guideline cannot be seen as a patent solution since the specifics of the respective localities must be considered. Every community has different characteristics that need to be considered.

5.2 Outpatient medical supply for people in rural areas

5.2.1 Six health care concepts reflected by the workshop participants

Six concepts, which are already mentioned in German policy considerations, were intensively discussed by the workshop participants.

Temporarily occupied practice: The participants suggest to offer flexible consultation hours in temporarily occupied practice (e.g. in the evenings) and to ensure the accessibility within walking distance for the village people. The cases of acute and chronic diseases are seen as problematical because they do not appear during consultation hours. A mutual trust in the contact between doctor and patient should also be existent. During the brainstorming of ideas, the participants also suggest that the community should provide practice rooms or ensure rotating physicians for the medical supply of rural areas.

Mobile medical practice: The possibility of a car with special equipage (ultrasonic system, lab, X-ray apparatus) is special. Though the full service provision is not be ensured, focusing on basic medical care is given. The arrangement of queue times in front of the car is to be seen as a problem. A lack of flexibility is also be criticized by the participants. The persona of the 78-year old lady with limited mobility should also have the possibility to receive home visits by the doctor with this car. In any case the car should come to the patients, because the mobility problems of patients should not limit consultations.

Community nurse: Already during the brainstorming part, the participants suggest that a doctor's assistant can be a trustworthy person that could support the provision of general medical care if a doctor is not on site. A community nurse is responsible for pre- and postcare, medical monitoring, supply of medicines and for medical counseling but is limited in the therapy of patients. She offers visitation services. Primarily the persona of the 78-year old lady, the community nurse is a grateful concept. She would use the concept more because she has the possibility to stay in contact with the outside world. Moreover she could hold conversations with the nurse. Hence, the care is most important. However the scope of action of the community nurse and her missing medical apprenticeship are seen as big complexes of problem by the participants.

Pick-up and delivery services: This concept is seen critical by workshop participants due to unclear financing and a high organizational effort. For the improvement of mobility, transport services like collective taxis or carpooling to consultation hours should be considered.

Telemedicine: The possibilities of remote diagnosis and the transmission of health problems and consultation hours via internet were discussed controversial. Telemedicine is more seen as an instrument in case of emergency or an auxiliary tool. Problems concerning technical handling (support is needed), perceived anonymity and a lack of mutual trust are mentioned. Moreover haptic checkups could be missing during the anamnesis.

Medical center in a neighboring village: The mobility of patients is in the foreground of this concept. Good connections to public transportation, the organization of neighborhood help arrangements or the possibility of home visits by the doctors are facts that should be given. Mainly the persona of the 78-year old lady is dependent on aid of her children or a good connection to public transportation to reach the practice in a neighboring village.

Further suggestions: There have also been further suggestions by the workshop participants that were not covered by the listed six concepts: it was important to have at least a minimum level of medical supply in the community for example by flexible practice hours in various forms: two to three times per week by phone or internet. Specialized training such as the use of home remedies or first aid (dealing with the defibrillator by volunteer fire department) were mentioned. A desire for advice in case of illness was crucial for the desire of having a local pharmacy - an internet pharmacy would not be sufficient. Another approach could be the existence of a health care manager who knows the community structures and its residents. He/her organizes transport services (e.g. taxi-orders) and supplies the local inhabitants with important information. The mayor and the municipality should fund and support this.

5.2.2 Requirements and acceptance factors for medical supply

Due to the specific statements on the individual concepts, it was possible to derive the determinants by Kollmann (see Figure 4).

Figure 4. Evaluation grid of requirements and acceptance factors of health care supply concepts in rural areas.

Product-related determinants: The physician’s know how is very important to the workshop participants. Inadequate treatment should be avoided by professional experience of the physician and a good previous education. Furthermore, the physician should constantly perceive training to be always in line with the current status of research. Furthermore, a full-time availability of a physician at least on certain days a week is important. This implies clinic organization and low latency, adapted to the habits and needs of the inhabitants. Health care should be guided by the needs of the individuals. Also, the aspect of data protection was noted by the participants. The fear of data misuse in a technical or scientific way must be considered. Safety aspects regarding the use of medical services have to be observed, for example in case of failure of house emergency call services. This also includes that quality of individual health services plays an important role especially in the technical field.

Adopter-related determinants: A trusted relationship to the attending person is most important. In particular, a need for a trusted sympathetic person is expressed, a special desire for detailed explanations of the disease and responding to personal needs. There should not be a sense of distance. The treating person should act as an attentive listener regarding disease history, family and knowing the personality of his/her individual patient. In particular, a frequent change of the treating person is not wanted. The need for human interaction is thus related. For example, telemedicine is not a replacement of the doctor. The technology readiness is a very important aspect regarding the use of technology in health care such as telemedicine. Some patients are getting used to it others feel fear and reject it. Especially elderly people feel fear of doing something wrong with the device. A direct interaction with a doctor is desired; an interaction via internet is seen quite skeptically.

Company-related determinants: A discharge of the physician by civic engagement was mentioned by the participants, e.g. through helpful neighbors and driving services. This could be established by the local community or church in order to organize the trip to the doctor. Nevertheless, the rideshare opportunity is seen rather critical because there is given a risk of infection. The customer-focused design of the place of health provision was important to the workshop participants. Especially regarding the mobile medical practice, the waiting area should be pleasant and independent of all seasons. Especially accessibility must be ensured, for example, with the establishment of space for walking aids or lifting aids. Furthermore, networking potentials and synergies with existing structures should be intensified, e.g. with home care service like Caritas and Diakonia.

Environment-related determinants: According to the participants, there must be political incentive systems for the settlement of doctors in rural areas. The community must support the settlement of doctors. Financial support through the municipalities should serve, for example, for the recruitment of doctors and the provision of consulting rooms as well as providing infrastructure (e.g. schools). Furthermore special information should be given to the doctors, especially about the composition of the community population or other doctors in the region. The attractiveness of the medical profession in the country is limited. Citizens could support their doctor by civic initiative for example through

petitions. The restriction on emergency care in place by a hospital outside the community is viewed critically: losing valuable time because of large distances. Also the extension of the scope for medical action of non-medical professionals was mentioned. For example, community nurses have legal restrictions regarding treatment and have to do a lot of paperwork. They could get more tasks and responsibilities in order to support the inhabitants much better. Unclear financing sources are an important obstacle in realizing new health care concepts. According to the participants, especially health insurance should support medical supply much more.

6 Conclusion

6.1 The key role of civil voluntary engagement in social innovation

As all workshop findings indicate: civil voluntary engagement has a significant relevance for the assurance of rural supply services, though it requires general conditions especially the existence of social rooms. Active local co-creators and empowered citizens are seen as an opportunity for designing functional and attractive villages in the future. In order to involve more citizens as new players into the field of general interest, legal aspects, possibilities for decision making financial incentives and professional support are needed as well as a creative collaboration with authorities and government. Successful support of civic commitment therefore is recommended to create structures in the long term, to specifically qualify volunteers, promote commitment of employees of the municipality and to develop an appreciation concept. Another important task is networking of organizations and associations. Modern Internet-based communication structures are essential and recommended. Given the demographic developments, it is important to strongly consider the commitment of elderly people.

By promoting the commitment of these people, their time, resources and especially lifetime experiences can be made available for the community. The increase of elderly in German population is an opportunity to shape the future. Especially given the growing importance of social innovation - this means the development of practice-oriented concept models and methods as well as application-oriented strategies for the conservation and participation of older people in work and social life - this is indispensable. (Future) projects of general interest require connection points in the commitment structure on site. Citizens are increasingly invited to create local infrastructures. For this reason they need a climate of participation and involvement that allows appreciates and supports. In order to activate more citizens, municipalities should create more decentralized structures for a community-based approach on the one hand. On the other hand, one has to motivate citizens as well, so they are willing to improve their microcosm and form their environment actively.

6.2 Limitations and further research implications

Based on the identified problem areas and needs for action, potential solutions have to be identified and a practical review is needed. The results of our workshop give hints which aspects are important and can indicate which aspects should be considered when creating rural supply concepts. Nevertheless it is necessary to repeat these workshops in those specific areas where people and local administrations think about basic supply of goods and services or outpatient medical supply. Especially the implementation of the proposed solutions in local communities plays an important role. Besides the conception in real rural regions, in particular issues of economic exploitation and further studies on the social acceptance of such systems are to be answered. Unanswered questions in relation to the success criteria and problem areas can be clarified by further quantitative analysis as well as through special community field-studies with enhanced involvement of local residents, institutions and political actors.

Users as effectual innovators: A new perspective into user and service innovation

Arja Kuusisto, Juha Arrasvuori, Jari Kuusisto, Liting Liang

University of Vaasa, SC-Research, Industrial Management, Vaasa, Finland

This study suggests that effectual logic can be used to understand and stimulate user roles in service innovation. When users' activities are effectual, they are driven by 'acting-to-see-what-goals-might-emerge' logic, rather than specific pre-determined goals. Empirically, the focus is on Internet services. The study analyses whether the use of Internet services such as Kickstarter and Pinterest is effectual in nature and develops a preliminary model of effectual process in the context of Internet service use. The idea that the use of Internet services can trigger effectual thinking and action is explored. The paper concludes with suggestions on how the service provider might benefit from understanding of its users as effectual actors.

1 Introduction: what can we learn from prior literature

1.1 Effectual logic

Effectuation, as introduced by Sarasvathy and his co-workers (Sarasvathy, 2001; Sarasvathy; Dew, 2005; Read; Sarasvathy, 2005) has been developed as a logic of entrepreneurial expertise. It is suggested as an alternative to the logic of predictive rationality. Predictive rationality involves two types of uncertainties or guesses: "a guess about uncertain future consequences and a guess about uncertain future preferences" (March, 1978, 587; cited in Sarasvathy; Dew, 2005, 386). The latter guess or uncertainty is particularly important to the present study: When we aim to understand human behaviour, we usually assume that people know what they prefer (in the future). However, it has been demonstrated that our goals and future preferences are ambiguous, inconsistent, conflicting and unstable (Sarasvathy; Dew, 2005).

The Harvard psychologist Daniel Gilbert has been exploring the nature of psychological mechanisms, which distort our perceptions of the future. In his hugely popular book, *Stumbling on Happiness* (2006), he discusses the many ways in which our mental processes make it practically impossible for us to know now what will make us happy in the future. To give one example: when we try to imagine how we would feel about things in the future, we actually image how we would feel if they happened now. Our mental picture of our feelings in the future will be strongly influenced by our current state of mind. Further, we are not able to imagine all the details that will very much influence the actual experience in the future. Things look and feel different once they happen, which makes our attempts to imagine the future feelings and preferences flawed. As strange as it may sound, because our beliefs about what will make us happy are often wrong, we might as well not invest much energy into thinking and planning of our goals but rather go toward them. As Sarasvathy and Dew (2005, 399) cite the poet Roethke: "I learn by going where I have to go".

Returning to entrepreneurial context, Sarasvathy and Dew (2005) and Read, Dew, Sarasvathy, Song and Wiltbank (2009) have demonstrated that expert entrepreneurs tend to use effectual logic to tackle the uncertainty of future preferences: rather than first defining goals and sub-goals to determine resources needed and action to be taken, effectual entrepreneurs begin with the means available and start doing what they can. The action is not arbitrary, because the expert entrepreneurs use questions such as, 'Who am I? What do I know? Who do I know?', to direct their actions. It can be said that the goals emerge through courses of action, which begins from available means. In their article, Sarasvathy and Dew (2005, 387) argue that "the existence of ambiguous and even conflicting preferences is necessary for the successful creation of entrepreneurial novelty".

If expert entrepreneurs employ means-driven processes to direct their actions, to generate new goals, and finally, to generate innovative market offerings – could service users also employ such a logic to direct their creative endeavours? In other words, do users focus on "what *can* be done, given existing means rather than what *ought* to be done, given existing goals"? (Sarasvathy; Dew, 2005, 388). Not always, but sometimes. If sometimes, when?

1.2 User roles in (service) innovation

Prior literature on user roles in innovation has very much relied on the presumption that goals determine resources and drive action. Most often, when we look into user roles in innovation (in firms or other organisations), the starting point of action is the innovation goal held by the organisation.

Obviously, the firm often first examines user needs and practices in order to specify the innovation goal (Kristensson, 2006, 131; Leonard; Rayport, 1997). The idea is that new service development begins with new insight into user needs, which helps to specify the innovation goal and resources needed for the development project.

The innovating firm may also directly engage users into its innovation activities. Here the firm typically defines goals for co-operation: for instance, users may be invited to participate to provide feedback in various stages of the

development project, or to provide a special resource such as technological expertise or testing facilities for development (Kuusisto et al., 2013a).

The goals for co-operation in innovation may also be, and some argue that they should be, co-created with the users: Lundkvist and Yakhlef (2004) stress that goals for new service development emerge through dialogue between the service provider and the customers. Jaworski and Kohli (2006, 111) argue that “the voice of the customer (what the customer would like the firm to do) must be co-created.” Jaworski and Kohli (2006, 112-13) further explain that in a true co-creation dialog between the firm and the customer, the end point of conversation is relatively unclear; ideas develop when one partner says something that triggers another idea in the other partner’s mind, and so on. Such co-creative dialog bears a likeness to effectual reasoning: goals develop in the process of dialog. However, even in a productive co-creation dialog as described by Jaworski and Kohli, the focus is on specifying what should be done, on customer-needs identification, rather than beginning with the means available as a way of creating new goals (effectuation).

In contrast to the above, in user innovation literature, it is the user who has the goal: the user is facing a specific challenge to be solved, which motivates his or her actions (von Hippel, 1988; 2005). User innovators expect to benefit from their innovation effort by using the innovation themselves (von Hippel, 2005). There is good empirical evidence that user innovation driven by the need to solve a specific challenge takes place (Kuusisto et al., 2013b). User innovators are primarily innovating outside of interaction with firms. However, many firms are encouraging and directing user innovation activities to later build on and commercialise user-generated innovations.

Overall, prior literature on user roles in (service) innovation implies a logic that goals are first identified and specified to direct innovation effort. The opposite, effectual logic, according to which means are given and they direct the search for possible effects (goals), is emerging in studies emphasising co-creational aspects in innovation (Lundkvist; Yakhlef, 2004; Jaworski; Kohli, 2006). A good empirical example is provided by Coviello and Joseph (2012, 94): They describe how the opportunity recognition in cases in which customers contributed to successful major technological innovations could be best described as “ongoing co-creation of opportunity” as customers and the firm interacted over time.

Another stream of literature that refutes the idea that goals need to precede innovation activities is provided by studies examining innovation in knowledge intensive business services (KIBS). It has been found that *one way* in which service innovations in effect emerge is the inverse of the traditional ‘idea-development-implementation’ model. Toivonen and Tuominen (2009) describe this practice-driven model of service development as a process that does not start from idea generation at all, but the idea is found subsequently to the implementation of a new service. Such practice-driven development, where the service is produced step by step together with the customer, and its innovation potential is observed only afterwards, shows that innovation is often intertwined with the actual service process in KIBS (Sundbo; Gallouj, 2000). Hence, innovation process can start without any conscious innovation goal.

In the present study, the focus is on users as effectual innovators. We assume that users may be creative and end up generating innovations driven by ‘acting-to-see-what-goals-might-emerge’ logic, rather than any specific innovation goals in mind – as opposed to user innovation literature (von Hippel, 2005). It is interesting to note here that even though in user innovation literature a specific innovation challenge is very much the starting point of the innovation processes, Raasch and von Hippel (2013) have recently examined another type of (user) innovation driver: participation value. Participation value refers to the value that the engagement in innovation activity itself can entail: enjoyment and learning, social stimulation, and feelings of personal satisfaction derived from contributing to a good cause. Though this characterisation does not directly support effectual logic, it takes into account the fact that users’ innovative behaviour is not necessarily driven by the pursuit of a specific innovation outcome, but may rather be driven by the process itself as a valued experience.

Next, we will start to develop a model of effectual process in the context of Internet service use. The following section first describes the case material that will be used.

2 Effectual process in the context of Internet service use

2.1 Empirical data

The case material is based on user interviews and user generated material on selected Internet service sites. In addition, business journal articles discussing features and user behaviour on various (social) Internet service platforms provide background material. In particular, user interviews, discussions, comments on the following Internet services sites (blogs) have been examined:

- Kickstarter – American-based crowd funding platform for creative projects,
- Pinterest – American-based Internet service where visually attractive ‘pin-boards’ are generated by users to collect and share their interests,
- Dreamdo – Finnish-based Internet platform, which encourages users to develop visual content of their dreams and get encouragement and help from others.

All these platforms rely on user-generated creative content, and thus, involve creative engagement from their users. However, the sites may also be used to follow what others are creating. Hence, users may be generating content to the

site, following and commenting on what others are doing, providing help and advice, and even funding to interesting creative projects (funding refers particularly to Kickstarter, which has a multi-sided business model with project creators and project backers).

The role of the empirical data is to help develop the preliminary model of users' effectual process in the context of Internet services. The role of the empirical data is to *illustrate the reasoning*: the short excerpts from user interviews and user comments will show that effectual thinking patterns and behaviours can be found among users of these services. However, this data does not show that such effectual behaviours would be common, nor does it yet show that innovations (to the service provider) are produced as a result of users' effectual processes.

2.2 Thinking effectually and behaving effectually in the context of Internet service use

We develop a model of effectual process in the context of Internet service use based on literature and empirical data on user experiences on the Internet service platforms presented above.

The first assumption is that users often have rather general aspirations as they use Internet services – such as need for diversion and social interaction. This assumption gets support from prior research literature and from the empirical data as discussed next.

Studies that have examined gratifications people seek from media use (Palmgreen et al., 1985; Lee; Lee, 1995), show that users often describe their media use in terms of rather general intensions, such as, 'to stay on top of what's happening', 'to make myself laugh', 'to be entertained' (Lee; Lee, 1995). The use of service platforms such as Pinterest and Kickstarter can be compared to the use of other media content – indeed, they are partly social media. Thus, the research on the motives of media use suggests that the use of Internet services can be driven by motives such as aesthetic pleasure, emotional or intellectual stimulation, and social interaction.

The most basic distinction between different types of motivation is "between intrinsic motivation, which refers to doing something because it is inherently interesting or enjoyable, and extrinsic motivation, which refers to doing something because it leads to a separate outcome." (Ryan; Deci, 2000, 55). It is logical to assume that effectuation processes take place when the use of the service starts with predominantly intrinsic motivation, that is, when the person *is moved to act* for the fun, for the challenge, for the feelings entailed, and not for any specific instrumental reasons that the action is expected to result in.

Accordingly, we suggest that the trigger of action, the trigger of effectual use of Internet services, is intrinsic motivation. This is the first step in the effectual process model presented in Figure 1. The following quotes of Pinterest user experiences illustrates this:

"For me it's actually a diversion. When I feel a need to step away from my work routine, I often turn to Pinterest." (Kary Delaria, Pinterest user. Interview on <http://www.arikhanson.com/2011/12/13/whats-behind-the-pinterest-craze-15-super-users-share-their-thoughts/>. Accessed 12.6.2014)

"I like logging on to Pinterest and admiring the beautiful pins for the boards I follow. It's like window shopping for all my interests at once!" (Mariam Shahab, Pinterest user. Interview on <http://www.arikhanson.com/2011/12/13/whats-behind-the-pinterest-craze-15-super-users-share-their-thoughts/> Accessed 12.6.2014.)

The following two quotes from Kickstarter backer interviews (backers help to fund creative projects introduced on the site) highlight the importance of social and emotional stimulation, and the emotional reward from participation:

"The biggest thing for me is actually feeling that you're part of something. ... But here there's a sort of weird and lovely magic of, I'm part of this, I helped create this, this exists because of me, isn't this fun!" (Neil Gaiman, Kickstrater backer. Interview on <https://www.kickstarter.com/blog/meet-a-backer-neil-gaiman> Accessed 10.6.2014.)

"The best thing is definitely getting to follow along as the project goes forward. You get an inside view of the process, and feel like you are part of the team, having helped make the final product happen." Espen Arntzen, Kickstrater backer. Interview on <https://www.kickstarter.com/blog/meet-a-backer-espen-arntzen> Accessed 10.6.2014.

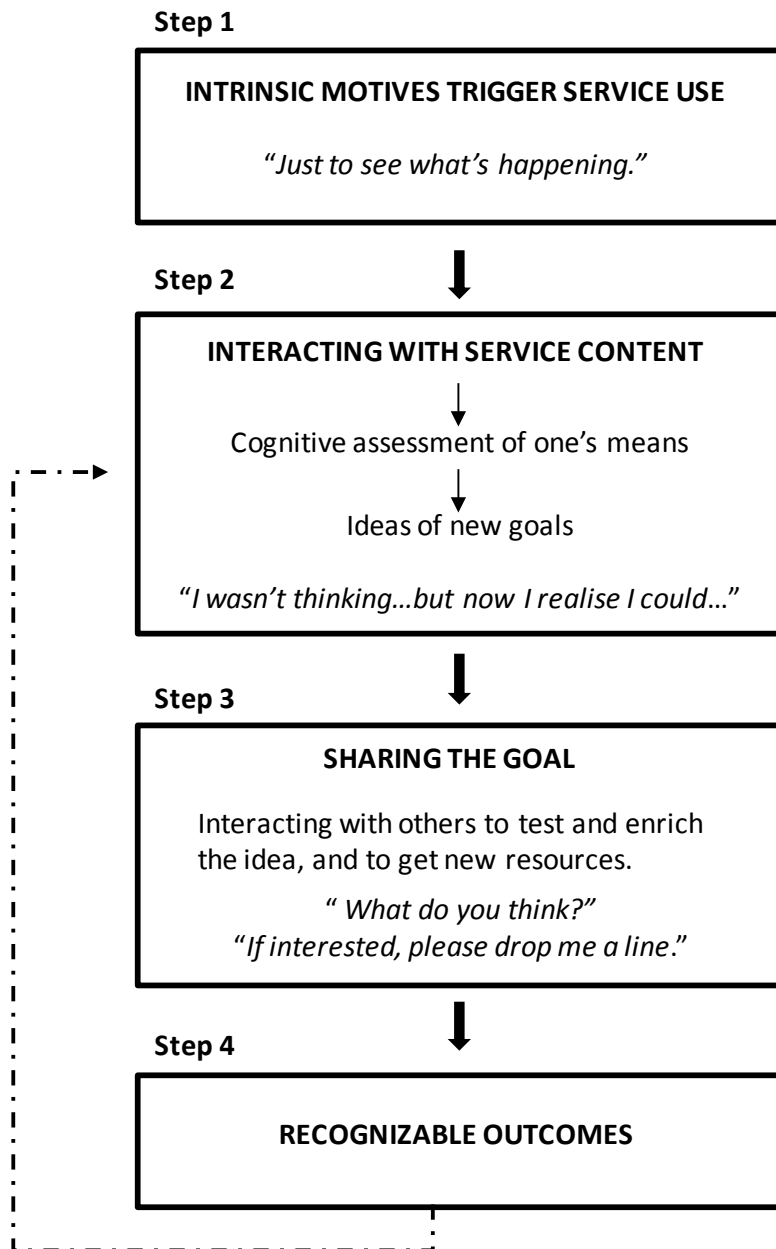

Figure 1. Effectual process in the context of Internet service use. Adapted from: Read et al. (2009), and, Fischer and Reuber (2011).

The second step in the suggested process model is when the user actually starts interacting with the service content: skim over, read, comment, copy material, and so forth – to check what’s happening now, how the project one has followed is developing, what’s new, who’s on the site, and the like. We argue that it is this actual interacting with the service content that will trigger the assessment of the user’s means in his or her mind.

When Sarasvathy and Dew (2005) describe the nature of effectual process in entrepreneurial context, they argue that the process starts with the entrepreneur assessing the means available to him or her, by considering questions such as, Who am I? What do I know? Who do I know?. Using the Internet service almost inevitably leads to some reflection of one’s means available, which may lead to new ideas of what one could generate with these means: ‘What (else) could I do?’ (also, Fischer; Reuber, 2011, 5).

With all our knowledge and experiences we simply cannot avoid generating new links between what we already know (and what will become activated in our mind) and the new stimuli we encounter (in cognitive psychology, new knowledge always becomes linked to some existing knowledge). In real life, we all are very familiar with the following type of reasoning: “I wasn’t thinking... but now when I see this / you mention this... I realize that...” Accordingly, we propose that the assessment of means, central to any effectuation process, is very much intertwined with actual use of the service. New insight into one’s means can lead to new ideas, to the generation of new goals, which the person did not imagine when starting to use the service site. This process may be very fast and take place in seconds, or it may be a longer one as exemplified next.

The first quote, is from the study by Fischer and Reuber (2011, 1), in which they examined “how effectuation processes are impacted when entrepreneurs adopt Twitter.” We reuse this quote from their interview material, because it provides such an excellent illustration of how the user’s following of others’ tweets leads him to recognize the means he has available and understand what he might achieve with his means:

“.. And I wanted to see the way that people were doing it. And so I sat on the sidelines for a couple of weeks. And then I started to find my voice. I realized that I read a lot and I’m exposed to some interesting things and I’ve got some interesting thoughts. Why don’t I put them up here and see what people think. And from there I’ve gone from zero followers to about 425 people that follow [Company] on Twitter now.” (Source: Fischer and Reuber, 2011, 8: excerpt from an entrepreneur interview.)

The following quote from a Kickstarter user interview gives another example of how spending time on the site, having interest in what others are doing, and learning from the others, makes the person assess his means anew (here as a creator of a graphic novel), which results in the emergence of a new goal for the person:

“After seeing that it was possible, ..., it was only a matter of time before I got the idea fixated in my head that I COULD and WOULD do this.”
(Trevor Charles, Kickstrater backer and creator. Interview on www.kickstarter.com/blog/backer-becomes-creator-trevor-charles-makes-a-grap Accessed 10.6.2014.)

The next quote exemplifies how a Pinterest user realized that her leisure usage of the service site can be useful in her work role as well:

“For instance, we recently provided some strategic guidance to a company that produces hand-crafted jewelry and I suggested taking a look at Pinterest as a means of sharing visuals of her designs. If you have a retail product line with great visual appeal, there’s likely a large group of “pinner” who will love to see your wares.”
(Kary Delaria interviewed on <http://www.arikhanson.com/2011/12/13/whats-behind-the-pinterest-craze-15-super-users-share-their-thoughts/> Accessed 12.6.2014)

Step 2 in the model, in which the user is interacting with the service content and a new goal is emerging, mainly refers to the cognitive component of the effectual process – thinking effectually (Fischer; Reuber, 2011). Next, we develop the idea of how the service user is behaving effectually. We propose that social interaction plays a major role here. In many Internet service sites, and not only in social media that focus upon networking (Facebook) or sharing of user-generated material (Youtube), interaction with other users is a key feature of the service. The two Kickstarter quotes underline the importance of the social dimension of the site:

“What if somebody out there is into it? What if a lot of people out there are into it? Kickstarter is wildly important. It’s not just a funding platform, it’s a testing lab for a new way of living.” (Lauren Krakauskas Kickstarter creator. Interviewed on <https://www.kickstarter.com/blog/ten-creators-one-question-what-did-you-learn> Accessed 10.6.2014)

“On Kickstarter you have the attention of people who want to believe, who want to help make something great come to life. That’s a one of kind opportunity. If you can’t connect to that audience then there’s no hope when you are in the real world..” (Coulter Lewis, Quinn Popcorn creator. Interviewed on <https://www.kickstarter.com/blog/ten-creators-one-question-what-did-you-learn> Accessed 10.6.2014)

Being able to easily interact with a great number of people, often from diverse walks of life, offers great opportunities for getting encouragement, feedback, advice – even partners and other resources for the endeavour. Very often, users start going toward their new goal by asking: ‘What do you think?’, or, ‘If you’re interested, please drop me a line’. Putting one’s idea for everyone to see to get feedback and other resources, is an important element of many Internet services. For instance, the service provider Dreamdo makes this feature of its service explicit when explaining ‘*What is Dreamdo*’:

“The best way to get inspiration and courage to pursue your dreams comes from following different people and brands doing exciting things. It works the other way round too: people anywhere in the world can follow your public dreams and offer help.” (<https://dream.do/en/about> . Accessed 18.7.2014)

Let us keep in mind that a person thinking effectually has not taken up to solve any specific challenge, but rather gets inspired along the way by what he or she now perceives as an interesting opportunity. It can be speculated that in such a situation the emerging idea is open to redirection: the person may be more willing to use the diverse knowledge and perhaps other help offered by people than if he or she had come to the site with a ready idea in mind. Elsewhere, such openness to experience from diverse sources has been shown to increase the probability of success of the innovative outcome (King; Lakhani, 2013). Sharing with others what one has in mind, and letting the committed others to further

shape the idea and the objectives for action is a typical response to environment by a person acting effectually (Sarasvathy; Dew, 2005; Read et al., 2009). This also seems to happen in the Internet service sites we examined:

“Michael Davis decided to make a version of the opening shot from the old Monkey Island game, where each pixel would be a Lego brick. ... It was exciting to follow the updates, from the beginning where it was just a guy with a cool project that might happen, through a sudden Twitter storm from famous game makers, and eventually he had a wall mural of 64,000 plastic bricks.”

(Espen Arntzen, Kickstrater backer. Interview on <https://www.kickstarter.com/blog/meet-a-backer-espen-arntzen> Accessed 10.6.2014.)

“We’re always talking to our community, and Kickstarter got that all started. Some of the folks on our team were our earliest Kickstarter backers.” (Sam Jacoby, Form 1 creator. Interviewed on <https://www.kickstarter.com/blog/ten-creators-one-question-what-did-you-learn> Accessed 10.6.2014)

“My favourite lesson is that if you believe in people a little, they believe in themselves a lot.” (Jay Silver, MaKey MaKey creator, Interviewed on <https://www.kickstarter.com/blog/ten-creators-one-question-what-did-you-learn> Accessed 10.6.2014)

Accordingly, in step 3, we propose that social interaction with other users on the Internet service site plays a key role in behaving effectually. Sharing the emerging idea, getting comments, advice, possibly committed partners and their resources along the way, helps to enrich and/or refine the idea and turn it into action.

The last step, recognizable outcomes of the effectual process may have various manifestations: in the Internet service sites we have looked into, from the point of view of the service users, they may be books, charity projects, innovative devices, travel projects, acquired new skills, new friends and relations, etc. Naturally such recognizable outcomes will lead to some re-assessment of the means (thus, feedback link from step 4 to step 2, Figure 1). From the point of view of the Internet service provider, these recognizable innovative outcomes might be, linking the service with other services, suggesting or adding new user groups or functionalities to the site, introducing new ways of making use of the service, and so forth. We will discuss the opportunities of the Internet service provider to benefit from effectual user behavior in the concluding section.

2.3 Can Internet services trigger effectual thinking and action?

Above we have introduced the possibility that the use of digital services itself may trigger effectual thinking and action. To our knowledge, this effect has been hardly examined. One exception is the study by Fischer and Reuber (2010): They got support for the argument that social interaction via Twitter can impact effectual thinking – how the entrepreneur assesses the means she or he has available and identifies the effects that may be generated with these means. But the idea that the use of (social) Internet service itself can trigger an effectual thinking and action process, though intuitively attractive, deserves further exploration.

In Figure 1, developed to characterise effectual thinking and behaviour in the context of Internet service use, we propose that *the stimulation provided by the service content* makes the user reflect upon his or her means and can lead to the identification of new goals for the person. Further, we propose that *social interaction*, which is a key element in many Internet services, helps the user further redirect the course of action, and often, quickly turn the idea into action with the support by interested others. Indeed such fast experimentation with even rough new ideas to get feedback and support from interested others has been argued to be key to innovative behaviour (Kelly; Kelly, 2013) and an essential feature of effectual behaviour: As Read and his co-authors (Read et al., 2009, 3) summarize (in an entrepreneurial context): “Share what you have with committed partners because relationships (particularly with shared rewards) shape the trajectory of the opportunity.”

Two characteristics of Internet services, in particular, are likely to contribute to effectual thinking and behaviour: first, many Internet services are themselves ‘means-oriented’, and second, many Internet services build a sense of community among their users.

First, many Internet services are themselves ‘means-driven’: the service idea is to help users collect, demonstrate, share, accumulate their resources in new ways, which may lead to new insights and the emergence of new goals (e.g., Pinterest, Dreamdo, LinkedIn, Scrapbook). Overall, (social) Internet sites can be seen as huge networks of people’s resources, which create great opportunities for creative associations and serendipity. A good example here is LinkedIn (www.linkedin.com): It is a social networking website for people in professional jobs, via which users can make connections with other professionals, share their profiles, look for jobs – and employers look for potential new hires. Though its use may be basically goal directed, for instance, to look for a new job, the use can also be described in terms of general intentions, such as, being visible and connected to others in a meaningful professional community. Such general aspirations leave room for effectual processes to take place (Sarasvathy, 2001). It is most interesting to note that the structural organization of the service – the site is organized under the headings of Profile, Connections, Jobs, Interests – directly helps to answer the questions at the hearth of effectual thinking (Who I am; What I know; Who I know) (Sarasvathy; Dew, 2005).

Second, an essential element of many Internet services is community features. Users may join user communities and special interest groups or set up new ones. Being an active member of a group of people sharing some interest(s) is also a way to build one's desired identity. Explaining actions in terms of one's identity, rather than in terms of expected consequences, is characteristic of effectual reasoning (Sarasvathy; Dew, 2005, 393).

The service providers often provide (peer) recognition tools, which further support the user's desired identity. TripAdvisor (www.tripadvisor.com), perhaps the most popular travel site today, which provides user-generated reviews and interactive travel forums, illustrates a well developed user recognition system: With every user generated review (of a hotel, restaurant, etc.), the number of reviews the user has made and the number of reviews that have been rated by other users as helpful, is shown. TripAdvisor further recognizes active reviewers by giving them different types of star badges (online) based on the number of reviews users have posted. One can also have a look at the reviewer's profile, which, for instance, shows on the world map how many cities the person has visited, how many miles travelled (naturally based on the data the person has shared on the site). This public recognition is an intangible reward to the contributor, but public recognition is also essential in building one's identity: 'I'm the type of person who likes to help people do worthwhile things.'

Above, we have just scratched the surface of the idea that some features of Internet services stimulate effectual processes in their users. The means-oriented, scrapbook nature of many services can trigger the assessment of one's means and stimulate the generation of new associations and new ideas. The easiness of engaging in social interactions and the related possibilities to build one's identity and to get committed partners can increase the person's willingness and ability to try out the new ideas.

3 Conclusion

3.1 Implications for the Internet service provider

We have developed the idea that users may engage in effectual thinking and action as they use Internet services, and that some features of (social) Internet services can stimulate effectual reasoning and actions. How can the service provider benefit from the understanding of its users as effectual actors?

We suggest three general strategies by which the Internet service provider might benefit from the creative activities of effectual service users:

1. Improving the service experience by supporting users' effectual behavior.

The logic here is simple: We are all creative and creative endeavors are inherently satisfying. The service provider can further enhance the creative service experience by facilitating and stimulating users' effectual thinking and action processes on the service site. The innovative Internet service provider might create new tools or service features to stimulate the effectual process outlined in Figure 1: for instance, to encourage user assessment of means available, or to facilitate sharing of resources between the users.

2. Learning from the creative users and formalizing innovative service features.

Sometimes user actions on the site suggest new features to the service. In particular, when the service relies on user-generated content, the users very much impact what the service looks like or is about. For instance, users may create new uses for the site and attract new user groups. These new 'innovative ways', which emerge as a result of creative user actions, may be recognized as possible new service features, which need to be formalized by the service provider in order to take full advantage of them. The service provider needs to be alert and responsive to developing its service based on user generated creative outcomes.

3. Using the effectual logic to unblock creative energy in the service provider organization.

Finally, the service provider organization might benefit from imitating the means-driven action logic in its own innovation system. For instance, some firms do allow their employees to work on their own projects some part of the working time. The innovation implications of a model, which relies on on employees' own means-driven creative processes need to be demonstrated. In any case, adding opportunities to the unexpected while inspiring own employees is an exciting option.

3.2 Directions for future research

Indeed, it would be strange if new ideas and creative outcomes would not be generated when a person is intrinsically motivated to engage in the production and diffusion of online content. Being playful and curious, acting on one's inherent interest without anticipating specific outcomes, is an important feature of human behaviour, learning and creativity (e.g., Ryan; Deci 2000), and key trigger of effectual thinking and action. It seems that Internet service sites with user-generated content have great opportunities to encourage such 'effectual creativity' among their users, and the service providers may also benefit from the users' creative activities.

We conclude this idea paper by suggesting three paths for research: First, the argumentation developed in the present paper needs to be tested and further developed with empirical data. The obvious option would be to identify and

examine important innovations (for the service provide; possibly, for third parties), which can be shown to have their origin in effectual user behaviors. Such innovation cases would also shed more light on the ways in which firms can identify and harness the outcomes of users' effectual behavior. Second, the analysis in the present paper has raised an interesting new question about the effectual process: If a new idea is a product of effectual thinking, does this increase the probability that the person will be open to redirecting or further developing the idea with others? In other words, does effectual thinking lead to effectual action? Third, the implications for service providers deserve attention. We should examine what pioneering Internet service providers are already doing to tap the creative outcomes of their service users. Also, the idea of applying effectual logic within the organization's innovation system (or ecosystem) is worth future study.

The way of public innovation in developing countries: An approach for Mexican local governments

Hector Javier Lagunes Marin

University of Alcala

A big portion of public innovation studies are based in the observation of public organizations in developed countries. Therefore, are their findings equally valid in the context of developing countries' public sector? This paper has a purpose to approach to the answer. The method consists in the analysis of initiatives participating in the Govern and Local Management Award, following a case-study approach. This contest awards initiatives of Mexican local governments with original design and remarkable positive impact after implementation. Results from observations support the idea that poorly developed institutions often fail in improving from innovation, since innovations requires an appropriate institutional set-up.

1 Understanding public innovation

Innovation is commonly understood as the implementation of something new; a change addressed to obtain an improvement. From many theoretical perspectives it is also traditionally been considered as a normative good; an ideal strategy to bring development and raise benefit (Borins, 2001; Mulgang and Albury, 2003; Vigoda-Gadot *et al.*, 2005). Its economic potential has led to produce a considerable bulk of studies in different sectors of the economy, where efforts have been made to provide a formal definition of innovation in order to help its analysis. Despite efforts for providing a definition of innovation equally valid in all contexts, this has proven to be a highly complex and difficult task (Koch and Hauknes, 2005; Windrum, 2008). The understanding of innovation depends on the activity context under consideration, the analysis built around it and the questions raised on it (Koch and Hauknes, 2005). Therefore, the analysis of public sector innovation requires a definition that attends the nature and the objectives of public sector activities.

After reviewing definitions of innovation in previous public sector focused studies (Koch and Hauknes, 2005; Hartley, 2005; Windrum, 2008; Langergaard and Scheuer, 2009; Matthews *et al.* 2009; European Commission, 2011; Brown and Osborne, 2013) the next elements have been found in common:

- *Newness*: Indeed, an adopted change for being considered as an innovation must show an essential element of novelty, which must be verified at least within the environment of the unit of adoption.
- *Implementation*: In order to be accounted, the innovation must be taken to its implementation.
- *View of innovation as a process*: Innovation ends with implementation but it has to go through a resource consuming process that includes idea generation and development.
- *Improvement*: Innovation is addressed to a specific objective whose purpose implies an improvement (even though this purpose could be finally achieved or not after implementation).
- *Significance*: The magnitude of the improvement and the novelty of the introduced change must be of relevance for the unit of adoption.

On a more technical analysis of the innovation process, some specific strategies are found enabling innovation in an important manner: participation of staff in designing and developing innovations; active involvement of organizations' managers for promoting generation of ideas and giving support to their implementation; rewarding innovative behaviour; allocating resources for innovation; taking advantage of experiences and information sources outside the organisation; making alliances and networks with other organisations and allowing experimentation and evaluation (Borins, 2006; Vigoda-Gadot *et al.*, 2005; Koch and Hauknes, 2005; Mulgang and Albury, 2003).

An organization's willingness to innovate depends significantly on those responsible of decision making being aware about potential benefits of innovation as a strategy of improvement (Borins, 2001; 2006; Mulgang and Albury, 2003; Potts, 2009). Here we have a positive association between innovation outputs, support and engagement of managers and authorities to innovation and resources set to innovation activities, with an emphasis on human resources (employee qualification and participation). It is then believed that Managers' involvement in the innovation process as well as use of resources and employee participation will help to better innovation performance (Vigoda-Gadot *et al.*, 2005; Klein *et al.*, 2009; Potts, 2009; Arundel and Hollanders, 2011).

As for assessment, there are already a few research works that review public innovation relying on extensive survey applications. Some good examples of these are: Innobarometer 2010 survey, funded by the European Commission; MEPIN, by the Danish Center for Studies in Research and other Nordic institutions; anda pilot survey for measuring innovation in the public sector, by NESTA. Also, some other publications use information systematically gathered for that purpose, like in Borins (2006), Arundel and Hubber (2013) and Bloch and Bugge (2013)

2 Understanding public innovation in developing countries

All work reviewed above give a useful insight into the issue of public innovation. However, this is largely based in situations and applications in the context of developed countries. It is common to find in them references to OECD countries, Commonwealth countries (Australia and the United Kingdom, in particular) and western European countries. Therefore, one could reasonably ask: what is innovation about public institutions in developing countries?

Public innovation studies highlight the need for more flexible public organizations that allow for experimentation, waste and failure (Borins, 2006; Potts 2009; Brown and Osborne, 2013), in such a way that the innovation process is enabled. At the same time, there is a claim for reforming public administration, so institutional bureaucratization might not be a barrier for implementing technical instruments and managerial strategies that help for increased efficiency, quality and effectiveness in public administration. This kind of observations recall highly regulated organizations with strong hierarchic patterns of authority and whose views on policy and accountability makes them to avoid implementations that represent a chance of failure. However, what could be expected about promotion and implementation of innovation in organizations that do not resemble the latter?

Expectations for development and improvement make implementation of innovations something desirable at all levels of all kinds of organizations. This is also true for regions where society, economy and public institutions remain at a developing state. Therefore, it arise a question on whether the understanding of processes enabling public innovation – acquired in developed contexts – is the same valid for organizations in developing regions, where weakness of public institutions might place more barriers to successful implementations.

As said before, it is little what have been said about the issue of public innovation relying on evidence from developing regions. Some publications, however, have documented results on the efforts for reforming public institutions and the elements that might have conditioned success or failure. This review let to know some important features of developing public institutions that differ from the context where public innovation is commonly observed and might lead to a different understanding of the innovation process. For example: Samaratunge and Bennington (2002) review the situation of Sri Lanka after a period of reform, Manning (2001) makes an analysis from many developing regions, Arellano (2000) explains the situation of Mexican local government institutions and Cabrero (1997) focus in the case of Latin American countries facing reforms. Their findings are similar in what makes durable sustainable reforms a difficult task.

Even if they are democratic states, it is common that local authorities in developing countries are taken by interest groups that dominate the local stage, which result in discretionary governs that use public administration as a political tool. Thus, articulation of levels of governance that should be given by law and institutionalization of authority is replaced by negotiation between local and central powers (Arellano, 2000). Public administration accountability is an issue in civil servants' discourse; however, without the adequate instruments for citizens' participation and lack of transparency in budget expense, accountability becomes a simulated compliance (Cabrero, 2005; Arzaluz, 2013). Hence, technical guiding is missed in policy planning, execution and evaluation (Samaratunge and Bennington, 2002; García, 2005).

3 The case of Mexican local government

Some deficiencies in Mexican local governments concerning to innovation development can be understood through a revision of the history of political and administrative arrangements since colonial times and after Mexico's independence. Arellano (2000) describes the idea of *patrimonialistic* values at the root of incapacity (or unwillingness) of Mexican municipalities to bear successful reform and innovation. Arellano explains patrimonialism as a tradition continued by those that held discretionary authority and power in local regions since governance was configured during the Spanish colony. According to this, *caciques* and similar forms of local domination have developed the ability to adapt to successive State reforms and keep their privileges: *in patrimonialism legitimacy is kept by tradition and the capacity of dominant groups to present themselves as advocates of a charity ethic (or welfare state)* (Arellano, 2000, p. 116).

The technocratic vision of government administration as a body led by policy planning and oriented to efficient and effective goals is not valid in the Mexican case, where public administration is an instrument for fighting the political arena and public accountability works as an appeal for justifying discretionary decisions in favor of groups and individuals whose collective benefits are not that clear (Arellano, 2002). In this context there is little place for processes – such as innovation – based on technical aspects like planning, efficiency, quality, measure and so.

There is a trend for institutionalize public innovation, framed by theories of change and reform in governmental institutions. Trying to embed these ideas into the context of Mexico's public administration has frequently worked as a mean to reinforce a discretionary way for policy implementation, rather than one guided by technical aspects. In this sense, there is an official speech claiming for change, reform and innovation as objectives for public administration improvement, while reform is carried in such a way that the arrangements that serve to keep a discretionary public administration remain unaltered: "change is for all to stay the same".

Additional to heritage in political uses, lack of social development has led to shortages in institutional development of Mexican public administration. This is even more sensitive in municipalities, with less faculties and resource availability than agencies from states or federal government. Deficiencies of municipal government can be observed in

factors at the operative level, such as: lack of formal education (especially higher education) of employees, high mobility of personnel in public office positions, lack of learned and established proceedings, deficient organization and lack of tools and resources for carrying tasks (computing systems, vehicles, technical support, etc.). Cabrero (2004) details some facts that help to make a picture of institutional under-development of Mexican municipalities. These can be read in Table 1.

Table 1. Lack and deficiencies in Mexican Municipalities.

The majority of Mexican municipalities are characterized by a weak normative and compulsory framework:
64% of the country's municipalities do not even have basic internal by-laws.
Nearly 80% of municipalities do not have regulations for planning.
52% of municipalities do not have regulations for public services.
20% of municipalities do not have strategic planning.
Obsolete administrative systems dominate the municipal scene:
60% of the country's municipalities do not have an administrative area specialized in expenditure, evaluation and supervision.
Almost half of the municipalities recognize having a goal-fulfillment level of less than 75%.
65% of municipalities do not have a Department of Personnel.
Most municipalities recognize having collected taxes and duties 75% below the estimations.
17% of municipalities still do not have a single computer for administrative work.
Mayors and civil servants are of a weak professional level:
18% of local government leaders do not have middle or higher education studies in any professional field.
Half of local government leaders do not have any previous experience in public administration.
Executive civil servants in municipal administration have little accumulated experience in their jobs: 30% have been working in their jobs for less than one year, 55% for less than three years; only 5% have been working for more than five years in their job.
Like local government leaders, half of the civil servants of primary level do not have any previous experience in public administration either.

Source: Cabrero (2004)

Rigid bureaucracies are mentioned in studies on public innovation as a barrier to innovation, since they do not allow for experimentation and 'try and error' processes, needed for successful innovation implementations to emerge. Thus, claims for a more innovative public sector imply the opposite: norms and authorities (managers, directors, presidents and any decision maker) that tolerate certain levels of waste and failure and that encourage employees to come up with new ideas (and take part in their development) in order to let the innovation process to take its way (Borins, 2006; Potts, 2009). To this respect, Garcia (2005) argues:

While the need to make a bureaucratic apparatus more flexible might be a goal in some spheres of Mexico's public administration, in the great majority of the municipalities the need to break the bureaucratic inertia in order to be able to innovate does not exist. This need does not exist because a bureaucratic organization has not yet been developed. (p. 3)... Most local governments have not yet developed an organizational capacity that could even be defined as bureaucratic, nor do they have the necessary technical, organizational and institutional tools to face the expectations and needs of their citizens. (p. 4)

In his work Garcia explains that the lack of systematized procedures and institutional tools in Mexican municipalities is the reason why they are constantly making use of "innovation" as a way to sidestep restrictions and policy challenges. However, these innovations – he says – are no more than *temporary solutions to permanent problems*. They act as a remedy for a lacking *rational structure* and in many times they will not be continued farther than the one period of governance in which they are implemented. Garcia claims that most of innovations taking place in Mexico's local governments do not occur in spite of bureaucratic rigidity but rather because of its absence. He makes a proposition that contradicts typical arguments of literature of public innovation in developed countries: in order to achieve durable higher leveled innovations Mexico's municipalities should regress in the classic sense of promotion of innovation; that is: to promote systematization, solid organizational structures and a regulatory framework that allow for innovation sustainability.

Another inconvenience that Mexican municipalities face towards innovation implementation is the impossibility to combine objectives of efficiency and *govern legitimation* in implementation of innovative initiatives. Legitimation is

pursued through actions addressed to highlight efficiency and effectiveness of performance and to promote citizen's participation in public policy planning (Cabrero, 1997). However, there is frequently the case in developing countries' local governments, such as Mexico, that actions addressed to improve public efficiency generate conflict and deteriorate government-citizen relations, while actions addresses to improve government-citizen relations tend to counteract public efficiency (Cabrero, 1997).

Focusing in the case of Mexican local governments, reviewed publications suggest some strategies for fixing the institutional weakness of local public administrations and help for effective sustainable reforms and higher level innovations that can actually bring expected development and improvement. These refer to instruments that allow for citizens' participation in favor of an authentic democratic government, increasing transparency in administration for reducing discretionary budget expense, actions for improving competencies of public servants (such as reducing mobility in job places due to change of governance periods and improving levels of preparation and formal education in public servants), establishing systems, norms and processes that can be a reference for operations after every end of governance periods.

Propositions aiming for more flexible chains of authority and a management style that encourages experimentation and is more tolerant to waste and failure, they would be futile in the context of Mexican local governments, where authority relations (from federal to local) are elusive, *experimentation* is the way to go and public accountability does not constraint for waste and failure. A similar situation can be verified in other developing regions (e.g. Manning 2001; Ziccardi, 2004). Therefore, contrary to relaxing solid bureaucracies, promotion of innovation within developing public institutions requires reforms that lead to institutional consolidation and advance in democracy and participation .

4 Mexican local governments in the way for successful innovation

In his work, Garcia (2005) points out differences in capabilities of Mexican municipalities according to their levels of social development. He suggests that some municipalities with certain demographic and development features are closer to *bureaucratic institutions* – resembling those depicted in publications on management reform and public innovation – while others remain in a *pre-bureaucratic* state. His propositions lead to believe that implementation of innovative initiatives is more feasible in big municipalities with higher levels of social development, while small municipalities with low levels of development do not provide the institutional foundations for useful sustainable innovations.

The next step in the analysis is to present some evidence on the achievements of Mexican municipalities towards implementation of innovative governance initiatives. To do so, it is going to be drawn information from the Government and Local Management Award¹⁶¹ (*Premio Gobierno y Gestión Local*). As explained in its own institutional web page, this is a yearly award, addressed for giving recognition to those *programs and local government policies which show a positive and remarkable impact in design and implementation*. Its objective is on *identify, analyze, recognize and disseminate the best local governance experiences in order to contribute to their institutionalization and for developing better practices of management and democracy*. For being considered for award recognition, municipalities should go through the award's submission proceeding by filling in basic information of the initiatives they want to propose. It is allowed that one single municipality proposes multiple initiatives in the same year (and it has been the case that one municipality has obtained more than one initiative awarded). These are recently implemented initiatives and – overall – addressed to improve attention to citizen needs, to solve a particular problem or to enhance local governance. Thus, novelty and significance at unit of implementation are constant elements in initiatives taking part in the contest.

The present analysis is going to rely on information gathered from all participating initiatives between years 2005 and 2011. We count on small briefings (less than one page) providing highlights of each of 2.301 initiatives participating in the award along seven years. This information is going to be complemented with demographic information specifically referred to population size and social development. Measures of social development come from the *National Population Council*¹⁶² (CONAPO). CONAPO offers a measure that classifies country regions and municipalities according to five stages of exclusion¹⁶³ suffered by their population: 1. High, 2. Medium-high, 3. Medium, 4. Medium-low, and 5. Low. Exclusion is revised every 5 years. During the period that covers the analysis, exclusion reports were released in 2005 and 2010. However, in order to keep consistence in descriptive statistics, and given the low rates of change in classification, the classification of 2005 will be defined for the whole seven years period. Likewise, basing on information from the *National Institute of Statistics and Geography*¹⁶⁴, the *National System of Municipal Information*¹⁶⁵ classifies municipalities according to the size and concentration of their population¹⁶⁶: 1.

¹⁶¹ <http://www.premiomunicipal.org.mx>

¹⁶² Consejo Nacional de Población <http://www.conapo.org.mx>

¹⁶³ For an overview of the 'exclusion' technical definition and calculation method see document in http://www.conapo.gob.mx/work/models/CONAPO/indices_margina/marg_local05/libro/IndiceMargLoc2005.pdf

¹⁶⁴ Instituto Nacional de Estadística y Geografía <http://www.inegi.org.mx>

¹⁶⁵ Sistema Nacional de Información Municipal <http://www.snim.rami.gob.mx>

¹⁶⁶ **Metropolis**: more than 50% of population lives in towns with more than 1 million of inhabitants. **Big-urban**: more than 50% of population lives in towns with more than 100 thousand and less than 1 million of inhabitants. **Medium-urban**: more than 50% of population lives in towns with more than 15 thousand and less than 100 thousand of inhabitants. **Semi-urban**: more than 50% of

Rural, 2. Semi-urban, 3. Mixed, 4. Medium-urban, 5. Big-urban, and 6. Metropolis. Measures on social exclusion and population will be used as reference to give an idea of differences in capabilities of local administrations. It can be observed different levels of institutional development among Mexican local governments, this presumably linked to the level of economic development and the size and concentration of their respective populations. According to municipalities' size and levels of social development, it can be observed differences in resource availability, civil servants capability and *bureaucratization* of organizations.

After reviewing the innovation panorama provided by initiatives participating in the award, a more detailed analysis will be carried by reviewing finalist initiatives. The second stage of the award contest consists of a pre-selection of initiatives. A specialized commission is in charge of evaluating participant initiatives and selecting some that show greatest potential according to the objective of the award. Selected initiatives will go through an in-depth evaluation at the places they are being implemented and the awarded initiatives will be nominated afterwards (around five initiatives are awarded each year). Finalist initiatives: those that were pre-selected by the specialized commission, they are going to be the base for the next part of the analysis.

For the analysis of finalist initiatives they will only be selected those submitted by municipalities at opposite ends of CONAPO's classification of social exclusion: High and Low. This is under the assumption that municipalities at ends of the classification are better comparable due to sizes of population and government apparatus, given that metropolis and big urban centers (with much bigger budgets and more complex government organization) are found in middle levels of the exclusion classification. The analysis has as purpose to identify relevant features in design and implementation of innovative initiatives, as read in their briefings, and build a characterization of initiatives implemented by low and highly excluded municipalities (different in development of their government institutions). The objective is to compare characterization with the ideas explained before on innovation and institutional development.

4.1 Frequencies and percentages of participant and finalist initiatives of the award

The contest for the Government and Local Management Award is carried every year since 2001. For the present analysis we count on information from initiatives between years 2005 and 2011. Total participant initiatives in that period of time sum up for 2.301 in all award categories, while total finalist initiatives sum up for 175 (a twenty each year, approximately). Initiatives are classified in categories that indicate the field of government action framing their implementation (category is selected by submitting municipalities when filling in submission). However, it can be verified that initiatives generally are not entirely delimited by one single category, due to the extent of application. Therefore, categories are just a guiding reference. Graphic-1 shows the sharing of categories among all participant and finalist initiatives during our period of time.

Graphic 1. Share of categories in total participating and finalist initiatives.

Four out of twelve categories gather around half of total participating initiatives: Social policy (16%), Municipal development (12%), Modernization of administration (12%) and Municipal infrastructure (11%). The image turns to be

population lives in towns with more than 2.500 and less than 15 thousand of inhabitants. **Rural:** more than 50% of population lives in towns with less than 2.500 inhabitants. **Mixed:** population is found distributed as in previous categories, but none of them gathers more than 50% of population.

more or less similar when we account only for finalist initiatives: Social policy (15%), Municipal development (14%), Public security (13%) and Modernization of administration (11%).

Graphic-2 shows percentages of all participating and finalist initiatives, by size and concentration of population in submitting municipalities. The column called ‘National’ does not account for initiatives, but for the total number of municipalities within the country (2.454). It works for comparison purposes, between proportion of submitted initiatives and proportion of country’s municipalities. It calls the attention that more than 50% of total initiatives come from municipalities classified as ‘Big-Urban’. That is also true for finalist initiatives. At the same time, initiatives from municipalities classified as ‘Metropolis’ account for 12% and 14% of finalist and total participant initiatives, respectively. This observation is quite remarkable, since Metropolis represent less than 1% of the number of municipalities in the whole country. Likewise, Big-urban represents 4.5% of country’s municipalities. Therefore, around 70% of total and finalist initiatives come from Metropolis and Big-urban municipalities, which these roughly represent 5% of the whole number of municipalities in the country. Another remarkable observation is that ‘Rural’ represents around 60% of municipalities in the country, while initiatives coming from rural municipalities barely account for 7% and 12% of total and finalist initiatives, respectively.

*Three initiatives, simultaneously submitted by multiple municipalities, were left out.

Graphic 2. Percentages of participating and finalist initiatives by types of population.

Same inverse relation can be observed when setting initiatives and municipalities according to levels of social exclusion, as shown in Graphic-3 (‘National’ column is for comparison purposes, like in previous chart). It can be verified that almost 90% of total participating initiatives come from municipalities with low and medium-low levels of social exclusion, while these kinds of municipalities account for less than a third of total country’s municipalities. At the same time, those with high and medium-high levels of exclusion account for 5% and 10% of total participating and finalist initiatives, while same levels of exclusion affect to half of country’s municipalities.

Graphic-4 shows shares of award’s categories among all initiatives submitted from municipalities with high and low levels of exclusion. These are compared to the total amount of initiatives submitted by Metropolis. All Metropolis within the country suffer from medium-low levels of social exclusion and account for 0,5% of total country’s municipalities. It is remarkable that initiatives submitted by Metropolis surpass initiatives respectively submitted by municipalities with low and high levels of exclusion. Three categories gather around a half of total initiatives from low exclusion municipalities: Municipal infrastructure (19%), Social policy (14%) and Municipal development (13%). Four categories gather around 70% of total initiatives from highly excluded municipalities: Municipal development (40%), Municipal infrastructure (10%), Citizen’s participation (10%) and Social policy (10%).

Five categories gather 65% of total initiatives from municipalities classified as Metropolis: Social policy (21%), Education, culture and sports (13%), Modernization of administration (12%), Public security (10%) and Municipal development (9%).

*Three initiatives, simultaneously submitted by multiple municipalities, were left out.

Graphic 3. Percentages of participating and finalist initiatives by level of exclusion.

Graphic 4. Share of categories in initiatives submitted by highly and lowly excluded municipalities and Metropolis.

4.2 Semifinalist initiatives from highly excluded municipalities:

Within the seven year period covering our analysis, 174 initiatives were pre-selected for the final stage of the award contest. From these, 12 initiatives (7%) were submitted by municipalities suffering from high levels of social exclusion. In Table-2 are presented short descriptions of each of these finalist initiatives and their submitting municipalities. Among these, half of municipalities are classified as ‘Rural’, according to their low size of concentrated population. Rural municipalities suffering from high levels of social exclusion are the most frequent within the country (28% from total number of country’s municipalities).As seen before, highly excluded rural municipalities are shortly represented among award’s total participating and finalist initiatives.

Table 2. Semifinalist initiatives from highly excluded municipalities.

State	Municipality	Population	Type	Initiative short description	Award category
Oaxaca	Santiago Comaltepec	1386	RU	Child music band. It was created to preserve traditional music and to breed values into child. Instruments were bought thanks to collaboration in funding from other public instances.	Education, culture and sports
Oaxaca	Santiago Yosondúa	7197	RU	New ecological nature park. The project was started by a civil association and sponsored by municipal government. Citizen assemblies and funds from higher government instances took part in the development process.	Municipal development
Jalisco	Cabo Corrientes	9034	RU	New eco-tourism attractions. Implementation of new touring routes and attractions. It includes training for local producers, promoting local tourism and restoring public spaces.	Municipal development
San Luis Potosí	Matlapa	29548	RU	Actions for reducing death in birth labor. Actions are focused in diagnosis, information workshops and legal counseling.	Public health
Michoacán	Chilchota	30299	SU	Education program for indigenous people. It includes building classrooms and new school spaces and buying new materials. State government participates in literacy activities and it was also created a 'municipal commission for education'.	Education, culture and sports
Michoacán	La Huacana	31774	RU	Municipal development strategy. It suggests and implements actions for introducing sustainability in all local government functions.	Municipal development
Michoacán	Huetamo	41239	MU	Program of economic incentives. Gives counseling and financial aid to the main economic activities of the region.	Municipal development
Yucatán	Tizimín	69553	MU	Delivery of basic public infrastructure. Financial resources from a Federal fund were taken to deliver basic public infrastructure to an area with high social exclusion.	Social policy
Chiapas	Cintalapa	73668	MU	Transparent public accountability program. Promotes access to information through a web page and a TV cast and also allows for participation of citizens in planning development and investment programs.	Transparency and public accountability
México	San José del Rincón	79945	RU	Civilian recruitment for policy functions. Neighbors in communities with greatly dispersed population are enrolled to help in policy functions.	Public security and civil protection
Chiapas	Villaflores (1)	93023	MI	Municipal development planning. Design of the plan for development and investment was carried through collective participation of citizens after a hundred of meetings in many areas of the municipality.	Citizen participation
Chiapas	Villaflores (2)	93023	MI	Forest fire prevention program. It is based on improvement of technical and material capabilities and participation of citizens and civil organizations.	Ecology and conservation

RU = Rural, SU = Semi-urban, MI = Mixed, MU = Medium-urban

Finalist initiatives from Matlapa, Chilchota, and San Jose del Rincon are good examples of implementations addressed to improve citizen's life conditions along with basic public service provision, not by its technical design nor by strategic investment, but by creative new ways to deal with resource scarcity and lack of *institutionalism*.

Remarkable are cases based on extensive citizen participation for designing and implementing policies and programs. Initiatives from Santiago Yosondua, Cintalapa and Villaflores (2) put in practice participation at early stages of implementation or as an instrument for an accountable application of core initiative actions. Meanwhile, the initiative from Villaflores (1) stands out from its vast implementation of participation strategies. Only the initiative from Villaflores (2) mentions collaboration of no-state entities.

Initiatives rarely mention considerable investments or great use of technical and financial resources in implementation. Nonetheless, in few cases where considerable investments are needed they are provided by funds from higher levels of governance.

Santiago Comaltepec, Santiago Yosondua and Cabo Corrientes are the smallest municipalities submitting a finalist initiative; their population size makes them to be classified as 'Rural'. Thus, their initiatives appear to be simple idea applications with little bureaucratic complexity (with significant positive effects, nonetheless). Here, social capital seems to be more relevant than govern institutionalism in idea generation and implementation.

Bureaucratic appeal is more evident in initiatives from bigger municipalities, with greater size and population concentration, such as the ones from Chilchota, La Huacana, Huetamo, Tizimin, Cintalapa and Villaflores (2).

No initiative seems to be addressed to improve efficiency in public administration. In turn, it seems that initiatives are addressed to strengthen links between public instances and citizens and to develop local government as institution; that is: increasing effectiveness in delivering to citizens' needs and a transparent management of public resources.

There is one particular case where highly excluded municipalities take part in an association with municipalities with low levels of exclusion; it will be described in the next section.

Highlights of finalist initiatives from municipalities with high levels of exclusion can be summarized as follows: i) Improvisation and ad-hoc strategies, ii) Citizen participation is a highlighting feature, iii) Investment and use of technical resources are low: social capital seems to be more relevant, iv) Initiatives acquire a more bureaucratic appeal as they grow in population, v) Goals for administrative efficiency seem to be absent in finalist initiatives, vi) Associating with other municipalities for service delivering, vii) Initiatives addressed to meet citizens' needs and to a more transparent use of public resources.

Semifinalist initiatives of municipalities with low exclusion:

Among 174 initiatives pre-selected for the final stage of the award contest 24 (14%) were submitted by municipalities with low levels of social exclusion. In Table-3 are presented short descriptions of each of these finalist initiatives and their submitting municipalities. In average, municipalities in here are bigger than highly excluded municipalities submitting finalist initiatives. However, the size gap is not as big as could be observed with respect of municipalities with medium-low and medium levels of social exclusion. Nonetheless, it calls the attention that medians of municipalities' population in Table-2 and Table-3 are very close.

Table 3. Semifinalist initiatives from municipalities with low exclusion.

State	Municipality	Population	Type	Initiative short description	Award category
Oaxaca	Capulálpam de Méndez	1313	RU	Municipal development program. Design of the program is based in high citizen participation, not just in planning of actions but also in its implementation.	Municipal development
Jalisco	El Limón	5410	SU	Inter-municipal actions for restoring Ayuquila river. A trusteeship and a technical commission were created. For carrying the job, complementary financing was obtained and citizens' participation was enabled.	Ecology and conservation
Tlaxcala	Ixtenco	6279	SU	Citizen council for public account supervision. Creation of a citizen council with the objective to keep surveillance over municipal public accountancies.	Citizen participation
México	Tonatico	10901	SU	Keeping links with emigrated people. Actions addressed to help emigrated people to stay linked to their community. Some other public organizations took part.	Municipal development
Tlaxcala	Panotla	22368	SU	Recondition public spaces for sport practice. Financial resources from the three levels of governance were taken to enable spaces to be used for sport practicing.	Municipal infrastructure
Jalisco	Ixtlahuacán de los Membrillos	23420	RU	Increasing revenues in real property taxes. A program of incentives for tax payers was implemented. It helped to overcome a situation where tax revenues were inferior to costs of collecting property taxes.	Modernization of administration
Guanajuato	Jaral del Progreso (1)	31780	MU	Scholarships program. Sponsoring education through scholarships.	Education, culture and sports
Guanajuato	Jaral del Progreso (2)	31780	MU	Citizen access. Opening access to citizenry by enabling special modules for attention and giving information on municipality's tasks.	

State	Municipality	Population	Type	Initiative short description	Award category
Jalisco	Tuxpan	32462	MU	Inter-municipal development plan. Design of the plan was coordinated between municipalities. It included participation of local producers and civil organizations. Links to universities and technology transfer is a remarkable part of the plan.	Municipal development
Jalisco	Tamazula de Gordiano	35987	MI	Broadcasting council sessions. A TV channel was created for broadcasting sessions of the municipal council.	Municipal development
Guerrero	Pungarabato	36466	MU	Inter-municipal actions for development. Include various actions framed by a whole development program: urban waste management, delivering basic services, sponsoring entrepreneurial projects.	Municipal development
Zacatecas	Ojocaliente	37545	MU	Hepatitis prevention program. Program includes latrines installation, information rounds and medical analysis and diagnosis.	Public health
Coahuila de Zaragoza	Parras	44715	MU	Enabling delegations to help communication between scattered communities and municipality head.	Modernization of administration
Jalisco	Zapotlanejo (1)	55827	MU	Urban development program. Building and restoring urban facilities. It includes participation of the three levels of governance and also private organizations and universities.	Urban planning
Jalisco	Zapotlanejo (2)	55827	MU	Integral health program. It includes itinerant health services, prevention campaigns, building and restoring clinics and sponsoring eye surgeries.	Public health
Veracruz	Coatepec	79787	MU	Forest and water conservation. Creation of a trusteeship for forest and water conservation purposes.	Ecology and conservation
Guerrero	Iguala de la Independencia	128444	UG	Inter-municipal urban waste management. It emerged in the context of an already existent association of municipalities. Being in an association has allowed obtaining funds from higher levels of governance.	Municipal infrastructure
Hidalgo	Tulancingo de Bravo	129935	MU	Paths for no-motor mobility. Setting of paths to help mobility among communities by means of no-motor vehicles.	Municipal infrastructure
Sonora	Navojoa	144598	BU	Actions for restoring the Mayo river. Implementing actions to solve river deterioration	Ecology and conservation
Veracruz	Córdoba	186623	BU	Restoring the urban area known as "Alameda Murillo Vidal"	Municipal infrastructure
Quintana Roo	Othón P. Blanco	219763	BU	Construction of community area. Financial resources from a Federal fund were taken to build and recondition a community urban area.	Urban planning
Puebla	Tehuacán	260923	BU	New 'Intra-family violence attention center'. Creation of a center for aiding and counseling people that suffers from family violence.	Social policy
Michoacán	Uruapan	279229	BU	New 'Council for municipal development'. A council was created with people representing territories of the municipality. Its purpose is to join citizen participation into planning of infrastructure building.	Municipal infrastructure
Guerrero	Acapulco de Juárez	717766	BU	Childs' municipal council. New council that meets regularly for ruling on childhood issues.	Citizen participation

RU = Rural, SU = Semi-urban, MI = Mixed, MU = Medium-urban, BU = Big-urban

Implementation of initiatives from municipalities with low exclusion looks more complex in management and proceedings (they have a more *bureaucratic* appeal). This is more or less observable among all initiatives, but

especially evident in initiatives such as the ones from El Limon, Ixtlahuacan de los Membrillos, Tuxpan, Pungarabato and Tehuacan.

Initiatives demanding citizens’ participation are also common here. Initiatives from Ixtenco, Uruapan and Acapulco de Juarez incorporate participation into the formal organization of the local government. Collaboration of no-state entities is rare. They are mentioned taking part in initiatives from Tuxpan and Zapotlanejo (1).

The use of technical and financial resources is more evident in finalist initiatives from municipalities with low exclusion, like those from El Limon, Panotla, Jaral del Progreso (1), Tuxpan, Ojocaliente and Navojoa. Also, from initiatives that go through widening public infrastructure, one could deduce public expense is bigger in initiatives from lowly excluded municipalities. Initiatives from Panotla, Zapotlanejo (1), Cordoba and Othon P. Blanco are good examples of it.

Initiatives based in unions of municipalities are frequent. Some of these are made up for services provision, particularly urban waste management. Award’s contesting allows municipalities to submit initiatives that are implemented together with other municipalities, as did by El Limon, Tuxpan, Pungarabato and Iguala de la Independencia. However, municipalities associated in the implementation of an initiative are allowed to submit and contest simultaneously. There are two finalist initiatives with significant presence of municipalities with low exclusion (see Table-4). Noticeably, in one of them appear highly excluded municipalities taking part.

Overall, initiatives seem addressed to strengthen local government institution (through promoting transparency and participation) and to improve citizens’ living quality. Initiatives addressed to improve efficiency or promote modernization of public instances are not specially highlighted. Certainly, one could think of municipalities associating for service delivering (waste management, in particular) as driven by management efficiency. Nevertheless, the initiative from Ixtlahuacan de los Membrillos is the only one that features the spirit of an efficient public administration (as it is subscribed to the ‘Modernization of administration’ category). This one of a kind among all finalist initiatives from low and highly excluded municipalities.

Table 4. Semifinalist initiatives from jointly municipalities’ submissions.

State	Municipalities	Exclusion	Type	Initiative	Category
Jalisco	Concepción de Buenos Aires, Santa María del Oro, La Manzanilla de la Paz, Mazamitla, Quitupan, Tizapan el Alto, Tuxcueca, Valle de Juárez	L, H, L, L, H, L, L, L	SU, RU, RU, SU, RU, SU, SU, SU	Inter-municipal urban waste management	Public services
Mexico	Amecameca, Atlautla, Ayapango, Cocotitlán, Chalco, Ecatzingo, Ixtapaluca, Juchitepec, Ozumba, Temamatla, Tenango del Aire, Tepetlixpa, Tlalmanalco, Valle ChalcoSolidadidad	L, L, L, ML, L, M, ML, L, L, L, L, L, ML, ML	MU, SU, RU, SU, BU, SU, BU, SU, MU, SU, SU, SU, MI, BU	Municipal association for development	Municipal development

L = Low, ML = Medium-low, M = Medium, H = High, RU = Rural, SU = Semi-urban, MI = Mixed, MU = Medium-urban; BU = Big-urban

Highlights of finalist initiatives from municipalities with low levels of exclusion can be summarized as follows: i) Initiatives look more complex in management and proceedings (they have a more bureaucratic appeal), ii) Citizens’ participation is incorporated into formal government organization, iii) Investment and use of technical resources are higher than in highly excluded municipalities’ initiatives, iv) Unions of municipalities are frequent, v) Initiatives are mostly addressed to enhance effectiveness in meeting citizens’ needs and to pursue legitimation; however, efficiency goals are also featured, to a lesser extent.

4.3 Discussion

Statistics show very low participation rates of initiatives from highly excluded rural municipalities. On the other hand, initiatives from big urban centers – typically with medium-low or low levels of exclusion – they show an extensive participation. This is opposed to the proportion that these kinds of municipalities represent among the total number of municipalities within the country. Suitable reasons for this to be the case might come from bias in award’s promotion of participation, lack of municipalities’ interest for taking part in the contest (together with lack of awareness), or that this actually is an indicator of capabilities and un-capabilities of Mexican local governments. Borins (2001, 2006) makes his analysis basing on information from the Innovations in American Government Awards¹⁶⁷: a contest with a format very similar to that of the Government and Local Management Award. Borins (2008, p. 4) says about information from the American Government Award: “Because the awards program casts its net so widely and generates so much interest, we can be confident that its pool of applicants represents the range of trends in innovation in government”. Having Borins argument as reference, if we assume that what can be read from the Local Management Award is a true image of local governments at national level, one could then interpret the small participation rates of highly excluded rural

¹⁶⁷ <http://www.ash.harvard.edu/Home/Programs/Innovations-in-Government/Awards>

municipalities as evidence of their low capacity for generating novel and significant government actions, while large participation rates of big urban centers might on the contrary be evidencing a larger capacity.

When grouping initiatives by characteristics of submitting municipalities, it can be observed different tendencies in award's categories where initiatives are subscribed. Social policy and Municipal development are among most frequent categories. This point to the importance of local government actions addressed to give attention to vulnerable population and to supplement backwardness of citizens' life conditions. On the other hand, categories more related with local government institutional appeal, such as Transparency and public accountability and Urban planning, they are less frequent.

It is remarkable that more than a third of initiatives from highly excluded municipalities are in the Municipal development category. In turn, the most frequent category among initiatives from municipalities with low exclusion is Municipal infrastructure, while initiatives from metropolis give some importance to categories that are less relevant among other kinds of municipalities, such as Education, culture and sporting and Modernization of administration. This gives support to believe that municipalities with low social exclusion (presumably, more institutionally developed) and metropolis (with larger financial capacity and more complex organizations) they have partially overcome the pre-bureaucratic stage that hinders the application of novel, sustainable and significant governance initiatives.

In general terms, initiatives encompass to a certain degree the previously described settings of Mexican local governments counteracting efficient-effective administrations' performance. To this respect, the 2011 executive report of the award remarks: *Our municipalities tend to high rotation in civil servants' positions, to give little or no continuity to the work of previous administrations and to start every new governance period with new personnel and new organization models... The challenge of our local governments is to lead to good results in short time and with scarce resources.* This is embedded in reviewed initiatives, where sidestepping and ad-hoc design are still noticeable. However, those initiatives submitted by municipalities with low levels of social exclusion appeal governmental organizations with greater institutional strength: perhaps a consequence from greater social development. Initiatives that formally incorporate citizens' participation into government organization, higher levels of expense and use of technical resources and certain efficiency pursuing features give evidenced in that direction.

In municipalities with high levels of exclusion weakness of the local governance institution (in what is been called *the pre-bureaucratic stage*) is more tangible. However, the profile of their finalist initiatives show some interesting characteristics that suggest innovative initiatives can be a way to enhance local government capability and, in the long run, allow for sustainable improvement through innovation. High levels of citizens' participation, use of social capital, aim for development and association with municipalities with better capabilities give evidence in that direction.

Initiatives from municipalities with low and high levels of exclusion have in common the aim for pursuing actions whose results lead to develop life conditions and government legitimacy, while actions towards a more efficient administration are rare in municipalities with low exclusion and inexistent in highly excluded municipalities. Here we might have additional evidence on the dichotomy between efficiency and legitimation. As it can be seen, legitimation is much more appealed in reviewed initiatives, which lead to believe that strengthening local government institution is still much needed among Mexican municipalities and it is still a fundamental objective. It is a requirement for a more efficient public administration, which allows for sustainable higher leveled innovation.

5 Concluding remarks

Organizations responsible for public administration in developing countries suffer from lack of legitimacy and institutional weakness. In the particular case of Mexican local government, where lack is more tangible than in higher levels of governance, institutional weakness lead to public administrations performing in discretionary ways. Lacks in regulation, continuation and systematization of activities lead to innovation as a policy strategy: innovation is a consequence of a groping and sidestepping management style. Thus, in most part, innovation in Mexican local governments does not appear as a virtuous process that brings improvement and technical enhancement, but as a process that encompasses inefficiency, backwardness and under use of public resources in its way to achieve some results.

An innovative implementation needs an institutional frame that allow for its systematization and continuity (i.e. solid institutions and strong regulations). Thus, for innovation to be successful in improvement it is necessary that public organizations previously went through a process in a way somewhat opposed to that of innovation: strengthening hierarchies and authority, processes and regulations, in such a way that they let for well-defined and established operations that can go over organizational changes due to changes in administration after elections (and such that it helps to moderate the dynamics of change). Hence, the paradigm of efficiency and improvement found in innovation require overcoming the *pre-bureaucratic* stage of public institutions, where excessive flexibility and lack of regulation make "innovation" the usual mean to operate. This situation leads to inefficient results and scarce chances to develop improvements. However, in so called pre-bureaucratic institutions innovation can be of special value and lead to sustainable efficiency and development when it is addressed to institutional strengthening. That is to say, when creative initiatives and search for alternative ways generate sustainable processes and help to more solid institutions.

Observation of initiatives taking part in the Government and Local Management Award gives evidence to believe that Mexican municipalities with low levels of social exclusion (presumably with higher institutional development) have more appropriate institutional characteristics for successfully implementing innovation as a tool for public service

improvement. And, on the contrary, poorly developed Mexican municipalities find more difficulties to achieve improvement and development through innovation. Observation of initiatives also yields an important conclusion: Innovation can be of special benefit for poorly developed municipalities when it is addressed to strengthen the institutional founding of local governments.

Co-designing Employee-driven Service Development Instruments for Public Health Care

Katriina Lahtinen¹, Hanna Laalo², Valtteri Kaartemo², Marika Järvinen³, Liisa Lumiaho⁴

¹University of Jyväskylä, ²University of Turku, ³Pirkanmaa Hospital District, ⁴Central Finland Health Care District

The paper presents an action research on co-designing employee-driven service development instruments for public health care professionals. The empirical study examines how the methods and tools co-designed for service development with the workers could support employee-driven innovation initiatives in health care organizations, and strengthen the approach and emphasis on the discovery of unmet human needs in service development. Particularly, the research findings focus on how the co-designed instruments overcome the identified barriers for engaging health care professionals in employee-driven innovation processes.

1 Introduction

Academic articles and mass media remind us frequently that health care is in crisis and that public health care is becoming too expensive (Kaplan; Porter, 2011). At the same time, the quality of health care should remain high with well-designed processes, committed patients and satisfied employees. To solve the crisis, public health care needs actions at both policy and grass-root levels. Part of the solution may be that employees take more initiative in developing more efficient processes and services.

Over the recent years, we have witnessed a hike of interest in employee-driven innovation (Kesting; Ulhøi, 2010). Some of this attention has even focused on health care context (Knol; Van Linge, 2009; Tsai; Liou; Hsiao; Cheng, 2013; Åmo, 2006). Yet, we still lack understanding on how to engage public health care professionals to design services and to renew everyday work practices. Based on our experience in the field, there are typically some individuals who are interested in planning the processes but it is challenging to have larger scale participation in development activities in public health care organizations.

Encouraging employee-driven innovation in public health care requires not only theory development in the field but practical solutions that are helpful for employees in renewing work practices. Our research is based on the research group's interest to combine entrepreneurial behaviour and innovation with design thinking to create new, flexible and rapid service development instruments in public health care.

Particularly, we are interested in how to take the contextual restrictions of public health care organizations into account in developing practical tools and methods for everyday innovation activity. In this paper, we present two service development instruments that were co-designed with health care professionals to enhance employee-driven innovations in public health care. They showcase instruments that overcome the constraints characteristic to the context. The co-designed instruments, the collective service development tool "Idea Window" and the customer participatory tool "Travelling With Change", were created as a part of the service design oriented joint development in the project.

We focus in our research paper on the discovery of new employee-driven service design instruments in everyday work for tackling the unknown – customer needs, user understanding, tacit knowledge in work, hidden possibilities and initiatives in work context – to be identified and clarified in service design, development and innovation processes. The study examines in particular how the methods and tools co-designed for service development with the workers could support employee-driven innovation initiatives in health care organizations, and strengthen the approach and emphasis on the discovery of unmet human needs in service development.

The paper is organized as follows. First, we briefly introduce available literature on employee-driven innovations with a specific focus on the context of health care organizations. Second, we describe the methods for co-designing the employee-driven service development instruments, and the methods employed for data collection and analysis. Third, we discuss our research findings. We focus on the factors that encourage employees to participate in the design and use of service development instruments. Thus, we contribute to the literature by identifying employee rationale on how to engage health care professionals in employee-driven innovation processes.

2 Employee-driven innovations

Innovation is a multidimensional process that covers various aspects of newness. It may refer to the development process with an outcome of new goods, services, marketing methods, or even organizational practices. Here, we do not approach innovations as commercial success stories. Instead, we refer to process innovations that are new ways of acting to diminish the cost or to increase the quality of health care services. This includes but is not limited to organizational innovations that are changes in the workplace practices to improve administrative efficiency.

Innovations may origin from 1) actors and other sources external to the organization, or 2) the internal actors, such as R&D staff and other employees (Cassiman; Veugelers, 2006). In this paper, we focus on the latter source of innovations. To be precise, we are interested in employee-driven innovations (EDI).

EDI refers to the exploration and exploitation of new processes and work practices that originate from a single employee or a group of employees to whom innovation development is not a part of job description (Kesting; Ulhøi, 2010). In EDI literature, it is considered that ideas how to improve processes and work practices stem from ordinary employees. In other words, internal innovation development is not only for the designated R&D people. In fact, research findings support EDI, as evidence shows that it is beneficial to engage ordinary employees in service development processes. However, it is also outlined that ungoverned participation is counterproductive. (Kesting; Ulhøi, 2010.)

Engagement of health care professionals in innovation processes has also been requested by both public health care organizations as well as professionals. Research findings by Oecon (2006) indicate that health care professionals do not perceive to have equal opportunities to participate in innovation processes. Particularly, staff in the lower ranks perceives that it is not suitable to enact innovative role at the workplace.

Therefore, there is a need to empower the staff to engage in innovative activities. In addition to structural empowerment which refers to power based on the employee's position in the organization, there needs to be psychological empowerment for the staff in the lower ranks (Knol; Van Linge, 2009). Psychological empowerment refers to the fundamental personal convictions that employees have about their role in the organization. As Tsai et al. (2013) have found, worksite support can support psychological empowerment. This support takes into account open communication systems which empowers employees and engages them in decision-making and EDI processes (Fees; Taherizadeh, 2012). Thus, management of health care organizations can create a supportive worksite where creative nurses are more likely to work and get engaged in development (Tsai et al., 2013). These findings are in line with the study by Wihlman; Hoppe; Wihlman; Sandmark, (2014) in the context of Swedish welfare services. Their research identified three main themes to support EDI, namely support (including leadership and innovation processes), development (including creativity and learning), and organizational culture (including attitudes and communication). In addition, it has been proposed that employees require incentives for engaging in EDI (Kesting; Ulhøi, 2010). This proposition is supported by evidence on rewards systems boosting creative activities in commercial organizations (Gupta; Singhal, 1993). In brief, public health care organizations need to create the right conditions to improve empowerment of health care professionals.

However, the creation of beneficial conditions is not always easy, as there are barriers for engaging in service development activities in health care organizations. For instance, Wihlman et al. (2014) have found that unclear or non-existing innovation processes with ambiguous goals, insufficient learning, and deficient organizational slack, attitudes of colleagues and lack of communication hinder the likelihood of innovation activities in welfare services.

To synthesize, the research indicates that EDI requires instruments that help in structuring the service development process. The practical tools and methods need to provide psychological empowerment and incentives to those in lower ranks in the health care organization. In addition, the instruments must encourage positive support to development activities and enhance open communication. These insights were taken into account in the action research project that focused on co-designing employee-driven service development instruments for health care professionals. We present the action research and the results in the following chapters.

3 Empirical study

In the action research project we co-designed two employee-driven service development instruments. Our aim was to create instruments which would help in overcoming the typical constraints in EDI in health care context.

3.1 Action research

The empirical study is based on a multidisciplinary action research project realized in two large public sector health care organisations in Finland. Two project case studies were realized in the Pirkanmaa Hospital District and in the Central Finland Health Care District. During the project, the project team co-operated with the health care professionals for creating new tools and methods for developing services in the context of everyday work practice. The co-operation was based on service design methodology and design thinking which were partly known and applied in co-operating organisations.

Co-designing service development instruments and test-using them with employees is a good approach to engage working community gradually and pragmatically in design thinking. Design thinking taps into capacities we all have but that are overlooked by more conventional problem-solving; it focuses on creating products and services in process which is deeply human (Brown; Wyatt, 2007). Design thinking relies on our abilities to be intuitive, to recognize patterns, to construct ideas that have emotional meaning as well as being functional (ibid.).

The designers in the project were facilitators helping the employees in the co-operating organisations to meet a need for service development but also to communicate and to "externalise ideas in a way that others (especially non-designers) can understand and so enable discourse and debate" (Koskinen; Zimmerman; Binder; Redstrom; Wensween, 2011, 125). The instruments were eventually created by group working which is a fundamental part of the service designer's function in any organisation given the multidisciplinary nature of the field (Callaghan 2009). The dialogue was facilitated through the creation and discussions initiated from ideation and use of instruments.

Instruments developed in the project were utilized as situated design methods to support employees' ability to better understand processes and to identify opportunities for learning, developing and renewal in different situations in one's own work and work community and this way to enhance change (Simonsen; Bærenhold; Büscher; Scheuer, 2010). The aim is hence, as Schön (1983, 68) describes it, that "The practitioner allows himself to experience surprise, puzzlement, or confusion in a situation which he finds uncertain or unique. He reflects on the phenomenon before him, and on the prior understandings which have been implicit in his behaviour. He carries out an experiment which serves to generate both a new understanding of the phenomenon and a change in the situation".

The two cases shared the context of public health care. However, they were different in terms of aim and approach of the co-designing process. In the first case (Pirkanmaa Hospital District) employees co-designed service by collectively observing customers without engaging customers in the actual design process. In the second case (Central Finland Health Care District), the instrument was designed for the employees but the actual content was mostly generated in the intensive collaboration with the customers. This enabled stronger focus on the customer viewpoint, whereas in the first case the focus was more on developing processes from the perspective of own tasks as well as customer benefits. These case studies are described in detail in the following.

3.1.1 Case Study of the Tampere University Hospital; Pirkanmaa Hospital District, Tampere Finland

In the Tampere University Hospital action research project was realized in close co-operation with the Department of Customer Services and its Customer Service Development Manager. The manager has successfully applied service design many years in different clinics in the hospital. The result of her team's work is encouraging and a good starting point for the project. The department operates with dozens of active and heterogeneous cases. A great number of health care professionals has been time-consuming but has also generated plenty of content for further development activities. The good work has caused a positive problem for the development team; service design is evidently useful and effective method to develop services but application of service design on a larger scale in the hospital requires new ways, tools and methods to inspire and engage personnel to participate in service development. Therefore, new tools and methods would be one way to apply service design in a variety of services and service development challenges, and to get health care professionals involved in development of new service solutions and in dissemination of the best practices and experiments.

The project design team analysed the situation with the development manager and had together an idea of a participatory service development tool that could be co-designed and prototyped with the group of employees in a brief experiment in spring 2014. The processes had been initiated in the case organizations before the designers stepped in. Therefore, the basis for the implementation of the service design tool had already been built. Anyway, in busy environments such as hospitals, it is difficult to get people to break away from the everyday work and to engage in a variety of development challenges, so one of the key features of the tool would be that it helps to see the work in everyday life from the perspective of the service development, and to realize the things that can be solved quickly and nimbly in normal work. Thus, the tool should function in daily work and strengthen employees' sense of initiative and activity. It also should help employees to detect the invisible side of the work, which affects the every day services and the quality of them. It should help in facilitating employees to observe and to record their experiences and ideas relating to services, and to pay attention to the customer's service experience and behaviour. Tackling the unknown – customer needs, user understanding, tacit knowledge in work, hidden possibilities and initiatives in work context would be identified more systematically by the tool. The data collected by the tool would be analysed and clarified together in workshops and used for customer service development.

Idea Window

Idea of employee-driven service development tool was matured in collaboration into a tool called *Idea Window*. The first version of the Idea Window was co-designed in close co-operation with the group of personnel of three clinics in the hospital. The Idea Window was designed to be easy-to-use touch screen computer with simple user functions on the graphical user interface which would be easy to find and available all the time. It was designed as a platform for workers' findings, initiatives, ideas and solution proposals to develop services. In the Idea Window, employees can enter their observations and ideas on the screen. In addition, an employee can propose solutions and experiments related to the findings and observations of the service experience. All the items can be combined together to form a variety of topic clusters on the screen. Employees can modify and store the clusters in the user interface according to what is meaningful to them. Any employee can anonymously leave a proposal in the Idea Window and read and move the items on the screen. The Idea Window was designed to put the patient at the service path clearly visible and to open the view into the customer's service experience. The material produced by the personnel was ground for joint development workshops and utilizable material in service design. In each clinic, two touch screen computers were located in central locations. The Idea Window was used for three weeks in each three clinics that participated in the project.

*Figure 1. The Idea Window in use in the Tampere University Hospital.
Photo by Minna Tuominen, Pirkanmaa Hospital District, 2014.*

During the Idea Window experiment, the personnel produced 75 ideas and comments related to patients' service experiences, 38 proposals for solutions and improving services and 4 proposals for experimentations. The material produced within Idea Window was analysed in two workshops with the group of personnel. Nurses, doctors and couple of members of the hospital administration found the data really revealing and were motivated to use Idea Window during longer time and for different purposes. The customer service unit and the administration representatives evaluated the Idea Window useful on a larger scale if some small changes were made to the interface. The nurses evaluated the Idea Window suiting well to everyday context. It was really important to them that ideation and customer experience observing tools are available all the time and thus are maintaining the customer focus in the service.

3.1.2 Case Study of the Unit of General Practice, Central Finland Health Care District, Jyväskylä Finland

The second research case was actualized in co-operation with the Central Finland Health Care District and more specifically with the Unit of General Practice. The unit had developed a group-based approach to support and guide people who have problems and changes in their health. The service model of the Lifestyle Change Groups (LSC-groups) was developed by the small group of health care professionals in the Central Finland Health Care District as a solution for a need to provide health guidance and support in more collective and interactive ways. The LSC-group activities are organised together by the health care district and the primary care. Also, health care professionals in other parts of Finland have been interested in organizing similar kinds of group meeting activities for customers in health care.

The project team met the LSC-group developers in joint planning workshops in the spring 2013 and together they made a preliminary plan for a series of experiments that could bring some new elements in developing group mentoring. Through participatory workshops and idea sessions the group leaders and developers wanted to form more comprehensive understanding of their customers' needs and life situations to design more interactive service. The service providers (i.e. the group developers and supervisors) had a shared view that good results of the service were due to the trust and transparency clearly apparent in group meetings but never been a specific point in development of the service. Inspired by the review of service design by the research the group organisers wanted to apply service design methods for gathering more information on the members of the LSC-groups and to process the information more consciously with the participants.

Travelling With Change

During the research project the LSC-group developers and leaders designed a printed material package called Travelling With Change. The first plan of the material was to make a guide or a book for LSC-group members, which, however, turned in co-design process into a collection of cards and posters that could function as a dialogic and interpretive situation mapping tool between LSC-group members and supervisors. The collection of the material was designed to be

modular and thus versatile to use in the group meetings and outside of them. The project team was actively involved in material planning and implementation.

The Travelling With Change material contains a variety of tasks and ideas for supporting the group members processing and reflecting their life with the change they have faced. The theoretical framework of the intervention was developed using elements of several theories in health promotion. One is Transtheoretical model, which begins with identifying group members' readiness for lifestyle change. The model also incorporated Social-cognitive theory, Self-regulation theories and motivational interviewing. In the intervention, these theories guide the concrete tasks in customer encounters. (Abraham; Michie, 2008; Prochaska; Redding; Evers, 1997; Prochaska; Velicer, 1997; Michie et al., 2009.) The content does not actually give instructions, but rather evokes group members to think about their individual life and wellbeing from more holistic perspective. The first version of the modular material was a poster with the view of sea in which the user can draw and write down thoughts and experiences related to tasks on the poster (Fig. 2). That version turned out to be effective particularly in opening discussion in meetings and enabling collective review on group members' different life situations and styles. It directed the service development focus on customer's value creation.

The layout and the content of the poster were changed after the first two months experiment. The later version of the material was designed to be a collection of cards and posters, so that it could be used more flexibly and selectively. The posters were still intended to use in joint discussions in the groups. The cards visually matched with the posters (Fig. 3) were clearer and more concise in content.

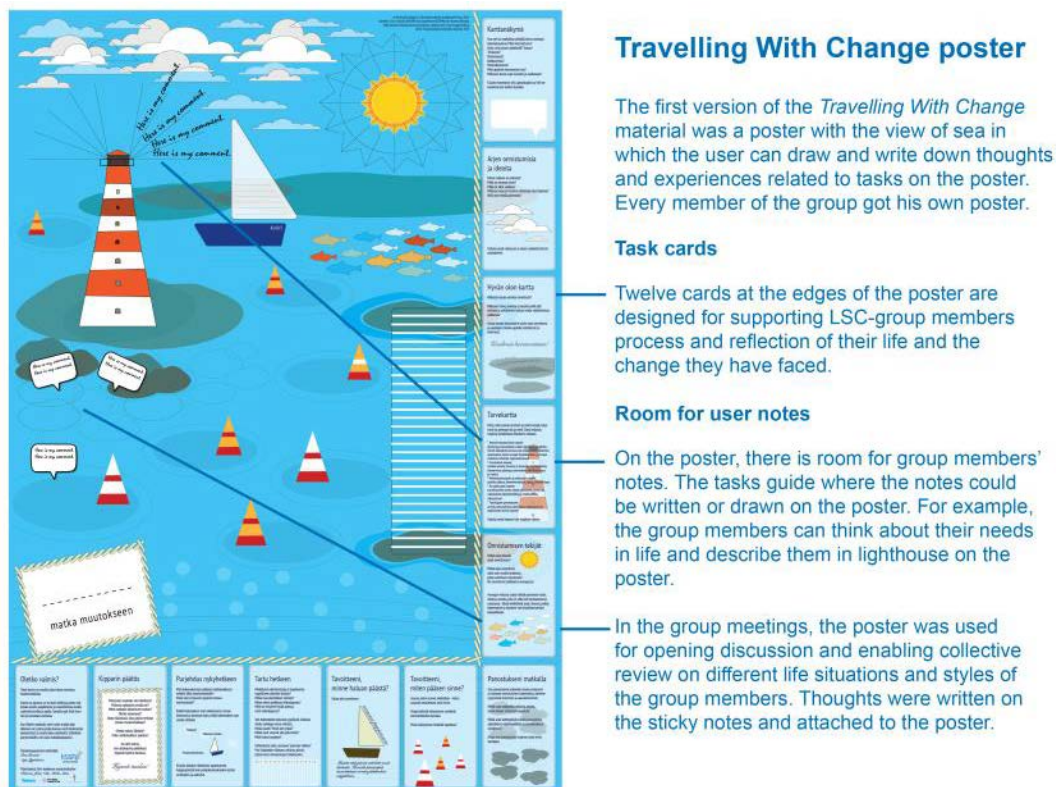

Figure 2. The poster was actively used in the beginning of the meeting for starting the discussion and for gathering customer information.

Figure 3. The new format of the Travelling With Change material was the result of a multi-stage design and experiment.

During the case study of the LSC-groups, 10 workshops were organised. Seven workshops were for health care professionals working as developers or supervisors of the groups, 3 workshops were directed to users. Co-design process with research team members was documented in written memos and partially in video format. The user targeted material package was changed twice during the project. Format changed on the basis of two user participatory test periods. The last version of the Travelling With Change package including cards and posters has received very positive feedback from the group supervisors who have not been involved in the design process. The material is considered as a tool to better align service to different user needs and situations. The form of the package is modular and thus suited for use in both in the group meetings and in privacy.

3.2 Data collection and analysis

Our study builds on field notes and video material from the co-design workshops as well as interviews with healthcare professionals in the participating organisations. Further, written reflections of employees' experiences about the developing are utilized as research material.

Data collected at the Tampere University Hospital consists of interviews with healthcare professionals. At this case organization, attendees were also asked, both in the beginning and in the end of the project, to literally reflect their experiences about the project and the tools used, and to generally describe their thoughts about developing and creating new ideas in their work community. The analysis of video material and field notes collected at the Unit of General Practice in the Central Finland Health Care District is also described for the purpose of this paper.

The data collected at the Tampere University Hospital was analysed by identifying themes that respondents brought up when describing their views and experiences about the development project. All the material was transcribed, read and coded carefully according to emerging topics. After this, the topics were categorized under different themes. In the analysis attention was paid especially on how health care workers experience the type of co-developing used in the project, and what are the preconditions required to support motivation towards EDI.

In the analysis of video material and field notes collected at the workshops organized at the Unit of General Practice in the Central Finland Health Care District the focus was on identifying central themes that were brought up in the co-ideation process when developing the Travelling with Change material package. Here attention was paid on the process of co-designing.

Based on the data and analysis of both cases we identified central experienced benefits of employee-driven service development instruments. These are presented in the following chapter.

4 Experienced benefits of employee-driven service development

In this chapter findings considering employees' experiences about employee-driven service development instruments are presented. The results are summarized in Figure 4. Particularly, we highlight the importance of open communication, meaningful development, and grass-root level development.

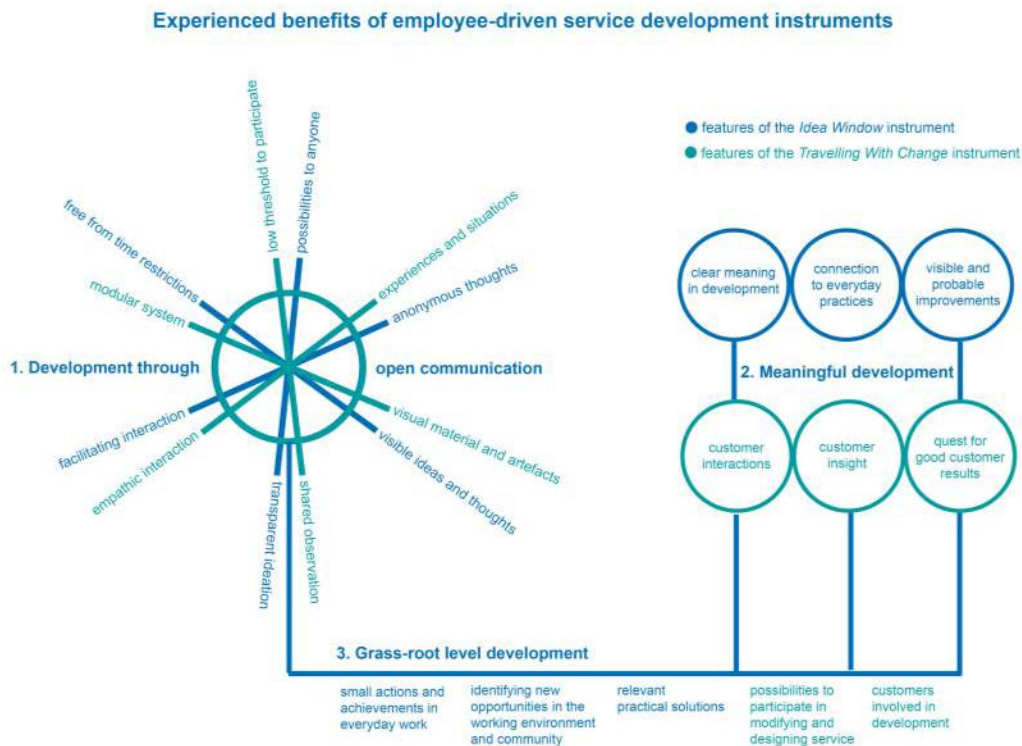

Figure 4. Experienced benefits of employee-driven service development instruments.

4.1 Development through open communication

Respondents brought up the benefits for communication that the new development tools involved. In the respondents' speech open communication is in fact depicted as a key factor in changing the practices of work community.

It was found important that the tools used in the project opened up possibilities to anyone in the work community, regardless of one's role or status, to anonymously present their thoughts. The Idea Window also appeared to be a practical tool to make ideas visible and to store them. Collecting the ideas made the ideation more transparent and concrete, which was seen beneficial in the hectic reality of a hospital organization where new ideas are often born along with the work and soon forgotten.

"Idea window has made it easier for people to bring up their thoughts/suggestions for renewal. When problems are visible to everyone there will be more suggestions for improvement and people more responsively tell about their thoughts when you have the possibility to anonymously propose ideas." (written answer, nurse 5)

"[...]And the best thing is that it's anonymous. So anyone had the opportunity to put their thoughts there and when you received a message from a patient it was brought there directly, and it's not just forgotten, we discuss about it, it's written down." (interview, nurse 1)

"There's a lower verge to go to write when there are no names." (interview, nurse 3)

Not only was the Idea Window appraised as a one-way channel to express and share ones' thoughts but it was also seen as a facilitator of interaction among employees. The opportunity to comment ideas presented by others and to make suggestions for developing them further opened up new possibilities for communication free from time restrictions caused by hectic reality in hospital or different shifts at work.

"Through idea window I understood things that I sometimes think about but I haven't realized that others think about the same things. I just never haven't mentioned about some things. Others might have a solution which you can't figure out by yourself." (written answer, nurse 4)

"[In idea window] Feedback comes so fast and it's possible to fast react. And it's open to everyone. Everyone can see it and it feeds itself -- it brings discussion at best." (interview, doctor 2)

“Each made it [wrote ideas] when they found the time. You didn’t have to write anything, you could read, you could make suggestions. So in that sense it was very good that it wasn’t scheduled to some specific time – it was always there. And you could go there when you felt like you have time. When the idea came up you wrote it and when something came from the patients you just went fast to write.” (interview, nurse 1)

“The trial didn’t take time from patient work but instead each made suggestions when they had the time and when they felt like it.” (written answer, nurse 1)

Open communication turned out to be experienced as a key component of successful developing also among LSC-groups. The co-designed instrument was to complete the existing set of supporting material in a good way, strengthening empathic interaction between the group members and supervisors, opening a new channel for sharing the observations and findings, gathering and visualizing customer experiences and situations, and lowering the threshold to participate in the joint development.

The LSC-groups in Central Finland Health Care District are co-created in collaboration with supervisors and developers. The developers have designed a rich set of supporting material, which is actively utilized in the groups. The material includes instructions, recommendations and hints for lifestyle change, and most are related directly to health promotion. The set is constantly revised. As a result, the supervisors receive a package with which it is relatively easy to launch new LSC-groups. In our research project developers were willing to experiment which kind of material they could co-design with the supervisors by bringing a group member and his or her experience and activities as the starting point for the development of the group activities. The aim was to create empathic interaction between the developers, supervisors and the users. The co-designed instrument was supposed to increase the real-life interaction between the employees and the customers. As one of the developers said “We may have too high-level ideas, where the customer’s everyday experience is.” (video, developer 1)

The developers and supervisors of the LSC-groups created Travelling With Change package to support co-operation process. Material was designed together with the group members to enhance the collection of different life stories and experiences. The aim was to increase the engagement of the members with the group and with their own lifestyle change. However, Travelling With Change package was also designed to support the work of the supervisors and developers. With the help of the material it is easier for them to follow the progress of the group members and their experiences of the group in its different phases and thus share observations.

In the best-case scenario Travelling With Change material collects and visualizes the customer experiences and situations. By evoking new thoughts and different interpretations the material may lower the threshold in taking up more sensitive personal issues in the group. Material was designed as visual as possible so that textual content and complexity was reduced to its minimum so that the material would not feel too overwhelming and would lower the threshold to participate in the discussion. The flexibility and modularity of the system is also perceived as a way to increase open communication within the groups as well as in the LSC-group development activities. A collection of cards was perceived as a natural format of the material for many employees. “If it were a starting picture that could be changed. Why not a collection of cards that could be used in different ways [...] Cards could be used in the group and alone.” (video, developer 3)

4.2 Meaningful development

When describing their experiences about various development projects respondents expressed strong frustration in the kind of developing in which the meaning was not clear for them. In these projects, it is difficult to find incentives for participating in development activities. If the connection to practices is seen weak not much value is given to the project, rather it is experienced as useless extra work.

“If it [developmental project] requires a lot of extra thinking or if it has not been presented clearly to us or if the point and benefits have not been marketed well to us -- then you react to it in a more aloof manner.” (interview, nurse 2)

Developing is experienced as important and meaningful if it is connected to the everyday practices in one’s own work and if the improvements are visible or highly probable. To get motivated, clarifying the link to practice seems evitable. This viewpoint was strongly emphasized especially among nurses. From this point of view developing is not successful if it is “too far from the practices. That you think too scientifically without facing the patient.” (interview, nurse 1)

What was brought up several times by the respondents when reflecting their experiences about the project was that the project especially directed one to think about the actions even more strongly from patients’ point of view. In evaluating the importance of developmental actions what counts most are the benefits they might produce to patients. Patients’ viewpoint is an important source of motivation and a central point in legitimating developing both among nurses and doctors.

“The targets of our work are patients, and their good care is the motivation why you do this work.” (written answer, doctor 1)

“You always think about the patient’s viewpoint but maybe along with this project you really stopped to think about their experience.” (interview, doctor 1)

“[After the project] you pay attention to the patient’s viewpoint more.” (interview, nurse 1)

The LSC-group supervisors (nurses) felt that customer encounter is often challenging. The customer can avoid of talking the actual issue by talking around. Identifying of customer's actual situation and needs would require a number of individual meetings and much discussion. The group members are a mixture of people who have multiple problems with health and life situation. The employees try to find the ways to support both the people who are really trying to make a change in their life and the people who are just adapting to a new situation.

“There are so many this kind of people who live their life through other people. This type is very common in the groups.” (video, developer 1)

“It would take perhaps several moments that she [patient] gets to the point. She must tell two or three times what her daughter or husband has eaten, or how her children eat and move. Before you get there, to her, who has come to the reception.” (video, supervisor 1)

“The group consists also of people who have newly received a diagnosis. These people I experience extremely difficult from the steering point of view. One may process the adaptation to the new situation. It would be better for that person to get adaptation training and not to join the lifestyle change group. This relates to the allocation [of service or guidance].” (video, developer 3)

In one workshop, the developers and supervisors of the LSC-groups agreed on that the lifestyle change support material should help group members to mirror their life situations in relation to their personal history and social networks. The health care professionals often have to open very challenging and sensitive topics in discussion with the patient and according to the LSC-group professionals it is one of the key factors to achieve positive results with the patient. Therefore, the careful and comprehensive study of the patient is one of the main conditions to provide good service. In the LSC-groups, the initial situation is also often difficult because the group members do not usually have clear thought of their situation or view of the target. Thus, the material package should function as an initiator and amplifier helping group members to frame and review their situations privately but also in the group meetings with the health care professionals.

“Now, it is tempting to say that this is one important question in our self-help book [LSC-group support material] context - mirroring own life to the very own family background. Somehow I feel that this will be extremely relevant in this case.” (video, developer 2)

“Target may not be clear. Maybe they haven’t internalized their own targets.” (video, developer 1)

“Tools would give that person an opportunity to begin to consciously seek change and to go towards the new.” (video, developer 1)

“Material can tingle a little bit, just positively, so that a person learns to identify his own special features and strengths.” (video, developer 3)

4.3 Grass-root level development

Related to the experiences of meaningful development, respondents find important the kind of developmental actions that are realized on grass-root level and in close co-operation with those who do the work in practice. Challenges for motivation seem to occur if the ideas for developing come from outside or top-down, without concretely understanding the grass-root level reality.

“When employees can themselves think about suggestions for how to correct things, these [ideas] are tested more bravely.” (written answer, nurse 1)

“There exists excitement in the work community to develop, people just need to be asked and they must be participated.” (written answer, doctor 3)

Ideas of participating, co-designing and entrepreneurial way of acting (intrapreneurship) were fundamental starting points in our research. This concrete ‘doing’ from real needs of the workers and patients, and the aim to empower the grass-root level professionals can be seen as key points that made people at the case organizations participate in and get excited about the project.

“The best ideas come from those who physically work in the centre of where things happen, from midwives in this case. I think not many doctors put their ideas there [to idea window] (more distant relationship to practices?).-- I find it extremely important that actions are developed in co-operation with those who concretely do the work, perhaps together with those who’ve got the tools.” (written answer, doctor 1)

“This is how it [developing] should be, that it’s targeted to us, that you act on the field so clearly.” (interview, nurse 3)

“Now there are more and more these [projects] that nurses start to develop or nurses and doctors in pairs develop. In this way it’s clearly more holistic. -- When the suggestions to change come from ourselves and not from what the administration says they are certainly much easier to accept.” (interview, nurse 1)

As in hierarchic hospital organisations major changes are very slow to realize, our project aimed at bringing attention to the small acts and achievements in every day work. Identifying new opportunities in the working environment and community was facilitated with the developmental tools.

“It is easier to bring up ideas/problems/solutions via idea window. If the solution is the kind that it doesn’t require organizational or structural changes it is easier to take forward. But if some bigger changes are needed it hardly happens.” (written answer, nurse 4)

Respondents reported that the Idea Window had produced small, concrete improvements in everyday work that were realized already during the project. For instance, handrails at the patients’ toilet been long missed were finally acquired, and the medicine cabinet was re-situated to better serve everyday actions and without disturbing patient operations. One example of the proposed solutions was based on the observation in which the patient had to wait twice to meet both the nurse and the doctor during the same visit. In the Idea Window, this observation generated the proposal in which all patients should go systematically first to the nurse and move flexibly from there to the doctor. These examples show how even the simple solutions can open a way to reduce patients' frustration and to incrementally improve the quality of service. The employees themselves can take many practical solutions that are relevant for the development of services and gradually get engaged in also more complicated service development.

However, respondents clearly experienced that concrete changes were still to come. They found it to be too early to evaluate which of the ideas would be implemented, when, how or by whom.

In the case study of the Life Style Change groups, the data generated in user participatory workshops stimulated the group leaders and developers to think their attitudes toward work. They noted that it is important that employees are able to apply large amount of knowledge and skills in work but they also should have a profound customer insight and possibilities to participate in modifying and designing service offering on grass-root level. Getting to know customer's ideas and needs can be a good way to strengthen understanding of what is the core of the service, and which parts of the service can be changeable and customizable. The group developers and supervisors wanted the Travelling With Change material to be a collection of relatively simple tools and instructions, but including also own thinking reviving tasks. They began to see the material as a tool or instrument that allows members and instructors of the group to shape the service together without losing sight of the central content and objectives.

“For us professionals it is typical that we harvest all the knowledge when we meet the customer. The customer's experience, however, is that it really wants simple things. The story plot is there that a person can get closer to the new over and over again through the simple things. I will say, the more I have made this group activity work, the simpler I would like to modify the body of the service. We have tried this, yes, but in reality things are rambling too much in all groups.” (video, developer 2)

5 Conclusion and discussion: Preconditions for engaging health care professionals in employee-driven service development

In this study, we showcase two service development instruments that were co-designed in two large public health care organizations. The initial aim and approach in the two projects were slightly different. Nevertheless, in both cases the development of the instrument enabled open communication, meaningful development, and grass-root level development. These features are important in a service development instrument in order to ensure EDI in the context of public health care. In both cases, co-designing a tool seemed to be a suitable and practical starting point to get employees interested in collaboration and to participate actively in project representing a totally foreign way of thinking and action.

The Idea Window experiment enhanced employees to pay attention to full complexity of service development. On one hand, it highlighted the service implementation and performance as important part of the service development, on the other hand it stimulated ideation and quick testing of services during their everyday work practices. Typically, service development involves certain stages from ideation to implementation and testing, each of which has its own time and place in the process. In the Idea Window instrument different service development stages are roughly apparent and neglected to each other in one flexible open communication tool used for gathering information on customer, ideating new service solutions, making quick and simple experiments for service improvements and for monitoring impacts of new solutions in everyday work context. The Idea Window can be helpful in enquiring knowledge and experiences on new opportunities and ideas more comprehensively and participatory. It can be used for gathering

broader and deeper information on the customer behaviour and values, and thus producing a good starting point for employee-driven service development in such hectic and very much routine-based working environment as hospitals.

The Idea Window experiment revealed that co-designing developmental instruments with employees to encourage and to stimulate them in their developmental purposes can help the organization getting beyond the assumptions that block effective and new solutions. Co-designing instruments for collegiate use provides employees a lens to consider their work site and practices from more developmental aspect. They focus on designing an instrument, which should match with their work context and be usable in practice but simultaneously bringing out and triggering variable reforming aspects and efforts of the working community. When designing a developmental tool for their own use, at the same time, they reflect and process their working practices, attitudes, meanings and conditions from multi-dimensional point of view. Employees' reflective process combined with customer information enquiry and analysis creates a very good base for renewing organisation more service-oriented.

In co-designing the Travelling With Change package the employees clearly understood the importance of customer information as a central element in development of the service and were interested in co-designing method or instrument to enable more open and continuous dialog with their customers. The developers of the LSC-groups were motivated to form profound understanding of customer processes and to design methods and tools for increasing customer interactions and strengthen supervisors' enthusiasm for the joint development.

The Idea Window and the Travelling With Change instruments seemed to help employees in recognizing the design and development process as a combination of overlapping phases of inspiration, ideation and implementation. Brown and Wyatt (2007) have called them as overlapping spaces of design thinking process. Rather than preparing a sequence of orderly steps in development process both instruments called the spaces of design in flexible, creative and collective communication and development process taking place in everyday work. As Brown and Wyatt (2007) have noted, design thinking can feel chaotic for the first time but the process makes sense and achieves results, even though it differs from the typical linear and milestone-based processes.

The approach based on EDI and design thinking was applied in a unique way in our project to facilitate EDI in health care sector. Service development tools and methods tested in the case organizations brought attention to the expertise and capabilities of health care professionals as a source of renewal and change. We believe that the same approach and tools could well be applied also in other contexts and more widely in different sectors.

As a theoretical contribution, the action research indicates that health care professionals are motivated to participate in designing and using service development (i.e. service design) tools and methods

- if the process is based on meaningful and practical frames which matter to health care professionals,
- if the process fits with contextual restrictions of healthcare organisation,
- and if employees have possibilities to modify the process and monitor the impacts and to apply the results in multiple ways.

Our project facilitated the ideation in health care organizations to enable rapid development of services. However, there seems to be a gap between the creation and implementation of the ideas. Although some of the shared ideas were implemented already during the project, respondents found it difficult to see how most of the new ideas would be implemented in the future. As one of our respondents put it: "The problem is often implementation, there are no resources/it's difficult to implement and so on. You can create ideas but it's more difficult to take them to practice level." (written answer, nurse 3).

Also, what was not spoken about was who would be responsible for bringing new ideas into action. Based on our perceptions we claim that rapid and more flexible tools and methods are needed for evaluating the ideas to enable faster reacting and implementation. There exists a research gap and need for further research in this area of study although for instance transformative service research literature has increasingly started to pay attention to the issue.

In the research paper, we focus on presenting and analysing the project results which open up new possibilities for more user-centric, employee-initiated, agile health service development and innovation processes in the context of everyday work practice of health sector. We combine the development needs from EDI literature with design thinking orientation in our action research project. Consequently, we discuss the insights for preconditions to engaging health care professionals in employee-driven service development. Co-designing tools and methods with health care professionals is a way to engage healthcare professionals in the service development domain and to support their opportunity identification capability and initiative in service development. Thus, co-designing service development instruments may provide psychological empowerment for nurses in the lower ranks of health care hierarchy.

Our research findings are in line with prior research on EDI in health care organizations. However, more research is needed on improving the incentive system, and the evaluation processes with the co-designed service development instruments. In addition to practical service design this also calls more empirical work on understanding what motivates health care professionals to engage in EDI and what kind of evaluation systems would encourage EDI in the context of public health care. Particularly, our study encourages finding how to design service development instruments that enable open communication, how to evaluate meaningfulness of initiated service development processes, and how to ensure grass-root level development. Based on our study and experience in the field, these are important questions particularly in the context of public health care. To advance our knowledge, we simultaneously call for more related research also in other contexts.

La gestion des leads, métamorphose des stratégies « métiers » dans le réseau automobile

Catherine Lande, Marianne Abramovici

Institut de Recherche en Gestion (IRG)
Université Paris Est, Marne-la-Vallée

L'industrie automobile continue sa mutation dans leurs pratiques commerciales et de l'après-vente. L'unique stratégie de consacrer ses efforts sur la qualité des produits vendus et non sur les offres de services (Bastien et Kapferer, 2012) ne suffisent plus. Les nouveaux comportements des prospects les contraignent à s'adapter en modifiant la gestion des offres de services. L'objectif de cette communication est d'analyser les impacts organisationnels et stratégiques de la gestion des leads dans une concession automobile, de caractériser les nouvelles compétences de chaque acteur impliqué dans ce processus et de s'interroger s'il existe une stratégie commune pour l'ensemble des marques automobiles.

The automotive distributor continues its transformation into their business practices and after-sales. The only strategy to focus its efforts on the quality of products sold and not on service offerings (Kapferer and Bastien, 2012) are no longer sufficient. New consumption patterns leads force them to adapt by changing management service offerings. The objective of this paper is to analyze the organizational and strategic impacts of lead management in a car dealership, characterize the new skills of each actor involved in this process and wonder if there is a common strategy for the all car brands.

L'intégration de nouvelles technologies est devenue indispensable à la performance et à la compétitivité des entreprises. Les constructeurs automobiles, face à la crise et à l'arrivée de nouveaux « pure players » de la distribution et/ou de la réparation automobile instaurant de nouveaux modèles dans la relation client, cherchent à reconquérir le client « perdu » et le fidéliser. Dans une étude précédente (Abramovici et Lande, 2012), nous avons montré les enjeux de transformation de l'expérience des services après-vente. Il s'agit, dans cette étude, de montrer les enjeux et les transformations à l'œuvre dans l'amont du processus, avant même que le client ne soit client.

Même si le marché de la location ne cesse de conquérir des parts de marché, 9 français sur 10¹⁶⁸ souhaitent toujours être propriétaire de leur véhicule. Ce comportement pourrait, à la lecture de cette première donnée, « rassurer » les constructeurs dans leurs relations privilégiées avec leurs clients. Mais les Français, face à la diminution de leur pouvoir d'achat, ont été nombreux à diminuer leur budget voiture en réduisant leurs déplacements et en favorisant l'achat d'un véhicule d'occasion (48% des Français¹⁶⁹).

Sur le marché du véhicule neuf, les comportements des consommateurs varient en fonction de la gamme du véhicule. Le marché des voitures neuves de marque premium (BMW, Mercedes, Audi) se porte bien, conforté par une clientèle fidèle. En revanche, les marques low-cost (Dacia...) attirant 1/3 des français, le marché des marques généralistes historiques (Renault, Peugeot, Opel...) ne réussit plus à capter sa clientèle « traditionnelle ». L'industrie automobile doit réussir sa mutation dans ses pratiques commerciales de l'avant et de l'après-vente.

Longtemps principalement basée sur une concurrence produit et une communication quasi-exclusivement consacrée à la valorisation de la marque et des produits, cette stratégie marketing ne suffit plus (Bastien et Kapferer, 2012). Dans un contexte de crise où le délai de renouvellement de son véhicule s'allonge et où la part du marché des véhicules neufs se réduit, ce sont l'ensemble des services proposés par la distribution automobile (service après-vente, pièces détachées, location...) qui permettent aux concessions de maintenir un chiffre d'affaires couvrant des coûts fixes importants (Donada et Vidal, 2001).

Par ailleurs, les nouvelles pratiques d'achat des consommateurs, dans un environnement où l'information est immédiatement disponible via des sites web contraignent les constructeurs à s'adapter en modifiant la gestion des offres de services et l'organisation de la relation commerciale. Constatant que le marché des véhicules neufs s'essouffle, les constructeurs doivent redoubler d'effort pour endiguer cette hémorragie vers le véhicule d'occasion. Pour cela, de nouvelles stratégies de gestion de la relation client sont mises en œuvre en investissant dans des systèmes d'information permettant d'accroître des échanges de données informatisées entre les différents acteurs présents dans les différents processus de la chaîne logistique.

Après avoir développé et intégré dans leur réseau des progiciels pour gérer l'ensemble des processus de gestion de la relation client (Peelen et alii, 2009), du sourcing ou, encore, le pilotage de la performance, les constructeurs automobiles mobilisent leur réseau pour développer de nouvelles pratiques dans la gestion des contacts commerciaux (les leads) (Bloch, 2012). Il s'agit pour les constructeurs de construire une relation commerciale riche et personnalisée

¹⁶⁸ TNS Sofres, Baromètre « les français & l'automobile » - vague 2013

¹⁶⁹ *ibid*

en amont du processus de vente, alors que le client n'est qu'un prospect engagé dans une démarche de renseignements. Notre travail souhaite montrer que, loin de n'être que de simples outils, il s'agit bien de nouvelles technologies permissives qui, conformément au modèle de Barras (Gallouj, 1997), sont en train de transformer en profondeur l'efficacité voir la qualité des services autour de l'achat du véhicule neuf.

Dans cette étude, le lead est un « contact commercial plus ou moins qualifié obtenu sur un site web ou une application mobile par le biais d'un formulaire ou d'une adresse Internet » (Bloch, 2012).

L'objectif de cette communication est d'analyser les impacts organisationnels de cette innovation marketing dans une concession automobile, de caractériser les nouvelles compétences de chaque acteur impliqué dans la gestion de ces leads et de s'interroger sur les stratégies des différents acteurs dans cette évolution. L'ensemble de cette étude doit nous permettre de comprendre la diversité des nouveaux parcours client possibles dans un environnement cross-canal et d'analyser les stratégies les plus performantes.

Les enjeux de cette étude exploratoire sont de trois ordres :

Les *enjeux stratégiques* : les nouveaux acteurs impliqués dans le processus et les relations entre les nouvelles parties prenantes doivent s'intégrer à de nouveaux modèles économiques (Abramovici et Lande, 2012).

Les *enjeux commerciaux* : afin d'adapter le rythme de l'entreprise aux besoins perçus des clients (besoin de réactivité, élargissement des plages horaires...) et aux besoins et aux comportements différents des clients selon l'offre de service choisi, le réseau automobile est conduit à développer des stratégies relationnelles différentes.

Les *enjeux des ressources humaines* : Certaines de ces nouvelles tâches sont confiées à la force de vente qui doit évoluer dans ses compétences mais, également, à de nouveaux acteurs répondant à des métiers et des nouvelles fonctions inexistantes jusqu'alors ce qui amène à une redistribution des tâches et des responsabilités.

1 Design de la recherche et méthodologie

Cette étude exploratoire vise à décrire et analyser le processus de décision pouvant conduire à l'achat d'un véhicule neuf dans un environnement cross-canal.

Nous examinons cette question du point de vue d'un concessionnaire indépendant disposant de relations privilégiées avec une ou plusieurs marques. Dans cette étude exploratoire, nous nous sommes limitées à l'examen des dispositifs mis en place pour faciliter l'achat d'un véhicule neuf.

L'organisation de l'offre de ce secteur et, en particulier, l'analyse des processus de production interne sont rarement étudiés. En France, les relations entre les directions Marketing des marques (françaises ou étrangères) et leurs réseaux sont compliquées et les entreprises sont réticentes à demander à des chercheurs de travailler sur ces questions. C'est ainsi que les rares travaux de recherche sur ce secteur épousent le plus souvent le point de vue des constructeurs et ne permettent pas de comprendre comment les décisions prises se mettent en œuvre dans les concessions (Bakiri, 2007 ; Gutierrez, 2006.)

Nous étudions les transformations de ce secteur depuis une quinzaine d'année. Notre point de vue, celui des enseignants responsables de formation dans les métiers de ce secteur soit au niveau techniciens supérieur soit au niveau Management (Marketing et Production des Services Après-vente), nous a conduit à avoir des relations régulières et de qualité avec des managers responsables travaillant soit au siège des constructeurs, soit dans des concessions.

C'est dans le cadre de ces relations que nous avons pu comprendre les questionnements des managers en charge de la direction commerciale, dans des concessions, sur la meilleure façon de gérer les nouveaux modes d'interaction avec les prospects : la gestion des lead.

Il s'agit de comprendre, dans le processus de la gestion des leads, quelles sont les nouveaux processus mis en place par le réseau automobile ? Quelles sont les compétences organisationnelles pour construire et piloter ces nouveaux processus tels que savoir gérer le travail à distance d'une équipe, savoir mobiliser les ressources clients disponibles et les enrichir, savoir inciter et piloter l'équipe pour accroître les expériences ? Quelles sont les compétences attendues des « conseillers client web » ? Quelles sont les compétences attendues des clients ? Ces deux dernières questions ne seront pas développées dans cette étude.

Une première étude de benchmarking sur le suivi du processus d'un essai de véhicule neuf en passant par les sites des marques de constructeurs automobiles distribués en France a permis d'établir comment se déroule ces nouveaux processus et de mieux en comprendre leur spécificité par rapport aux processus de vente traditionnel. Quel est le temps de réaction du constructeur et de son réseau ? Quelle est la forme des réponses et des prestations proposés ? Comment est contrôlé le comportement du client ?

Une seconde étude qualitative exploratoire à l'aide d'entretiens auprès de directeurs de sites (3), des directeurs commerciaux (3) et de directeurs après-vente (3) couvrant une marque premium et huit marques généralistes, a mis en évidence les enjeux des nouveaux processus mis en place. Comment les tâches sont réparties et à qui ? Comment sont perçues ces nouvelles stratégies ?

Dans cette étude exploratoire, notre propos est de mettre en évidence le processus générique (Bakiri, 2007) induit par ces innovations technologiques, d'en proposer une description permettant de mieux en appréhender les enjeux relationnels et de production de service puis de proposer une première typologie des modes de gestion des leads, issus de nos entretiens avec les directeurs de sites et commerciaux.

2 Un contrôle organisationnel pour optimiser le parcours client

Chaque constructeur développe son propre réseau de distributeurs/réparateurs composé de concessions et de succursales. Tandis que les succursales dépendent directement de la société mère (constructeur), les concessions peuvent appartenir à un groupe multimarques (regroupement de plusieurs concessions n'appartenant pas à une même marque constructeur). Cette configuration n'avait pas été un frein, jusqu'à présent, dans les relations entre constructeur et son réseau de distributeurs. Une relation privilégiée existait entre eux où chacun avait un rôle bien défini, l'un fabriquait et communique au niveau national sur ses produits tandis que le second vendait et réparait tout en communiquant localement. L'apparition des sites internet n'ont pas changé ces prés carrés. Chacun avait son site vitrine distinct et dédié à une seule marque.

Dans le but de vouloir capter le client à la source de son processus de décision lors de l'achat d'un véhicule d'occasion, les distributeurs ont concédé une partie de sa communication web aux infomédiaires (l'argus, eBay, La centrale...) spécialisés dans la vente de véhicules d'occasion. En s'intégrant sur ce marché, les infomédiaires ont créé une étape à la source du processus de décision du client et le réseau a dû s'adapter au mode de diffusion choisi par les infomédiaires pour la gestion des leads, principalement par mail. Ainsi, le service commercial des véhicules d'occasion, chez un distributeur, a été le premier dont les pratiques ont dû évoluer.

Puis pour redynamiser le marché du véhicule neuf, le constructeur a pris l'initiative de créer du trafic dans les show-rooms que le client désertait en proposant depuis leur site vitrine une nouvelle offre de service « la prise de rendez-vous pour l'essai d'un véhicule ». Pour cela, il imposa un processus de la gestion des leads, en provenance du site « constructeur », à son réseau avec des modalités et un temps de « traitement du lead¹⁷⁰ » en moins de 4h puis de 2h. Pratiquement dans le même temps, les distributeurs ont pris également l'initiative de proposer la même offre sur leur site en développant leur propre processus de gestion des leads, en provenance de leur(s) site(s) mono-marque ou multimarques.

Puisque aucun standard de diffusion des leads n'existe, chaque protagoniste a essayé d'imposer son processus et ses méthodes de pilotage. Le problème rapidement rencontré par le réseau a été d'adapter leur système d'information et d'intégrer différentes pratiques auprès de leur personnel pour des objectifs commerciaux différents.

C'est dans ce contexte un peu chaotique où chacun essaye d'imposer « son » process que le prospect et le personnel en contact ont dû s'adapter.

2.1 Du processus générique de la gestion du lead aux processus particuliers

Quel que soit l'origine du lead, site constructeur, distributeur ou infomédiaire, il convient de distinguer les différentes étapes possibles de la gestion du lead qui sont :

- Génération d'un lead
- Confirmation au client de la réception de sa demande
- Qualification du lead
- Assignation et allocation du lead
- Prise en compte de la demande du client
- Suivi (pilotage) des leads

Un prospect, après consultation du site, va **générer** un lead en remplissant un formulaire en ligne. Dès qu'il l'a validé, le prospect peut recevoir une confirmation.

La préoccupation des professionnels est, généralement d'avoir un contact le plus tôt possible dans le parcours du client mais, surtout, d'informer le prospect que sa demande a été effectivement prise en considération et qu'elle est une priorité pour l'entreprise. C'est la raison pour laquelle beaucoup d'acteurs (mais pas tous) ont choisi d'envoyer une réponse automatique par l'affichage d'un message instantané. Cette première réponse peut être suivie d'une **confirmation** par courriel personnalisée.

Ce lead va ensuite être **qualifié** par l'acteur le recevant, cette qualification pouvant être faite automatiquement ou manuellement.

Enfin, le lead est **assigné** à un personnel commercial et les moyens nécessaires pour le traiter (temps, supports, propositions commerciales) sont **alloués** en conséquence.

Si la génération du lead n'est faite qu'une seule fois, il n'en va pas de même pour les étapes suivantes. En effet, ces dernières seront identifiées autant de fois qu'il y aura d'intermédiaires sans pour autant avoir les mêmes tâches répertoriées.

Par exemple, un client demandant un essai de véhicule en se connectant directement sur le site du constructeur (une étape) sera pris en charge par ce dernier qui utilisera les informations collectées pour alimenter ses bases de données marketing puis le redirigera, selon des modalités variables, vers un ou plusieurs concessionnaires. Ces derniers, en fonction de leur propre organisation et processus, collecteront à leur tour les informations transmises par le client.

¹⁷⁰ Le « temps de traitement du lead » par le réseau, défini par le constructeur, représente la durée maximale accordée pour essayer d'avoir un 1er contact avec le prospect et mettre à jour la base de données du constructeur. Ce temps de traitement est décompté en fonction des plages horaires d'ouverture du distributeur.

Lors de ce processus de gestion, il est donc important de distinguer les différents acteurs intervenants dans ce processus

- Le **prospect** qui peut être déjà considéré comme client par le distributeur
- Le **constructeur** gère une marque avec un réseau de distributeurs. Depuis son site vitrine, il peut être possible, pour le prospect, de faire une demande d'essai de Véhicule neuf, d'accéder aux offres du réseau de véhicules d'occasion et, parfois, de prendre un rendez-vous pour un entretien
- Le **distributeur** peut gérer une seule ou plusieurs marques de constructeur et appartenir à un groupe lui-même monomarque ou multimarque. Depuis leur(s) site(s) internet, il offre la possibilité au prospect/client de faire une demande d'essai de Véhicule neuf, d'accéder aux offres du distributeur ou de tout le groupe de véhicules d'occasion et, parfois, de prendre un rendez-vous pour un entretien ou de faire une demande de renseignement auprès du service après-vente
- L'**infomédiaire** publie toutes les offres de véhicule d'occasion quel que soit la marque, le distributeur ou le type de véhicule

Table 1. Processus générique de la gestion du lead.

Process	Lead	Prospect/client	Constructeur	Distributeur	Infomédiaire
Prise de rendez-vous	Génération de lead	Lead généré par un tiers ou lui-même quel que soit l'heure et le jour depuis son ordinateur, tablette ou téléphone	Mise à disposition d'un service client : formulaire ou messagerie électronique ¹⁷¹	Mise à disposition d'un service client : formulaire ou messagerie électronique	Mise à disposition d'un service client : formulaire ou messagerie électronique
Gestion de la demande	Confirmation	Réception du message électronique	Réponse automatique au prospect par pop-up ou mail	Réponse automatique au prospect par pop-up ou mail	Réponse automatique au prospect par mail
	Qualification du lead		Mise à jour de la base de données prospects et distributeurs	Mise à jour de la base de données prospects/clients	Mise à jour de la base de données clients et distributeurs
	Assignation et Allocation du lead		Assignation et allocation du lead au distributeur désigné par le prospect ou pas	Assignation et allocation du lead au référent du service, à une personne ou dans un pot commun	Transmission du lead au distributeur désigné
Confirmation du rendez-vous par le service commercial dédié	Suivi des leads	Répond ou pas au(x) sollicitations du commercial		Commercial contact le prospect (jusqu'à trois tentatives).	
		Si le prospect répond et accepte un rendez-vous	Mise à jour de la base de données du constructeur par le commercial	Commercial contact le prospect par mail ou téléphone et propose un rendez-vous Mise à jour de la base de données du distributeur par le commercial	
		Si le prospect ne répond pas	Mise à jour de la base de données pour le suivi, le lead est classé. Considéré comme « lead perdu »	Commercial contact le prospect (jusqu'à trois tentatives). Mise à jour de la base de données pour le suivi, le lead est classé. Considéré comme « lead perdu »	
		Si le prospect ne souhaite pas donner suite	Mise à jour de la base de données pour le suivi, le lead est classé. Considéré comme « lead perdu »	Mise à jour de la base de données pour le suivi, le lead est classé. Considéré comme « lead perdu »	

La mise en place d'un processus de gestion des leads par un constructeur fait naître des interactions avec ses distributeurs pendant le parcours client qui, jusqu'alors, n'existaient pas. Il en est de même pour un distributeur entre sa direction et son équipe commerciale.

¹⁷¹ Il n'a pas été retenu le service client par téléphone dans cette analyse.

Ainsi, comme cela a été précisé précédemment, nous retrouvons les mêmes étapes génériques (Qualification, Confirmation, Assignment/Allocation, Suivi) pour chaque intermédiaire. La multiplication du nombre d'intermédiaires peut avoir une incidence notable sur le parcours du client.

2.2 Les stratégies mises en place pour s'adapter aux nouveaux comportements du prospect/client

La grille d'analyse qui suit (Abramovici et Lande, 2012) a pour objet d'analyser l'environnement de la coproduction pour l'achat d'un véhicule neuf dans deux situations possibles : un contact classique, où l'essentiel de la relation de service se déroule en face à face et un contact commençant par un lead, en réponse à une action promouvant l'essai d'un véhicule.

Dans ces deux processus, c'est le client qui initie la relation de service. Le rôle du personnel en contact est de comprendre la nature de la demande du client et, en particulier, son degré d'engagement afin de savoir si la visite relève d'une prise d'information voir d'une curiosité ou bien si elle est la première étape d'un processus d'achat.

La principale différence est la servuction (Eiglier et Langeard, 1987) environnant les étapes amont de ce processus ainsi que les signes qui permettent (plus ou moins) aux acteurs de la relation de service de procéder à une évaluation de l'intérêt du client.

Nous avons repris la grille d'analyse proposée par Codello et alii et déjà mobilisé dans une autre étude sur le secteur automobile pour mettre en évidence les principales différences qui découlent de l'évolution du processus d'achat.

Nous avons en effet montré dans un travail précédent (Abramovici et Lande, 2012) que cette grille facilitait l'explicitation du modèle de coproduction (Codello et alii, 2012) et l'analyse des ressources du système de production de service mobilisés dans la relation de service.

Table 2. Environnement de la coproduction pour l'achat d'un véhicule neuf.

Caractérisation des dispositifs de contrôle	Dans le modèle de coproduction normal	Demande d'essai d'un véhicule
	Face à face	À distance
Sur quoi s'exerce le contrôle du comportement du client ?	Sur la pertinence de la demande du client/prospect Sur le résultat de la vente d'un véhicule neuf ou d'occasion	Sur la pertinence de sa demande au vu de l'état des informations disponibles dans la messagerie électronique Sur les échanges et le niveau d'engagement fait entre le client/prospect et le vendeur Sur le résultat de la vente d'un véhicule neuf ou d'occasion Sur les connaissances du client (normes d'entretien, capacité à détecter et interpréter des anomalies de son véhicule)
Qui contrôle le comportement du client ?	Le vendeur lors de la vente	Les différents acteurs professionnels gérant le lead et le prospect lors de la vente
Quand le contrôle organisationnel des comportements du client a-t-il lieu ?	Essentiellement à la validation du contrat de vente par le client et son départ	Lors de la qualification du lead (contrôle amont) Lors des différents contacts avec le client (accepte ou refuse de répondre ou donner suite aux messages...) A la validation du contrat de vente par le client et son départ
Quels sont les processus de contrôle organisationnel des comportements du prospect ?	Contrôle par le vendeur (par rapport aux données connues et aux informations du client)	Contrôle des données, avec le client, avec possibilité d'une participation active du client (décisionnaire de la relation) Par le vendeur : Appel du prospect (si coordonnées disponibles) Envoi d'un mail (si coordonnées disponibles)
Quels sont les moyens de contrôle organisationnel du client ?	Base de données du distributeur	Base de données du distributeur et du constructeur

Caractérisation des dispositifs de contrôle	Dans le modèle de coproduction normal Face à face	Demande d'essai d'un véhicule À distance
Quelle est l'attitude du client contrôlé ?	Aliénation (le client est dépendant d'une expertise externe) associée à une méfiance du client	Implication associée à une attitude plus experte du client : capacité à intégrer des informations liées à son véhicule, capacité à prendre des décisions (accepter ou non)

3 Une gestion des leads dépendante du leadership des acteurs

Chaque intermédiaire a mis en place des dispositifs de contrôle qui permettent de suivre l'évolution du traitement de lead.

Pour le cas de l'essai d'un véhicule neuf, il existe deux niveaux de contrôle organisationnel suivant l'origine du lead
Si le lead est généré via le site d'un constructeur, il existe alors deux dispositifs de contrôle : un par le constructeur et un autre par le distributeur.

Si le lead est généré via le site du distributeur, uniquement le dispositif de ce dernier est mis en action.

Certains constructeurs ont mis en place une gestion des leads générés sur leur site via un intranet dédié. Dans ce cas, il est attendu que tous les acteurs (constructeur et distributeur) qui interviendront pendant le processus de gestion du lead se connectent et complètent au fur et à mesure de l'évolution du traitement du lead depuis l'intranet du constructeur. Ce dispositif permet au constructeur de suivre la gestion du lead en temps réel mais cela n'exclut pas le personnel en contact de mettre à jour la base de données du distributeur.

Si du point de vue du constructeur, il y a un support de gestion des données unique, du point de vue du distributeur, surtout s'il est multimarques, c'est plus variable (n intranet pour n constructeurs, avec des structures de données différentes...). Selon les droits d'accès aux données qu'il a, les possibilités d'exports vers d'autre(s) système(s) ou l'absence de communication entre les systèmes engendrent une multiplication des tâches identiques.

Ce dispositif d'intranet permet au constructeur d'être intrusif dans la gestion des activités du personnel dans tout le réseau. Il lui est possible de contrôler la performance de l'ensemble du personnel. Il lui sera possible d'être plus interventionniste dans le management des équipes et/ou, tout au moins, d'identifier les besoins de formation pour réduire les écarts de pratiques au sein du réseau indépendamment du distributeur.

La mise en place de ce processus multipartie-prenante permet d'initier un partage d'informations cohérentes (sur le prospect). Ainsi, même si les différents acteurs s'appuient sur des systèmes d'information propres, la gestion des leads permet à ces différents acteurs de récupérer une partie des informations générées via les actions d'un autre acteur. Ce nouveau mode relationnel permet donc aux constructeurs de s'engager dans un processus de capitalisation des informations commerciales générées par leur réseau de distribution.

Un aparté est nécessaire pour comprendre le caractère "nouveau" de cette évolution. Une des contreparties entre un constructeur et un distributeur (qu'il soit succursale ou indépendant sous contrat) est le partage d'un certain nombre de données commerciales. Cependant, jusqu'ici, ces données ne permettaient pas d'analyser le comportement du client tout au long de la "consommation" de ce produit-service qu'est le véhicule automobile. Très riche sur les conditions environnant l'acte d'achat (données personnelles, financières, type de véhicule acheté...), elles s'appauvrirent dès lors que le client s'affranchissait du réseau de distribution dans le cadre de l'entretien de son véhicule. Même quand un client restait fidèle à un réseau, la qualité des informations sur la nature des travaux réalisés était très variable dès lors que ces prestations sortaient du cadre des contrats de service ou de garantie constructeur. Enfin, même si le réseau était incité à alimenter de façon proactive la base de données relatives au client si il était informé de changement dans ces données personnelles (naissance d'un enfant, déménagement...), le taux de remontée du distributeur vers le constructeur était faible et de qualité médiocre.

Avec la mise en place de la gestion des leads, l'enrichissement des bases de données ne se font pas sur l'aval (le service après-vente) mais sur l'amont (la recherche d'information (dont l'essai de véhicule constitue un moment de vérité (Normann, 1994) de l'acte d'achat. Pour autant, ce que cette étude exploratoire a permis de révéler est l'engagement des différentes parties prenantes dans l'alimentation de ce processus virtuel.

3.1 Un management des leads dépendant d'un leadership

Si le constructeur peut intervenir à l'aide d'un support de communication (intranet) pour la gestion du lead, il ne peut pas, pour l'instant, imposer un mode de gestion et de management du personnel dans le réseau.

Actuellement, il existe trois possibilités pour un distributeur de qualifier un lead : lead récompense, lead open bar et lead efficacité. Suivant le mode choisi, le lead a une fonction et/ou un statut spécifique au sein de l'organisation. Cette gestion aura des répercussions sur le management des équipes et des objectifs fixés individuellement ou collectivement.

Lead « en récompense » : un outil de gestion des ressources humaines : Dans ce mode de gestion, la qualification du lead est centralisée. Le responsable de la qualification assigne un lead à un acteur et un seul sans autre incitation. Les responsables de chaque service considèrent en effet qu'un lead, par principe, permet

d’aboutir à une vente plus facilement. L’attribuer à un collaborateur revient donc à augmenter son potentiel de vente et donc de primes. Ainsi, le responsable assignera le lead en fonction de différents critères qui sont indépendant du prospect tel que le niveau d’implication du commercial (dans le bon fonctionnement du show-room, par exemple).

Lead « Waiting pool » : un outil d’animation commerciale : Dans ce mode de gestion, l’ensemble des leads entrants sont regroupés dans un espace ouvert où le principe est « premier arrivé, premier servi ». Il n’existe aucun arbitrage entre les vendeurs sur leurs actions commerciales pour la mise à jour du site, la réactualisation des données avec les partenaires.

Lead « Customer/Product knowledge » : un pilotage global cherchant une réponse sur mesure. Les responsables de service souhaitent motiver et surtout modifier les pratiques de leur équipe pour augmenter l’efficacité globale. Pour ce faire, il tente d’arbitrer entre une gestion équitable entre tous les commerciaux permettant le temps de réponse le plus court et une allocation optimisée visant à attribuer le contact au « meilleur » vendeur en tenant compte de

- leur performance commerciale : plus le vendeur arrive à conclure une vente pour un produit donné, plus le responsable est enclin à lui assigner le lead
- leurs connaissances techniques du véhicule : plus un vendeur a des connaissances d’expert sur un véhicule et qui vont au-delà de celles d’un client expert, plus il réussira à conclure la vente

Table 3. Qualification du lead dépendante du management des équipes commerciales.

Lead \ Qualification	Qualification inexistante	Qualification en fonction des commerciaux	Qualification en fonction du lead
Lead « en récompense »		Implication des commerciaux dans leurs activités	Implication des commerciaux dans leurs activités
Lead « waiting pool »	Performance des commerciaux Accroître la compétitivité des collaborateurs		Disponibilité du commercial Ou Équipe commerciale réduite
Lead « customer/product knowledge »		Résultats des commerciaux Connaissance produit Priorité à la vente	Résultats des commerciaux Priorité à la vente Connaissance produit et/ou client

3.2 Des indicateurs de performance pour un management intrusif

Deux familles d’indicateurs de performance ont été mises en place pour optimiser la gestion des leads. La première se focalise sur la connaissance de ses prospects en devenant de plus en plus exigeant sur la qualité des données. La seconde évalue la performance d’une Supply Chain mise en place par le constructeur et le réseau (Baron et Fender, 2012) à celui du parcours client.

Maitriser les données de ses prospects...

Traditionnellement, c’était à l’initiative des commerciaux que les informations liées aux prospects étaient recueillies. Le lead a inversé la prise d’initiative. Les constructeurs ont mis en place tout un process pour avoir une maîtrise des données du prospect. Leur atout majeur a été de donner la main au prospect qui est maintenant à la source de l’initiative de la création de son « compte ». Puis, ils ont incité leur réseau à mettre à jour directement sur leur propre système d’information les informations recueillies sur les prospects/clients. Ces deux actions permettent de définir le **lead scoring** de chaque distributeur, chaque commercial. Ces leads scoring permettent aux constructeurs d’affiner et, surtout, de maîtriser les stratégies de chacun pour transformer un prospect en client dans le court ou long terme. Dans le cas où le prospect ne souhaite pas donner suite à sa première initiative ou les informations disponibles sont erronées ou insuffisantes, le lead peut être considéré comme « perdu » (**lead lost**). Dans le cas contraire, le lead va être classées dans un vivier de comptes de prospects pour des actions commerciales à venir (**lead nurturing**). Les technologies nécessaires pour qualifier correctement les contacts ayant de la valeur pour une relance commerciale, sur le produit recherché ou sur un produit connexe (cas de la revente d’informations) sont complexes à développer et nécessitent de lourds moyens financiers qui ne sont pas à la portée de beaucoup de distributeurs. Ainsi, les constructeurs en maîtrisant les données de ses prospects s’initient dans l’intégralité du processus de conquête des prospects.

... tout en augmentant la performance de la Supply Chain

Sachant que le lead est toujours initié par le prospect quel que soit l’heure et le lieu, il est essentiel pour le constructeur de bien « faire voir » au prospect que sa demande a bien été prise en considération. Ainsi, dès que le lead a été généré, un message électronique automatique, personnalisé ou pas est envoyé au prospect avant même que le lead ait été qualifié. Cette première action du constructeur est là pour « rassurer » le prospect. Cette réponse automatique permet de créer un lien relationnel entre l’entreprise et le prospect et, surtout, de pouvoir évaluer un temps de gestion du lead dans le parcours client (**lead time commercial**) et un temps de traitement du lead réellement consacré dans le processus de production par le constructeur (**lead time réel**). Ainsi, quand il existe une action de réponse automatique, les temps des lead time commercial et réel sont quasi-immédiats.

À partir du moment où le lead est transmis par le constructeur à son réseau, la durée lead time commercial devient supérieure au lead time réel. La gestion du lead dans le processus de production par le réseau nécessite une mobilisation des ressources du distributeur qui doit faire face à des contraintes telles que les plages horaires d’ouverture du distributeur, le nombre d’intermédiaires, les supports de communication choisis, les horaires de travail du personnel concerné et/ou leur disponibilité.

Table 4. Indicateurs de performance par rapport au prospect et la Supply Chain.

Process	Lead	Prospect/client	Constructeur	Réseau
Prise de rendez-vous	Génération de lead		Lead scoring par rapport au prospect	Lead scoring par rapport au prospect
Gestion de la demande	Confirmation	Indice de satisfaction prospect/client par rapport à l’usage du site	Lead time commercial Lead time réel	Lead time réel
	Qualification du lead		Mise à jour de la base de données	Mise à jour de la base de données
	Assignation et Allocation du lead		Lead scoring par rapport au(x) distributeur(s)	Lead scoring par rapport au(x) commercial(aux)
Confirmation du rendez-vous par le service commercial dédié	Suivi des leads	Si le prospect répond et accepte un rendez-vous		Lead scoring par rapport au prospect
		Si le prospect ne répond pas	Lead lost	Lead lost
		Si le prospect ne souhaite pas donner suite	Lead nurturing	Lead nurturing

3.3 Les comportements dysfonctionnels du prospect non contrôlé par le distributeur

Lors de la génération du lead, le prospect doit compléter un formulaire plus ou moins « riche » ou précis (intrusif) suivant les marques.

Il ressort différents comportements dysfonctionnels du prospect qui peuvent être mis en évidence tout au long du processus de la gestion du lead :

Lors de la génération du lead : Données enregistrées par le client

- le client donne ses coordonnées partiellement exactes
- le client complète partiellement le formulaire : lors de la qualification du lead l'absence du numéro de téléphone peut être un critère permettant d'évaluer un niveau d'intérêt
- le client se crée une nouvelle identité

Lors de la qualification du lead : Croisement des données avec le fichier interne au distributeur

- le client a également pris contact par le site d'un ou des distributeurs appartenant à une même marque
- le client a déjà demandé des renseignements directement à la concession, il est connu par un vendeur. Les informations le concernant sont déjà enregistrées dans la base de données

Lors du suivi du lead (après assignation et allocation du lead)

- le client ne donne pas suite aux appels ou messages du personnel en contact

Ces données brutes auraient un intérêt économique (par exemple, en priorisant certaines demandes) pour le distributeur. Elles devraient permettre de mieux qualifier le lead afin d'optimiser le parcours du client.

Ces données devront être croisées ensuite avec les indicateurs de performance (lead scoring, lost et nurturing) afin de réduire les comportements dysfonctionnels ou en tout état de cause, d'en réduire les conséquences opérationnelles. La maîtrise de ces données faciliterait de ce fait la définition de nouvelles stratégies de gestion des parcours client.

Même si certains comportements peuvent être supprimés, notamment la mise à disposition de toutes les informations attendues dès la génération du lead, par un système d'information plus « verrouillé », il serait trop hâtif de retenir cette solution. La gestion des leads étant ressentie pour les distributeurs, il serait prématuré de définir des stratégies pertinentes dans la valorisation directe et indirecte.

Les constructeurs, en proposant à la fois un système d'information compatible avec les systèmes "maison" de leurs distributeurs et des outils de qualification (lead scoring) utiles ont gagné, auprès des réseaux de distribution, une légitimité nouvelle.

Les responsables des ventes, au sein des concessions, sont unanimes quant à l'intérêt commercial de bien gérer un lead « *Si au départ le lead était considéré comme une contrainte, il est devenu une véritable opportunité pour nos vendeurs.* » (Dirigeant d'un groupe monomarque). C'est bien parce qu'il est plus facile de conclure une vente dans le cadre d'un processus d'achat commencé en ligne et rapidement géré par l'ensemble des acteurs de la chaîne que le réseau de distributeurs a intérêt à s'engager dans ce processus, par ailleurs couteux en temps et en ressources.

On pourrait en conclure un peu rapidement que l'intérêt du constructeur est de renforcer la capacité de son réseau de distribution à transformer des demandes d'information en ventes de véhicules neufs, favorisant ainsi l'écoulement de ses produits. La bataille de la gestion des leads semblent cependant plus complexes et importantes encore. L'élaboration d'outils permettant le lead scoring, pour être commercialement performant, suppose à la fois des compétences (data mining...) et des données qui ne sont pas à la portée de la majorité des réseaux de distribution. Cet investissement ne peut être fait uniquement par le constructeur. Comment expliquer que ce dernier se lance dans un processus si couteux et incertain ?

Les bénéfices escomptés sont-ils uniquement captables par le réseau de distribution ?

Cette conclusion serait méconnaître la réalité économique de ces nouveaux processus d'achat. Comme nous l'avons plus haut, avec le principe du lead nurturing, un lead a de la valeur même quand il ne se traduit pas par un acte d'achat.

Dès lors, c'est bien cette capacité à transformer l'information recueillies tout au long du processus de renseignement par le client en de la valeur, à destination du réseau de distribution (court terme), de la marque (moyen terme) voir d'acteurs tiers (court et moyen terme) qui est en jeu.

Conclusion

Nous avons mis en évidence les transformations profondes des pratiques autour de l'avant vente. Nous avons mis en évidence que les nouvelles pratiques des prospects, encouragés par le développement de sites d'information et de nouvelles pratiques commerciales, avaient nécessité de mettre en place une organisation d'un véritable processus de production de service nouveaux, se traduisant à la fois par une diversité de canaux de communication pour attirer le client (dans une optique de cross-canal) mais également par de nouvelles pratiques de collectes et de capitalisation de données commerciales.

Au-delà des transformations sur le processus de production et la répartition du travail au sein des équipes de commerciaux dans le réseau de distribution, nous avons cherché à mettre en évidence les enjeux stratégiques de ces nouvelles pratiques commerciales. Alors que, en commençant cette étude, nous pensions mettre en évidence le poids grandissant des infomédiaires, c'est la nouvelle légitimité des constructeurs que nous avons mis en évidence.

Or d'autres indices (développement de showroom développés et gérés directement par les constructeurs), montrent que les constructeurs sont en cours de réflexion pour développer un e-commerce indépendant de leur réseau de distribution. Il semble cependant que le réseau veuille réagir pour rester un acteur indispensable pour l'achat d'un véhicule.

Ces différents axes de réflexion ouvrent vers de nouvelles stratégies permettant de convertir un prospect en client. Pour l'instant, les constructeurs désirent être à la source de ces innovations. Par la maîtrise de leur base de données, des

processus organisationnels, n'y a-t-il pas une volonté de maîtriser leur réseau ? Par cette action, les constructeurs s'orientent vers une maîtrise de leur réseau en vue d'une uniformisation de l'offre vis-à-vis du réseau tout en recherchant à segmenter l'offre pour le client en créant des parcours client dédiés....

Malgré tout, il ne faut pas oublier les distributeurs : quel vont être leur rôle ? Sachant qu'il y a de plus en plus de groupes multimarques, quelles vont être leurs positions vis-à-vis des constructeurs ?

Rien n'est encore « joué », les innovations technologiques vont avoir un rôle clé dans les stratégies à venir des constructeurs qui auront à composer entre l'évolution du comportement et des attentes des prospects, la place de plus en plus ambiguë de certains groupes multimarques détenant une base de données et des pratiques multimarques souhaitent imposer leur stratégie aux constructeurs.

Ces relations de pouvoir entre constructeur et distributeur, à priori indépendantes du parcours client, ont une réelle incidence sur l'avenir de chacun et l'attribution des rôles attribués. Les constructeurs doivent développer leur propre modèle économique qui peut aller jusqu'à la volonté de la maîtrise du parcours client pour la vente du véhicule neuf, dans un premier temps, en l'intégrant dans leur supply chain.

Does Lithuanian resorts' branding as the medical, health and wellness destination differ from other Baltic States?

Neringa Langviniene, Liudmila Bagdoniene

Kaunas University of Technology

The aim of the paper is to define whether Lithuanian NTOs, resorts' branding as the medical, health and wellness tourism destination differs from other Baltic States. The qualitative analysis of tourism websites of Lithuania, Latvia and Estonia, their resorts city Council websites was performed. The framework for content analysis of websites of tourism authorities, city Councils is provided in order to monitor the branding tool for medical, health and wellness tourism destination. Guidelines for Lithuanian medical, health and wellness branding for foreign tourists are developed.

Introduction

Traveling outside one's country for medical, health and wellness services is constantly growing in the world. This phenomenon can be explained by different reasons. The first of them is the free movement of goods and services under the auspices of the World Trade Organization and its General Agreement on Trade in Services. It has accelerated the liberalization of the trade in health services. The second one is the Directive 2011/24/EU of the European Parliament and of the Council of 9 March 2011 on the application of patients' rights in cross-border healthcare, commonly known as the Patients' Rights Directive (the PRD). As health care is predominantly a service industry, this has made health services more tradable, global commodities (Lunt et al., 2014). In the tourism industry medical, health and wellness tourism emerges as niche tourism with the growing competition among multiple destinations. These geographic locations possess the resources, attractions, infrastructure and facilities that attract people to visit these places for diverse reasons (Tasci, 2011). The medical treatment, rehabilitation and wellness are often included in the set of tourist intentions. Destinations offer many similar goods such as quality accommodations, beautiful scenic view, and friendly people (Qu et al., 2011). Despite the reasonable price for services, comparable or even better quality, shorter waiting for treatment procedures, and the quicker access to the care (Cormany, Balogdu, 2011); more and more destinations face with rising competition and need to differentiate. Therefore the destinations are forced to rethink their branding strategy.

Destination branding (DB) helps destinations to be known and observable. It is treated as one of the most important factors influencing the competitiveness of a destination. DB enhances a destination's positioning and stimulates tourists' choices and their satisfaction (Del Chiappa, Bregoli, 2012, p. 51). Brand blends functional, rationally assessed performance-based values with emotional values (De Chernatony, 2010, p. 30). Well-known brands influence customers' decisions to buy products, services as well as the destination.

Destination brand can be developed in a variety of ways, i.e. advertising through direct marketing, personal selling, and brochures. Since Internet plays a significant role in attracting visitors and facilitating their trip planning, the website of a destination has become a crucial branding channel (Baggio, 2003; Balakrishnan, 2009; Law et al., 2010; Cormany, Baloglu, 2011) and the most flexible tools for communicating the value for a customer (Fernández-Cavia et al., 2014). Due to the quick information dissemination on the websites many of emerging countries are successfully entering to the global tourism market (Pike et al., 2010; Tang-Taye, Standing, 2013).

The Baltic States – Lithuania, Latvia and Estonia – are in sense new players in world and the EU medical, health and wellness tourism market. Nonetheless they exert in communicating themselves as medical, health and wellness services providers (Smith, Puczkó, 2014). Lithuania has formulated the vision for medical tourism development as “the fastest health tourism growing country in the Baltic and Nord European Region“ (Lietuvos medicinos turizmo plėtros ir medicinos paslaugų eksporto skatinimo galimybių analizė ir rekomendacijos, 2012). This brings a lot of opportunities, as well as challenges for the Lithuanian medical, health and wellness services providers. Growing recognition and enhanced positioning of Lithuanian, Latvian and Estonian resorts as medical, health and wellness destination intensify the competition among these three countries. Therefore Lithuanian resorts as medical health and wellness destinations need to find and communicate their differences and attractiveness for customers using different tools of destination branding.

The aim of the paper is to identify whether Lithuanian medical, health and wellness NTOs, resorts' branding differs from Latvian and Estonian. This research pretends to be one of the first researchers' efforts to try to identify Lithuanian resorts' branding specifics comparing to neighbouring medical, health and wellness destinations, which possess actually the same traditions, resources and other conditions. Websites in the research are analysed as a tool for destination branding and communication with foreign medical, health and wellness tourists.

To achieve this aim, the paper is structured as follows. In Section 1 we discuss the concept of destination branding; Section 2 describes the destination brand positioning; Section 3 deals with the activities of destination marketing organisations (DMOs); Section 4 focuses on research methods and research design; in Section 5 the results of websites content analysis are presented. Finally, we outline some managerial implications for Lithuanian medical, health and

wellness destination branding improvement that should be augment for Lithuanian opportunities to attract EU citizens, note the limitations of our analysis, and suggest ways to enrich this line of the research.

1 Destination branding

Brand is multifaceted concept. Over the years the brand has been defined in many different ways, depending on paradigm from which the brand is perceived (Mitchel et al., 2011). One of the more established definitions of a brand was proposed by the American Marketing Association: brand is a name, term, design, symbol or any other feature that identified one seller's good or service as distinct from those of other sellers. A brand can be defined as a consistent group of characters, images, or emotions that consumers recall or experience when they think of a specific symbol, product, service, organization or location (Simeon, 2006, p. 464); as a cluster of functional and emotional values that promise a unique and welcome experience between a buyer and a seller (Lynch, Chernatony, 2004); as the total sensory experience a customer has with some company and its product or service (Hammond, 2008, p. 14). Obviously, these definitions stress the different key aspects of a brand. According to Brodie, De Chernatony (2009), there will never be a unifying definition of the brand because it is constantly evolving and depending on contexts or lenses through which the phenomenon is viewed. Notwithstanding the different approaches on brand definition there is an agreement that branding must attract and keep customers by promoting value, image, prestige, or lifestyle; it must communicate information, minimize risk or increase trust; help identify or recall key factors, differentiate from competition and facilitate recommendations (Balakrishnan, 2009).

In a destination management context branding is a key differential component of marketing strategy. Destinations are places that attract visitors for a temporary stay, and range from continents to countries, to states and provinces, to cities and villages, to purpose build resort areas. These geographic locations command the resources, attractions, infrastructure and facilities that attract people to visit these places for diverse reasons (Tasci, 2011). Today the customers are offered various destination choices that provide many similar goods such as quality accommodations, beautiful scenic view, and friendly people (Qu et al., 2011). Every country claims a unique culture, landscape and heritage, describes itself as having high standards of customer service, etc. As a result, these factors are no longer differentiators (Hudson, Ritchie, 2009). The destination needs to be unique and differential to be selected as a final decision. As Morgan, Pritchard (2004, p. 60) note, the choice of vacation destination has become a significant lifestyle indicator for modern customers and the places where they preferred to spend their holiday time and income have to be emotionally attractive. In other words, customers' interest is not restricted to purely functional benefits but to the consumption of a total experience (Leighton, 2007). Consequently, the battle for customers in the tourism industry will be fought not over price but over the experiences or "hearts and minds". Experiences involve the senses, the mind, emotions (affect), active/passive participation and social interaction (Gover, Go, 2009, p. 17). Uysal et al. (2011, p. 101) note the different phases of the traveller experience, ranging from pre-trip planning (anticipation stage), to on-site experience, to the post-trip experience (reflective stage). In respect of this viewpoint the destination branding becomes the crucial for places to be identified and differentiated from alternatives in the minds of target customers (Qu et al., 2011).

Destination branding is a way to communicate a destination's unique identity by differentiating a destination from its competitors and combining all things associated with the place (i.e. its products and services from various industries) that collaborate under one brand (Cai, 2002, p. 734). Thus the objective of destination branding is to select a consistent mix of brand elements to identify and distinguish a destination through positive image building. Gover, Go (2009, p. 17) notice that for destinations this is challenging as they attract a diversity of customers and the delivered products and services are often highly customized with the customer in control.

Destination brand is considered as a relational network developed by a destination among itself and certain target markets and stakeholders in order to affirm its own offer (Chiappa, Bregoli, 2012, p. 52). It conveys the promise of a memorable travel experience that is uniquely associated with the destination; serves to consolidate and reinforce the recollection of pleasurable memories of destination experience (Blain et al., 2005). Park, Petrick (2005) stress the key of destination branding to be developed as an emotional link with the tourist. Destination brand exists only if it is able to stake out a position in tourist's mind and not because it has recognized name, distinctive logo, tagline or symbol (Del Chiappa, Bregoli, 2012, p. 52). To realize its purpose destination branding integrates three components – brand identity, brand positioning and brand image. Brand identity reflects how place (it could be country, region, city, resort, etc.) developers want the brand to be. This supply-side approach is strategic, active and looks to the future. Brand image shows how the brand is perceived by tourists and reflects the demand-side standpoint; it is tactical, passive and looks on the past. Brand positioning is now recognized as a key construct in branding (Pike, Mason, 2011) and is the part of the value propositions communicated to a target group that demonstrates competitive advantage (Kavaratzis, Ashworth, 2005). As Pike, Mason (2011) state, the purpose of brand positioning within supply-side and demand-side framework is to enhance congruence through marketing communications between brand identity and brand image.

2 Destination brand positioning

Positioning is viewed as source of competitive advantage. It is important to distinguish between strategic (market) positioning and brand (operational) positioning. Strategic positioning refers to the competitive market standing of a firm

against its competitors; brand positioning focuses on the process of creating and altering perceptions of customers about an organisation's (in our case – destinations) products or brands. Strategic positioning forms the main direction for the development of the brand positioning (Fuchs, Diamantopoulos, 2010). Our research is concentrated on brand or operational positioning. Brand positioning refers to the functional or emotional benefits or 'images' associated with a brand or can indicate to where a brand is seen in a category of a relative to its competitors (Rosenbaum-Elliott et al., 2011, p. 112). The former viewpoint reminds us that all consumer choices are made on the basis of comparison. Hudson, Ritchie (2009) also assert that brand communications can be based around logical features (*mind or head*) or emotional benefits and associations (*heart*) although there is an increasing focus on the latter. These emotional attributes underlie the concept of brand promise, in which destinations must communicate to visitors (potential and/or current) the benefits and experiences that they can expect to receive upon arrival. This meaningful distinction inspires confidence in travellers' purchase decisions and represents the most critical component of the brand (Hudson, Ritchie, 2009). This understanding entails a brand owner/manager to make well-considered choice of which aspects of the brand identity must be emphasized. These chosen aspects have to be relevant to the target group and differentiate the brand from competing brand (Riezebo, van der Grinten, 2012, p. 17). The core of brand positioning is the destination's name, logo and value proposition (slogan) (Pike, Page, 2014). Through right decisions positioning creates a unique, credible, sustainable and valued place in consumers' minds for the brands (Sengupta, 2005, p. 17). Positioning results from an analytical process are based on the following four questions: (1) a brand for what benefit; (2) a brand for whom; (3) a reason, and (4) a brand against whom (Kapferer, 2008, p. 177). Effective positioning ensures that a brand attracts the attention of customers, and that the associations evoked by the communication are sufficiently relevant to get people to buy the brand product. The outcome of the positioning process will have to be that the desired set of associations surrounding the brand name is created in the mind of the receiver.

3 Destination marketing organisations as agent of destination brand positioning

Destination is a complex organizational structure or relational network where multiple and diverse agents (local institutions, hotels, restaurants, transportation, etc.) interact with the aim of providing an attractive tourism experience (Camprubi et al., 2014). These tourism agents, whether autonomously or in a coordinated way, decide on the promotional strategy of the destination. In the latter case there are the organisations named destination marketing organisations (DMOs) that are responsible for destination tourism development. According to Pike (2004, p.14), a destination marketing organisation is any organisation, at any level, which takes charge of marketing of an identifiable destination (i.e. National Tourism Organization (NTO), Regional Tourism Office (RTO), Local Tourism Association (LTA)). The purpose of DMOs is to enhance the competitiveness of their destinations. It needs to present an integrated destination product that encompasses all specific tourist attractions and services provided at that destination. Destination brand is communicated in three different ways: (1) architecture and real place offering, (2) formal communication through official media and (3) *word of mouth* (WOM) reinforced by the media and residents (Del Chiappa, Bregoli, 2012, p. 54). In communication stage DMO is the principal institution that is responsible for destination brand promotion. More and more DMOs are joined to the bandwagon of creating catchy slogans in the name of destination branding as well as other place marketing activities.

But in markets crowded with marketing communications from huge number of rival destinations offering similar benefits competitiveness has become increasingly challenging (Pike, Mason, 2011). In the positioning process DMOs can face with the trouble to create the laconic theme to cut through the noise of competing destinations offering similar products, services and attractions and be noticed by the right audience, for the right reasons, at decision time (Pike, 2012). DMOs are also hampered by various challenges in engaging stakeholders in the overall brand positioning process and appealing to tourists at the same time. They are pressured to harmonize local and regional interests while promoting their brand identities in acceptable way for public and private organizations; they have to confront the culture collision influenced by different values systems of public and private sectors. DMOs of small destination often have the limited budget and lack of human resources to develop differentiated branding strategies to compete with larger destinations (Park et al., 2009, p. 76).

Destination brand can be developed and presented to audience in a variety ways, i.e. advertising, direct marketing, personal selling; some destinations cooperate with journalists, film-makers, etc. (Morgan, Pritchard, 2004, p. 59). A tourism product is intangible therefore a destination is almost entirely depending upon representations and descriptions to help tourists make a purchase decision. Thereby, the availability of up-to-date, accurate, attractive, and accessible information is regarded as crucial for the success of a destination brand.

With the widespread diffusion of the Internet, destination marketing has changed from passive to active promotion, from one-way to interactive communication (Mistilis et al., 2014). The World Wide Web as a global channel offers interactivity and multi-media experience (text, images, sound, and video). With the increasingly popularity of the Internet, tourists will primarily base their decisions about which destinations to visit on the information available to them. Obviously, if using the Internet one DMO can better present its destination than another, so it may win attention of tourists who have some doubts about where to travel. A website is the most advanced medium to address such a need (Beldona, Cai, 2006). Websites enable anyone with an Internet connection access, irrespective of geography, time zone, or computer system to surf and gain information about the country, resort, services, prices, etc. Thus a destination's website has a strategic relevance in order to attract potential tourists. But website does not serve just as an informative

tool. As Beldona, Cai (2006) affirm, it can initiate key emotions, feelings that would eventually enable the purchase decision.

4 Research method and design

For destination DMO website has a significant contribution in its branding communication; it is the central point from which it directs online visitors to attractions and services providers (Beldona, Cai, 2006). Cronin (2003) notes websites evaluation promises strategic benefits as leadership with the competition and customer retention. As the above-mentioned the aim of this exploratory study is to identify whether Lithuanian as medical, health and wellness destination branding is different from other Baltic States – Latvia and Estonia. To achieve this aim we need to find the answers for the following questions: Do NTOs websites of these three countries differ in destination branding and what is a specific is of Lithuanian NTO website? What are differences in destination branding on websites of Lithuanian and Latvian, Estonian resorts’ City Councils? Are the Lithuanian destinations branding dimensions unique to the destination in order to distinguish them from others?

Few steps were followed in this research. First, based on meta-analysis methodology of the outcomes of various studies related of destinations as well as the niche tourism web sites’ evaluation (Florek et al., 2006; Fernández-Cavia et al., 2014; Balakrishnan, 2009; Pike et al.,2010; Hakala et al., 2013; Tang-Taye et al., 2013; Sirisuthikul, 2006; Cormany, Baloglu, 2011; Smith, Puczkó, 2014; Law et al., 2010), the dimensions/factors which will be used for inquired Lithuanian, Latvian and Estonian destinations web sites evaluation were extracted. The synthesis of these dimensions is presented on Figure 1.

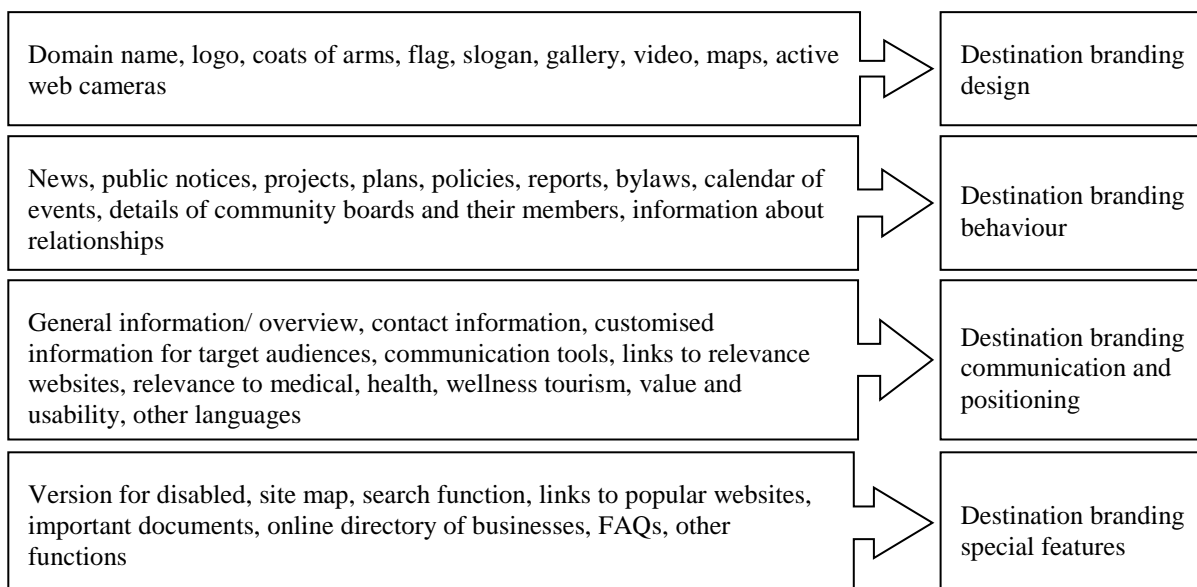

Figure 1. Dimensions of destination branding of three Baltic States and their resorts included in the research.

Secondly, the websites of NTO as gateway to a country/region were identified (Table 1). After that the Lithuanian, Latvian and Estonian resorts websites were chosen. For information retrieval by Google’s search engine keywords in English were only used. The NTO and resorts cities Councils perform the functions of destination marketing organizations and are responsible for brand positioning. Consequently their websites were analysed as more credible sources of information than commercial sites of tourism operators.

Table 1. Websites of the Baltic States included in the research.

Country	The World Wide Web
Lithuania	http://www.lithuania.travel/
Latvia	http://www.latvia.travel/
Estonia	http://www.visitestonia.com/

Despite the focus of this research on medical, health and wellness tourism all resorts in Lithuania, Latvia and Estonia were included in study. The list of three Baltic States resorts’ cities Councils’ and their websites addresses is given in Table 2.

Table 2. Websites of resorts' Cities Council's included in the research.

Lithuania	Latvia	Estonia
Druskininkai http://www.druskininkai.lt/	Jurmala http://www.jurmala.lv/	Haapsalu http://haapsalu.ee/
Birštonas http://www.birstonas.lt/	Saulkrasti http://www.saulkrasti.lv/	Narva-Joesuu http://www.narvajoesuu.ee/
Trakai http://www.trakai.lt/	Sigulda http://www.sigulda.lv/	Otepää http://www.otepaa.ee/
Ignalina http://www.ignalina.lt/	Salacgriva http://www.salacgriva.lv/	Parnu http://www.parnu.ee/
Zarasai http://www.zarasai.lt/		
Anykščiai http://www.anyksciai.lt/		
Neringa http://www.neringa.lt/		
Palanga http://www.palanga.lt/		

Websites are a dynamic means of communicating with audiences; its content could change during and after our research. Thus the outcomes of Lithuanian, Latvian and Estonian NTO and resorts websites reflect the situation on June–July 2014.

For analysing the websites of the Baltic States NTO and the resorts cities Councils the English version was used. Not all information in English was provided on resorts Cities Councils' websites, a few of them even have not had the English version at all, or just the short version.

The coding of the websites' text upon the destination branding dimensions was done by both authors of the paper, separately. Separate coding enabled to check the correspondence among the same information, text, dimensions, to ensure the validity of the research. Destination branding dimensions – design, behaviour, communication and positioning as well as special features – were firstly identified, the items of these dimensions (textual or visual, or both) were examined afterward. A few of items (i.e. bylaws, details of community boards and their members) are excluded from examined NTO websites as unnecessary.

The frequency of presence or absence dimension in the research of City Council websites is calculated upon all possible cases (in Lithuania – 8 resorts, Latvia and Estonia – 4 resorts). The ranking and frequency of brand design, behaviour, communication and special features was calculated among each country's resorts separately in order to indicate (if it is as any) the specifics of Lithuanian destination branding in medical, health, and wellness tourism destinations.

The results were presented in two parts. In first part the outcomes of content analysis of three Baltic States national official tourism websites are presented; in second part the results of comparison of Baltic States resorts' cities Councils websites are layered.

5 Findings of the research

5.1 Results of exploration of NTOs websites

The domain name directly influences the accessibility of website for information seekers. In case of finding a country as destination, name of a country is generally used. The other keywords such as *travel*, *tourism*, *visit*, etc. can be employed too. As well as the range identified by search engine results is very important.

Seeking the countries upon the keyword of the country's name Lithuanian NTO website is given in the 6th position while Latvian and Estonian – in the 4th (Table 3).

Table 3. The range of results in Google search engine upon the keyword of the country.

Country	Keywords used for Google’s search engine		
	Name of country	Travel + Name of country	Tourism + Name of country
Lithuania	6	2	3
Latvia	4	1	1
Estonia	4	1	1

The results of the search show that Lithuanian position in the results supplied by Google is in the worst position comparing to Latvian and Estonian, but still is in the first page of results in Google.

Domain name of NTO website of Lithuania is similar to Latvian, but differs from Estonian. Brand design of the countries differs by its content, logo, and keywords used (Table 4). The websites of Lithuanian and Latvian NTOs have elements of destination brand – logo, slogan. On Estonian NTO website the coat of arm is not provided. It should be noticed that Lithuanian slogan relates to the promoting a country as a destination that provides amber in its routes, resources, medical, health and wellness packages. The gallery of pictures that can help tourists to discover the destination is not provided in NTO websites. However, Estonian website provides links to “Images” in the bottom line, where a few of pictures explained in Estonian language could be found.

Table 4. The logos, coats of arms, and slogans used in the NTO websites.

Country	Logo	Coat of arm	Slogan
Lithuania			<i>Amber road</i>
Latvia			<i>Getting to know Latvia and Latvians</i>
Estonia		Not provided	<i>Estonia positively surprising</i>

There are many videos in Lithuanian and Estonian NTO websites, Latvian in many cases are “under construction”. The first video on the homepage of Lithuanian NTO website provides information about spa bad, swimming pools, major wellness and spa hotels in the country. A few video supplied information in Lithuania, as post-Soviet country tourism destination, as many tourists can visit the country because of nostalgia for the Soviet period; as destination which does not depend on seasonality. The content of the videos of three Baltic States is rather similar, representing medical, health and wellness tourism possibilities, and attractions such as theme parks (more in Latvia and Lithuania than in Estonia).

Maps provided on Lithuanian NTO website are both interactive and static. There is a separate selection in the menu of the website as “Routes”, where an information seeker can find such selection capabilities as: Route of three Baltic States capitals, Vilnius route, Kaunas and its premises, Klaipėda and sea resort route, Mineral water resort route, Lake Area route, Amber route, etc. Other items in the menu, such as “About the country”, “Attractions”, “Events”, “Links”, “Publications”, “Contacts”, and “Amber road” do not include any maps. The virtual map is provided in majority of items’ selection in the menu of Latvian NTO website: “About Latvia”, “Where to go and what to see”, “Destinations”, and “Travel and transport” (except the menu item “Accommodation”). The same opportunities to use active travel map on Estonian NTO website are provided. Each item (“About Estonia”, “Things to see and do”, “Destinations”, “Accommodation”, “Travel and transportation”) in the menu provides the virtual map, except the “Travel planner” what itself provides interactive travel planning tool.

NTO websites of Lithuania, Latvia and Estonia are not equipped by active web cameras. The results of examination of brand design on Lithuanian, Latvian and Estonian NTO websites are presented below (Table 5).

Table 5. Destination brand design elements in the NTO websites.

Brand design elements	Lithuania	Latvia	Estonia
Domain name	“Name of country” + “travel”	“Name of country” + “travel”	“Visit” + “Name of country”
Logo	+	+	+
Coats of arms	+	+	-
Flag	+	+	+
Slogan	+	+	+
Pictures’ gallery	Not identified as separate menu item	Not identified as separate menu item	Not identified as separate menu item
Video	Related to thematic of destination or route	Related to thematic of destination or attractions	Related to culture, traditions of country
Maps	Interactive and static maps as separate menu item, as well related to route	Interactive maps in any page of website, except one. Static for download is provided	Interactive maps in any page of website, except one, which is interactive travel planner
Web cameras	-	-	-

Items of destination branding behaviour dimensions contain the customised information, i.e. news, for target audiences differs in tourism national websites. Lithuanian NTO website provides a part of each page, not only homepage with news in Lithuania, as news from Tourism Association, Family Holiday Association, news from Lithuanian in the UK (separate news for Lithuanian-emigrants), makes access to networks, such as Facebook, Twitter as well as other social media, i.e. *Youtube.com*, Blogs. Also a separate item in the menu as “Publications” is provided. Latvian NTO website provides “Related news” on any page of the website, for example, “Destination”, “About Latvia”, etc. Estonian NTO website offers “Press” with news related to tourism.

Content of public notices, plans relate to news, as well as announcement about events in all three websites. Lithuanian, Latvian and Estonian NTO websites give the information about participating of these countries in tourism development projects founded by the European Union.

Reports in Lithuanian NTO website are containing rather differentiated information on tourism attractions, kinds of tourism such as “Travel round cultural cities”, “Active tourism”, “Taste it! Love it!” (Restaurants report)”, “Lithuanian meetings guide”, “Lithuanian report on year of EU presidency”, etc. Reports on Latvian NTO website also relate to differentiate information, target audiences: “Top tourism destinations”, “Day trips around Riga” (Capital of Latvia), “Health, wellbeing, harmony”, “European Culture capital Riga-2014”, “Recreation for families”, etc. Reports on Estonian NTO website grouped upon language, upon subject, upon the target of travel (“Cultural”, “Conference tourism”, “Nature holiday”, “Family holiday”, “Wellness holiday”).

The calendar of events on Lithuanian NTO website has its own button in the menu and is used as interactive tool, choosing any day and finding information about events, links to events (Tourism information centre, Maps, Websites, etc.), pictures’ gallery. This interactive tool gives a possibility to filter events according to type and locality. The same as news, information about events in Latvian website is provided related to the page in website, for example, in the page of “Destinations” an announcement of Sings festival. On Estonian NTO website there is difficult to find information about events, as it is in the fourth level of the page starting from homepage (Press, Press room, RSS).

Relationship is provided in the Lithuanian NTO website with geographically neighbouring countries, information about NATO, EU, etc. Latvian NTO website provides the information about membership in EU, Estonian – geographical neighbours and membership of EU. Summary of destination branding behaviour is done in table below (Table 6).

Table 6. Branding behaviour elements found on the NTO websites.

Branding behaviour elements	Lithuania	Latvia	Estonia
News	Special information block in each of site, plus special site “Publications”, news in social networks	Classified news in any site of website, as well as special News item in menu	News provided as special site in website
Public notes	Related to news item	Related to news item	Related to news item

Branding behaviour elements	Lithuania	Latvia	Estonia
Plans	Related to news item	Related to news item	Related to news item
Projects	Common with EU	Common with EU	Common with EU
Reports	Differentiated reports concerned different types of tourism and attractions	Differentiated reports, differentiated target audiences	Reports upon languages, subjects and types of tourism
Events calendar	Special menu item, interactive tool, related information provided. Special block of major events announcement in each page	Information about events is provided in each page, relating to the category of page. No separate menu item for events	Special information on events in 4th level of page, difficult to find. Information rather brief, no links attached
Relationship	EU, NATO, geographical neighbours	EU	EU, geographical neighbours

General information is provided by all three examined websites; still its layout and content differ. Lithuanian NTO website offers general information about the country, holidays, local time, transport, emergence phones, communication as well as the information about the largest cities. Users can “sign in” and get newsletter about tourism activities. Latvian NTO website consists of “Latvian in brief”, population and territory; actually this information does not differ a lot from Lithuanian and Estonian ones. Estonian NTO website gives more information about the country; the “dry facts” are complemented by information “What people are talking about Estonia”, “What is special about Estonia”. The content of this website demonstrates the country intentions to show Estonian oneness starting from the first page.

Contact information on Lithuanian NTO website is provided on the special page with the menu button “Contacts”. Contact data include the name of a related institution (i. e., tourism information centres, resorts’ tourism information centres, national parks, etc.), address line, opening hours, phone, fax number, e-mail, and hyperlink to the website. Contact of State Department of Tourism is provided. On Latvian NTO website there is no selection opportunity as *contacts*. However, contact information line is shaped in the bottom of each page where anybody can find direct link to Latvian tourism development agency and secondary links to the largest cities, regions (Kurzeme, Vidzeme, Zemgale, and Latgale Tourism Association). Contact line on the Estonian NTO website links directly to Estonian Tourist Board. Quick links contacts line is supplied on the bottom of the pages with links to the capital and two resorts of Estonia.

Customised information on the homepage of Lithuanian NTO website is targeted at specific information seekers: “Business”, “Active”, “Cultural”, “Health”, and “City breaks tourism”. Besides that, there are other selection opportunities for target audiences in the menu, as “Attractions” with interactive tool-filter for any interest (water entertainment, spa, religion, theatre, music, beauty services) or possibility to mark all of them. The Amber Route defines different target audiences, as tourists for the amber road, water entertainment, seashore, etc. They are less than on Lithuanian NTO website choices for tourists on the homepage of Latvian NTO website: adventure parks, fishing and cultural tourism. The second level page “Where to get and what to see” offers wide range of services and activities: “Spa and wellness”, “Medical”, “Business”, “Green tourism”, “Leisure”, etc. The information on “Top destinations” is also provided. Two possibilities on the Estonian NTO website are for customized information: “Things to see and do”; and “Destinations” choices on menu. There are many customized information starting from “Wellness and spa”, “Nature tourism”, “Active tourism”, “City break”. Actually it is the same as on Lithuanian NTO website, but in the homepage.

Communication through social networks, online forums is provided by Lithuanian NTO website, but there is not the online form for asking/suggesting any information. Latvian NTO website provides the interactive online asking form with asking the user to make web better, proposals, content, photo, etc. – sending message online. This interactive tool is provided from any page on the website and it is easy to find “Feedback”. The same online tool is used for communicating on Estonian NTO website.

Specific information and links to relevance websites is provided by Lithuanian NTO website on each page at the bottom line, as well as in the information about “Tours operators”, “Contacts”, etc. Latvian NTO website provides the link in the bottom line of each page, in the second level page of “Accommodation”, “Destinations”, “Travel and transport”. Estonian NTO website gives quick links on the home and the second level pages.

The items important for the medical, health and wellness tourists communicated on the examined websites differ. The homepage of Lithuanian NTO is linked to the health tourism, which provides information about water parks, sanatoriums, resorts, rehabilitation institutions. As mentioned above, the video is also related mainly to spa, sanatoriums in Lithuania. The second level page provides the selection among many attractions, where 4 out of 21 attractions could be defined as medical, health or wellness activities (“Beauty services”, “Nature”, “Spa, sanatoriums”, “Water entertainment”); 2 routes out of 9 also are related to medical, health and wellness tourism (“Mineral water resort route”,

“Klaipeda and sea resort route”). Differently than on Lithuanian NTO website only the second Latvian NTO website page “Where to go” directs to the medical, health and wellness activities: 2 out of 12 activities are directly related (“Spa and wellness”, “Medical tourism”). Also the “Accommodation” page provides customized information for spa tourists providing “Spa accommodation”. Links to spa holidays are provided already on the homepage of Estonian NTO. The second level page “Things to see” provides 1 out of 11 activities related to medical, health and wellness (“Wellness and spa”). The heading *Accommodation* provides 1 type of the accommodation “Spa hotels” out of 9 types possible. In summary, the destination branding communication and positioning elements in the Baltic States NTOs websites are provided by Table 7.

Table 7. Destination branding communication and positioning elements in the NTO websites.

Branding communication and positioning elements	Lithuania	Latvia	Estonia
General information/ overview	Common facts, more details on largest cities, newsletter for users	Common facts, more details on cultural-historical divisions	General facts, “life stories”, targeting, specializing the tourism destination
Contact information	Specific menu item with categorized contact details	Bottom information line with contacts to tourism authorities and tourism departments	Specific menu item only for contacts with tourism association. Bottom contact line to largest cities
Customised information for target audiences	Homepage with customized information, second level page with target upon interest. No destinations included	Narrow specialization of tourism located on the homepage, wide in second level page. Destinations excluded	Wide choice of target information in specific page. Destinations excluded
Communication tools	Facebook, online forums	Facebook, Twitter, online communicating forms/ tools	Facebook, online communicating forms/ tools
Links to relevance websites	Home page, second level page, separate page	Home page, second level page, separate page	Home page, second level page, separate page
Relevance to medical, health, wellness tourism	Homepage: customizing the health tourists. 2 nd level page: medical, health, wellness.	Homepage: no information customizing the health tourists. 2 nd level page: medical, health, wellness.	Homepage: customizing the wellness tourists. 2 nd level page: medical, health, wellness.

Information accessibility for tourists on foreign languages is one of the most important factors for destination branding communication and positioning. In this point of view Estonian NTOs website is the most attractive (Table 8).

Table 8. Foreign languages used for destination branding communication and positioning on the NTO websites.

Country	EN	RU	DE	PL	NO	IT	EE	FR	SE	FI	LT	ES	LV	CN	KR/KP	Total
Lithuania	+	+	+	+	+	+	+	+	+	+						10
Latvia	+	+								+	+					4
Estonia	+	+	+	+	+	+		+	+	+		+	+	+	+	13

Site map, search function, search engine, and filter for information as special destination branding features are used by all three countries NTOs websites. Lithuanian NTO website provides separate menu item as “Links” to popular websites (i.e. “Hotels”, “Events”, etc.).

Version for the disabled is provided by Lithuanian and Estonian NTOs websites. Interactive tool with current temperature and local time is offered by Lithuanian NTO website. Estonian NTO website for weather forecast provides links to *tripadvisor.com*. The Travel Planner Interactive Tool is provided on the separate page of Estonian tourism website. Programs for downloading for smart phones are provided by Latvian NTO website. Lithuanian NTO website has a special online forum organized for Lithuanian emigrants to the UK on Facebook, as majority of emigrants from Lithuania live in the UK now.

Lithuanian NTO website users can use the print function on the homepage. Also brochures in the “Publication” menu could be obtained in print version. Downloading and printing the information guides on Latvian NTO website is allowed. Estonian NTO website provides the possibility to print or save as pdf file each page.

5.2 Findings of resorts' websites exploration

The resorts Cities Councils' websites identified by Google's search engine and included in this study are presented in Table 9.

Table 9. The range of results in Google search engine upon the keyword of the resort city.

Lithuania		Latvia		Estonia	
Resort name	Range	Resort name	Range	Resort name	Range
Druskininkai	4	Jurmala	6	Haapsalu	6
Birštonas	3	Saulkrasti	4	Narva-Joesuu	2
Trakai	1	Sigulda	50	Otepää	2
Ignalina	1	Salacgriva	4	Pernu	15
Zarasai	1				
Anykščiai	1				
Neringa	1				
Palanga	1				

The larger and more famous resort city, the larger likelihood it appears in the further than the first position. Such websites as *booking.com*, *tripadvisor.com*, website of tour operators and hotels are found by Google's search engine in the higher positions. The authors of the research have made attempts in order to find resort name with the second keyword travel, as well as with *tourism*, for example, "Travel" + "Druskininkai". Unfortunately, they were not found in the first ten pages of the results in the Google's search engine. It means that the domain of a resort city (non-resort City Council website) is not found easily by website readers/users.

The domain names of Lithuanian, Latvian and Estonian resorts' cities Councils websites are constructed of the *name of the resort* and *abbreviation of the country* (accordingly "lt", "lv", "ee").

Brand design elements, used in the resorts Cities Councils websites, are presented in the tables below (Tables 10, 11, and 12). The resorts on their websites usually do not use logo and country flags. In many cases the logo is changed by the coat of arm. Lithuanian resorts do not provide flags on their official websites. The only resort in Latvia (Salacgriva) and two in Estonia (Otepää and Pernu) do that.

Table 10. Lithuanian, Latvian and Estonian resorts' logos.

Lithuania		Latvia		Estonia	
Druskininkai		Jurmala		Haapsalu	
Birštonas		Saulkrasti	-	Narva-Joesuu	-
Trakai	-	Sigulda		Otepää	-
Ignalina	-	Salacgriva		Pernu	
Zarasai	-				
Anykščiai	-				
Neringa					
Palanga	-				

Table 11. Lithuanian, Latvian and Estonian resorts' coats of arms.

Lithuania		Latvia		Estonia	
Resort name	Coat of arms	Resort name	Coat of arms	Resort name	Coat of arms
Druskininkai		Jurmala	-	Haapsalu	-
Birštonas		Saulkrasti		Narva-Joesuu	
Trakai		Sigulda		Otepää	
Ignalina		Salacgriva		Pernu	
Zarasai					
Anykščiai					
Neringa					
Palanga					

A few of slogans are translated to English if the websites of the resorts' Cities Councils provide the only version in their native language (Lithuanian, Latvian). The Estonian resorts' Cities Councils websites provided (whose do that) a slogan in Estonian and English.

Table 12. Lithuanian, Latvian and Estonian resorts' slogans.

Lithuania		Latvia		Estonia	
Resort name	Slogan	Resort name	Slogan	Resort name	Slogan
Druskininkai	Sveikatos šaltinių kurortas (Resort of health resources)	Jurmala	Pilsēta uz viļņa! (Town on the wave)	Haapsalu	-
Birštonas	Tavo istorijos harmonija (Harmony of your history)	Saulkrasti	-	Narva-Joesuu	-

Lithuania		Latvia		Estonia	
Resort name	Slogan	Resort name	Slogan	Resort name	Slogan
Trakai	-	Sigulda	Sigulda aizrauj! (Siguda fascinates)	Otepää	The Jewel of Estonian Landscape
Ignalina	-	Salacgriva	-	Pernu	Try it yourself
Zarasai	-				
Anykščiai	-				
Neringa	Legenda, kuri įkvepia (Legend which inspires)				
Palanga	-				

The analysis of Lithuanian resorts' Cities Councils websites shows that the maps of the city are the most popular (7 out of 8 resorts use it) brand design elements. The gallery of pictures are provided more seldom. One of the resorts in Lithuania has got its own TV. That is why a lot of videos are used as design elements on their website.

The summary of Lithuanian, Latvian and Estonian resorts' destination brand design elements is provided below (Table 13). Latvian resorts' Cities Councils websites use the galleries of pictures, video, mostly of them interactive maps. Palanga, the Lithuanian resort, and Jurmala, the Latvian resort, provide active camera from the beach. In case of destination branding as some additional (or supplementary) element are used the national flag, coat of arm, as well as maps. The maps are used by all Estonian resorts' websites. Video and active cameras are not popular, except Otepää resort that has the active video camera with transmission of views in a city.

Table 13. Ranking and frequency (%) of destination brand design elements used in the resorts websites.

Design element	Lithuania		Latvia		Estonia	
	Rank	%	Rank	%	Rank	%
Logo	5	37.5	2	75	3	50
Coats of arms	1	100	2	75	2	75
Flag	7	0	4	25	3	50
Slogan	5	37.5	3	50	3	50
Pictures' gallery	3	62.5	1	100	2	75
Video	4	50	1	100	4	25
Maps	2	87.5	2	75	1	100
Active cameras	6	25	4	25	4	25

Table 14 provides the information about destination branding behaviour elements used by resorts' Cities Councils websites. Lithuanian resorts' Cities Councils websites use majority of branding behaviour elements. 6 of 8 resorts (it is 75 percent of them) used reports and mentioned about relation with other cities Councils, national tourism association, etc. Latvian resorts' websites use rarely information about relation in what municipality is engaged (only two of them mentioned this fact). The events' calendar usually is interactive tool in Lithuanian, Latvian and Estonian resorts websites. That is important information's tool for potential domestic or foreign tourists and links to rather broad information on coming events.

Table 14. Ranking and frequency (%) of destination branding behaviour elements used on the resorts websites.

Branding behaviour element	Lithuania		Latvia		Estonia	
	Rank	%	Rank	%	Rank	%
News	1	100	1	100	1	100
Public notes	1	100	1	100	1	100
Plans	1	100	1	100	4	25
Projects	1	100	1	100	3	50
Reports	2	75	2	75	3	50

Branding behaviour element	Lithuania		Latvia		Estonia	
	Rank	%	Rank	%	Rank	%
Bylaws	1	100	2	75	2	75
Events calendar	1	100	1	100	1	100
Details of community board and their members	1	100	1	100	1	100
Relation	2	75	3	50	3	50

The branding communication and positioning elements in Lithuanian, Latvian, and Estonian resorts Cities Council’s websites actually do not differ (Table 15).

Table 15. Ranking and frequency (%) of destination branding communication and positioning elements used on the resorts websites

Branding communication and positioning elements	Lithuania		Latvia		Estonia	
	Rank	%	Rank	%	Rank	%
General information/ overview	1	100	1	100	1	100
Contact information	1	100	1	100	1	100
Customised information	1	100	1	100	1	100
Communication tools	1	100	1	100	2	75
Links to relevance websites	1	100	1	100	1	100
Relevance to medical, health, wellness tourism	2	75	1	100	1	100
Foreign languages	3	75	2	75	1	100

General information is provided on each of the analysed website. Only Lithuanian resort Neringa City Council website has the link with Facebook and other social networks. Two of four Estonian resorts’ Cities Councils’ websites provide such communication form. Customized information of resorts website relates to information for the citizen, tourists, businesses, etc. Two out of eight Lithuanian resorts (Anykščiai, Ignalina) Cities Councils’ websites do not focus on the items related to medical, health and wellness tourism.

Special features on resorts websites are also used (Table 16).

Table 16. Ranking and frequency (%) of destination branding special features used on the resorts websites.

Branding special features	Lithuania		Latvia		Estonia	
	Rank	%	Rank	%	Rank	%
Version for the disabled	1	100	2	75	5	0
Site map	2	87.5	2	75	3	50
Search function	1	100	1	100	2	75
Links to popular websites	2	87.5	1	100	2	75
Important documents	1	100	3	50	5	0
Online directory of businesses	5	12.5	4	0	4	25
FAQs	4	62.5	4	0	4	25
Print/download version	4	62.5	3	50	1	100

Some notes about using the languages could be noticed: two resorts (Druskininkai and Neringa) Cities Councils’ websites provide the information only on the Lithuanian language. These two resorts in Lithuania are visited by many foreigners whose opinion could be used as promotion in WOM for other potential visitors. Even if these resorts have active tourism information centres, this failing should be eliminated. Such languages as English and Russian are used on many of Lithuanian, Latvian, and Estonian resorts websites. The only website in Lithuania (Trakai) can provide four languages except native: English, Russian, German, and Polish. Jurmala, as internationally acknowledged resort, also uses the German language, except Latvia, English and Russian. Haapsalu in Estonia uses two more: Finish and Swedish.

Concluding remarks

Websites can have possibility to play an important role not only as *passive transmission* of information, such as general information about country, resort, destination, and unique branding identity, but *interactive communication* with users, citizens, tourists, individuals or businesses' representatives, community of a country or any foreigner who has never been in the country or resort till the moment. The customized information for the target audience allows getting feedback from potential tourists, who find or cannot find relevant information for their interest. Calendar of events, interactive tools in finding them according wishes and needs, maps, routes, virtual sightseeing – all these tools on the World Wide Web enable to shape the destination branding in entire destination marketing. Destination branding elements through the web could be changed very quickly into response of users, tourists, feedback, etc. Website can act as tool for communicating very different auditorium, shareholders, not only because of send message, but also because user, information seeker can act its role in contributing to the web.

Answering to the research questions the authors of this paper should stress that Lithuanian destination branding is similar to Latvian and Estonian. Still feedback from websites users should be improved, using active online forums, questionnaires, etc. More clear keywords on the website such as not only *health tourism* but also *medical, wellness, spa* could be used in order to attract medical, health and wellness foreign tourists. Lithuanian resorts' Cities Councils should include the pictures' galleries and video on the homepage of their websites, as well as active cameras could be used. Slogans should be used by every resort in order to underline the essence of the resort; they should be translated to English, German, Polish and other languages as they pretend to be internationally acknowledged. As communication in foreign languages is very urgent for destination branding, necessity to provide NTO, resorts' City Councils websites in other than Lithuanian – is crucial. Behaviour elements, as well as destination branding communication and positioning elements are similar to the Latvian and Estonian practice. However, the same direction for improvement as well as for national tourism website could be formulated: Lithuanian resorts' City Councils website should use more clearly identified keywords for medical, health and wellness tourism, their value for the tourists.

Lithuania as destination having eight resorts has more opportunities to attract medical, health and wellness tourists from neighbouring, the EU or even other foreign countries comparing to Latvia and Estonia. It is simply essential that resorts would be more specialized and, at the same time, would cooperate together. In addition, Lithuanian NTO and resorts' City Councils trying to specialize, for example, in medical tourism (as well as health, wellness tourism), should supply relevant information about potential treatment services and contacts on their websites. Respectively health and wellness resorts should follow this strategy in the destination branding. The websites should provide clear information that Lithuanian medical, health and wellness resorts, their tourism enterprises cooperate in order to provide the higher value for their tourists.

Risk-conscious value creation

Marinka Lanne, Markus Jähi, Mervi Murtonen

VTT Technical Research Centre of Finland

The concepts of value creation and risk management are commonly used by management researchers, business consultants and firms. However, the interrelationship of these concepts is rarely considered in academic research. This paper approaches value creation from the perspective of risk management. The main research question is “How the concepts of value creation and risk management interrelate?” In addition, advantages and disadvantages resulting in tying these concepts together are discussed. The results show that even though risk is acknowledged as an important variable in value creation, the current discussion does not proceed from risk identification further to risk analysis and management. The paper concludes that tying up the concepts could bring some benefits as well as new opportunities to consider risk-conscious value creation.

1 Introduction

Delivering superior value has been a key theme in marketing and management research for some time, as it is widely acknowledged to lead to higher customer satisfaction, greater level of customer loyalty, long-term industrial relationships and overall firm success (Ulaga; Chacour, 2001). It also appears that there is a need for a wide scope of research to refine the existing elements of value creation and add new ones in the near future and beyond (Lindgreen et al., 2012). Several scholars argue that although widely discussed in the current literature, value creation is still a complex and multifaceted concept in need of clarification (see, for example, Saarijärvi et al., 2013; Bowman; Ambrosini, 2010; Lepak et al., 2007). One such element that could be further refined and would benefit from clarification is risk and risk management in value creation.

Risk management has deep roots in late 1900s' product-based business logics. The need to identify, analyse and mitigate risks in different circumstances has evolved from avoiding accidental losses (e.g. McCahill, 1971). Another discipline has been financial risk management originated from Markowitz's (1952) portfolio theory. Risk management refers either to a formal or an informal process of planning, organizing, leading, and controlling the activities of an organisation in order to minimize the effects of risk (e.g. Zimolog; Elge, 2006). A risk can arise wherever a potential source of damage or loss (i.e. a hazard) to a target exists. Nowadays, the subject of risk plays a relevant role in design, development, operation and management of processes, systems and structures in all industrial areas (Avent; Zio, 2011).

Although the procedures for risk management are well established in various industrial sectors and research disciplines, they have reached service research and value creation studies only in limited manner. Some scholars have analysed the relationship between risk and value in business-to-consumer (b2c) context covering industries such as retailing (Sweeney et al., 1999), e-commerce and -services (Chen; Dubinsky, 2003; Kleijnen et al., 2007; Shamdasani et al., 2008), mobile phones (Snoj et al., 2004) and accommodation (Chang; Hsiao, 2008; Lei et al., 2008). These studies approach the customer value through the concept of perceived risk, and give empirical evidence to the likely assumption that risks are included in the value perceptions of the customers. Quite surprisingly only one reported study examining the relationship of risk and value in business-to-business (b2b) context could be identified. The study of Faroughian et al. (2012) explores the role of risks in value perceptions within the e-banking industry. In line with findings of the b2c domain, they confirmed the view that risk is a significant determinant of value also in b2b context.

In this paper, we go one step further and approach value creation from the perspective of risk management. That is, in addition to discussing how the risks in value creation could be identified, we also consider how risks could be managed in the context of value creation. Thus, the purpose of the paper is to identify and discuss the similarities and contradictions between the processes of value creation and risk management. The main research questions to consider is “How the concepts of value creation and risk management interrelate?” In addition, advantages and/or disadvantages resulting in tying these concepts together are discussed.

In this paper, we first describe our literature review methodology. Then, we take a closer look at how risks are considered in the current value literature. This is followed by an introduction to risk management. As a result of the literature analysis, the similarities as well as the differences of value creation and risk management approaches are illustrated. The paper concludes with a discussion on how a more risk-conscious approach to value creation could benefit both parties – the firm and the customer – and how the current risk management practices are applicable for this purpose. Finally, we draw conclusions and point out some research gaps and opportunities.

The interest towards integrated value creation and risk management has arisen from the authors' research background from different disciplines. We have been involved in several research projects concerning value creation in service business (e.g. Hämäläinen et al., 2014; Murtonen, 2013; Rajala et al., 2013; Jähi et al., 2013; Murtonen et al., 2012; Jähi, 2011) and in projects concerning risk management in various business sectors (e.g. Leppälä et al., 2012; Rääkkönen et al., 2012; Tukiainen et al., 2010; Lanne, 2008; Lanne; Sarsama, 2008; Ojanen et al., 2008, Lanne, 2007). We have also conducted and facilitated risk assessment and management development projects both with private and

public sector customers. Following the processes of risk management and value creation closely in these real-life cases has raised questions of their similarities and contradictions, and on the other hand, awoken our interest to look closer at the overlaps between these two approaches.

2 Methodology

The methodology of the paper is twofold: First, we seek to review the relevant literature on value creation and risk management. Thus, we attempt to produce a useful understanding of the key aspects of the two approaches and their relationship. Second, we conduct a comparison of the key aspects to identify similarities and differences between value creation and risk management.

A literature review is usually regarded as an essential step in understanding and structuring a research field (Easterby-Smith et al., 2002) as well as understanding the conceptual content of it (Meredith, 1993). As both value creation and risk management are wide-ranging approaches, it is not feasible to present complete reviews of them in this paper. Instead, we give a brief overview of some of the extant literature. To conduct our analysis, we selected publications (mainly journal articles) that were either commonly referenced in the more recent literature or they had high relevance from the viewpoint of the paper. Moreover, we use the literature review as a platform to comparison and discussion. Thus, we aim at identifying relevant key aspects of the literature instead of summarizing and giving a full account of the existing research.

To set limits to the review, individual perceptions of risk and value are excluded from this paper. Rather, the focus is more on value creation and risk management processes within organisations and inter-organisational relationships. With regard to value creation, this turns the focus to value creation in business-to-business setting. In relation to risk management, we put the emphasis on enterprise risk management.

3 Value creation and risks

At a fundamental level, creating value is the basis of all business and critical to all firms. Value creation refers to a process or activities that provide more novel and appropriate benefits than target users (internal or external customers of the organisation) currently possess, and that they are willing to pay for (Lepak et al., 2007). Each firm has several processes and activities (Bowman; Ambrosini, 2007; Wynstra et al., 2006; Grönroos; Voima, 2012), through which they create value in many different ways to shareholders, customers and other stakeholders (Khalifa, 2004). Nevertheless, customer value is regarded as the source of all other values (Grönroos, 2000 ref. Khalifa) and predominates in the current literature.

Drawing from the transaction cost theory, value is often considered as a ratio between expected or perceived benefits and sacrifices (Khalifa, 2004). In this view, the expected benefits comprise various positive consequences and desired outcomes of the targeted action, such as improvement of performance or experience, increased profit or higher customer satisfaction; while the sacrifices refer to all negative outcomes and costs that arise from the targeted action. These are, for example, loss of time and money, increased effort and psychosocial stress, reduced efficiency and other negative consequences. There are other voices in management research, however, who try to reach beyond the prevalent cost-benefit form of value adding more dimensions to it. They emphasise, for example, several dimensions of relationship value (Biggeman; Buttle, 2012), value as the user experience (Helkkula et al., 2012), or more context-specific and perception-focused approach (Sánchez-Fernández; Iniesta-Bonillo, 2007).

Several scholars argue that although widely discussed in current literature, value creation is still a complex and multifaceted concept in need of clarification (see, for example, Saarijärvi et al., 2013; Bowman; Ambrosini, 2010; Lepak et al., 2007). This can be seen, for example, in the most oft-cited sources that give several definitions to value (Zeithaml, 1988). In addition, there are some biases in the value studies. For example, customer value studies have been far more focused on benefits and usually pay much less attention to the sacrifice aspects, like time costs, risks and the destruction of value (Graf; Maas, 2008). General assumption in most value studies is that all activities that aim at creating value within a company or in interactions between companies end up at with expected results, and value is created as a result. In a value creation process, value can be both increased and decreased, however, and the net amount of created value can also be negative (Grönroos, 2004). In addition, value creation is not always symmetrical and balanced, and positive added value to one party may result in negative added value for the other (Rosqvist et al., 2010; Plé; Cáceres, 2010). To balance the currently dominant over-positive view, we will now turn our attention to the element of sacrifice and try to clarify some aspects related to risks attached to value creation from a firm's and a customer's perspective.

From a **firm's perspective**, risk refers to all possible negative outcomes that may result from the value creation activities. One of the risks is that after making significant investments in the value creation process, a firm is not able to capture enough value or not all the value created. This is referred as value slippage (Lepak et al., 2007). Value slippage may also occur if the target user or competitors gain enough knowledge to replicate the value creation process, thus becoming a competitor to a firm (Mustak et al., 2013). Such replication may follow from industrial espionage, key employee resignation, patent expiration or breakthrough technologies. Accordingly, all firm's activities that aim at developing innovative offerings and unique resources and know-how that are difficult to imitate mitigate the risk of value slippage.

Parallel to value creation activities, all firms also have value destroying activities (Bowman; Ambrosini, 2010). Value destruction refers to activities that do not add benefits and decrease sacrifices, but have negative effect on value creation activities instead. Value destruction can also occur in interorganisational relationships. In service science, value co-destruction refers to “an interactional process between service systems that results in a decline in at least one of the systems’ well-being” (Plé; Cáceres, 2010, p. 431). Value co-destruction results from the accidental or intentional failure to use the resources of the service systems in a manner that is expected or appropriate for the firm or for the other parties of the process (Plé; Cáceres, 2010).

Taking the **customer viewpoint**, risk in value creation has been defined as those uncertainties or possible negative consequences that the customer must accept before, during, or after the purchase of a product or a service (Graf; Maas, 2008; Huber et al., 2001). The two most often suggested value related risks being financial and performance risk (e.g. Agarwal; Teas, 2004; Faroughian et al., 2012; Lei, de Ruyter; Wetzels, 2008; Sweeney et al., 1999). When a product or a service is bought, there is always the chance that the purchase will not deliver the expected satisfaction over time, thus risk represents a potential sacrifice (Sweeney et al., 1999). Here, financial risk can be understood as referring to dissatisfaction caused by higher than expected financial burden, and performance risk to lower than expected performance. Additionally, other types of risks, such as social or psychological risks, have also being suggested having a role in value creation (e.g. Snoj et al., 2004).

Despite offering a consistent view that risk is an important variable in value creation, literature seems to give little advice on how to move forward after this initial identification of risk. That is, how to analyse, prioritise and mitigate the risks related to value creation once they are recognized. There are some studies that do offer industry-specific managerial implications how to avoid and mitigate negative experiences that would constitute a risk for the customer. For example, according to Kleijnen et al. (2007) managers should pay attention to alleviating the effort required for consumers to use mobile services by providing simpler service designs and more instructions to consumers. Respectively, providers of e-banking services are advised to emphasize how adherence to security protocols minimise performance and financial risks and help business customers to reduce costs such as the need for additional security software and special training of the staff (Faroughian et al., 2012). However, any generic and systematic efforts to manage risks and uncertainties in the value creation process seem to be lacking from the literature so far.

Next, to further explain the advantages of the risk management activities to the value creation potential, we will take a closer look at the procedures of risk management, which aim at identifying and managing uncertainties in the organisational context.

4 Risk management

All organisations face a wide range of uncertainties that may have an impact on their operations in various different ways. With the help of risk management, organisations are trying to identify, evaluate, control and monitor those uncertainties. In organisational context, risk represents simply “anything that can impact the fulfilment of corporate objectives” (Hopkin, 2012, p.14). This quote implies that risk is something uncertain that may have either positive or negative influence to the strategic objectives of a firm. However, this overall definition might not be suitable in every case, and also more precise definitions exist. For example, in the context of safety management, Aven et al. (2011) characterise risk based on three categories: (a) risk as a concept based on events, consequences and uncertainties; (b) risk as a modelled, quantitative concept; and (c) subjective risk descriptions. In the context of business management, the first category (a) is the most relevant, although the subjectivity of risk perceptions should also be noticed.

In common language, risk typically means the probability or threat of damage, loss, or other negative occurrence caused by vulnerabilities, and also something that can be avoided through preventative action. In the context of safety engineering risk is often considered as the combination of the probability of a hazard-related incident occurring (likelihood of a hazard being realized and initiating an incident) and the severity of harm or damage that could result (e.g. Manuele, 2005, p.36). In the context of managerial decision making, an often-cited definition of risk is “the variance of the probability distribution of outcomes” (March; Shapira, 1987, p. 1404). This view that the effect of risk can be both negative and positive, has become more popular during the last decade even in the international standards (cf. ISO 3100; 2009). This dualistic view of risks draws the attention away from the damage and loss and turns the focus on the objectives that the firm pursuits to achieve.

In the context of internal control and management, discussions on risks are strongly guided by several national and international standards. The international standard ISO 31000 (2009) provides principles, a framework and a process for managing risk. Another well-known and widely-used framework for enterprise risk management (ERM) is proposed by The Committee of Sponsoring Organizations of the Treadway Commission (COSO, 2004). In comparison to the long history of the risk management methodology, the ERM approach is quite new, originating only from the 1990s. ERM links risk management with business strategy and objective-setting, entering the domains of control, accountability and decision making. (Arena et al., 2010) ERM is clearly intertwined with corporate governance and internal control (Liebenberg; Hoyt, 2003; Drew et al., 2006).

ERM can be defined as a process of identifying and analysing risks from an integrated, companywide perspective (Chapman; 2003). The following definition has also been used for separating ERM from traditional risk management: “ERM is the management of operational and financial risks simultaneously in order to maximize the cost-effectiveness of risk management within the constraints of the organisation’s tolerance for risk” (Kleffner et al., 2003, p. 64). The

goal of ERM is to coordinate all risks of the firm, including risks related to corporate governance, auditing, supply chains, IT and human resources (McShane et al., 2011). Especially, the need of integrating ERM and supply chain risk management has recently been pointed out (Scannel et al., 2013).

In the international standards risk management is often described as a process consisting of several phases: event/hazard identification, risk estimation, risk evaluation and decision making (Fig. 1). In risk assessment the most relevant and plausible scenarios should be identified and described with details (e.g. van Dujne et al., 2008). According to the ISO 31000 (2009), risk assessment consists of three steps: 1) risk identification, 2) risk analysis and 3) risk evaluation. In risk identification, risks are defined and risk drivers and categories are identified. After that, in risk analysis, the risks are evaluated by determining potential business consequences and the occurrence likelihood. In risk evaluation, risks are categorised as acceptable and unacceptable risks requiring treatment. Finally, options for treating the unacceptable risks are identified. Typically, when competitive advantage is achievable in business, risk can be accepted, and when avoiding the risk is preferred way to proceed, the consequences and likelihood should be reduced or the risk removed. In addition to avoiding, accepting and reducing risks, sharing and transferring risks are also options for risk treatment selected by management. (ISO 31000, 2009)

ERM framework of COSO (2004) includes similar components as ISO 31000 (2009). However, the framework also highlights risk management philosophy, risk appetite, integrity and ethical values. For example, it has been pointed out that overall objectives of a company should be consistent with firm's risk appetite. It has also been reminded that developing a set of actions should be in line with firm's risk tolerances and risk appetite. (COSO, 2004) Risk appetite and tolerance are typical concepts especially in financial risk management. International standard ISO Guide 73 (2009) defines risk appetite as "amount and type of risk that an organization is prepared to seek, accept or tolerate". Tolerance is the acceptable level of variation around objectives (IIA, 2004) and it is understood as the organisation's or stakeholders' readiness to bear the risk after treatment in order to achieve its overall objectives (Znaniacka; Wieczorek-Kosmala, 2013). In addition, the ERM framework entails information sharing, communicating and monitoring the entirety of ERM in order to improve the process and share knowledge (COSO, 2004).

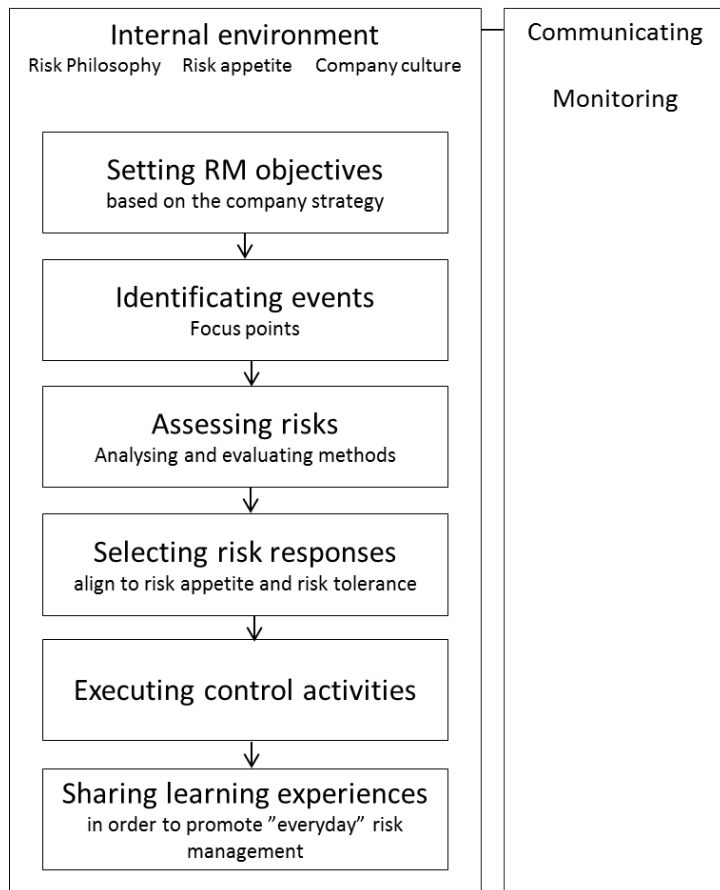

Figure 1. Risk management framework (adopted from ISO 31000, 2009; IRM; AIRMIC; ALARM, 2002; COSO, 2004; Lanne, 2007).

Even if some large international companies have adopted procedures for internal control, based on our experiences of company customers, in smaller companies risk management is often quite informal: company characteristics, organisation culture and customer's demands direct how they deal with the risks. We have seen many companies to flourish without any formal risk management procedures in use. Similar findings can be found in the literature. Some authors (e.g. Demidenko; McNutt, 2010) have also posed the critique towards formality and lack of practicality of

ERM. For example, Lalonde and Boiral (2012, p. 272) suggested that risk management should be seen more as a practice-based approach, “a strategy that managers *do* and not a strategy that managers *have*”. This is in line with the third definition of risk in Terje Aven’s abovementioned paper (2011): That is, risk is also a subjectively perceived phenomenon, the management of which depends not only on the formal procedures, but also individuals’ own interest and sensitivity.

Although the ERM concept is widely known, a lack of empirical research considering the effectiveness of ERM limits the maturity of the concept (Hoyt; Liebenberg, 2011). In the context of financial research Kraus and Lehner (2012) have systematically reviewed 25 articles regarding ERM and the value creation nexus. They found evidence of positive correlation between the implementation of an ERM program and value creation. However, more empirical research is still needed. In addition, there is still a lack of the research knowledge concerning effects of strong ERM culture to firm growth and its market value (McShane et al., 2011). Even less is known about the influence of ERM to value creation process and customer value and also vice versa.

5 Comparing value creation and risk management processes

The purpose of this paper is to identify and discuss the similarities and contradictions between the processes of value creation and risk management and to point out possible advantages and/or disadvantages that result from tying these approaches together. To identify and analyse the similarities and contradictions better, we have gathered the key features of both approaches in Table 1.

Table 1. Comparing the features of value-creation and risk management.

Features	Value creation	Risk management
Definition	A process that provides more novel and appropriate benefits than target users currently possess, and that they are willing to pay for (Lepak et al., 2007)	A process of identifying and analysing risk from companywide perspective (Chapman, 2003)
Aim	Competitive advantage, firm success, customer satisfaction and loyalty (e.g. Ulaga; Chacour, 2001)	Business continuity, preventing and avoiding losses, promoting increased risk awareness facilitating decision making, increasing shareholder wealth (Hoyt; Liebenberg, 2011)
Research disciplines	Marketing, management, service research	Engineering, management, psychology, insurance, accounting and finance
Theories	Transaction cost theory, resource-based theory, relational view to a firm	Financial theories, managerial theories, OHS management theories, risk compensation theory
Approach	Context-dependent, no formal procedures	Procedures based on standards and/or formal guidelines, process management, subjective perceptions (Aven, 2011)
Characteristics	Interactive, multifaceted, subjective, perceptual, experience (LaRocca; Snehota, 2014)	Managerial, formal/guided, integrated, preventative, perceptual, subjective
Elements	Benefits, sacrifices (Zeithaml, 1988)	Hazards, losses, possibilities, various impacts, uncertainty
Methods, tools	Value propositions, service development, service concepts, co-operation	Qualitative and quantitative risk assessment methods, checklists, (group) discussions, observation (van Duijne et al., 2008)
Participators	All levels of organisation, customers, suppliers and other stakeholders, shareholders	All levels of organisation, suppliers and other stakeholders, shareholders
Highlighting	Target user’s perspective, perception, co-operation	Early identification, prevention, internal control, decision-making
Critique	Ambiguity, too weak link to managerial practise (LaRocca; Snehota, 2014)	Focusing on negative effects, formality (Lalonde; Boiral, 2012)

At a fundamental level, there is a difference in the immediate aims of value creation and risk management. Whereas risk management aims at preventing and avoiding losses (Hoyt; Liebenberg; 2011), value creation is focused on firm's overall success through improving customer satisfaction and loyalty (Ulaga; Chacour, 2001). Though, in addition to preventing and avoiding losses, the ultimate goal of risk management is also in supporting firm's overall success through risk analysis, where all potentially harmful events are identified, prioritized and suitable risk mitigation actions are planned to prevent those harmful events from happening. Accordingly, the aim of ERM procedures is to coordinate management of all risks faced by a company. Especially systematic understanding of the interdependencies among risks is sought to support decision making. However, the ultimate goal has been seen more as allocating risks to play on a company's strengths rather than just reducing total risks. (McShane et al., 2011). This target comes closer to the aim of value creation – firm success and customer satisfaction.

Another difference between value creation and risk management stems from the traditions of different research disciplines. The roots of risk management are in a product-based industrial sector rather than in service business, although there is clear link to corporate finance. On the contrary, value creation has mainly been discussed and developed in the field of marketing and management sciences and service-oriented business. It is also our empirical notion that most sales managers prefer discussing value to risks with the customer, mainly due to its positive undertones that present the selling company in a more positive light than the negative risks do. Having its roots in accident prevention and insurance, risk management has mainly targeted firm's production processes and operations. Therefore, the customer perspective to risks and firm-customer co-operation in risk management seems to be overshadowed by the firm's internal perspective.

As an approach, risk management has a much higher level of formality than value creation. Risk management procedures are usually based on standards and/or formal guidelines (Aven, 2011), and specific methods like qualitative and quantitative assessments, checklists, (group) discussions and observation are applied (van Duijne et al., 2008). Formality in risk management has been seen as a necessity to ensure the comprehensive results of the analysis. In practice, this means that risk analyses typically yield a long list of issues that can go wrong. Not surprisingly, risk management has been sometimes criticised from being too negative as well as from too much formality (Lalonde; Boiral, 2012).

In contrast, value creation is regarded more as a perspective than a formal process. Specific methods or process phases are rarely mentioned in the context of value creation. Instead, more emphasis is put on developing and testing constructs and concepts like 'value proposition' or 'service concept'. As a result, conceptual ambiguities are claimed to be one reason why it has been difficult to turn the theories of value creation into managerial practice (La Rocca; Snehota, 2014). One way to do so would be to determine more carefully who creates what kind of value for whom, what kinds of resources and mechanisms are used, and from which perspective this process is approached (Saarijärvi et al., 2013). This shows some resemblance to risk management which emphasizes, for example, taking into account firm's internal environment, setting the objectives and the systematic identification of events.

Even though differences of value creation and risk management are salient and obvious, there exist some similarities as well. In addition to supporting the same ultimate goal – firm success – both approaches deal with intangible and context-dependent phenomena and emphasize subjectivity and the perceptions of customers or participants. Both risk and value have inherent uncertainties that require future-oriented approach. This is also why collective engagement and co-operation of various parties is essential to both approaches. On the other hand, both value and risk may relate to trade secrets, which hinder the open discussion between firms. Both approaches are also reminding decision makers to consider not only the direct cost advantages, but also consequences to processes, client-producer relationship, consumer behaviour etc. More recent developments in risk management, where risks are seen as both negative and positive impacts to the targeted activities, bring risk management one step closer to value creation ideology.

6 Conclusions

Risks have attracted the attention of some authors in value creation literature, but the visibility gained by the risks has – by no means – been extensive. Risks are considered as one of the least studied elements of perceived sacrifices by the marketing literature, and more focused research on risks has been requested. In this paper, we have tried to shed some light on the relationship of value creation and risk management through the review of selected literature and by comparing the key features of the approaches from firm's and customer's perspectives.

In this paper, we consider risks in value creation as all uncertainties related to the outcomes of the value creation process. These uncertainties can have either positive or negative impacts. The sources of risks are internal or external for a firm, and they may affect a firm and/or its customers, suppliers and its other stakeholders. Some risks are firm-specific, the others are shared, and the consequences may be similar or different to the different parties of the value creation process.

The concept of risk brings many rarely discussed issues of value creation together. That is, the component of sacrifice gets more attention. It is acknowledged that the value created can also be negative and that some value creation activities actually do not create value or even destroy it. Identifying these value creation related aspects, concerns or problems as risks, gives us a possibility to also consider risk management in the value context. As introduced in this paper, risk management is often described as a process consisting of several phases: identification of risk sources, risk assessment and decision making. In the value creation context, this would mean, first, identifications of internal and

external aspect affecting achievement of objectives – that is, value creation – and also distinguishing between risks and opportunities. Then, identified risks should be analysed by considering likelihood and impact of the identified risks to different parties. Finally, responses to risks should be selected and adequate risk mitigation measures should be taken into action. Here, avoiding, accepting, reducing, or sharing risks are identified as possible treatment of risks.

What are, then, the benefits that risk management would bring to value creation? At this point, we do not want to propose a formal risk management process for value creation as such. However, adopting some key features of risk management could already bring some benefits to value creating companies. These are the following:

- **Event identification.** A more risk-conscious approach to value creation would require becoming aware of the possible negative value outcomes and courses of events that lead to these. As more attention is usually paid to the positive outcomes of a product or a service, considering the possible negative aspects could serve as a means of raising ‘what if’ questions. For example, what if the production of a service is 30% more expensive than anticipated? What if the customer does not see the benefits of the updated product and is not willing to pay? From a firm’s perspective, this would mean a systematic stance towards identifying all the possible negative outcomes, value destroyers, slippage of value, sources of negative value, etc. From customer perspective, hazard identification should focus especially on possible performance and finance risks.
- **Risk assessment.** A good risk management process is not only about a large number of identified risks but also conscious risk comparisons and prioritisation. Categorizing likelihood of an incident that could initiate a negative outcome to the customer (and further to the firm), and also estimating severity of harm or damage, gives an option to increase firm’s sensitivity to customer’s (and their own) problems and also makes the decision-making on risks more visible and consistent.
- **Decision making.** In risk management, the systematic evaluation of risk lays the foundation for the selection of response measures targeted for avoiding, accepting, reducing, or sharing the identified risks. From the perspective of value creation these risk mitigation activities are trying to protect the process of value creation and the ultimate value created. However, ensuring that value is not destroyed via preventative actions should also be considered.

Through better risk management activities in a firm, risks falling upon customers could be prevented. By hindering service related incidents that could lead to negative outcomes, value is added to the customer. Turning this around, uncertainties in the business processes and environment may jeopardize firm’s ability to create value. Following Ravald and Grönroos (1996), who state that customer value can be increased not only by offering more benefits to customer but also by reducing customer-perceived sacrifices, we argue that more value can be added by reducing uncertainties involved in value creation, and that risk management offers appropriate tools for this purpose.

For a firm, implementing risk management practices could give an impulse to develop practical methods that support value management as well. Respectively, value creation emphasizes customers’ world and positive value adding consequences. These have traditionally attracted less attention in risk management and, thus, could widen the scope of risk management. Beside various obvious advantages, some disadvantages may also result in tying these concepts together. For example, higher level of formality, which is typical of risk management practices, may harm the creativity and agility of value considerations. Alongside changes in management practices, risk awareness may necessitate cultural learning. This, however, may cause a clash of views.

Instead of adopting high formality level and philosophy of internal control from risk management, we suggest to increase risk consciousness in value creation. The logic is to add value by decreasing uncertainty and become aware of risks that are generated to customers and further to firm’s own operations. Although we acknowledge the difficulties in open discussion and co-operation in risk management between firms, we encourage firms to take the risks of value creation to sales agenda. This would lead to a more risk-conscious value creation on both sides of the dyad. Moreover, identified and assessed risks should be treated with proper mitigation activities. Risk treatment actions aim at stopping the sequence of events that generates negative outcomes, or at least hinder the negative impacts to enter ‘customer’s side’.

We conclude that the interrelationship of value creation and risk management is interesting and offers new insights to both approaches, but more research work is still needed in order to understand abilities to amalgamate the benefits of value creation and risk management. At first, empirical research considering the effectiveness of risk management in service business is required. This includes, for example, consideration of risk management methods and practices used in service business as well as the impacts of risk management from the firm and customer perspectives. After that, the connection of value creation and risk management can be studied in more detail.

Ecologie industrielle et développement territorial durable le rôle des services

Blandine Laperche¹, Antje Burmeister², Céline Merlin Brogniart³, Fédoua Kasmi⁴

¹Clersé, ULCO; ²IFSTTAR; ³Clersé, Lille 1; ⁴ULCO

Potentiellement créatrice d'effets d'agglomération favorisant la génération et l'attractivité d'activités nouvelles, l'écologie industrielle peut être considérée comme un vecteur de développement territorial durable. Mais il est nécessaire de pallier aux difficultés (techniques, économiques, informationnelles...) liées à la mise en œuvre des symbioses industrielles. Nous étudions le rôle que peuvent jouer les activités de services, publiques et privées, dans la réduction de ces difficultés. Par leurs fonctions relatives à l'organisation des relations marchandes, à l'acquisition ou au maintien des capacités par les agents ou encore à l'aide à la décision, les services peuvent réduire les coûts de transaction engendrés par la mise en œuvre de symbioses industrielles et accompagner les décisions stratégiques des entreprises.

Industrial ecology may generate agglomeration effects favorable to business development and territorial attractiveness. As such, it may be considered as a tool for sustainable territorial development. But it is necessary to reduce the (technical, economic, informational...) difficulties ensuing from the implementation of industrial symbiosis. We study the role that service activities, whether public or private, play in the reduction of these difficulties. Through their functions linked to the organization of market relations, to the acquisition and the strengthening of agents' capabilities and to decision support, services can reduce transaction costs ensuing from the implementation of industrial symbiosis and be a support to strategic decisions of enterprises.

Mots clés : écologie industrielle, symbiose industrielle, activités de service

Introduction

L'écologie industrielle cherche à créer une analogie entre les écosystèmes naturels et les systèmes industriels afin d'aboutir au développement durable (Frosch, Gallopoulos, 1989). Elle s'appuie sur quatre leviers d'actions : la valorisation systématique des déchets comme ressources, la minimisation des pertes par dissipation (énergie, émissions polluantes...), la dématérialisation de l'économie (qui se traduit par le remplacement des produits par des services) et l'objectif de décarboner l'énergie (Erkman, 2004). Si les expériences d'écologie industrielle se sont multipliées de par le monde depuis la fin du 20^e siècle, les expériences « réussies » sont beaucoup moins nombreuses. De nombreuses difficultés apparaissent en effet dans la mise en œuvre de l'écologie industrielle, qu'elles soient de nature technique, économique, informationnelle, organisationnelle, infrastructurelle ou réglementaire (Erkman, 2004, Gibbs et al., 2005, Sakr et al., 2011, etc.).

Dans cette recherche, nous faisons l'hypothèse que l'écologie industrielle, potentiellement créatrice d'effets d'agglomération favorisant la génération et l'attractivité d'activités nouvelles, peut être un vecteur d'un développement territorial durable (Laperche et al., 2014). Un territoire entrepreneurial durable peut être défini comme une zone géographique caractérisée par des relations synergiques entre les acteurs, dont le développement repose sur un cadre institutionnel propice à la création d'éco-entreprises et à la transformation des activités existantes dans une perspective de développement durable (voir Boutillier, Uzunidis, 2014). Nous nous situons donc dans les préoccupations de « l'écologie industrielle et territoriale » (Buclet, 2011), qui cependant n'explique pas précisément les mécanismes économiques par lesquels le développement économique local peut émerger des expériences d'écologie industrielle. Selon nous, la première étape pour favoriser le développement territorial durable à partir de l'écologie industrielle consiste dans la réduction des difficultés liées à la mise en œuvre des symbioses industrielles.

Nous étudions dans cette recherche le rôle que peuvent jouer les activités de services, publiques et privées, dans la réduction de ces difficultés. Au-delà des prestataires de service traditionnels liés à l'écologie industrielle (ex : services liés au traitement des déchets, services proches de l'industrie), certaines activités de services non encore totalement exploitées par les entreprises industrielles peuvent pourtant s'avérer être des atouts dans le cadre d'une stratégie d'écologie industrielle. Ainsi, par leurs fonctions relatives à l'organisation des relations marchandes (fluidification, coordination amont et aval), les activités de service peuvent en effet réduire les coûts de transaction engendrés par la mise en œuvre de symbioses industrielles. Par les fonctions relatives à l'acquisition ou au maintien des capacités par les agents (en particulier en matière de formation, d'éducation), les services peuvent aussi fournir les ressources humaines nécessaires au bon développement de ces stratégies. Les services cognitifs d'aide à la décision et de recherche, en ingénierie industrielle mais aussi en sciences sociales, pourraient également accompagner les décisions stratégiques de ces entreprises, et notamment réduire ou prévenir les problèmes organisationnels et humains liés à la mise en place de l'écologie industrielle.

Ce document se compose de trois parties : la première partie revient sur la définition de l'écologie industrielle et son rôle dans la construction de milieux innovateurs. La seconde partie traite des difficultés liées à la mise en œuvre des symbioses industrielles et la troisième partie étudie le rôle des activités de service dans la réduction de ces difficultés.

1 Ecologie industrielle, circuits courts industriels et milieux innovateurs

1.1 Ecologie industrielle, métabolisme et symbiose industriels

Si la réflexion sur les manières de réduire l'impact environnemental des activités industrielles est ancienne et s'est particulièrement développée dans le courant des années 1970 dans le cadre de l'UNEP (United Nations Environment Program), c'est dans les années 1990 que l'expression se popularise notamment avec la publication de l'article de Robert Frosch et Nicholas Gallopoulos (1989), tous les deux ingénieurs chez General Motors. Les auteurs définissent l'écologie industrielle comme « *l'ensemble des pratiques destinées à réduire la pollution industrielle, elle vise à réorganiser le système industriel de façon à ce qu'il soit compatible avec la biosphère et viable à long terme* ». La pollution, l'accumulation des déchets et l'épuisement des ressources naturelles sont des éléments qui ont conduit Frosch et Gallopoulos (1989) à remettre en cause le modèle de développement des économies industrielles et à formuler la notion d'écosystème industriel (Diemer, 2007) : « *Ainsi dans un système industriel traditionnel, chaque opération de transformation, indépendamment des autres, consomme des matières premières, fournit des produits que l'on vend et des déchets que l'on stocke. On doit remplacer cette méthode simpliste par un modèle plus intégré : un écosystème industriel* », (Frosch et Gallopoulos, 1989, p. 106). Ils développent l'idée selon laquelle il devient nécessaire de recycler et d'échanger les biens utilisés, afin de réduire l'épuisement des ressources naturelles et de rechercher des matières premières de remplacement.

Cet article a suscité un intérêt très important dans la communauté scientifique, notamment par sa publication dans un contexte de prise de conscience croissante de l'importance de l'impact des activités humaines sur l'environnement et de la nécessité de mettre en œuvre un mode de « développement durable », tel que défini en particulier de la rapport Brundtland en 1987 (voir Laperche et al., 2009).

Pour Suren Erkman (1998, 2001, 2004), l'écologie industrielle, qui peut être perçue a priori comme un oxymore, repose sur l'idée selon laquelle le système industriel peut être décrit, tout comme un écosystème naturel, par une circulation particulière de matières, d'énergie et d'informations. De plus, le système industriel dans son ensemble repose sur des ressources et services fournis par la biosphère. Pour l'auteur, l'écologie industrielle offre des solutions concrètes en faveur du développement durable et s'éloigne en particulier des solutions en bout de chaîne (end of pipe) habituellement proposées pour faire face aux problèmes environnementaux.

D'un point de vue pratique, l'écologie industrielle repose sur 4 piliers (parfois aussi déclinés en 7 propositions) rappelés de l'encadré 1.

Encadré 1 : les 4 piliers de l'écologie industrielle (selon Erkman, 2001)

- **La valorisation systématique des déchets et des sous-produits**, qui doivent être vus comme des ressources potentielles et des gisements de matières premières à exploiter
- **Les pertes par dissipation doivent être minimisées**, (énergie, émissions polluantes ...), en effet, les dissipations peuvent être inhérentes aux produits mais aussi aux processus de production ou d'utilisation,
- **L'économie doit être dématérialisée** par la minimisation des flux totaux de matière tout en assurant des services au moins équivalents (économie de la fonctionnalité,...etc.),
- **L'énergie doit être décarbonée**. Depuis un siècle et demi, elle est principalement obtenue à partir d'hydrocarbures d'origine fossile (charbon, pétrole, gaz), responsables de nombreux problèmes tels que l'augmentation de l'effet de serre, les marées noires, etc.

Sa mise en œuvre repose sur la notion de **métabolisme industriel** qui correspond à l'ensemble des flux d'énergie et de matière qui circulent dans le système industriel. Il s'agit d'une approche descriptive qui recense et mesure les différents types de flux. Mais l'écologie industrielle va au-delà de l'analyse du métabolisme industriel et intègre la compréhension de la manière dont le système fonctionne, la manière selon laquelle il est régulé et ses interactions avec la biosphère. Pour Erkman, elle repose sur trois éléments clés : une vision systémique et intégrée de tous les composants du système

industriel et de ses relations avec la biosphère ; l'accent mis sur le substrat biophysique des activités humaines ; le rôle central de la technologie comme un des éléments cruciaux de la transition du système industriel actuel non durable en un écosystème viable à plus long terme. Cette vision systémique et globale du système industriel confère selon l'auteur un rôle clé en matière de développement économique, en particulier au niveau régional.

Pour autant, tous les auteurs ne partagent pas cette confiance dans la technologie comme vecteur de transition du système industriel et il existe en réalité deux visions opposées dans l'analyse et la mise en œuvre de l'écologie industrielle (Buclet, 2011).

- Pour les uns, comme pour Erkman évoqué ci-dessus, la mise en œuvre de l'écologie industrielle dépend du progrès technique (Allenby, Richards, 1994 ; Erkman, 1998). En terme de développement durable, cette approche empreinte de déterminisme technologique relève d'une soutenabilité/ durabilité faible¹⁷².
- Pour d'autres auteurs, la mise en œuvre de l'écologie industrielle nécessite un changement radical et une interface nouvelle entre les sociétés humaines et les écosystèmes naturels (Erhenfeld, 2004). Cette approche, critique de la société consumériste, s'inscrit alors d'avantage dans une approche relevant de la soutenabilité/ durabilité forte¹⁷³.

Entre les deux, de nombreuses approches mettent en particulier l'accent sur l'importance du facteur humain (rôle de la confiance et des réseaux) dans la mise en œuvre de l'écologie industrielle, qui dans la réalité est inhérent à tout processus de diffusion des innovations (qu'elles soient techniques ou organisationnelles).

La notion de **sybiose industrielle** (Chertow, 2000) met l'accent l'échange de flux de résidus issus d'un processus de production pouvant être de la matière, de l'eau ou de l'énergie à destination d'un autre procédé de production, de façon à ce que les déchets ou sous-produits des uns deviennent des ressources pour d'autres. La mise en œuvre d'une sybiose industrielle repose sur la mise en place de synergies entre les acteurs. On distingue deux formes de synergies : les synergies de substitution et les synergies de mutualisation (encadré 2).

Encadré 2 : Synergies de substitution/ synergie de mutualisation

Synergie de substitution

« Une synergie de substitution consiste à substituer un flux entrant neuf par un flux sortant d'une autre entreprise qui est mal ou pas du tout valorisé. Par exemple :

- remplacer un flux de matières premières « neuves » consommés par un procédé par un flux de déchets ou de co-produits,
- un flux d'eau propre par un flux d'effluents liquides ou d'eau industrielle,
- un flux de combustible fossile par un flux de combustible alternatif (issu de déchets) ou par de l'énergie rejeté par une autre entreprise (vapeur excédentaire...).

Ce type de synergies peut permettre de **faire diminuer les coûts d'approvisionnement ou les coûts de traitement pour un flux sortant.**

Sur le plan environnemental, il peut permettre d'économiser des ressources non renouvelables et d'éviter les émissions de polluants et de déchet liés à la production des matières premières neuves qui ont été substituées »

Synergies de mutualisation

« Lorsque plusieurs entreprises consomment ou rejettent le même type de flux il existe une possibilité de mutualiser la fourniture ou le traitement de ces flux en réalisant des économies financières et environnementales.

Lorsque plusieurs entreprises voisines utilisent le **même type de vecteur énergétique** (vapeur, air comprimé), il peut s'avérer intéressant d'en mutualiser la production. Une optimisation de cette production, une limitation des matériels à acheter et à maintenir permettrait de **rationaliser les coûts d'approvisionnement mais également, sur le plan environnemental, de diminuer la consommation énergétique des différentes entités »**

Source : UVED (Université Virtuelle environnement et développement durable, <http://www.uved.fr/>)

L'écologie industrielle a très vite été conçue comme un outil de développement local et régional (Gibbs et al., 2005). En effet, outre ses impacts positifs sur l'environnement, ses potentiels effets positifs sur l'économie et la société ont été mis en évidence. Dunn et Steinemann (1998) listent ainsi un ensemble d'effets positifs

- les déchets produits par une industrie produisent des inputs pour une autre, réduisant ainsi le coût de ces inputs
- la réduction des déchets signifie des coûts de l'élimination des déchets plus faibles
- les déchets ont dorénavant une valeur économique, accroissant les profits
- création d'une base économique plus variée

¹⁷² Dans le cadre de la **soutenabilité dite faible**, l'épuisement d'une ressource naturelle n'est pas une difficulté en soi car un autre capital, humain, matériel, technologique pourra s'y substituer.

¹⁷³ Dans le cadre de la **soutenabilité dite forte**, le capital naturel est reconnu comme apportant des fonctions extra-économiques et dans ce cas, la substituabilité n'est pas parfaite, et est donc en principe exclue, voir Vivien (2005).

- potentiel de création d'emplois par la création d'entreprises spécialisées dans des niches
- la réduction d'émissions signifie un moindre besoin de séparer les terrains industriels des terrains résidentiels ce qui conduit à la réduction des mouvements entre les deux

En définitive, l'écologie industrielle serait une stratégie « win - win - win » pour le développement durable, apportant des avantages financiers aux entreprises, mais ayant aussi des avantages sociaux plus globaux intégrant un impact environnemental moindre et une amélioration des conditions de travail.

L'écologie industrielle s'inscrit ainsi d'emblée dans une logique territoriale, et à ce titre on peut les rapprocher de la notion de circuit court, dont elle se présente comme l'une des formes.

1.2 Ecologie industrielle : une forme de circuit court

Les circuits courts sont définis de manière générique comme étant « les circuits directs d'échange ou de distribution de ressources contribuant à un développement territorial intégré » (Laudier et al., 2013, p.115).

Cette notion a d'abord été développée dans le cadre de l'agriculture et de l'alimentation (« circuits courts alimentaires ») pour exprimer la proximité entre le producteur et le consommateur. Si cette pratique est ancienne (elle était en particulier largement développée en France après la seconde guerre mondiale), elle s'est toutefois fortement développée depuis le début des années 2000 sous la forme d'AMAP. La notion de circuits courts repose sur une double proximité, de nature relationnelle (limitation du nombre d'intermédiaires) et spatiale (distance à parcourir entre le producteur et le consommateur).

Comme le soulignent Laudier et al. (2013, p.7), les circuits courts peuvent recouvrir des objets très variés, agriculture, recyclage, énergie, éco-industries, transports, innovation, circuits financiers... mais partagent le point commun d'un fonctionnement en boucle locale, dans le cadre d'une proximité territoriale.

A ce titre l'écologie industrielle peut être considérée comme une forme de circuit court, et partage ainsi un grand nombre de ses problématiques, que nous recensons en particulier à partir de Laudier et al., 2013.

- Elle repose en effet sur une approche d'interdépendance entre activités, destinée à valoriser les produits ou sous produits d'une activité dans le processus de production d'un autre.
- Elle repose également sur une vision systémique et intégrée du développement territorial, dans lequel le territoire, loin d'apparaître comme un espace géographique ou légal, est davantage considéré comme un système économique, caractérisé par les relations de proximité (organisationnelle, cognitive et spatiale) entre acteurs et qui vise à favoriser le développement économique et humain, tout en respectant l'environnement, donc un développement orienté vers le développement durable.
- Si la logique de l'écologie industrielle est territoriale (ce qui est affirmé en France par la dénomination « Ecologie industrielle et territoriale » qui met précisément l'accent sur cette dimension territoriale dans la mise en œuvre des pratiques de l'écologie industrielle (Buclet, 2011)), tout comme dans la logique des circuits courts, elle nécessite une articulation des échelles territoriales (locale, régionale, nationale, voir même internationale). La cohérence et le rôle moteur ne peuvent émerger que s'il existe une massification des flux qui nécessite souvent de dépasser l'échelle locale.
- Enfin, tout comme dans la problématique des circuits courts, l'écologie industrielle renvoie aux enjeux de gouvernance des territoires et en particulier des coopérations qui doivent se nouer entre acteurs privés et entre acteurs privés et institutions publiques locales. Au-delà des innovations technologiques, la mise en œuvre de l'écologie industrielle et surtout son utilisation dans un but de développement intégré des territoires repose en effet sur des innovations organisationnelles et sociales destinées à coordonner les coopérations existantes ou à en engendrer des nouvelles.

1.3 Ecologie industrielle et milieu innovateur

Le concept de milieu innovateur a été proposé par le groupe de recherche européen sur les milieux innovateurs (GREMI) en Suisse (Aydolot, 1986 ; Camagni, Maillat, 2006). L'hypothèse des chercheurs était que ce sont les milieux régionaux qui secrètent les différentes formes de l'innovation. Cette recherche a été à l'origine du développement de la science régionale¹⁷⁴. C'est une remise en cause des conceptions top-down, dans laquelle les progrès étaient censés venir de l'extérieur (de l'Etat notamment). Ils sont aujourd'hui considérés comme le « bloc cognitif » (ou encore le « cerveau ») dont dépend le fonctionnement des systèmes de production localisés (SPL), qui désignent un ensemble d'activités interdépendantes, techniquement et économiquement organisées et territorialement agglomérées (Torre, Tanguy, 2014).

L'économie locale peut alors être définie, lorsqu'elle est un milieu innovateur, comme un espace géographique formé en tant qu'ensemble de rapports systémiques entre entreprises et entre entreprises, Etats et collectivités (Uzunidis, 2007). Ces rapports systémiques caractérisent l'espace localisé par un certain type d'activités et de productions finales. Il est composé de trois niveaux :

¹⁷⁴ Avec aussi l'analyse des districts industriels qui remonte à A. Marshall (1919), et qui a été redécouverte par les économistes italiens de la troisième Italie (Brusco, 1982 ; Garofoli, 1992)/

- L'économie territoriale au sens géographique, historique et administratif
- Les institutions : entreprises de toutes tailles, Etat, collectivités territoriales en étroite relations (les relations peuvent être commerciales, financières, productives, informationnelles)
- L'action individuelle et relation personnelles et interpersonnelle

Ces trois niveaux sont en interaction.

En définitive, le milieu innovateur constitue « une agrégation des capacités d'actions et des facultés cognitives des différents acteurs » (Torre, Tanguy, 2014, p.311).

L'économie locale acquiert les caractéristiques d'un milieu innovateur grâce aux relations de proximité qu'elle propulse entre agents économiques. La notion de proximité est aujourd'hui une notion clé entre économie industrielle et en économie de l'innovation. D'abord, l'accent a été mis sur la proximité géographique (ou spatio-temporelle). Mais ce type de proximité n'est pas suffisant pour faire émerger une dynamique locale de création d'entreprises ou d'activités nouvelles et donc d'émergence d'un milieu innovateur. La coopération ne se décrète pas. Dans cette perspective, on peut séparer analytiquement (bien que les différents aspects soient indissociables dans la réalité) la proximité spatiale d'un côté et la proximité organisée de l'autre (Torre, 2009). Dans sa dimension organisationnelle, la proximité décrit des acteurs qui font partie d'une même organisation. Cette appartenance à une organisation (formelle ou non, firme, réseau,...), par l'intermédiaire des interactions, crée un apprentissage qui se renforce progressivement. On est proche parce que l'on travaille ensemble. Dans sa dimension institutionnelle (qui peut être intégrée dans la dimension organisationnelle), la proximité fait référence aux dispositifs institutionnels rendant les interactions possibles : des représentations partagées, règles, normes, cadres cognitifs ainsi que des institutions formelles qui stabilisent le contexte des interactions. On est proche parce qu'on partage un cadre institutionnel. Dans sa perspective cognitive, la proximité fait référence aux référentiels et aux acquis communs qui permettent aux acteurs de partager des connaissances et des savoir-faire, etc. (Martin, Boschma, 2010, voir aussi partie 1).

La localisation d'entreprises à proximité les unes des autres mais surtout le développement de formes de proximité plus complexes entre elles et également avec les institutions partenaires sont à l'origine d'effets d'agglomération. Cette notion déjà mise en évidence par A. Marshall et redécouvertes dans les analyses de la nouvelle économie géographique ; ces effets sont les suivants :

- la concentration géographique de l'activité permet de créer un marché du travail spécialisé et partagé
- un site géographique peut développer des inputs spécialisés (des actifs spécifiques) qui améliorent la productivité des entreprises (infrastructures communes : routes, communication ; accès à des matières premières spécifiques ou autres ressources spécifiques comme des compétences et des savoir-faire)
- la concentration géographique permet d'entraîner des retombées technologiques en termes de diffusion des connaissances. Alfred Marshall parlait à ce sujet d'« atmosphère industrielle ».

Nous considérons dans cette étude que l'écologie industrielle peut être un atout et un outil dans le renouvellement du tissu économique du territoire et la construction de milieux innovateurs. Les symbioses industrielles qui caractérisent l'organisation de l'écologie industrielle intègrent en effet les formes de proximité géographique, cognitives et organisationnelles fondatrices des milieux innovateurs. Notre approche va au-delà des analyses qui soulignent le rôle de l'écologie industrielle dans un projet de territoire (Beurain, 2008, Beurain, Brullot, 2011) et plus globalement des travaux de l'écologie industrielle et territoriale qui, rattachant l'écologie industrielle au territoire, semblent postuler un rôle actif de celle-ci dans son développement économique (Buclet, 2011).

Notre approche cherche au-delà à mettre en évidence les mécanismes par lesquels l'écologie industrielle peut être un outil dynamique de 1) stabilisation des activités économiques existantes, 2) d'attractivité de nouvelles entreprises et 3) de création d'une dynamique endogène de créativité et d'innovation. Elle vise aussi à en montrer les difficultés et à mettre en exergue les moyens de les résorber.

Cette approche dynamique s'appuie sur la mise en évidence des effets d'agglomération générés par les formes de proximité et qui peuvent avoir un effet positif sur la stabilisation des activités économiques, favoriser la création et la localisation d'autres entreprises. Les entreprises en place peuvent en effet bénéficier d'économies d'échelle externes, issues de la taille et des caractéristiques du milieu dans lequel elles sont insérées – économie de terme de coût du travail, infrastructures disponibles, matières premières, connaissances – qui justifient leur maintien ou leur installation sur place. En définitive c'est l'ensemble de l'attractivité structurelle du territoire qui peut être renforcée par la mise en œuvre de stratégies d'écologie industrielle (schéma ci-dessous). Une meilleure attractivité permettra la diversification économique par le biais de la création de nouvelles filières (comme des filières de traitement de déchets et de transformation de ceux-ci en matières premières utilisables par d'autres).

Schéma 1. L'écologie industrielle et la construction de milieux innovateurs.

Pourtant, ce schéma vertueux se heurte à de nombreuses difficultés dans sa mise en œuvre. Comme souligné plus haut, la coopération ne se décrète pas. La mise en œuvre de l'écologie industrielle nécessite des formes de coopérations multiples (et de formes de proximité multiples). Les stratégies d'écologie industrielle se heurtent ainsi à des difficultés / limites que nous recensons dans le point suivant et qu'il faudra résorber pour que l'écologie industrielle puisse jouer ce rôle dynamique dans le développement économique des territoires.

2 Identification des limites et difficultés dans les expériences d'écologie industrielle.

Dans la mise en œuvre de l'écologie industrielle et la création des synergies éco-industrielles, l'existence des synergies entre des entreprises ne veut pas dire pour autant qu'elles seront facilement réalisables. Des premières études portant sur le cas de Kalunborg (Danemark) aux multiples expériences de parcs éco-industriels qui ont fleuri de par le monde depuis quelques années (Gibbs et al., 2005, 2007), les principales limites et difficultés suivantes peuvent être mises en évidence (tableau 1) (Erkman, 2004, Gibbs et al., 2005, Geldron, 2012, Adoue, 2007, Duret, 2007, Sakr et al., 2011, Laperche et al., 2014, etc.).

Tableau 1. Limites et difficultés dans la mise en œuvre des symbioses industrielles.

Types de limites et difficultés	Explications
Techniques	Complexité des flux de déchets, dégradation de la matière, tri
Economiques	Rapport coût/bénéfice, échelle temporelle, limites quantitatives à la rentabilité
Informationnelles	Coordination/diffusion/confidentialité
Organisationnelles	Micro : l'organisation de l'entreprise n'est pas adaptée Méso : technologie indisponible, manque d'expérience
Réglementaires	Insuffisance des incitations / réglementation trop lourde
Infrastructurelles	Absence de services de transport, de stockage, de traitements adéquats
Humaines	Confiance insuffisante entre les acteurs

Source : auteurs

Les limites techniques de la synergie : l'entreprise doit faire face à la complexité des flux de produits à recycler, à la dégradation de la matière (Geldron, 2012), et à l'impureté des sous-produits utilisés dans le processus de recyclage.

Les caractéristiques physiques des flux valorisables peuvent rendre impossible l'établissement d'une synergie (Adoue, 2007), l'état physique et les dimensions des composantes de ces derniers sont parfois incompatibles avec le processus de fabrication du produit.

Le recyclage industriel dégrade les matières, les extraits de gisements perdent leur pureté dès les premiers stades de la fabrication, ils sont en effet mélangés et traités de divers additifs afin qu'ils aient les propriétés recherchées. Après le recyclage la matière se dégrade, (par exemple les caractéristiques mécaniques des fibres de cellulose diminuent à chaque cycle de recyclage), il ne suffit pas de récupérer les déchets mais il faut aussi conserver leurs propriétés durant le recyclage.

Le tri et la séparation des déchets sont également des défis techniques du recyclage (Erkman, 2004). Le tri des plastiques, des ferrailles mélangées, et de tous les types de déchets reste très coûteux, puisqu'il engendre des frais supplémentaires liés à la collecte et au transport. Cependant, il existe des matières qui n'ont pas été conçues pour être recyclées et qui sont pratiquement impossibles à valoriser, puisque la séparation de leurs composants pose plusieurs difficultés et représente des coûts importants pour l'entreprise

Limites économiques : la réalisation d'une synergie pour les entreprises dépend essentiellement de son intérêt économique puisque la décision de la mise en œuvre de celle-ci est basée sur le calcul des coûts, des prix et également la prise en compte des risques, la quantité des déchets est aussi considérée comme une limite économique, puisqu'elle engendre des coûts supplémentaires dans le cas où cette quantité est réduite.

La transformation des déchets en matière première nécessite des investissements importants puisqu'elle implique souvent l'achat de nouveaux équipements, l'exploitation et la maintenance de ces équipements. De ce fait, le besoin en ressources humaines qualifiées augmente et la formation de ces derniers est nécessaire afin de pouvoir maîtriser la mise en place d'une démarche d'écologie industrielle (Adoue, 2007). Les dirigeants des entreprises hésitent à investir dans l'écologie industrielle, étant donné le fait que la rentabilité de celle-ci se réalise sur le long terme, et ne répond donc pas forcément aux logiques et stratégies de rentabilité de court terme, s'ajoutant à cela le manque de fiabilité des démarches, ainsi que le manque d'expériences quant au cadre financier et juridique en matière d'écologie industrielle.

La rentabilité économique des pratiques d'écologie industrielle peut aussi se heurter à des limites quantitatives. Considérant le traitement des déchets comme une chaîne de production à part entière, la corrélation inversée des quantités traitées et des coûts reste la même que pour toute autre chaîne de production, dont la maîtrise en termes de coûts dépend essentiellement de la réalisation d'économies d'échelle. Autrement, les quantités de matières premières à traiter ne sont pas localisées chez un même « fournisseur », puisqu'il s'agit de déchets dont les quantités ne sont pas forcément importantes et qu'il faudra collecter jusqu'à atteindre un certain seuil de rentabilité qui permettra d'entamer le traitement.

Alors qu'il s'agit de plusieurs parties prenantes possédant des quantités différentes d'une même matière à traiter, il faudra sensibiliser ces acteurs-là quant à la nécessité de leur collaboration afin de parvenir à une gestion de cette chaîne de manière optimale à travers la massification des flux de matières.

Les limites informationnelles : les informations nécessaires à la mise en œuvre de l'écologie industrielle (notamment les éléments descriptifs du métabolisme industriel) ne sont pas toujours disponibles et nécessitent un travail de mise en commun, de traduction (mise en place d'un vocabulaire commun) de coordination et de diffusion. Elles sont aussi parfois rendues difficilement accessibles, et la culture du secret industriel peut freiner la circulation de l'information entre les entreprises. D'une part, la diffusion des informations sur les procédés (caractéristiques des matières utilisées, composants, quantité...) est parfois difficile pour les entreprises, d'autre part, les industriels n'arrivent pas à s'entendre et n'ont pas de confiance réciproque (Adoue, 2007) et préfèrent garder confidentielles les données des bilans des flux entrants/sortants qui sont nécessaires à l'établissement des relations éco-industrielles, ce qui rend l'établissement des synergies plus difficile entre ces dernières. L'indisponibilité des informations sur l'ampleur des impacts environnementaux de l'industrie peut être également un frein à l'écologie industrielle.

Les limites organisationnelles : l'indisponibilité des dispositifs productifs et des technologies adaptées aux traitements des déchets au sein des entreprises, ainsi que l'absence de culture du partenariat et du changement et la confidentialité des données affectent directement l'intérêt de mise en place des synergies.

Les limites réglementaires : la réglementation est un facteur essentiel pour le développement des synergies éco-industrielles. Elle a un impact sur l'intérêt des échanges de flux entre les industriels ainsi que sur la motivation de ces derniers. La réglementation et les outils fiscaux peuvent faciliter les opérations de valorisation, mais inversement l'insuffisance des incitations des autorités publiques, peut également négativement influencer sur la décision d'établir des synergies entre les entreprises.

Les limites infrastructurelles : les infrastructures nécessaires ne sont pas toujours disponibles notamment, les prestataires de service de transport et logistique, les services de traitements des déchets, les services des eaux, et les services de transformation des énergies et des flux de gaz.

La dimension humaine : le facteur humain joue un rôle primordial dans la réussite ou l'échec de cette stratégie environnementale, même si la réalisation des synergies s'avère économiquement possible, la résistance des dirigeants à la coopération avec d'autres entreprises, le manque d'implication dans une telle démarche, et même la réticence au partage des données sont des éléments qui font partie de la culture de la concurrence et du secret industriel et qui non seulement freinent la mise en place de l'écologie industrielle, mais qui aussi les empêchent de créer des synergies pouvant être rentables à moyen terme, et faire en sorte que les coûts résultant de cette première soient couverts.

Ces difficultés dans la mise en œuvre pratique de l'écologie industrielle font que très souvent les parcs industriels ne correspondent pas à une définition stricte de l'écologie industrielle comme un ensemble de flux de déchet devenant la matière première d'un ensemble de processus de production mais intègre une « palette éco-industrielle » plus large s'intégrant dans une stratégie de développement durable (Gibbs et al., 2005).

Pour que l'écologie industrielle puisse être utilisée comme un outil de construction d'une économie territoriale fonctionnant sur la forme d'un milieu innovateur, il est alors nécessaire de réduire les difficultés/ limites auxquelles se heurte sa mise en œuvre opérationnelle. Nous considérons que ce sont les activités de services (publiques et privées) qui peuvent avoir cette fonction, comme expliqué dans le point suivant.

3 Quelles réponses les activités de services peuvent-elles apporter ?

3.1 Définition des activités de service

Si les activités de services ont une place et un rôle croissant dans l'économie, l'analyse du rôle des services aux entreprises dans le développement local et leur prise en compte dans les politiques d'aménagement du territoire font rarement l'objet d'une attention spécifique. La prise en compte de leur rôle est souvent indirecte (Gallouj, Kaabachi, 2011 ; Gallouj et al., 2006).

Au sens traditionnel de l'INSEE, « une activité de service se caractérise essentiellement par la mise à disposition d'une capacité technique ou intellectuelle. A la différence d'une activité industrielle, elle ne peut être décrite par les seules caractéristiques d'un bien tangible acquis par le client. »¹⁷⁵.

Cette définition de l'institution statistique peut être complétée par des définitions plus analytiques, permettant d'isoler plus facilement certaines activités de service en fonction soit du destinataire du service, soit de la nature du prestataire de service et de son statut. Ainsi J. Gadrey (1996, p. 17) définit une activité de service comme « une opération, visant une transformation d'état d'une réalité C, possédée ou utilisée par un consommateur (ou client, ou usager) B, réalisée par un prestataire A à la demande de B, et souvent en relation avec lui, mais n'aboutissant pas à la production d'un bien susceptible de circuler économiquement indépendamment du support C (on reviendrait alors à des situations de production agricole, industrielle ou artisanale.) ». Cette définition a été représentée sous forme schématique par son auteur de la façon suivante (cf. figure 1).

Schéma 2. Le triangle des services.

Source : J. Gadrey (1996), p. 19.

Parmi les activités de service ainsi identifiées, certaines d'entre elles ont un rôle d'intermédiaire ou de facilitateur de l'organisation des relations marchandes. Elles sont indispensables au bon fonctionnement de la société et de l'économie. Elles appartiennent soit au tertiaire marchand (en particulier, les services aux entreprises, les transports, les activités immobilières et financières), soit au tertiaire non-marchand (notamment les services d'éducation, les administrations...).

¹⁷⁵ Insee <http://insee.fr/fr/methodes/default.asp?page=definitions/services.htm>

Comme nous le verrons, nous ne pouvons nous arrêter à cette définition statistique pour identifier les activités de service propices à l'écologie industrielle car le découpage d'entreprises réalisés par l'Insee exclus de la catégorie service aux entreprises certains types d'activités pour les remettre dans des rubriques plus homogènes non pas par activités de service mais par domaine d'activité.

Ces activités de service peuvent avoir un rôle direct dans la mise en place ou le fonctionnement de la stratégie d'écologie industrielle choisie, ou servent de « support » à un grand nombre d'entreprises (industrielles ou de services).

A partir du schéma précédent, il est possible de définir les activités de service qui nous seront utiles pour analyser les apports de ces services à l'écologie industrielle. Il s'agit d'activités de service dont le prestataire peut être soit une entreprise, soit une organisation (rarement un particulier) et dont le destinataire est généralement aussi une entreprise ou une organisation. Dans le cadre de l'écologie industrielle, on peut imaginer des prestations de service rendues pour le compte d'une entreprise mais dont la collectivité est aussi bénéficiaire (volontairement de la part de l'entreprise ou par externalités positives).

Ces activités de service proposent un certain nombre de fonctions (ou ont un certain nombre de rôles) qui participent activement au bon fonctionnement des processus d'écologie industrielle. Or, ces fonctions lorsqu'elles sont délivrées par des activités de service, sont souvent négligées par la littérature économique consacrée à l'écologie industrielle. Les auteurs ont tendance à se focaliser sur les techniques, les procédures de production et les innovations d'ingénierie industrielle. Ces auteurs mentionnent généralement ces activités de services plutôt comme des activités annexes, de soutien ou de support aux processus d'écologie industrielle mais n'y consacrent pas d'études indépendamment de l'ingénierie industrielle.

Cette mise à l'écart des activités de service est d'autant plus préjudiciable à la compréhension de l'écologie industrielle qu'une partie des limites de mise en œuvre de l'écologie industrielle ne relève pas de contraintes techniques mais plutôt de problèmes organisationnels ou de problèmes d'acquisition de capacités et de management des relations humaines, problèmes qui peuvent être résolus en faisant appel à des prestataires de service. Le tableau suivant répertorie de manière synthétique les fonctions de service permettant de répondre aux limites de l'écologie industrielle. Ces fonctions peuvent intervenir en amont (en prévention) lors de la réflexion sur la stratégie d'écologie industrielle, ou en aval (en réparation) lorsque ces problèmes sont apparus

Tableau 2. La contribution des services à la résolution des difficultés/limites de la mise en œuvre de l'écologie industrielle.

LIMITES Ecologie industrielle	Activités de service répondant à ces limites
<ul style="list-style-type: none"> - Technique (Echange technique irréalisable : cf. stabilité des déchets, continuité des flux, nécessité de retraitement) - Economique (économiquement non rentable ou risqué pour l'entreprise) - Informationnelle (l'information nécessaire n'est pas disponible) - Organisationnelle (micro: l'organisation de l'entreprise n'est pas adaptée; méso: implication des PME) - Infrastructure (les infrastructures nécessaires ne sont pas disponibles) - Régulation (pas d'incitation) - Humaine (Problème de confiance entre entreprises, problème d'organisation ou de confiance au sein de l'entreprise) 	<ul style="list-style-type: none"> - Services larges de formation éducation DD. <i>Ex: Commerciaux avec formation écologie industrielle (vente particulière des déchets)</i> - Réflexion sur un nouveau business model et pas seulement une stratégie (activités de conseil, recherche en sciences sociales) - Activités de coordination des acteurs locaux (publics-privés-associatifs) afin de faciliter les échanges d'informations et de connaissances ou d'expériences entre entreprises, développer les Mutualisations, Prospections. - Services d'aide à la décision (conseil, juriste, ingénieurs, mais aussi conseil en sciences sociales (management etc.)) - Prestataires de service avec solutions existantes Transport, logistique, circuit court Service de traitement des déchets, Services des eaux, Services proches de l'industrie

3.2 Les fonctions des activités de service dans l'écologie industrielle

Il est possible de regrouper ces prestations de service en plusieurs grandes fonctions de service (ou rôle de ces activités) susceptibles d'intervenir dans les processus d'écologie industrielle :

1) Le premier rôle est relatif à l'organisation des relations marchandes :

Certaines activités de service contribuent à **améliorer ou fluidifier l'information** entre les activités (industrielles, de services). Il s'agit des services de collecte et de mise à disposition d'information, ou de services d'ingénierie...

D'autres activités de service ont une **fonction de coordination « en amont »**. Elles permettent par exemple d'améliorer la prise de décision dans les négociations : Une fonction d'aide à la décision (de conseil), ou d'améliorer la phase recherche nécessaire à la mise en place de l'écologie industrielle (Prospection, Management, Organisation...).

D'autres encore ont une fonction de **coordination « en aval »**, autrement dit, ce sont des services périphériques que l'entreprise pourrait réaliser par elle-même en interne ou faire faire par un prestataire. Ces services constituent une fonction support pour l'entreprise (comptabilité, nettoyage, logistique, transport ...)

Dans le cadre de l'écologie industrielle, la proximité de ces partenaires ou prestataires de service est un élément important, comme nous l'avons étudié plus haut. Les services impliqués peuvent être des services marchands (sociétés privées d'ingénierie et de conseil) ou non marchands (administration territoriale, associations à but non lucratifs). Ces différents types de services jouent un rôle clé dans la coordination des acteurs et la fluidification des informations et donc dans la construction des liens systémiques entre eux, caractéristiques des milieux innovateurs.

Ces fonctions de coordination ou de fluidification élaborées par les activités de service sont génératrices d'innovations. Les innovations les plus visibles sont les innovations techniques. En suivant cette idée, nous pouvons remarquer que l'écologie industrielle, telle qu'elle est étudiée, l'est essentiellement dans une logique industrielle d'ingénieurs qui mettent en place des solutions techniques, ou des opérations de rationalisation de la production (Cf. par exemple Dannequin, Diemer, 2009 ; Diemer, 2012). Or, les travaux consacrés à l'économie de l'innovation montrent que les innovations organisationnelles (Modification substantielle de l'organisation du travail, de la gestion des connaissances et des relations avec les partenaires extérieurs, coopération entre services par exemple), sont essentielles à la bonne réalisation de ces solutions techniques. Même si elles ne sont pas l'apanage des activités de service, un grand nombre de ces activités de service (activités de conseil, etc.) facilitent le repérage ou la mise en place de ces innovations organisationnelles. Ces innovations peuvent être développées et intégrées grâce à l'apprentissage (ex : formation aux nouvelles pratiques de management environnemental, Innovation organisationnelle, développement de nouvelles formes institutionnelles).

Les transports sont incontestablement un exemple d'activité de services ayant un rôle important dans l'écologie industrielle. Ils permettent une coordination externe de la production dans sa dimension spatiale et temporelle et par conséquent ont un impact important sur la proximité et la dimension territoriale.

Focus sur la place des transports dans l'écologie industrielle

L'importance de la problématique du transport dans la ville entrepreneuriale durable apparaît d'emblée dans les chiffres sur ses impacts environnementaux. En effet, le transport dans son ensemble compte pour près d'un tiers de la consommation finale d'énergie et pour 27% des émissions de gaz à effet de serre (Ministère du Développement Durable, 2013). Le transport de marchandises, en particulier, contribue pour environ 10% aux émissions de CO₂ au niveau mondial. Comme le montre la revue de la littérature (cf Encadré), les transports sont ainsi généralement perçus comme défavorables au développement durable en raison des externalités négatives importantes, et, comme un facteur limitant le potentiel de développement de l'écologie industrielle.

Depuis une vingtaine d'années, les travaux sur les impacts du transport du point de vue du développement durable et sur les leviers d'action publique se sont multipliés. Une majorité de ces travaux portent sur le transport de personnes, en particulier sur le report modal (du recours de l'automobile vers le transport collectif et les modes plus doux) et plus récemment sur l'économie de la fonctionnalité (autopartage, covoiturage, systèmes de vélo en libre service...). En revanche, dans ce focus sur le transport dans la ville entrepreneuriale durable, nous nous intéresserons plutôt au transport de marchandises et à son insertion dans le fonctionnement de l'écologie industrielle.

L'insertion du transport de marchandises dans le fonctionnement d'une écologie industrielle territoriale

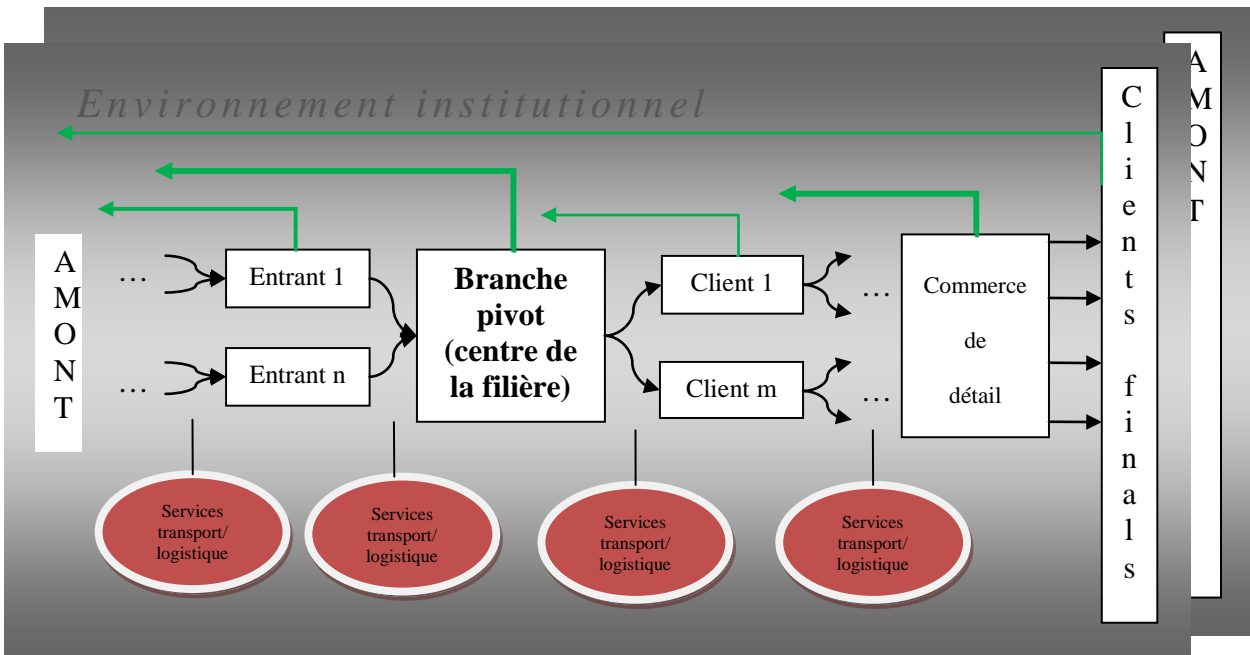

Il ne s'agira pas principalement d'analyser le transport de marchandises comme un secteur producteur de services ni du point de vue du développement durable en général (externalités négatives environnementales et sociales), mais de le prendre en compte dans son lien avec le système productif afin de mieux comprendre son insertion possible dans le fonctionnement d'un système territorialisé d'écologie industrielle. En effet, les services de transport de fret et de logistique contribuent à la circulation des biens et des informations au sein du système productif. Le schéma ci-dessous, inspiré des travaux de l'école suédoise des réseaux (Hakansson, 1987), représente la coordination du système productif en distinguant entre coordination *interne* (la transformation d'inputs en outputs) et coordination *externe* (avec l'environnement de ressources et de demande – fournisseurs, sous-traitants et clients). Les services de transport et de logistique sont un vecteur essentiel de la coordination externe de la production dans sa dimension spatiale (déplacement des inputs et des produits dans l'espace) et temporelle (stockage, mise à disposition des inputs et des produits à un moment donné, juste-à-temps). Le transport et la logistique font donc partie intégrante du système productif en ce sens qu'ils participent à sa coordination externe.

Schéma 3. Le transport et la logistique dans la coordination des systèmes productifs – cadre conceptuel.

Le schéma suivant part de la représentation classique de la filière de production pour y introduire le transport des flux de biens de l’amont vers l’aval. Les services de transport et de logistique interviennent entre toutes les étapes de la filière (autrement dit, à chaque flèche dans le schéma). Si l’on passe du schéma linéaire de la filière (de l’amont vers l’aval) à une représentation du système d’écologie industrielle en forme de boucle, il s’agit alors d’inclure les flux retours (représentés en vert sur le schéma 2), réinjectés dans le système à différents stades de la production. Or, à chaque flux dans le système correspondent des services de transport et de logistique.

Schéma 4. La place des services de transport de marchandises et de logistique – de la filière à la boucle de l’économie circulaire.

Ce schéma suggère donc une omniprésence des services de transport et de logistique (externalisés ou non) dans un système d’écologie industrielle territorialisée. Cependant, cette omniprésence ne signifie pas que ces services ont nécessairement un caractère essentiel ou stratégique dans le fonctionnement de l’écologie industrielle. En effet, une partie des services de transport concerne des opérations de logistique matérielle simple, techniquement peu complexes et réalisées par des prestataires non spécialisés. En revanche, d’autres services peuvent être techniquement plus complexes (nécessitant des équipements ou des compétences spécifiques, comme le transport de matières dangereuses), ou inclure des flux d’informations associés (logistique en juste-à-temps avec tracing/tracking et EDI, par exemple), ou encore nécessiter une coordination complexe et des connaissances et méthodologies spécialisées (systèmes logistiques complexes).

Encadré 3 : Le transport dans l'écologie industrielle, une revue de la littérature

Une première revue de la littérature nous montre que les questions de transport et de logistique ne sont que très rarement abordées dans la littérature sur l'écologie industrielle. En effet, dans ce domaine, le transport apparaît, tout au plus, comme un facteur limitant le potentiel de développement de l'écologie industrielle. Il est clair que si les coûts de transport pour les flux de matières, sous-produits et déchets réutilisés dans d'autres processus de production sont trop importants, pour des raisons techniques (nécessité de matériel spécifique, dangerosité des matières transportées), économiques (faible valeur des matières) ou organisationnelles (flux trop petits, trop fractionnés ou trop rares), le potentiel de l'écologie industrielle se trouve limité. De la même manière, si les externalités générées par le transport des flux retour (en termes de pollution, d'émissions de GES et de consommation de ressources) sont trop importantes en comparaison aux bénéfices attendus de la réutilisation des matières, le fonctionnement en symbiose industrielle n'a pas de sens.

Si le transport, et notamment les problèmes de coûts de transport, ne sont que rarement abordés explicitement dans la littérature économique sur l'écologie industrielle, il est souvent cité comme facteur limitant par les entreprises, comme le montrera notre enquête auprès des entreprises dunkerquoises. Les coûts de transports expliquent aussi en partie la dimension spatiale limitée des systèmes d'écologie territoriale. Cependant, le dernier rapport de la Fondation Ellen McArthur (vol.3, 2014) avance la possibilité de « boucles globales » (*global loops*) : sous certaines conditions de coût de transport, il est envisageable d'étendre les supply chains de l'écologie industrielle du niveau local ou régional à un niveau global. Le rapport cite en particulier les opportunités offertes par le déséquilibre des flux maritimes de conteneurs : du fait que les flux de conteneurs Est-Ouest (notamment depuis la Chine vers l'Europe ou vers l'Amérique du Nord) est plus important que dans le sens Ouest-Est, les prix de transport dans le sens Ouest-Est sont suffisamment bas pour pouvoir envisager d'envoyer des flux de déchets depuis l'Europe vers l'Asie pour traitement et réutilisation.

Constatant que la littérature économique sur l'écologie industrielle ne fait que peu de cas de la problématique des transports et de la logistique de ces flux, nous avons cherché à explorer deux autres domaines de la littérature : celle de l'économie des transports, d'un côté, et celle du Supply Chain Management en sciences de gestion, de l'autre.

Du côté de l'économie des transports, la problématique du transport de marchandises face aux enjeux de développement durable peut se résumer comme une limitation des effets externes négatifs, autrement dit comment « verdier le transport ». Les solutions proposées sont soit d'ordre technique (développement de véhicules, carburants, infrastructures etc. plus « propres »), soit de nature organisationnelle : comment encourager le report modal, la massification, la mutualisation des ressources et des équipements, l'optimisation des taux de charge et la limitation des retours à vide (Ernst&Young/PIPAME, 2013).

Du côté des sciences de gestion, la littérature sur le *supply chain management* (SCM) a connu un développement important autour des problématiques de développement durable depuis une quinzaine d'années. Nous avons identifié quatre approches en lien avec notre problématique :

La *reverse logistics* (Fleischman et al., 1997) s'intéresse aux supply chains dans le sens inverse des chaînes habituelles, mais il s'agit généralement d'une problématique de gestion optimale des flux retours de biens de consommation et non de gestion des flux de déchets.

La littérature sur les supply chains vertes (*green supply chains*) et le *sustainable supply chain management* (SSCM) a connu un développement très important. Le survey de Belin-Munier (2010) montre que les contraintes de développement durable modifient non seulement les objectifs du SCM, mais aussi sa mise en œuvre, en renforçant la dimension interorganisationnelle et l'intégration.

Les travaux en termes de *Logistics Social Responsibility* (LSR) (Carter/Jennings, 2002) appliquent la RSE (responsabilité sociale de l'entreprise) aux chaînes logistiques. Belin-Munier (2010) montre notamment que la RSE s'étend avec la diffusion des pressions de développement durable le long de la chaîne logistique et devient donc une problématique non plus de la firme, mais du réseau de firmes impliqué dans la chaîne logistique globale.

Le courant de l'*Integrated Chain Management* (Seuring, Müller, 2007) s'est développé surtout en Allemagne. L'ICM se fonde sur le cycle de vie du produit et avance la notion de « closed-loop supply chain management » qui englobe la logistique inverse et le recyclage. La gestion des produits en fin de vie, le recyclage des composants ou des produits, le traitement et la réutilisation des déchets suscite la création de nouvelles activités économiques qui peuvent restructurer les filières existantes ou créer des filières nouvelles. Cependant, la question du transport n'est pas abordée explicitement.

C'est donc surtout l'approche de l'*Integrated Chain Management* que nous retiendrons, en raison de sa proximité évidente du courant de l'écologie industrielle d'un côté, et d'une prise en compte explicite des institutions et de la dimension méso-économique.

2) Le second rôle est relatif à l'acquisition ou au maintien de capacités par les agents

Une seconde grande série de fonctions de service (ou un second rôle des activités de service) susceptibles d'intervenir dans les processus d'écologie industrielle consiste en **l'acquisition ou au maintien de capacités par les agents**. Nous avons précisé précédemment que les innovations relatives à l'écologie industrielle peuvent être développées et intégrées grâce à l'apprentissage.

Certaines activités de service proposent ainsi une fonction de formation, d'éducation (des étudiants ou salariés) ou encore une fonction d'aide à la décision plus ciblées sur les questions d'aide à la décision plus ciblées sur les questions de formation. Il pourrait s'agir également de fonction d'aide à la personne, de soins, etc. Dans le domaine de l'écologie industrielle, Boiral O. et Kabongo J. (2004), Boiral (2005) mettent en avant les savoir-faire organisationnels comme source de différenciation et d'avantages compétitifs (savoirs tangibles et intangibles), ainsi que la mobilisation de compétences spécifiques relatives aux procédés, aux matières résiduelles et aux différentes façons de les valoriser. Ces savoir-faire organisationnels, souvent étudiés essentiellement à la lumière de l'ingénierie, sont aussi en grande partie obtenus par des activités de service (conseil formation).

3) Le troisième rôle est relatif à l'émergence de nouvelles pratiques

Un troisième axe, concernant les prestations de service impliquées dans l'écologie industrielle n'est pas uniquement dédié aux activités de service. Il peut être développé au sein des activités industrielles. Il s'agit du développement de **nouvelles pratiques**, voire d'un **nouveau business model**, proposé par l'économie de la fonctionnalité (cf. D. Bourg, 2005, D. Bourg, D. Buclet, 2005 ; W. Stahel, 2006 ; Gaglio G., Lauriol J., Du Tertre C, 2011).

L'économie de fonctionnalité consiste en la substitution de la vente d'une fonction d'usage (un service) à celle d'un produit, et étudie la production d'une solution intégrée de biens et de services (la vente d'une performance d'usage) permettant la prise en charge des externalités environnementales et sociales. Dans une telle optique, la valeur économique du produit ne repose plus sur sa valeur d'échange, mais sur sa valeur d'usage. L'objectif est d'optimiser l'utilisation – ou la fonction – des biens et services, en employant des richesses existantes (produits, connaissances, capital naturel).

Dans cette optimisation ou mutation économique, la place accordée aux services est importante, et la solution proposée s'inscrit dans une sphère **fonctionnelle** (mobilité, santé, habiter, etc.). Elle regroupe des acteurs issus de différents secteurs d'activité.

Un certain nombre d'entreprises industrielles proposent à côté de la production de biens, des prestations de services (Les exemples les plus connus concernent l'entreprise Michelin, Xerox, Dow Chemicals) participant à un développement durable. Il s'agit donc d'une forme de *servicisation* des entreprises industrielles dans la mesure où ces entreprises fournissent des systèmes produits-services de plus en plus sophistiqués. Ces solutions sont généralement entreprises dans le cadre de la mise en œuvre de stratégies environnementales (Laperche, Picard, 2013, Boutillier et al., 2014) et peuvent être entreprises dans une stratégie d'écologie industrielle.

Pour se développer, l'économie de fonctionnalité a besoin de faire évoluer les dispositifs institutionnels d'innovation, d'évaluation et de professionnalisation. Ces nouvelles solutions s'appuient sur (et développent) le patrimoine immatériel territorial. Par ailleurs, elle nécessite de profonds changements dans les relations entre producteurs et consommateurs. Cette recherche de nouvelles approches commerciales, de changements dans les modes de vie, de changements dans les pratiques et les comportements mobilisent bien entendu les activités de service (recherche, conseil, éducation, formation).

Ainsi, certaines solutions techniques sont davantage orientées vers les dimensions sociales du développement durable. Certaines innovations technologiques répondant aux problèmes de l'écologie industrielle peuvent constituer une trajectoire d'innovations environnementales et sociales qui profitent à l'ensemble de la collectivité.

Les services développent aussi des solutions plus spécifiques (perspective de différenciation, Djellal, Gallouj, 2009). Les services de conseil ou plus généralement les services de traitement de la connaissance, investissent de nouveau champ d'expertise (droit de l'environnement, conseil en développement durable, conseil méthodologique), qui auront un impact dans le domaine de l'écologie industrielle.

Par conséquent, dans la recherche de nouveau business model ou de nouvelles solutions innovantes, à côté de la création d'innovations technologiques (comme les technologies propres), il existe des relations plus complexes entre innovations technologiques (développés par exemple par les entreprises industrielles dans le cadre d'une stratégie d'écologie industrielle) et activités de service (Gadrey, 1996). On peut identifier des relations de substitution (on peut substituer totalement ou partiellement un outil technique innovant à un service, tel que les bornes d'information et de conseil) ; des relations d'identité (le service rendu constitue la valeur d'usage de la technologie. Ainsi, les biens matériels peuvent eux aussi être définis par le service qu'ils rendent. C'est ce qui fonde l'économie de la fonctionnalité) ; des relations de détermination (l'innovation technologique détermine l'apparition de nouvelles fonctions de service. Ex : conseil en environnement suite à l'apparition de technologies propres) ; des relations de diffusion (certains services participent à la diffusion des innovations technologiques et organisationnelles, ex: activités de conseil en haute technologie) et enfin des relations de production (les entreprises de service produisent elles-mêmes des innovations technologiques).

Conclusion

Nous faisons l'hypothèse que l'écologie industrielle peut être un outil dynamique de 1) stabilisation des activités économiques existantes, 2) d'attractivité de nouvelles entreprises et 3) de création d'une dynamique endogène de créativité et d'innovation. La mise en œuvre de ce type de circuit court industriel peut ainsi participer à la construction d'une économie territoriale fonctionnant sur la forme d'un milieu innovateur et orientée vers le développement durable ;

en d'autres termes à la construction d'un territoire entrepreneurial durable. Mais pour cela, il est nécessaire de résoudre les limites fréquemment rencontrées dans la mise en œuvre de l'économie industrielle. Selon nous, les activités de service peuvent répondre aux limites/difficultés de la mise en œuvre de l'écologie industrielle. Ils sont un ainsi un gisement de création et d'attraction d'activités nouvelles.

Notre cadre d'analyse est actuellement appliqué au cas l'agglomération de Dunkerque. Nous cherchons dans ce travail empirique à

- identifier les atouts et les limites dans la mise en œuvre des symbioses industrielles à Dunkerque
 - identifier les activités de services (publics, privés, parapublics) potentiellement liées à l'écologie industrielle sur le territoire dunkerquois et étudier leur implication réelle dans les pratiques d'écologie industrielle à Dunkerque
 - identifier les activités de services (publics, privés, parapublics) utiles au bon fonctionnement du métabolisme industriel mais non présent sur le territoire
 - définir des recommandations pour favoriser l'amélioration des pratiques d'écologie industrielle à Dunkerque.
- Les résultats feront l'objet de publications ultérieures.

Value co-creation and digital services in the book publishing industry

Seppo Leminen^{1,2}, Anu K. Nousiainen¹, Mika Westerlund³

¹Laurea University of Applied Sciences, ²Aalto University, ³Carleton University

The book publishing industry is in transition due to the digitalization of production, content, consumption, and practices. The increasing popularity of self-publishing services and the new generation of digital natives emerging as semi-professional writers revolutionize the conventional role of literary authors and the traditional value chain. To understand the change, this study focuses on the new logic of value co-creation underlying digital services. It places authors, readers, and stories at the core of the interaction, investigation, and innovation. As a result, the study provides three diverse value co-creation platforms responding to the digital transition within the book publishing industry.

1 Introduction

The book publishing industry is in the intersection of several industrial sectors. It is a part of graphical mass media in conjunction with the entertainment economy (Wolf, 1999) and the experience economy (Pine; Gilmore, 1999), and a sector of the cultural (Throsby, 2001; Hesmondhalgh, 2002; Van der Ploeg, 2004) and creative industries (Florida, 2002). According to O'Reilly (2006), book publishing industry is an exercise in the social production and distribution of art where publishing houses spread the business risk by building an offering portfolio in the value chain.

The advent of digitization has led to the blurring of borders between media channels and their artifacts (Xuemei et al., 2008). However, innovations and new competence are expected to be born in the hybrids of technology, business, and culture (Florida, 2002; Miles; Green, 2010). The fashionable concept of e-book is evolving in the midst of convergence, and there are readers with different offline/online reading practices (Marshall, 2010; Schultz Nybacka, 2011). Furthermore, a growing number of online book titles give rise to grey literature and the majority of books fail to receive enough attention from the audience due to the emergence of self-publishing services (Chandler, 2006) and the "long-tail" effect (Anderson, 2006).

The book publishing industry is being redefined upon the changes in digital work space for amateur writers and established authors that can cut out the middlemen in the existing value chain for business offerings. Following the notion of Normann (2001, 2007), the business offering development has three strong directions that redirect the focus of operations: servitization, experiences, and networks. Similarly, Lloyd (2008) states that the very nature of the book needs to be rethought in the digital networked era by approaching the book from the content perspective instead of a product or category approach, and by placing the book at the center of business operations rather than at the end of the production chain.

The growing roles of servitization, experiences, and networks have led scholars to acknowledge customer's active role in the consumption process and value co-creation processes that build on intangible resources and symbolic value (Vandermerwe, 1992; Prahalad; Ramaswamy, 2004; Payne et al., 2008). For instance, service-dominant logic (Vargo; Lusch, 2004) is a recent approach highlighting that the customer is always a co-creator of value. Co-creation of value is a hypernym that distinguishes the service-dominant logic from conventional goods-oriented production (Lusch; Vargo, 2006; Vargo, 2008).

The applicability of co-creation increases while firms and their value networks target to serve segments of one and provide unique experiences through individual tailoring, customization and innovation enablers (Etgar, 2008; Prahalad; Ramaswamy, 2004). Heinonen et al. (2010) suggest taking customer-dominant logic in services to focus on customer's life, practices, and goals related to the service instead of company actions. The provider supports customer's value creation processes (Grönroos, 2006, 2008) and customers determine the value in their own context (Heinonen et al., 2010). Service design, with its holistic process, method, and discipline, has been geared on understanding people's value creation elements and processes aiming at innovation and new value creation (Moritz, 2005; Maffei et al., 2005; Brown, 2009).

Customers have adopted the role as the main source of innovation, and service organizations design services with them – not for them (Ojasalo; Ojasalo, 2009). Building on service logic and value co-creation, this study aims to understand value co-creation underlying digital services. In particular, the study takes customer-dominant logic in service innovation and examines the consequences of digitization for the benefit of literary authors, their stories, and readers as well as value co-creation opportunities within service design. The research questions are:

- (1) What does value co-creation mean in the book publishing industry?
- (2) What types of authors, readers, and books there are in the digital era?
- (3) How authors and readers create value in the digital era?

The remainder of the study presents the theoretical foundations of user-driven service innovation and the value network paradigm in the digital context. Then, the paper describes the research methodology and data collection. After this, the findings from empirical research will be presented, including the types of digital era authors, readers, and books, and

related value co-creation platforms. Thereafter, the study reviews key findings and discusses implications to theory and practice. Finally, it concludes by presenting the limitations of the study and providing future research avenues.

2 Theoretical foundation

2.1 User-driven service innovation

Any service offering begins as a potential promise or value proposition (Vargo; Lusch, 2006; Barcet, 2010). Services are complex interactions that evolve through different relationships forming hybrid systems with people, places, organizations, networks, and related service systems (Manzini, 2011; Patricio; Fisk, 2011). Normann (2007), Lovelock and Wirtz (2011), and Grönroos (2006, 2008) regard services as (social) processes, whereas Tyagi and Gupta (2008) describe services as transactions or experiences that are co-created between customer and service provider (Vargo; Lusch, 2004). Heinonen et al. (2010) consider services from the customer's viewpoint and state that they are: i) outcomes of the service provider's internal activities, ii) co-creation processes and their outcome elements, and iii) process and outcome elements of the customer's own activities.

Innovation in services can take place in organization's capacity to deliver value, value offerings, and delivery interfaces (Maffei et al., 2005, Grönroos, 2010). Service management system quality (Normann, 2007), the management quality, and business model (Hamel, 2007) can be also regarded as sources of innovation. Ordanini and Parasuraman (2011) list service innovation sources as i) collaborative competences, ii) customer orientation, and iii) knowledge transfer. Den Hertog et al. (2010, 494) define service innovation "that consists of one or several of the following dimensions: new service concept, new customer interaction, new value system/business partners, new revenue model, new organizational or technological service delivery process".

However, the central role of users is frequently addressed in the innovation processes (Leminen et al., 2012; Nyström et al., 2014) and in service innovation research, in which focus is steered towards the interactive nature of innovation and the role of the customer (Howells, 2010). Placing the customer at the center of value creation directs focus on customer prerequisites to engage in value creation with their own resources, knowledge, and skills (Edvardsson et al., 2010) and on their unique interpretation of value (Michel et al., 2008; Heinonen et al., 2010). Consequently, a prerequisite for service innovation success is that the service provider and the customer recognize each other's value-creating strategies (Möller et al., 2008), companies actively participate in the customer's processes (Heinonen et al., 2010) and customers are provided with the knowledge and tools necessary for them to perform the tasks (Normann, 2007).

The key to user-driven innovation seems to be satisfying latent needs of the customer instead of expressed needs (Narver et al., 2004). Latent needs reflect what customers truly value but cannot explicitly request from the service provider (Senge, 1990; Matthing et al., 2004). Service design as a discipline focuses on understanding the elements of value through investigating the latent needs and hidden motives with multifaceted toolkits (Stickdorn et al., 2012; Polaine et al., 2013). Many of the early design researchers have a background in digital interface and interaction design (Blomkvist et al., 2012; Goodwin, 2009) where IT-related usability focus has transformed towards Human Centered Design (Meroni; Sangiorgi, 2011; Rogers et al., 2007). The meaningful design goes beyond technology-driven innovation by addressing people (Kim; Mauborgne, 2005) and by integrating concepts of business, technology, and design (Mager, 2004) to create different and differentiating value to the market (Drucker, 2007).

2.2 Value network paradigm

The Internet can be seen as an infrastructure of service economy in which networking is a basic form of human relationships (Barney, 2004; Castells, 1998) and a regular part of business processes (Hsu, 2009; Funk, 2009; Qualman, 2011). Mobile computing technologies provide users with ubiquitous access and enable user-generated content creation (Stewart; Pavlou, 2002; Krishnamurthy; Dou, 2008; Shao, 2009) as well as social object creation: "something that people look at, discuss, and pass from person to person, putting their own stamp on it" (Metz, 2012, 2). The most meaningful and interesting content affecting the purchase decisions is the one created by like-minded individuals, peer-groups, and horizontal networks (Funk, 2009; Kotler et al., 2010; Qualman, 2011).

The power in the network society is about abilities to access networks and control various flows (Barney, 2004). The "network effect" (Normann, 2007, 33) takes place each time a new member is added and the value accrues to the other members of the network. Therefore, the new economy has heightened the importance of relationship marketing (Gummesson, 1999) and customer relationship management (Greenberg, 2009). In marketing theory, the network approach confronted the traditional marketing mix of the 1980s by emphasizing that "relationships do not exist in isolation but are connected to each other so that every relationship is part of a wider network of relationships in the market" (Lindstrand et al., 2006, 2-3), whereas Vargo (2008) highlighted the network-to-network perspective in service-dominant logic.

In order to both increase knowledge within the organization and to maximize knowledge exchange with the outside world, companies increasingly cooperate beyond dyadic relationships creating dynamic inter-organizational networks, and, thus, transforming to network paradigm of business management (Kanter, 2001; Normann, 2007; Doz; Kosonen, 2008, 56). Markets have converted into forums for dialog and co-creation among customers, communities, companies,

and networks of companies (Prahalad; Ramaswamy, 2000, 2004; Ramaswamy; Khrisnan, 2008). Hence, customers have become equivalent to other participants (Edvarsson et al., 2010) in the enhanced network in which they co-create and extract business value with collaborators, co-developers, and competitors (Prahalad; Ramaswamy, 2000).

The position and power conception (Santos; Eisenhardt, 2005) in the value creating networks or value constellations (cf. Ramírez, 1999) can provide companies with knowledge and resources, new business potential, and an innovation boost as part of the collaboration and co-creation efforts (Camarinha-Matos; Afsarmanesh, 2004; Prahalad; Krishnan, 2008). Together with other organizations, companies may end up providing a particular piece of a complete ecosystem and thereby do things in the modular way (Doz; Kosonen, 2008; Bask et al., 2011). Moreover, they can build innovation labs (virtual and public beta labs) and living labs (which emphasize user’s role in innovation in real-life contexts) to share new tools and to co-create, validate, and test new ideas (Leminen; Westerlund, 2012; Guzman et al., 2013; Nyström et al., 2014). Hence, the open innovation model provides an alternative to the conventional development (Chesbrough, 2003; van de Vrande et al., 2009). Its benefits include cost savings (Von Hippel, 2007), improved user value (Almirall; Casadesus-Masanell, 2010), and better innovation performance (Chiaroni et al., 2010).

The greatest positive impact on innovation comes from networks comprising different types of partners (Nieto; Santamaria, 2007), varied resources, and the ability to establish diverse relationships (Calia et al., 2007). Shirky (2008) reminds that the facilitation of goal-oriented collective action (i.e. groups acting as a whole) is the most demanding mode of social media practice even after collaborative production (cf. crowdsourcing, a term coined by Howe, 2006). Co-creation requires using user’s operand (material objects) and operant resources (intangibles) (Arnould et al., 2006), understanding both intrinsic (experience is appreciated for its own sake) and extrinsic (experience is appreciated as means to an end) values (Holbrook, 2006), and fostering a broad array of reproducible and repeatable practices in order to build co-creative brand partners (Schau et al., 2009).

3 Methodology

3.1 Research design

The study follows design thinking principles and service design methods to gain insights on different authors, readers, and interaction needs/opportunities in the digital context. Concordant with the suggestions by Meroni and Sangiorgi (2011), this study focuses on digital service design from the perspective of functional paradigm (i.e. what services represent and can offer) as opposed to the interaction paradigm (i.e. how services are performed). Since the objective is to create novel and meaningful people-oriented solutions (cf. Verganti, 2009), the study takes an abductive method of reasoning (originated by Peirce, 1903) to foster something completely new by placing the story as a platform for value creation and co-creation between authors and readers.

3.2 Data collection

Credibility/reliability in this qualitative and adaptive research was addressed by focusing on the methodology and procedure (Kirk; Miller, 1986; Strauss; Corbin, 1998; Flick, 2002; Silverman, 2006). Several research methods were used (Aaltonen; Sanders, 2005) and the sample size and insights were evaluated throughout the process (Kvale, 1996; Glaser; Strauss, 1999). Furthermore, the strategy of theoretical sensitivity across categories (Glaser; Strauss, 1999) was needed in finding multiple sources for the investigation and to guarantee diversity and multidisciplinary essential for service innovation. In addition, the research took the grounded theory approach of “everything is data” (Ibid.).

Figure 1. Main research entities and methods.

A careful documentation of the process benefits research reproducibility and generalizability (Straus; Corbin 1998) where validity relates to the aspects of what has been studied and how it has been interpreted (Kirk; Miller, 1986). Overall, the data was gathered by utilizing several strategies and sources to comply with the principle of data triangulation (Denzin, 1970) (Figure 1). The primary research was conducted in 2011 in Finland and the secondary research, taking place in 2013, enhanced existing results towards final outcomes.

The first step included semi-structured interviews with fiction and non-fiction authors as well bloggers (Appendix 1). They were interviewed mainly face-to-face about their creative processes and related interaction needs based on tested and thematized semi-structured agenda (cf. Kvale, 1996), including directive storytelling, broad descriptive key topics, and further questions (Flick, 2002; Silverman, 2006; Rogers et al., 2007; Goodwin, 2009; Saffer, 2010). The recruitment focused on the most appropriate informants with purposive and convenience sampling strategy (Morse, 1998; Tuchman, 1998) and with the objective to have both typical cases and dissimilar cases (Patton, 1987).

The top informant profile of fifteen readers was created and approached with self-documenting tools to understand the interactive process of reading. The study used convenience sampling when recruiting readers (Goodwin, 2009; Patton, 1987). The design probe (Mattelmäki, 2006; Polaine et al., 2013) was materialized to be a mobile and simple paper bookmark focused on the dialog and actions that the story evokes on emotional and cognitive levels. Bookmarks included the following sections: 1) instructions, 2) participant background information, 3) Free-form entry, 4) structured checklist for diary notes, and 5) statements about anonymous and confidential processing of data (ref. Silverman, 2006; Rogers et al., 2007; Kvale, 1996).

Twelve experts of various backgrounds were interviewed face-to-face, via Skype, and by email to gather insights about digitalization and the future digital books. These individuals were selected and approached through peer networks according to their expected level of new insights (Flick, 2002; Glaser; Strauss, 1999) and from the non-expert point-of-view (Van der Duin, 2006) to engage potential future value network actors. Each participant was emailed five statements regarding the future of e-reading (based on Leminen, Salo et al., 2010) and a couple of open-ended questions. Altogether, these questions formed the agenda for the expert discussions.

Finally, fourteen participants from different fields were invited to attend a service ideation/co-design workshop. The participants were divided into three teams. Each team completed a set of exercises according to created author personas and persona brainstorming (Curedale, 2013). The participant groups had two objectives; firstly, to generate ideas through divergent thinking (generating options) and secondly, to converge and co-design solutions based on the author persona understanding (making choices by evaluating) (Brown, 2009). Exercises resembled the storytelling game (Vaajakallio, 2012), as the participants discussed their own persona by changing perspectives each round, and they continuously recorded ideas.

3.3 Data analysis

Different types of data were recorded in the study: (i) Voice recordings, (ii) written documentations, (iii) research templates, and (iv) digital pictures. All data were prepared for the analysis and translated into Post-it notes. The data was coded, categorized, and clustered on different affinity walls for the purpose of designing the needed artefacts and outcomes. The analysis took advantage of various analytical approaches to find a reliable categorization scheme and to ensure that the analysis can be replicated (Flick, 2002; Goodwin, 2009; Rogers et al., 2007).

Author personas were created for the service design workshop purposes (Williams, 2006) both to inspire service ideation and to validate the personas. Single and cross-case analyses were used for identifying differences and commonalities between author respondents, and continuums were created from the single cases with primary spectrums related to needs, resources, and practices (Flick, 2002). Then, similar single cases were identified and divided into three possible personas. The personas were tested with inductive reasoning by deriving a statement based on the primary data and finding explanations from the secondary research (Goodwin, 2009).

Reader profiles were identified on the basis of desk research and supported by the conducted reader study. The data were coded and analyzed similarly to author persona creation, but the approach was more in deductive reasoning which started by creating a secondary research based statement and tried to find supportive data from the primary research data. Deductive reasoning was utilized especially with more future-oriented readers, authors, and digital book evolution. Three types of digital book were created on the basis of desk research, supported by the conducted expert interviews. However, the analysis required pattern experience (Richardson, 2010) and previous knowledge (Glaser; Strauss, 1999) from the researchers.

Finally, a qualitative content analysis (Flick, 2002; Rogers et al., 2007) was once more utilized for coding service ideas that were gathered throughout the research, in particular from the service design workshop. The coding distributed service ideas into actor-based categories, such as author- or reader-specific features of the digital book, and services concerning current or future value network members. The data were filtered aiming for the most potential service concepts; forward-looking, yet feasible concepts, which present user value and business potential (Moritz, 2005; Brown, 2009). These priorities were already discussed in the service design workshop with experts and stakeholders.

4 Findings

4.1 Three platforms to digital era storytelling

The study identified three types of authors, readers, and books for digital era (Table 1). Further, focusing on co-creation and value creation opportunities among authors, stories, and readers, the study identified three value co-creation platforms for the digital era (Figure 2). Considered from the perspective of sequences, the value co-creation platforms in Figure 2 include the aspect of evolutionary development. This is noticeable in terms of digital technology advancement

and the growing number of digital natives as authors and readers. The evolutionary aspect highlights the increasing control of the reader on social reading practices through modular making.

The platforms in Figure 2 also consider the aspects from customer-dominant logic in services (Heinonen et al., 2010), namely: 1) co-creation processes and their outcome elements, and 2) process and outcome elements of the user's own activities, and 3) user values (cf. Holbrook, 2006). However, the platforms are not only serving the needs of authors and readers, but are regarded as the most potential responses to the challenges in digital transition and transformation faced by the existing book publishing industry. The next sections describe each value co-creation platform.

Table 1. Types of authors, readers, and books in the digital era.

AUTHOR TYPES & NEEDS	WRITER is the closest to the contemporary cultural and commercial author (O'Reilly, 2006; Brown, 2006; Boorstin, 1992) who concentrates on publishing titles and evolving "own recognizable style and tonality" (Author A6). Writer wants to engage with readers in digital space.	PROCESSOR feels that "a variety of writing projects supports creative process rather than disturbs it" (Author A5). Processor is digital native who posts topics that matter and educate to "solve things or bring up new and fresh approaches" (Author A9). S/he wants to engage with people "who matter the most" (Self-publisher B11).	CONDUCTOR neglects existing boundaries and categories by establishing and blending things into totalities or "sensorial spaces" (Author A3) for the story. Conductors do not ask who they are "which combination of my selves am I today" (Barney 2004, 18) and who are with me in creative process.
BOOK TYPES & CATEGORIES	LAYERED BOOK A digital book as a hub for new content elements, features and services related to the story. These elements result different interaction layers "on top of" the original story serving fiction oriented category and readers.	CO-CREATED BOOK A digital book is a result of collaboration by multiple people. Further, its lifecycle from creation and publishing to commercial processes is facilitated in digital space. Co-writing between authors is common in non-fiction category.	HYPERMEDIA BOOK A digital book is a space for continuous exploration of the story. Storyline's past, present and future are available for the creation of new elements to listen and to play. The format has potential in book series and fantasy categories.
READER TYPES & NEEDS	GOURMAND Intensive readers (Marshall, 2010) driven by meaning . They practice the interactive nature of reading (Rentola, 2003): "[After reading this book] now I want to google the places to go and look for books about Berlin on Amazon" (Reader R4).	PRACTITIONER Extensive and target oriented readers (Marshall, 2010) fluent with multiple formats. They want to be recognized as educated readers: "I contacted authors and pointed out an error in the concept that they had presented" (Reader R9) and often practice writing/blogging.	ADVENTURER Ergodic readers (Aarseth, 1997) who continuously select between alternatives and want to influence on resulting reading experience. They "listen to literature and watch books" (Watson, 2010, 22) and have Pro-Am spirit (Leadbeater; Miller, 2004).

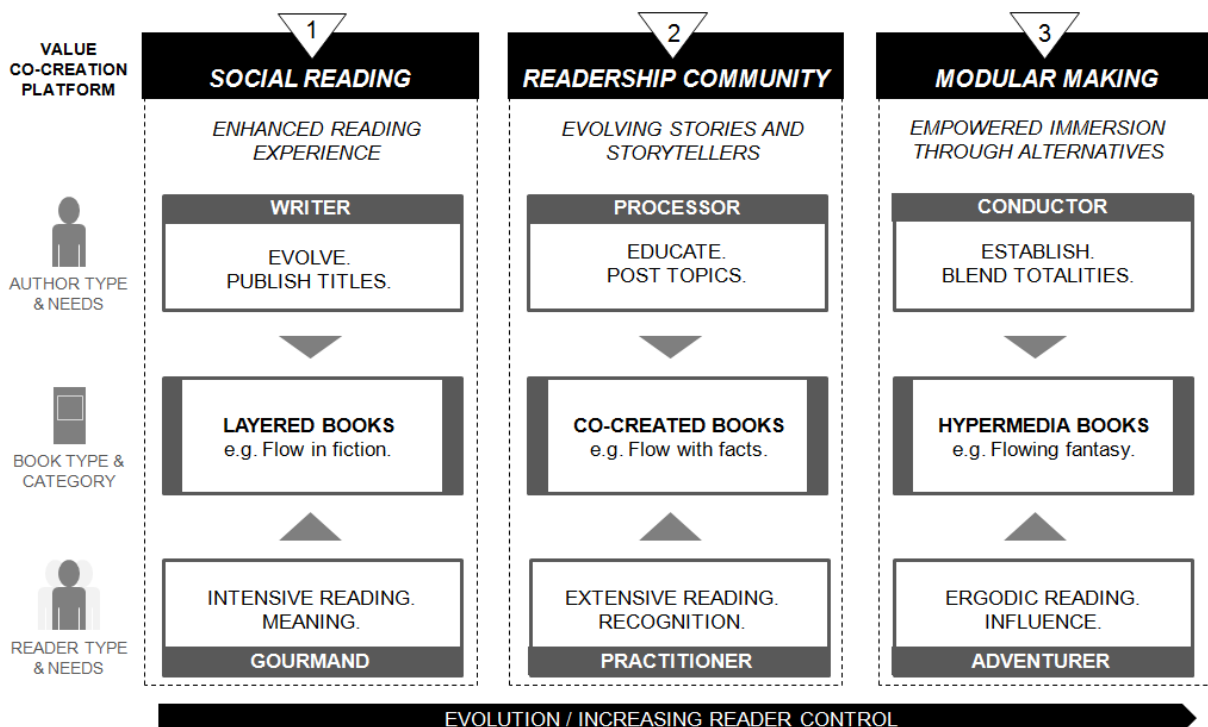

Figure 2. Three diverse value co-creation platforms in the digital era.

4.2 Platform 1: Social reading enhanced experience

The first value co-creation platform with social reading and layered book type responses to the challenge of grey literature. Digital book is a hub for “Title” related social objects and (commercial) services. The more there is new content creation and interaction, the more the “Title” gets attention, and its lifespan prolongs. Schultz Nybacka (2011, 72) argues that we need to understand both “how readers seek new texts and how texts seek out new readers”. The layered book type therefore confirms Drummond’s (2006) notion on that inspired readers want similar books and “google” more about the story related topics and the author (Reader R4). This relates to the interactive nature of the reading: “any text that is read is understood like a hypertext: it forms links, associations and connections to places that awaken images and needs in us” (Rentola, 2003, 32).

The greatest value of reading among fiction oriented “Gourmands” is reflecting the stories and understanding life, others, and self (Schultz Nybacka, 2011; Shankar, 2006): [The story got me to realize] “how lucky I am to be a woman living in Finland!” (Reader R5). According to Bianchi (2008, 244), people reflect cultural values (see also Thorsby, 2001; Van Der Ploeg, 2004) depending on their capability for “change, novelty, and self-renewal”. Furthermore, reading is social (Marshall, 2010). In a book group, for instance, other members influence how the book is read and interpreted as they are omnipresent in the individual reading experience (Shankar, 2006; Brown, 2006) which relates to the key tribal characteristic called “puissance” (a term coined by Maffesoli in 1996), meaning the energy and force of masses of people.

Layered book type, with social reading as the value co-creation platform, enables readers to link and create social objects, annotations (Marshall, 2010), and feedback related to the story serving the interactive and meaning-oriented reading culture. The value of reading enhances further with the social aspect of reading while other readers, author(s), and service providers create new content, services, and interaction layers for the story and for the book group. Social reading serves also “Writers” who want to get closer to their readers and receive feedback in order to evolve and grow as literary authors and brands (Author A6).

4.3 Platform 2: Community of evolving storytellers

The second value co-creation platform with readership community and co-created books reflects the already existing practice of co-writing. This collaboration can be initiated “either by surprising encounters or by joint research and analysis of the title portfolio together with publishers and peers” (Author A8). However, there is a growing need to facilitate the commercial process of storytelling and manage the story lifecycle: “It is quite understandable that publishers cannot endorse all of us writers in the sales, launches, and marketing of books these days. But what can I do on my own to cover the lack of resources?” (Author A4).

The readers can have multiple value creating roles in the creative and commercial processes. “Practitioners” in Pro-Am spirit (Leadbeater; Miller, 2004) can bring their skills and expertise in writing, illustrating, marketing, editing, or translating the story to other languages. There is no need to underestimate crowdsourcing practices, social media platforms and communities: Israel (2009) - the author of the book “Twiterville” - reports that Twitter users generated about three-fourths of the stories in the book. Furthermore, crowdsourcing can be harnessed to influence the forthcoming stories by voting favorites, proposing new “Topics”, or funding promising pilots with readers’ own resources and skills.

The most interesting value creating services from both the reader and author perspectives are the ones that facilitate and mentor recognition-oriented readers as storytellers and thus, reflect the growing number of semi-professional writers. Therefore, value co-creation opportunity can be realized through a readership community targeted to mentoring and training its members’ writing skills and thus, bringing forth new phenomena and talents.

4.4 Platform 3: Immersion through making

The third value co-creation platform with modular making and hypermedia books responds to common fear among professionals that the desire for intensive reading will eventually become marginal/niche (Marshall, 2010; Schultz Nybacka, 2011). The goal of hypermedia books and “Totalities” is to “give readers the freedom to choose among multiple options on how to read, experience and immerse in the story” (Expert E8) and to let “Conductors” to facilitate a story creation that “Adventurers” can “see, hear and play with” (Author A3).

The provision of options encourages also re-reading (Schulz Nybacka, 2011). Readers can influence their experience by changing the storyteller when they revisit the storyspace or by creating new experience elements together with the tribe of readers. The text defines and differentiates hypermedia from gaming and multiplayer online role-playing games (Funk, 2009). However, hypermedia is regarded a highly potential platform due to its gaming metaphor: “Very interesting and inspiring in the Finnish society that is focused on gaming and reading” (Expert E12).

Hypermedia book and its co-creation platform require enabling, user-friendly, and modular components, and lead user behavior: enjoyment and learning through making (von Hippel, 2005; Thomke; von Hippel, 2002). Moreover, it needs a pool of likeminded people (Kotler et al., 2010; Godin, 2008) who are inspired by the story and who service the members (Fournier; Lee, 2009) in the storyspace. Therefore, “Adventurers” are not only co-creators but they are

pioneers establishing a novel value creating network and have the greatest control of the reading experience compared to the previous platforms of social reading and readership community.

5 Discussion and conclusions

5.1 Theoretical contribution

This research focused on understanding value co-creation underlying digital services in the context of book publishing industry. As to findings, the study evidenced, concretized, and introduced three types of a digital book: (i) layered book, (ii) co-created book, and (iii) hypermedia book. Next, the study extended the role of contemporary authors towards the digital and social era as (i) writers, (ii) processors, and (iii) conductors, highlighting their unique needs and approaches to conventional publishing. Similarly, the roles of readers were extended from (i) gourmants and (ii) practitioners towards (iii) adventurers with their own motivations and reading cultures. Furthermore, this study placed digital book at the center of value co-creation between different types of authors and readers, and recognized three value co-creation platforms: (i) social reading, (ii) readership community, and (iii) modular making. Last, the study distinguished actors, content, and value co-creation for the purpose of digital service innovation, and integrated these findings in the novel framework showing three evolutionary and co-existing value co-creation platforms for digital era storytelling.

5.2 Managerial implications

For managers, this study addresses ‘rethinking’ as the key for understanding value creation in digital services. First, by freeing the traditional book from its format, and exploring the story elements from multiple perspectives – including service logic and user based approach presented in this study – provide an opportunity to prolong the story lifecycle, to discover new means for marketing, and to consider related price tags in the digital context. Second, the study encourages firms to move away from contradistinction (either-or) to co-existence (both-and) mindset when developing and designing user-driven digital services. The co-existence of different reading cultures and digital skills means that organizations can only bring value to people’s lives by understanding and supporting their resources, needs, and practices. Third, the starting point for digital service development might not be the technology-driven digital book and its format, but the understanding of value co-creation opportunities between authors, readers, and stories. By understanding the value creating opportunities, required value network partners can be identified to succeed in moving from digital transition to digital transformation. To summarize, the managers in the book publishing industry can utilize the key findings and the approach of the study for the purposes of (i) reflecting and redefining their strategic vision and assets, (ii) enhancing and modularizing the digital book and its lifecycle to enrich the reading experience and to capitalize on the story, and (iii) to develop co-creation and value co-creation motives and practices with value network partners, authors, and readers.

5.3 Limitations and further research

Every study has its limitations. Although extensive data were gathered from a number of actors and attention was paid in variety of respondents, this study calls for more research on the further possible types of authors and readers, and on value co-creation practices underlying digital services. The validation or prioritization of digital era storytelling presented here could be conducted in terms of the contemporary tendency among book publishing industry players to clearly separate non-fiction from fiction. However, it is hard to dissect the converging categories and new genres such as faction, infotainment, or edutainment. Thus, research on the categories is proposed to focus on story optimization in digital and traditional print contexts: What is the optimal production and publishing format for specific story types? What kind of competences and partners are needed in digital production and the related value network? What kind of criteria can be established for the value co-creation potential related to the story and supportive production platform? Further research should also focus on validating and identifying other digital book types, as well as digital era authors and readers for new opportunity identification for the book publishing industry.

Ecosystem Business Models for the Internet of Things

Seppo Leminen^{1,2}, Mervi Rajahonka^{1,2}, Mika Westerlund³, Riikka Siuruainen¹

¹Laurea University of Applied Sciences, ²Aalto University School of Business, ³Carleton University, Sprott School of Business

This study investigates ecosystem business models (“value designs”), in the context of the Internet of Things (IoT). Based on a literature review and data from a Delphi study and ten in-depth interviews, we show that as IoT companies transform focus from industry-specific applications to applications spanning over multiple industries, the challenges increase substantially. There is a need for changes in industry boundaries and service architectures, which will require developing value designs with the entire IoT ecosystem. Companies and customers are still searching for their roles, and the ecosystems lack many actors. Ecosystem view to business models helps to analyse IoT business models and challenges in building them.

1 Introduction

An increasing number of connected “things” create opportunities for fitting the digital and physical worlds together (Gershenfeld; Vasseur, 2014). This is because commonplace objects around us can be equipped with digital logic, sensors, and networking capabilities. For instance, the recent concept of Industrial Internet refers to integration of complex physical machinery with networked sensors and software to processes (Leber, 2012). Companies are able to use data collected from all kinds of objects, devices, and industrial machines to adjust and automate machine performance. Moreover, many applications will emerge on the consumer side. In this paper, we view that the Internet of Things (IoT) covers both the Industrial Internet and the consumer-oriented Internet of Things. New business models and methods are valuable for delivering services that can be developed through the IoT. Haller and colleagues (2009) define the IoT as a world where physical objects are seamlessly integrated into the information network, and where these objects can become active participants in business processes.

The IoT constitutes a significant potential both for companies and their customers to create new and/or better services, increase revenues or reduce costs, improve quality of processes, and generate new business models. For example, applying IoT information exchange and structures in hospitals, patients will get better and individualized care; in factories the manufacturing processes will become more efficient; all around us devices, vehicles, and machines will last longer with anticipatory maintenance; and traffic will become safer with exchange of weather or traffic information. The IoT bundles together diverse technologies and systems (Fleisch et al., 2009). According to Bucherer and Uckelmann (2011), networked infrastructure of the IoT enables both incremental and radical innovations and business changes and there are almost endless ways to utilize information, because the IoT enables pooling of resources.

Nevertheless, the full potential of the IoT has not yet been leveraged (Bucherer; Uckelmann, 2011), and the business promises of the IoT have not been realized. Previous literature on the IoT has emphasized technology and the business potential, but business models of the IoT have been discussed sparsely. In particular, there is a pressing need for research on the emerging IoT ecosystems from the business perspective (Leminen et al., 2012). Moreover, Westerlund and colleagues (2014) address the urgency to widen current business model studies from a single company point of view to an ecosystem perspective. Thus, this study investigates ecosystem business models, or as Westerlund and colleagues (2014) call them, “value designs”, in the IoT ecosystem context.

This study aims at increasing the understanding on how the business potential of the IoT can be seized, and how the “value designs” in the IoT ecosystems can be built. More specifically, our research questions are:

- What are the challenges and opportunities of IoT-based “value designs”?
- What are the current and future “value designs” of the IoT ecosystems?

The paper is organized as follows. After this introduction, we review previous literature on business models and ecosystems. Thereafter, we explain the methodology and discuss our key findings. Finally, we conclude by discussing the key implications for managers and to the theory, and provide avenues for future research.

2 Literature review

Research on business models has become increasingly popular since the late 1990s. However, literature on business models is still scarce with no commonly accepted view of what the definition of a business model should comprise (Morris et al., 2005; Osterwalder et al., 2005; Schweizer, 2005). According to Zott and colleagues (2011), the literature has viewed business models in many ways, including a statement, a description, a representation, architecture, a conceptual tool or model, a structural template, a method, a pattern, and a set. Moreover, business models are often studied without an explicit definition of the concept. Although there is no widely accepted definition of the concept, scholars have commonly agreed that the *business model of a firm* defines how the company operates in the market and how it creates value (Osterwalder et al., 2005; Rajala; Westerlund, 2008; Casadesus-Masanell; Ricart, 2010; Teece,

2010). Business models are often understood as consisting of components or modules. Shafer and colleagues (2005) identify as many as 20 business model components and categorize them into four main areas, while Osterwalder and Pigneur (2010) discuss nine distinctive business model pillars. It has also been argued that the business model thinking has changed lately. Achtenhagen and colleagues (2013) claim that there has been a change from ‘what business models are’ towards understanding ‘what business models are for’.

Scholars have widely agreed on that a business model is a firm level construct, but they also argue for the business model’s systemic nature (cf. Rajala; Westerlund, 2008). Tikkanen and colleagues (2005) emphasize the role of managerial cognition in the business model evolution, and argue that a business model can be conceptualized as a combination of company related material structures and processes and intangible cognitive meaning structures in the minds of people. The intangible structures of business models consist of belief systems – reputational rankings, industry recipes, boundary beliefs, and product ontologies – and those belief systems may act as constraints in firm’s business model development. Industry recipes express the persuasions of the management related to economic, competitive, and institutional logic of the firm. Boundary beliefs define the identity of the company with a certain inter-organizational community. Product ontologies link product or service attributes, usage conditions, and buyer characteristics into a hypothetically superior offering on the target market. Reputational ranking denotes the own performance of the firm related to its socially evaluated competition.

Zott and colleagues (2010) state that business models represent a unit of analysis nested between a single company and network levels, and they claim that business models help explain both value creation and value capture. Furthermore, Zott and Amit (2008) suggest the business model’s link with the business ecosystem. A firm’s business model is a system of activities dependent of each other not only through the focal company but also through the surrounding network (Zott; Amit, 2010). Hence, business models are linked with the principles of value chains and value networks, as well as business ecosystems. The emerging literature on business ecosystems also suggests the need for a deeper network view on business models (Muegge, 2013). However, it may be argued that the existing business model templates and frameworks are not well suited for analysing the interdependent nature of companies that are evolving in the same ecosystem, because they have been designed for examining the challenges faced by single existing organizations (Weiller; Neely, 2013).

The concept of *business ecosystem* was introduced by James F. Moore in 1993. It stems from the insight that innovative businesses cannot evolve in a vacuum, but they rely on different external resources – they need capital, partners, suppliers, and customers with which they create cooperative networks. According to Moore (1993), a company is – rather than a member of a single industry – a part of a business ecosystem that crosses many industries. Companies act cooperatively and competitively in a business ecosystem to develop and advance new products and to satisfy customer needs. In emerging technological fields, the members of an ecosystem also together create symbolic systems, technological artefacts, relational systems, and routines (Gustafsson, 2010). Thus, an ecosystem and its members coevolve and share a destiny. Furthermore, Westerlund and colleagues (2011) propose that by linking business models with the firm’s external strategy and relationships, researchers can characterize various business models and their differences in the ecosystem context. They (ibid.) emphasize that business model management is important especially when targeting the emerging markets and domains. Bucherer and Uckelmann (2011) stress that involving all stakeholders in a “win-win” information exchange is essential for designing IoT business models.

The IoT is about a large numbers of small and specialized "things", i.e. devices and sensors connected (often wirelessly) to each other and to the Internet. According to Leminen and colleagues (2012), these "things" expand existing Internet applications and services and enable new ones. The IoT increases complexity of communications, and creates and requires increasingly adaptive technical solutions and technical components, as well as new roles. Leminen and colleagues (2012) also argue that the existing literature lacks sufficient understanding and empirical research on what IoT business models are and how they are connected to the underlying ecosystem. The authors (ibid.) also present a framework where they use infrastructure and customer dimensions to visualize a variety of existing and potential IoT business models and to distinguish four diverse IoT business model categories.

Considering the ongoing development of the IoT field, it is obvious that the ecosystem view is becoming more and more important due to actors’ interdependency through technical and business ties. Thus, Westerlund and colleagues (2014) suggest that managers need to shift their focus from the business model of a firm to ecosystem business models, which they refer as “value designs”. They distinct three interpretations of ‘ecosystem business models’: i) a business model with specific properties, or in other words, a business model anchored in ecosystem concepts (cf. Westerlund, 2013); ii) an ecosystem business model (or category of business models) shared by participants of an ecosystem (cf. Low & Muegge, 2013); and iii) a construct explaining how the entire ecosystem works towards common goals rather than how the firm-level business works (cf. Battistella et al., 2013). Following Westerlund and colleagues (2014), we understand these three interpretations as complementary views for understanding business models of ecosystems.

Figure 1. Key pillars of a business model design tool for IoT ecosystems (Westerlund et al., 2014, p. 11).

Westerlund and colleagues (2014) argue that there are deficits in the existing business model frameworks. According to them – besides concentrating on the firm level and not the ecosystem level – the current frameworks focus on the architecture of the business model, showing the “parts of an engine”, but not capturing the dynamics of the model, or “how the engine works”. Thus, they establish a foundation for a business model tool that considers the ecosystem nature of the IoT and focuses on the action instead of the parts. They (ibid.) also argue that because the term ‘business model’ predominantly focuses on a single organization’s business model, “value design” is better suited for ecosystems. The concept of value design illustrates how value is deliberately created and captured in an ecosystem. According to the authors (ibid.), the value design can be conceptualized by four pillars, i.e. ‘value drivers’, ‘value nodes’, ‘value exchanges’, and ‘value extracts’ (see Figure 1).

Value drivers express individual and shared motivations of diverse participants to fulfil a need to generate value, realize innovation, and make money. Especially shared value drivers are important in creating a non-biased, win-win ecosystem. Value nodes include various actors, activities, or (automated) processes, individuals, commercial and non-profit organizations or groups of such organizations, networks of organizations, or even groups of networks linked with other nodes to create value. Value exchanges (or flows) describe an exchange of value by different means, resources, knowledge, and information. Value extract refers to a part of ecosystem that extracts value. It shows the meaningful value that can be monetized and the relevant nodes and exchanges that are required for value creation and capture. Value extract enables to “zoom in” and “zoom out” in the ecosystem to focus on something beneficial for the business. Both a firm’s business model and any part of the ecosystem’s business model can be described with the value design, because value pillars are anchored in ecosystems.

Prior studies on IoT business models have identified versatile challenges in IoT ecosystems (Haller et al., 2009). Westerlund and colleagues (2014) identify the diversity of objects, the immaturity of innovation, and the unstructured ecosystems as challenges to design and monetize the IoT business models. *Diversity of objects* refers to the multitude of different types of connected objects with only modest standardization of interfaces; *immaturity of innovation* means that technologies have not yet matured into products and services, and *unstructured ecosystems* refer to that the participants and their roles are not yet clear in the emerging IoT ecosystems. The authors (ibid.) claim that it is possible to overcome these challenges and design successful business models by focusing on the ecosystem approach of doing business and using business model design tools that consider the ecosystem nature of the IoT.

The challenges presented by Westerlund and colleagues (2014) have certain parity with the managerial cognition perspective towards business model evolution presented by Tikkanen and colleagues (2005). However, Tikkanen and colleagues understand a business model as a company level concept and therefore also the main challenges being at the company-, or particularly managerial level, whereas Westerlund and colleagues emphasise ecosystem level challenges.

3 Methodology

3.1 Research setting and research design

We analysed 47 expert views on IoT business models via a Delphi study as well as in-depth interviews of 11 IoT experts in Finland. We chose the IoT as a research setting in order to contribute to the discussion on ecosystem business models, because emerging ecosystems offer a multitude of opportunities to explore business models and their challenges. Research design explains the path from data and methods to answer to the research questions. This study adopted a multiple-case study design with cross-sectional data from different industries to generate reliable evidence on the challenges and opportunities of business models in the IoT ecosystems. As suggested by Jensen and Rogers (2001) we deploy snapshot studies on cases. Halinen and Törnroos (2005) identify network boundaries, complexity, the role of time, and case comparisons in network research. Instead of focusing relationships between organizations in IoT ecosystems, we focused on case comparisons because each analysed case share similar elements, allowing us for typifying challenges and opportunities, as well as different value design pillars of business models in the context of the IoT ecosystems.

3.2 Data collection

The empirical data were collected from 2012 through 2014, comprising a three-round Delphi study to understand the IoT ecosystems and challenges in those ecosystems. Moreover, we used ten interviews with 11 participants representing eight key organizations in emerging IoT ecosystems to further understand value designs in cases identified in the Delphi Study. We focused on the core actors in the IoT ecosystems, because covering extensive networks requires a substantial amount of time and resources. The interviews were carried out face-to-face and varied between 60 and 120 minutes. The interviews were audio-recorded and transcript for the analysis. We followed an interview guide as suggested by Patton (1990) and collected information on various themes. We discussed with the informants to verify the key findings.

Besides the thematic interviews of Finnish IoT experts this study applied a three-round Delphi study investigating IoT business models. The Delphi study aimed at mapping Finnish experts' views on current and future IoT business models. The first round of the study was launched in early 2012, and the 3rd round took place in mid-2013. Participating experts represented versatile industry fields in Finland; i.e. telecommunication companies, electronics and other manufacturing, related research institutes, and so on. The Delphi method is a systematic, interactive forecasting technique, which relies on the panel and group discussions of experts and participants of the study. The method has been widely used for business forecasting and it has certain advantages over other forecasting approaches. Delphi is based on the idea that the forecasts or decisions originating from a structured group of individuals are more accurate than those from unstructured groups. This has been indicated with the term "collective intelligence". In the standardized Delphi study version, the experts answer to a questionnaire in two or more rounds. After each round, the facilitator summarizes the answers. (Rowe; Wright, 1999)

During the first two rounds of the study we asked the experts to provide case examples of current and potential business models in the IoT context, as well as challenges and success factors regarding these cases. After the 1st round the answers of the experts were summarized by the researchers into nine cases, and the purpose of the 2nd round was to further elaborate these cases and the opportunities and challenges of them. The summarized cases based on rounds 1 and 2 are presented in Appendix 1. According to our criteria, the summarized IoT cases 1) have IoT initiatives on IoT ecosystem, and 2) include several organizational actors involved in the development of a new product/service, a business concept, or social innovation based on IoT. The 3rd round of the Delphi study was more structured and focused on increasing our understanding on the features, success factors, and challenges of the nine cases. The 3rd round questions were structured so that we could analyse the results through classifying theoretical frameworks used in this study. In all of the Delphi rounds, we included open ended questions. By combining all the empirical material gathered with these different methods, we aimed at getting as deep understanding as possible on the new phenomenon and the logics behind new business formation in the IoT environment. Table 1 presents an overview of the empirical material used in this study.

Table 1. Overview of the empirical material of the study.

3.3 Data analysis

We organized the empirical data according to the informant, the date of interview, and the type of informant. First, we organized empirical material, the Delphi study and the interviews, to determine challenges and opportunities of the business models. The original transcribed interviews were analysed using a coding method by the researchers. The words associated with challenges, opportunities and business activities were searched by using the content analysis technique. Following Roberts (1997) and Neuendorf (2002) the aim of the coding and content analysis was to understand the cases. The empirical material was first coded by two authors, and later the identified challenges and business models were jointly compared, discussed and agreed by all the authors. In the second phase, a first round of coding described managerial challenges on business models and compared it to typology on Tikkanen and colleagues (2005). Third, we analysed opportunities of business models in IoT ecosystems. This involved a second round of coding using content analysis with the aim of understanding value linked to the business models in the IoT industry. The value designs were coded and compared with the four pillars suggested by Westerlund and colleagues (2014). Fourth, we investigated the value designs in the IoT ecosystems. At this stage, we analysed case-specific value design in detail, particularly from the point of view of the pillars suggested by Westerlund and colleagues (2014), i.e. value drivers, value nodes, value exchanges, and value extracts. After comparing our interpretations with prior research (cf. Westerlund et al., 2014), we identified previously unknown value designs and opportunities and challenges in IoT ecosystems. Fifth, we synthesized the results and concluded with characteristics of value design business models in IoT ecosystems. Table 2 gives an overview on our data analysis and the phases of the study.

Table 2. Data analysis process.

Data analysis phases	Task	Outcome

4 Findings

This research aims at understanding business models or “value designs” for the IoT and their challenges in the emerging ecosystems. In this paper, our main theoretical starting points included the frameworks presented by Tikkanen and colleagues (2005) and Westerlund and colleagues (2014). We used these frameworks for analysing the empirical material and the existing and future IoT business models presented by the experts in our study. The managerial cognition framework on business models, originally presented by Tikkanen and colleagues (2005), helps to visualize managerial cognitions on business models for the IoT, while the framework by Westerlund and colleagues (2014) enables us to identify and understand the underlying value design – and therefore the firm-, network-, and ecosystem level challenges – in the development of new business models.

The Delphi study helped us to form nine cases on the IoT (cf. Appendix 1). The challenges of these nine cases were analysed via the managerial cognition framework by Tikkanen and colleagues (2005) on the basis of the third round of the Delphi study. We deepened our understanding on the challenges of building ecosystem business models via interviews. A breakthrough observation in our research (before we could proceed in analysing the IoT business models) was to realize that the interviewees were talking about challenges in building ecosystem business models at different levels. Thus, we have to pay regard to the level where the challenges are: are they at the level of a specific firm, its

network, or the emerging ecosystem? We maintain that in building business models for emerging ecosystems, the most critical challenges typically are not at the firm level, but at the ecosystem or network level.

Next, we will discuss our findings; first, we discuss challenges and opportunities in the nine Delphi study cases with the managerial cognition framework presented by Tikkanen and colleagues (2005) and more generally based on our in-depth interviews categorizing them at ecosystem, network and company levels; and, second, we discuss current and future value designs with three additional cases, or ecosystem extractions, based on our interviews with the value design framework presented by Westerlund and colleagues (2014).

4.1 Challenges and opportunities in building IoT value designs

During the first two rounds of our Delphi study, we asked the experts to provide case examples of current and potential business models in the IoT context, as well identify challenges and success factors in these cases. Their case examples were summarized into nine cases. Appendix 1 provides a brief summary of all nine cases retrieved from the experts in the Delphi study. The third round of the Delphi study focused on further inspection of the challenges in the cases and relied on the managerial cognition perspective to business models suggested by Tikkanen and colleagues (2005). We asked the experts if the nine cases would require changes in industry boundaries or operating models (testing industry recipes), in product/ service architectures or structures of the participating actors (testing product ontologies), in the partner or customer base of the participating actors (testing boundary beliefs), or, if the current position/ reputation/ brand of the participating actors would limit their potential in the cases (testing reputational rankings).

Our analysis of business models from the managerial cognition perspective suggests that the most likely challenges in all cases are changes required in industry boundaries or service architectures. Changes in industry boundaries would be needed very likely in five of the nine cases, and changes in service architectures (product ontologies) would be needed very likely in four of the nine cases. Building new IoT-enabled services, such as services for elderly people living in their homes, will require cooperation with actors from many different industries, and very likely also making significant changes into operating models and industry boundaries of these industries. Also, there is a need to develop completely new service architectures for services that span over multiple industries. A summary of all the answers based on the managerial cognition perspective suggests that the most challenging case – according to the experts’ views – is health related products and services. It has challenges in all the four areas of managerial cognition perspective on business models (cf. Table 3).

Table 3. Challenges of the Delphi study cases according to the managerial cognition perspective (Tikkanen et al., 2005) (xx – very likely, x – rather likely).

	INDUSTRY RECIPE: industry boundaries	PRODUCT ONTOLOGY: service architectures / structures	REPUTATIONAL RANKING: position/ reputation/ brand	BOUNDARY BELIEFS: partner/ customer base
1.Traffic Data Marketplace/Databank	xx			
2.Food security tracking system			x	
3.Real-time waste management		x		
4.Health related products and services	xx	xx	x	xx
5.Health guidance service	x	xx		x
6.IoT-adapted manufacturing processes	xx	x		
7.Electronic shopping assistant				
8.Home owner's digital service to monitor and manage facilities	xx	xx		x
9.Saving energy	xx	xx		xx

Our Delphi study suggests that there is a trend of moving from closed, private cost reduction- and efficiency-driven ecosystems towards open, horizontal and networked value adding ecosystems and business models which are spanning over multiple industries (see also Leminen et al., 2012). Moreover, our interviews support these views. When asked about the opportunities of the IoT, the experts mentioned that previously separate industries like health services and housing may be able to offer joint services related to smart home services based on the IoT technologies.

“When services are seen from the consumer's point of view, the same service may include many services from different industries, such as bank, government, and shopping services. In the future, there will be more multi-

sectoral services. If we think too narrowly, we would leave out perhaps the most potential services.” (Manager, Network Company, 2014)

Based on our Delphi study, we found that the challenges are significant, as firms aim at transforming from vertical, industry-specific IoT applications to horizontal applications spanning over multiple industries. Major changes especially in industry boundaries and product and service architectures will be needed. Therefore, we will discuss the challenges raised in the Delphi study and interviews from the value design perspective, and categorise the challenges at the ecosystem, network, and company levels, and thereby “zoom in” and “zoom out”, as Westerlund and colleagues (2014) suggest. In the following section, we present three cases, or ecosystem extractions, to illustrate how the analysis of ecosystem business models can be done using the value design framework presented by Westerlund and colleagues (2014).

When asked about *ecosystem level challenges*, the experts mentioned that – at least in Finland – for the time being there are only isolated actor- or industry-specific incremental innovations in the IoT field, with no clear killer applications or dominant designs or standards. There are lots of small applications that fail to work together. Some of the experts suspected that IoT services will be fragmented by nature, because the customer needs are and will become more and more fragmented. Also standardization of service interfaces, which will be needed in the IoT field in addition to technological standards, will be far more difficult than standardization related to physical things. Although there are publicly funded projects in Finland related to the IoT, proper ecosystems have not yet been formed. Some respondents argued that there is not enough trust among actors; that there are missing actors in the emerging ecosystems, and that there is need for intermediaries who would discuss with potential ecosystem actors and their customers on possible IoT solutions. Many respondents emphasized that the only way to bypass this deadlock situation would be to get concrete pilot projects up and running. These would also concretize the benefits of the solutions for the potential customers. Some respondents wished for new legislation that would force the development of new commercialized IoT innovations, i.e. being value drivers for the IoT ecosystem (e.g., road tolls, stricter rules on food security, energy consumption, or eco-efficiency).

Regarding the more general ecosystem level challenges, the experts mentioned that in some industries there are factors that may slow the development down; for example, the dominance of incumbents, such as ICT or device suppliers, or fragmented structure of the market, or regulation that creates barriers for entering the market. Our Delphi study indicates that developing IoT-enabled solutions for the health sector will face many challenges, and the interviews strengthen this view. The health sector has all the factors mentioned above, namely strong incumbents, fragmented market, and strict regulation, and the experts found it as a particularly challenging, although interesting field. Health-related solutions are difficult to advance because the customers are often public institutions – which are not always considered to be agile or eager to invest or change their partners, or to take new technology into use – and there are many restrictive regulations, which also vary from country to country and sometimes even from city to city.

“As to the IoT, there is not an actor or role of a system integrator, a mediator who would discuss with customers.” (Manager, Network Company, 2014)

“The companies want to focus on their own issues, and this is a major challenge. We have to make somehow them share information and experiences, and form ecosystems.” (Researcher, Technology, Academia, 2013)

“It is unclear who would be interested in driving standardisation in for example health care sector.” (CEO, Sensor Manufacturing company, 2013)

“In elderly care efficiency and cost savings are critical issues in the near future... New business models and service concepts will certainly be needed.” (CEO, Sensor Manufacturing company, 2013)

“Regulation in the public sector makes it fragmented, and it is very difficult to develop services or to get customers there.” (CEO, Local Telecom operator, 2014)

According to the experts, the actor who gathers the data would be the most viable choice for managing the IoT *network*. However, the data must be opened so that several actors have possibility to receive and refine the data that is gathered with the help of the IoT technologies. The actors have to be able to step out of their current roles and develop new services with new partners, including customers and end-users. In order to succeed, the IoT business models need to take account and motivate all actors. Networking and offering wider total solutions with partners is of importance. It is also crucial that the end-customer understands the benefits and wants to pay for the products or services; only this makes mass-markets to come true.

“People understand technology better today. This makes it possible to involve them more in developing services. Customers and end-users should be involved.” (CEO, Sensor Manufacturing company, 2013)

“The actors are stuck into their present roles. They do not see the end-user behind their own customers. The entire value chain should get involved into developing services.” (CEO, Local Telecom Operator, 2014)

Commercialization and networking are considered major challenges for *companies* in Finland. This was emphasized also in the experts' opinions: there is a strong belief among Finns that the Finnish people are good at technology but worse in turning the technology into commercial success. An important point is that the old organizational structures or operating models do not change easily into IoT-enabled models. In the companies, it is nobody's business to develop IoT solutions, there are no incentives to sell them, IoT solutions are not easy to sell because they are not off-the-shelf products, and neither the seller nor the buyer knows what the benefits are of using the IoT. Moreover, as in any ICT or automation solution, business customers are afraid that they will lose their jobs if they buy them. Although the interviewees saw biggest potential of the IoT in new cross-industry services and value creation, a bit surprisingly, among the most common drivers of IoT at the company level were generally mentioned efficiency (including energy efficiency, cost efficiency, efficient production of services, etc.).

"IoT will have a breakthrough only when and if people get clear and concrete benefits." (Manager, Multinational Telecom operator, 2013)

"Communication failures between organizations and within organizations are the reason why innovations do not get commercialized and spread." (CEO, Construction company, 2013)

Based on the situation in Finland, we conclude that congruent to the arguments by Westerlund and colleagues (2014), there are versatile challenges at the ecosystem-, network-, and company levels, and related to unstructured ecosystems, immaturity of innovation, and the diversity of objects (and customer needs).

4.2 The current and future value designs of the IoT ecosystems

In this section, we will further study the value designs for IoT ecosystems, and present three cases, or ecosystem extractions, based on the in-depth interviews. We will employ the value design framework suggested by Westerlund and colleagues (2014) for analysing business models in the ecosystems.

Development of new IoT-enabled business models in the telecom operator industry

The first extraction of an ecosystem illustrates the use of the framework in describing the potential changes in telecom operator industry due to development of new IoT-enabled business models. The extraction covers three different value designs in the ecosystem. The pillars of value designs consist of *value drivers*, such as offering value-adding services or aiming at efficiency, *value nodes*, i.e. actors and resources in the ecosystem, *value exchanges*, such as money and service flows, and *value extracts* which describe the level where the current description of value design is focusing or "zooming" (cf. Table 4).

Some interviewed experts in the operator industry perceived the IoT as 'business as usual' for their company, as machine-to-machine solutions have been around since the 1990s. However, most of them viewed at least some seeds of possible disruption in their own networks due to the global nature of the IoT business or in the birth of global IoT actors (e.g. Jasper Wireless offering global SIMs). As Audi or other manufacturers aim at getting into direct contact with the end-users and bypassing delivery channels by assembling e-SIMs into their products, telecom operators will face both new opportunities and competition, because e-SIMs are not proprietary for a single operator and the customers will be able to easily switch their IoT operators. Both local and multinational operators we interviewed regarding their *value drivers* for getting into IoT business viewed that they want to offer value-adding services for their customers and guarantee efficient use of existing telecom networks. The local telecom operator emphasized offering IoT-based services which make their customers' lives easier and provide them with better customer experiences. As for *value nodes*, both local and multinational operators want to build IoT solutions together with partners. In particular, they want to find smaller firms who develop IoT services in close cooperation with the customers. However, there are missing actors in the emerging networks. The local operator pursues for a role as a local business developing company and, therefore, aims at working with local partners. They are especially interested in offering services for municipalities, although they see that working with those municipalities brings forth many challenges. In the IoT field, there will be also global actors who will act according to their own logics and rules. There is a challenge in the home environment for the local and multinational operators that the IoT increases traffic in the telecom network if people make their own IoT systems or buy IoT services from global actors such as Google or Apple. However, the telecom operator is the one who has to keep its network customers happy and make investments to increase the network capacity, and the challenge is how they will get earnings out of these investments.

Table 4 presents the global telecom operator business model from the perspective of a company using its services. For the companies using services of global operators the benefits, or *value drivers*, will be place independency, global coverage, bypassing supply chains, and being able to offer value-adding services for their customers. A challenge is that it is difficult for the companies to know what the winning technology or who the winning actor will be in the IoT field.

Development of IoT applications for sustainability-based business models

The second extraction on the IoT ecosystems is a company-driven model. For the small company developing IoT applications the *value drivers* are offering services for measuring and calculating energy consumption and ecological

footprints of buildings. For the real estate owner buying these services the *value drivers* are sustainability, and cost- and eco-efficiency. There are challenges in building ecosystem business models for these sustainability-based services at the IoT developer company level related to the *value nodes* – for example finding right pilot customers and partners, and developing suitable algorithms for calculations. In addition, there are challenges at the network level – especially for the telecom operator company whose *value drivers* are building a bundle of sustainability related services or a bundle of real estate services; the operator faces the challenge of missing actors (i.e. *value nodes*) as there are not enough promising IoT service developers. Also at the ecosystem level there are challenges like ownership and opening of the data – if or not the data is available for building the necessary benchmarking databases (which are ecosystem *value nodes*), or if or not there are standards that make it possible or easier to design these kinds of services (which are ecosystem *value flows*). Seen at different levels of the ecosystem or from different actors’ perspectives also value designs, including value drivers, value nodes, and value exchanges, may be slightly different. However, an individual actor confronts the challenges at all levels of the ecosystem – the pains are shared, or as one of the interviewed experts put it: “*We all have the same challenges.*”

Development on bottom-up models for the IoT

The third extraction illustrates bottom-up models of the IoT. In big companies there are certain inertias preventing innovations that in case of the IoT could be overcome with emergence of bottom-up IoT-developer and user communities. The experts we interviewed mentioned some examples of bottom-up models; for example after the disaster at the Fukushima nuclear plant a group of citizens organized radiation follow-up with their own sensors and published their observations in the Internet besides the official follow-up organized by the authorities. Other examples referred by the experts are weather detection networks, e.g. Blitzortung or Lightningmaps (www.blitzortung.org, www.lightningmaps.org), which are communities of volunteers: station operators who transmit their data to the central server, programmers who develop and/or implement algorithms for the location or visualization, and people who assist to keep the system running. These networks consist of several inexpensive lightning receivers and one central processing server, where the stations transmit their data. The *value drivers* for an individual person involved in these kinds of bottom-up models can be tapping into trust-worthy information services cost-efficiently. This means that users may share their own expertise and knowhow and become producing actors (Fleisch, 2010; Kortuem et al., 2010).

Table 4. Three extractions on value designs in the IoT ecosystems

#	Type of business model	Value drivers	Value nodes	Value flows /exchanges	Value extracts	Challenges
1	Network connections and value adding services for local customers (Local telecom operator)	Value-adding services, efficient usage of existing network	Local telecom operator and its partners and customers (businesses, consumers; public sector, municipalities)	Information, service and money exchange between the telecom operator and its customers (also between the customers), network service	Network	Finding partners, getting public sector customers/ partners, getting fair compensation of network investments
	Network connections and value adding services for customers in target countries (Multinational telecom operator)	Value-adding services, efficient usage of existing network	Multinational telecom operator and its partners and their customers	Network service, money exchange, service provided by partners	Network	Finding partners, getting fair compensation of network investments
	Network connections and value adding services for customers globally (Global telecom operator)	Place independency, global coverage, value-adding services for customers, bypassing supply chain	The company and its customers, the telecom operator	Information, service and money exchange between the company and its customers	Company using the service	Relying on a winning technology and actor
2	Sustainability for real estates	Value-adding services for real estates	IoT developer company, customers (real estate owners), telecom operator; databases, algorithms	Information, service and money exchange	Ecosystem	Is the data open? Are there standards?

#	Type of business model	Value drivers	Value nodes	Value flows /exchanges	Value extracts	Challenges
	Value adding services for sustainability or real estates (Local telecom operator)	Creating bundles of value-adding services, efficient usage of existing network	Telecom operator and its customers	Information, service and money exchange between the telecom operator and its customers (also between the customers), network service	Network	Finding partners, getting customers
	IoT service developer	Measuring and benchmarking eco-efficiency (footprint)	Company and its customers (real estate owners), databases, algorithms	Information, service and money exchange	Company developing the service	Developing algorithms, finding partners, getting pilot customers; Who owns the data?
	Real estate owner	Sustainability, cost- and eco-efficiency	IoT service developer/ provider, telecom operator, company and its customers (home owners)	Information, services for home owners, money exchange, brand value	Company using the service	What are the benefits?
3	Bottom up models	Tapping into trustworthy information services cost-efficiently	Individuals producing and consuming, possibly a roof organisation	Peer-to-peer information, central database, payments for devices, programming, visualisation etc. work	Individuals co-producing and using the service	Getting fair compensation of work and investments

5 Conclusions

This research aims to increase understanding on the business models, or “value designs”, of the IoT ecosystems, and the challenges that are faced in building them. In this paper, we showed that designing and analysing business models for the IoT ecosystems require new methods. We presented value designs of three ecosystem extractions with the value design framework by Westerlund and colleagues (2014). The analyses show that there may be many value designs at the same time also in the same ecosystems, and they may coexist. For example the analysis of the telecom industry with the value design framework helps to understand the value drivers, value nodes and value exchanges of different actors and at different levels, as well as, challenges that are confronted in building IoT-enabled ecosystem business models. Both a firm’s business model and any part of the ecosystem’s business model can be described with the value design.

There are three key findings in this research based on the Delphi study, interviews and our analyses above, and they are the following.

There is a trend towards open horizontal IoT applications spanning over multiple industries

According to the Delphi study and interviews of the IoT experts, there can be seen attempts from vertical industry-specific applications towards open horizontal IoT applications spanning over multiple industries, but challenges are still considerable. Today numerous incremental innovations exist, but they are actor or industry-specific and lack working together. Our analysis based on managerial cognition perspective originally presented by Tikkanen and colleagues (2005) showed that building business models that employ opportunities created by the IoT will not be possible without changes in industry boundaries and service architectures. Also according to our Delphi study and interviews, there are a lot of challenges in building business models for IoT-enabled horizontal applications, and they can be classified at ecosystem, network and company levels following Westerlund and colleagues (2014).

Both companies and the customers are still searching for their roles, and the emerging ecosystems lack many actors

Presently, although there already now might be enough awareness on new market opportunities created by the IoT among relevant actors, there is no pressure from the potential customers, because both the business users and consumers seem to be wondering what the application areas and the concrete benefits from emerging IoT technologies would be. We assume that the first killer IoT applications will be rather limited, but revolutionary enough for constituting clear proof for the benefits. So to say, “the proof of the budding is in eating”. The global nature of the IoT may bring forth powerful new actors or user-centric bottom-up development models, and therefore possibilities for disruption. Based on our observations, the IoT experts are becoming aware that the barriers for change will not be overcome without increased networking and cooperation with partners, including potential customers and end-users. However, several actors and particularly intermediaries are still missing in the emerging ecosystems. Also deeper service thinking is needed. End-users should be activated more in developing new innovative services. The managers are aware that

solutions will require developing and piloting services and their business models together with the entire IoT ecosystem. It is not possible to build sustainable business models without moving from fragmented to systemic view on business models, applying the stakeholder win-win approach, and utilizing business model frameworks that take into account the whole ecosystem.

Ecosystem view to business models helps to analyse IoT-based business models and challenges in building them

As discussed earlier in this paper, the majority of business model literature considers a business model as a company level concept, and therefore an implicit assumption is that, also the challenges at building new business models would lie at the company level. However, we argue that the major challenges in emerging technology fields and in emerging business ecosystems, such as the IoT environment, do not lie at the company level, but at business network or ecosystem levels. It is challenging to design business models based on new radical technologies, because the technologies have not yet matured into products and services, and the actors and their roles are not yet formed in the evolving IoT ecosystem (cf. Westerlund et al., 2014). Therefore this study proposes a need for instead of focusing on a company-related business models to more widely sketch ecosystem-wide business models. With case examples of ecosystem extractions we have shown that the “value design” perspective presented by Westerlund and colleagues (ibid.) is useful in the IoT context. Applying their (ibid.) value design framework enables us to define the characteristics of the ecosystem at different levels of it with value design pillars – value drivers, value nodes, and value exchanges – and focus and classify challenges at different levels of the ecosystem by “zooming in” and “zooming out” with value extracts.

The theoretical contribution of this research is increased understanding of how business models can be created in emerging technological fields, such as the IoT environment. For managers, the study illustrates how a novel tool developed by Westerlund and colleagues (2014) for designing IoT-enabled business models in an ecosystem can be used. The results enable managers to route on business model design by focusing on industry-specific or cross-industrial opportunities in an ecosystem.

There are always limitations in research. In this study, we presented the first attempt to analyse ecosystem business models with the “value design” tool for the IoT ecosystems. The data covered emerging IoT ecosystems from the Finnish perspective, in early stages. In other words, the IoT ecosystems are about to emerge and develop, whereas the ecosystems do not have all stakeholders or the stakeholders may change. Acknowledging these limitations, this study calls for more research on IoT-enabled business and value designs in IoT ecosystems. There are ample research gaps related to IoT business models, because generic business model research frameworks have challenges in dealing with emerging ecosystems as the IoT (Westerlund et al., 2014). There are almost endless possibilities to connect a thing, a business, and a consumer together, which makes it virtually impossible to invent a particular “killer” business model (Leminen et al., 2012). Ecosystem business models should be studied more in the future. To sum up, there is need for more research and understanding on ecosystem-wide business models, the roles of actors in ecosystems, and the dynamics of emerging ecosystems, where different industries and clusters are in process of integrating into a larger ecosystem, as in the IoT. The frameworks and methods presented and tested in this paper constitute first attempts to show how ecosystem business models can be analysed.

Following Westerlund and colleagues (2014) an interesting future research topic is how the growing need for the IoT will effect on business model designs more generally. Leminen and colleagues (2012) attempt to distinguish IoT-enabled business models in one industry. Business models crossing various industries are increasingly emerging. Thus the IoT and its value designs have a potential not only to radically change the business, but also our mental models and our ways of thinking about business. More specifically, new research questions may be articulated: how the growing need for the IoT will effect on the value designs of ecosystems; how will this reflect to value designs on IoT-enabled ecosystems particularly.

APPENDIX 1.

Nine cases created based on the experts' answers to the Delphi study, their descriptions and challenges.

	Case	Description	Challenges mentioned
1	Traffic Data Marketplace/Databank	Real-time traffic, environment, weather, condition, incident, etc. related data collected from all possible sources, both public and private. Data collectors, data storages, value added service providers and developers can use the collected data on commercial bases to build end-user services. The customers are value-added service providers (paying for the "raw data") and the users of their services/products.	There should be a focal actor, "marketplace owner" that takes care of data storages and interfaces to/from the storages. Stakeholders are competing of the driver's position in the value chain. Commercial model is pretty challenging / unclear. Proper business models are needed, as well as standards.
2	Food security tracking system	Trace of food products from original material providers to consumers. This model needs to involve multiple IoT service providers. The actors could be for example food manufactures, food vendors, importers, exporters, retailers, standardization organizations, government authorities.	In this system, an international steering group or actor will be needed to take care of the network. Requires many parties and especially international standardization, governmental and other authorities to agree. This model needs to involve multiple IoT service providers.
3	Real-time waste management	Real-time waste monitoring and management uses sensors to reduce the costs of waste collection. Customers will be waste management companies. Those who are paying for waste collection (both private and businesses) may also benefit from reduced costs of waste collection. The technology is likely to be proprietary, potentially using commercial off-the-shelf (COTS) components. The focal actor is a waste management company, or its spin-off. The supply network shall include component providers, communication module providers, communication network providers, solution providers, and an integrator.	
4	Health related products and services	The model is based on sensors and IoT communication infrastructure together with medical expertise. Health is primary need for all the population, and that is why everyone is and will be customers. The model improves quality of life, and reduces sicknesses and costs of health services. Government and public health institutions should trigger the deployment and awareness in the population. Private companies can offer tailor made services and applications for wealthy people.	Issues with standardization, legislation. The need, solution and business case have to be addressed more thoroughly. Too many roads to go - dispersed or overlapping technologies and applications.
5	Health guidance service	Health guidance service can be offered for young and middle aged people. Sensors monitor key parameters and these are analyzed by medical experts. Users will receive warnings on certain parameters and proposals how to improve health status. Technologies for these products and services are sensors and IoT connectivity. Earning comes from private services that provide specific information and additional checkpoints that can be performed with medical experts.	
6	IoT-adapted manufacturing processes	Situation-aware smart machines and robots in manufacturing lines can customize products during the production process. This is cheaper, more flexible and there is less need for human interaction. This also enables decentralization of business processes. Cost savings can be gained, because efficient production lines require fewer employees. Higher average production output generates more revenue. The customers are owners of production lines, warehouses, automated storage facilities or similar. Systems need to be setup by b2b partners, so b2b channels are used to reach customers. Focal actors are producers of smart supply chains and robots or machines for supply chains.	Challenges include high investment costs and interoperability of production line elements with existing IT environment. If used technologies are not be standardized, this causes problems when integrating new machines from other vendors (vendor-lock!).
7	Electronic shopping assistant	Customers are anyone who goes shopping. By pointing on a particular product, key information about this product is listed: price per unit, production/expiration date, ingredients, calories, country of origin, "green information" (emissions etc.), alternative products, cheapest price in surrounding supermarkets, etc. Customer benefits are fast, transparent, reliable and independent information, customized warnings (for diabetics etc.), money savings, healthy and environmentally friendly products. Technology needed is data warehousing, sensor data, and reader devices for users. Focal actors are supermarkets, governments or the WHO (world health organization).	Challenges include high costs of establishing product information system and gathering data. Model is not doable without legislation. Electronic shopping assistant, if understood as "warehouse logistics applied to home icebox etc." does not seem credible, people do not want it (for now at least)
8	Home owner's digital service to monitor and manage facilities	The service would be provided based on plug-and-play devices and access points available to the customer as an installation package. Open and user-friendly applications would be provided, and a possibility to pool services in the neighborhood area, if so wished for example during vacations. The service operator would be a central stakeholder. No expensive built-in technologies would be required and therefore construction companies do not play a role in the business. Still, a version of the service could be directed to publicly owned properties, expanding the present security and maintenance services.	Cost vs. willingness to pay; users technical competence.
9	Saving energy	By measuring temperature with sensors it is possible to decrease energy consumption.	Issues with standardization.

Servitization and Sustainability in the Italian Manufacturing Firms

Luna Leoni

University of Rome "Tor Vergata"

The following is a working paper that aims to analyse two key trends of the modern economy: the Servitization and the Sustainability related to the competitiveness and the survival of the manufacturing firms. Specifically, the main research question of this work is: "What is the situation of the Italian manufacturing firms – both individually considered and compared to EU manufacturing firms average – respect Servitization and Sustainability concepts?". In order to answer the research question, the secondary data analysis has been chosen as the research methodology.

1 Introduction

The last decades are being driven by two key trends: on the one hand Services and on the other hand Sustainability.

We can look at these phenomena as a "new industrial revolution", particularly important for the manufacturing firms, where they could be considered in a circular relationship.

The latter, in fact, in order to stay alive in the current competitive environment and to defend themselves against competition (Santamaría et al., 2012), get closer and closer to the services world, and to the Servitization strategy in particular, thus offering no more than "just" a tangible product, but a *solution* (i.e., a combination of product(s) and service(s) in a single package). These solutions offering has also encouraged the manufacturing industry to approach the renewed needs of sustainability (economic, social and environmental) of its production process in order to better meet the global environmental challenges. The switch towards better environmental performance, manufacturing firms need to apply a more integrated approach, between products and services, often referred to as Product-Service System (PSS).

The importance of both these concepts is particularly acute at the European Union level.

In this vein, we can consider, in particular, two OECD reports. The first one, entitled "Eco-Innovation In Industry: Enabling Green Growth" (2009), said that manufacturing firms "have the potential to become a driving force for realising a sustainable society by introducing efficient production practices and developing products and services that help reduce negative impacts. This will require them to adopt a more holistic business approach that places environmental and social aspects on an equal footing with economic concerns". It is possible to describe this process through the term Eco-Innovation, that "can be generally defined as innovation that results in a reduction of environmental impact, no matter whether or not that effect is intended". Figure 1 provides a description of the steps that a company must address in order to be sustainable.

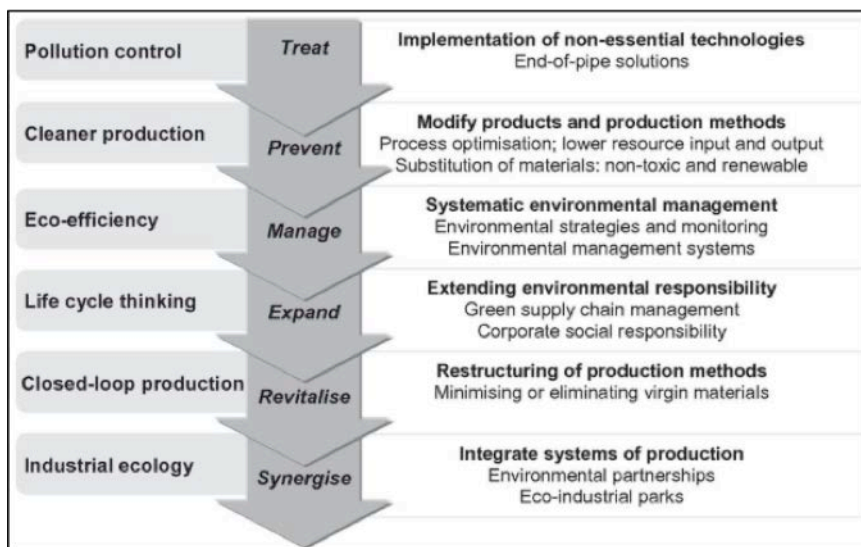

Figure 1. The evolution of sustainable manufacturing concepts and practices.

Source: OECD Report, 2009.

The second OECD report, titled "Manu-services: best of both worlds" (2011), states that more and more manufacturing firms combine products and services into a single offer, becoming service providers (Lay et al., 2010). The term "manu-services" describes this combination and represents "a broad group of activities that involve combining manufactured goods with services. These activities range from fairly simple combinations of goods and complementary services (such as maintenance and installation) to complex integration of manufacturing and services (which may involve providing services such as development, design and after sales care in close integration with the production of a good) [...] but

manu-services are complicated activities, which require firms to coordinate fundamentally different skills. Manu-service firms – especially smaller firms – face a range of challenges and barriers to growth”. In effect, it is a shift that requires to manufacturing firms to change their strategies and to develop new business concepts (Neu and Brown, 2008).

Moreover, services are the main source of job creation across the OECD area, and in the EU-28 the contribution of services (as the sum of the value added by activities such as: financial, insurance, accommodation, business service, etc.) to the gross value added was 73.0%, while that of industry was 19.3%. Focusing specifically on Italy, the contribution of services was 73.7%, a similar percentage to the average of the EU-28 (OECD Factbook, 2014).

2 Theoretical framework

Thus, if manufacturing companies of our time want to continue to operate in the market must therefore take into account the two above-mentioned trends: *sustainability* and *services* (in particular the *servitization* aspect).

Both topics have been studied a lot over the last few decades, but for the purposes of long-term survival of manufacturing firms they must be treated together, both at theoretical level – by researchers, and at practical level – by managers belonging to the manufacturing firms.

Thanks to the numerous studies on the two topics under analysis, it is possible to identify five common points (see Table 1) between servitization and sustainability practices.

Table 1. Common points between Servitization and Sustainability.

COMMON POINTS	SERVITIZATION	SUSTAINABILITY
BE COMPETITIVE	<ul style="list-style-type: none"> • Manufacturing companies are also beginning to realize the strategic importance of servitization in gaining a competitive advantage (Lin et al.,2014) • The debate about services-led competitive strategies continues to grow, with much interest emerging around the differing practices between production and servitized operations (Baines et al.,2011) 	<ul style="list-style-type: none"> • Manufacturing organizations adopt sustainability manufacturing in their attempt to address the triple-bottomline (TBL): environmental stewardship, economic growth, and social well-being (Ocampo and Estanislao-Clark, 2014) • Design for sustainable manufacturing enterprise (DFSME) is considered to be a new ideologue regarding survival of manufacturing enterprise and it can also be considered as one of the most important solutions to deal with the existing global financial crisis (Garbie, 2013)
BE INNOVATIVE	<ul style="list-style-type: none"> • As manufacturing businesses operate in an ever more competitive, global economy where products are easily commoditized, innovating by adding services to the core product offering has become a popular strategy (Visnjic Kastalli and Van Looy, 2013) • The term servitization refers to innovation in company's capabilities to shift from selling of goods to selling of products and services that deliver value in use (Baines et al.,2009a) 	<ul style="list-style-type: none"> • Assessing and selecting the optimal technological alternatives in industrial sector is a fundamental tool to improve and adapt the industrial processes to the European legislation, which encourages the incorporation of new technologies for minimising the environmental impacts of companies such as Best Available Techniques. (Ibáñez-Forés et al., 2014)
ACQUIRE NEW KNOWLEDGE	<ul style="list-style-type: none"> • This company added higher-valued service to their original specialty in the business, transforming an OEM, via industry knowledgelization, to a new model of industrial tourism (Yang and Chiu, 2014) 	<ul style="list-style-type: none"> • Depending on whether initiatives are led by strategic or ad-hoc decisions, firms have to explore new knowledge and/or exploit existing knowledge to realise competitive advantage (Schrettle et al., 2014) • how manufacturing companies can economically introduce environmentally friendly practices to their production operations, whilst at the same time encouraging organisational and operational learning with the aim of eventual evolution of the firm into an eco-efficient concern (Davies, 2012) • It mentions the importance of knowledge and value creation for technological

COMMON POINTS	SERVITIZATION	SUSTAINABILITY

MANAGER INVOLVEMENT	<ul style="list-style-type: none"> • The study unveils buyer-supplier relationships in a servitized context and provides managers with a better understanding of some of the potential implications that the adoption of a servitization strategy may have for managing buyer-supplier relationships (Bastl et al., 2012) 	<ul style="list-style-type: none"> • The Cleaner Production model stands out for promoting the approach of nurturing the concurrent strengthening of quality, productivity, and sustainability in the existing manufacturing processes by dealing more comprehensively with factors internal to the firm that may be directly controlled by the managers (Manzan and Ikuo Miyake, 2013)
CUSTOMER INVOLVEMENT	<ul style="list-style-type: none"> • How resources (both material and human) are optimally designed to co-create customer value (Smith et al., 2014) • Servitization centres on the transfer of risks from the customer to manufacturer (Gubric, 2014) • Servitization aims at supplying a bundle of products and services that offers complete solutions for customers (Demeter and Szász, 2013) • One of the main features of strategies related to servitization is customer centricity (Baines et al., 2009b) 	<ul style="list-style-type: none"> • For manufacturers to fully realise the performance potentials of GSCM (green supply chain management), they need to integrate internal GSCM practices emphasising functional coordination with external GSCM practices such as cooperation with suppliers and customers in the implementation (Zhu et al., 2012)

Source: own elaboration.

Manufacturers need to jointly consider these five aspects in order to be successful.

3 Research methodology

In order to answer the research question, the secondary data analysis has been chosen as the research methodology.

3.1 Research model

Hakim (1982) defined the secondary data analysis as “any further analysis of an existing dataset which presents interpretations, conclusions or knowledge additional to, or different from, those produced in the first report on the inquiry as a whole and its main results”. It is the analysis of data or information that was either gathered by someone else (e.g., researchers, institutions, other NGOs, etc.) or for some other purpose than the one currently being considered, or often a combination of the two, thus it “can include any data that are examined to answer a research question other than the question(s) for which the data were initially collected” (Vartanian, 2010).

Secondary data can arise from both cross-sectional and longitudinal research designs. While SD coming from cross-sectional designs can be helpful for understanding the prevalence of different outcomes at a slice in time (e.g., physical health or the unemployment rate), there are particular benefits of using longitudinal SD. Longitudinal panel data allow comparisons that are otherwise impossible in cross-sectional and trend designs. Longitudinal SD can also be used to explore population-specific characteristics (e.g., urban or rural environments) from currently available datasets that include decades of economic and census data (Feenberg; Miron, 1997). Moreover, longitudinal data inform theory development by providing opportunities to posit causal explanations of events and explore the mechanisms by which processes unfold.

Having regard to Smith *et al.* (2011), Andersen *et al.* (2011), Doolan and Froelicher (2009) and McCaston (2005) works, it is possible to identify 5 key stages that researchers need to follow during a secondary data analysis:

1. Statement of purpose: it refers to the definition of both research topic and question;
2. Identify a research design: a step-by-step plan to guide data collection and analysis;
3. Data collection:
 - Select dataset(s): finding the type of data needed to answer one’s research questions and planning the construction of a personalized data file. The first step in collecting secondary data is to determine which institutions conduct research on the topic area or country in question;
 - Identify the target population and the appropriate unit of analysis of the target population to best address the research question;

- Get information on the dataset;
- Address missing data: Secondary datasets, particularly in longitudinal studies, often have missing data. Procedures for ‘imputing’ values for missing data values have been developed that use information from observed data to create data points that are used to fill-in missing values. One of these imputation methods, mean substitution, substitutes the mean of the variable into the missing values for the variable. This method is generally not recommended because it ignores observed information about the subject for whom the mean is substituted and it can lead to biases in the standard errors. More rigorous multiple imputation procedures have been developed that use the original data to create several different datasets, each with the missing values imputed. The general idea behind these procedures is that observed data from a specified set of predictor variables are used to ‘predict’ or ‘impute’ values for the missing values;
- Record variables;
- Create new variables: Given the breadth of variables generally available in SD, it is advisable to extract a wider range of variables than might originally be thought useful to allow for unique comparisons and possible scale development or the creation of proxies (variables that similarly explain the constructs of interest);

4. Data analysis:

- Structure the analysis: Based on research question, identify appropriate statistical analysis; Select software package that will implement analysis and account for complex sampling; Examine unweight descriptive statistics to identify coding errors and determine adequacy of sample size; Identify weights; Identify variance estimation method (and corresponding variables) and Conduct diagnostic analyses (identify outliers, non-normality, etc.);

5. Findings presentation: conduct primary analysis and interpret results.

It is possible and important highlight the major advantages and disadvantages of this research methodology.

The secondary data analysis advantages are:

- The possibility to save time and resources by making good use of available data rather than collecting primary data, thus avoiding duplication of effort;
- Depending on the level of data disaggregation, secondary data analysis lends itself to trend analysis as it offers a relatively easy way to monitor change over time;
- Persons with limited research training or technical expertise can be trained to conduct a secondary data review;
- Studies funded by the government generally involve larger samples that are more representative of the target population determining a greater external validity;
- Oversampling of low prevalence groups/behaviours allows for increased statistical precision;
- Datasets often contain considerable breadth (thousands of variables);
- The public availability (via electronic records) of most large data repositories enables researchers at any location and level of expertise to access these resources.

While the disadvantages of the secondary data analysis are:

- Compared to primary data, secondary data are imperfect reflections of reality. Without proper interpretation and analysis they do not help understand why something is happening;
- The person reviewing the secondary data can easily become overwhelmed by the volume of secondary data available, if selectivity is not exercised;
- Sources may conflict with each other;
- Because secondary data is usually not collected for the same purpose as the original researcher had, the goals and purposes of the original researcher can potentially bias the study;
- Because the data were collected by other researchers, and they decide what to collect and what to omit, all of the information desired may not be available;
- Data may potentially lack depth (the greater the breadth the harder it is to measure any one construct in depth);
- The inability to select specific questions or measurement instruments, as well as the lack of control over the precise timing of the data collection.

3.1.1 Research question

The arguments in the previous sections allow formulating the following research question:

RQ: What is the situation of the Italian manufacturing firms - both individually considered and compared to EU manufacturing firms average – with respect the Servitization and the Sustainability concepts?

3.1.2 Data sources and datasets

Data were collected by selecting four different data sources. Most of them are official statistics collected by governments and their various agencies, bureaus, and departments. These statistics can be useful to researchers because they are an easily obtainable and comprehensive source of information that usually covers long periods of time. However, because official statistics are often “characterized by unreliability, data gaps, over-aggregation, inaccuracies, mutual inconsistencies, and lack of timely reporting” (Gill, 1993), it is important to critically analyse official statistics for accuracy and validity.

In addition to the official statistics, also technical reports have been considered. Technical reports are accounts of work done on research projects. They are written to provide research results to colleagues, research institutions, governments, and other interested researchers.

When choosing data sources, it is important to consider the level of data aggregation or disaggregation, which refers the extent to which the information or data is broken down. In particular: aggregate data are data that describe a group of observations, with the grouping made on a defined criterion; while, disaggregated data are data on individuals or single entities. These data are generally more informative and useful than aggregate data, because the more aggregated the data, the more invisible the people.

According to the research purpose of this paper the following data sources, datasets and publications have been selected:

4 The Italian manufacturing firms: work in progress

4.1 Macroeconomic framework

In order to analyse the situation of the Italian manufacturing firms both from a servitization and a sustainability perspective, first of all, it is important to describe the macroeconomic framework in which the Italian manufacturing firms operate.

In this context, the first data that it is necessary to consider is the GDP.

Table 3. Gross Domestic Product.

	2007	2008	2009	2010	2011	2012	2013
World	5,3	2,7	-0,4	5,2	3,9	3,2	3,0
Advanced Economies	2,7	0,1	-3,4	3,0	1,7	1,4	1,3
Emerging Economies	8,7	5,9	3,1	7,5	6,3	5,0	4,7
Central and Eastern Europe	5,3	3,3	-3,4	4,7	5,4	1,4	2,8
Italy	1,7	-1,2	-5,5	1,7	0,5	-2,4	-1,9

Source: International Monetary Fund – World Economic Outlook, 2014.

How it is shown in the table 3 in Italy the economic growth remained weak and inferior to both the pre-crisis pace and respect to the average of the other economies considered.

4.2 Work in progress

This paper aims to analyse the situation of the Italian manufacturing firms through the analysis of secondary data.

In order to do so, four different data sources have been selected and twenty datasets have been found.

The next step will be the identification of new variables to analyse the secondary data available through a statistical programme (e.g., SPSS, STATA, etc.).

Challenges of customer oriented health care service models – Perspectives from the renewal of a primary health care and integrated care system

Johanna Leväsluoto, Hannamaija Määttä, Kirsi Hyytinen, Johanna Kohl, Marja Toivonen

VTT Technical Research Centre of Finland

A transition towards a customer-orientated health care service system requires a broader socio-technical and paradigmatic change. The current service system includes established practices which make the paradigmatic changes appear difficult to health care professionals and customers. By using multi-level perspective, social innovation and a chronic care model, we have examined these factors and analysed the challenges from the perspective of two case studies: an integrated care system and the primary health care. As a result, new services, a shared vision, linked development activities, changes in the mindsets and empowering customers to manage their health and participate in developing activities are necessary.

Keywords: Health care, innovations, service innovation, social innovation, systemic change, multi-level perspective

1 Introduction

Chronic diseases are increasing and the ageing of population accelerates this phenomenon. The ageing population means that a larger proportion of people has chronic diseases and at the same time medical scientific knowledge is growing quickly leading to more diagnostic procedures and treatments. At the moment, chronic diseases account for most of health care expenditure. In Europe an estimated 86% of the deaths and 77% of illnesses are caused by chronic diseases (WHO 2014). As a result, major challenges emerge in the health care service system, threatening individual welfare as well as society's development and growth. Because of chronic diseases, health care has changed from individual consultation to multi-professional teamwork with many health care providers (Ouwens et al. 2005). It is also critical to emphasise the role of self care, when dealing with chronic diseases. The WHO's definition of health minimises the role of people's capacity to cope with chronic diseases, as it defines health as a state of complete physical, mental and social well-being, and not merely the absence of diseases or infirmity. There have been suggestions (Huber et al. 2011, Godlee 2011) of changing the definition of health towards the ability to adapt and self-manage when it comes to social, physical and emotional challenges.

Customer-oriented thinking and ways to coordinate services have been suggested as a solution. The aims of integrated care programmes are usually to reduce fragmentation and improve continuity and coordination of care by placing customers in a central position. (Ouwens et al. 2005) However, the discussion on customer-oriented health is not new and the problem has been in identifying effective ways to develop new relationships between health professionals and customers within integrative services delivery systems. Service innovations are needed in order to improve or create new health products and ways of interacting. The individuals and institutions need to move in the same direction and customers need to be empowered to have the knowledge and skills to deal with their illnesses and also with new changes in the health system.

These requirements also reflect a paradigmatic shift in the public sector. This is an important factor, since in most countries the state and local authorities are more or less the organizers and funders of healthcare. The role of the professions has traditionally been very strong in healthcare: interaction has been based on knowledge asymmetry highlighting the position of doctors (and to some extent nurses) over customers (Alvesson, 2004; Löwendahl et al., 2001). The paradigm that understood the public sector in terms of top-down policy activities, was dominant until the so-called 'New Public Management (NPM)', which introduced market mechanisms into the public context: business-type management, lean processes, performance focus, and contracting-out (Hartley, 2005; Hess and Adams, 2007; Windrum and García-Goñi, 2008). One of the most important ideas has been treating the patients as customers who have the right to require a high quality of service (Langergaard, 2011). The limits of NPM, however, have become apparent along with the development towards increasingly complex issues, multiple actors and need for open dialogue (Sørensen, 2002). NPM is still the dominant public paradigm, but there is a new paradigm emerging: so-called 'network governance', which highlights relationships and partnerships, and co-production as the service model (Newman and Clarke, 2009). For the professional practice in public services, it means additional challenges because efficient in-house processes are no longer sufficient, and the crucial issue is the empowerment of citizens and stronger customer orientation.

A change towards a customer-oriented service system is not straightforward. Conversely, the challenges require large-scale socio-technical changes based on the simultaneous development of organisations, technologies, services and multiple network relationships (Gallouj, 1994, 2002; Windrum and García Goñi, 2008; Harrison et al., 2010; Rubalcaba et al., 2011). New innovations are needed so as to ensure the quality of health services and the effective use of resources. Furthermore, understanding of the whole socio-technical system, including the dynamic and interplay between parts of the system as well as the social support and social engagement are essential in aiming at the system

level solutions (Geels, 2002, 2004). New visions and models of health care are needed outside the current system. Koivuniemi and Simonen (2011) have also argued that perspectives from different fields could provide a breakthrough, because the perspectives are not locked into present system and therefore new ideas can occur.

This paper examines the development and introduction of customer-oriented service models in the Finnish health care services. It studies how the transition can be carried out from production-oriented to customer-oriented care models. The analysis is carried out from two different perspectives: from an integrated care system point of view and from a municipal primary care organization. The development of customer-oriented service models in Finnish municipalities can be seen as a niche level innovation. At the same time, it requires system level change.

The purpose of our paper is to identify the challenges of implementing an integrated care model and thus to understand the challenges of socio-technical change in Finnish health care service system. The following research questions are guiding our work:

- What kind of challenges occurs when tackling socio-technical change?
- What are the key factors required to tackle the socio-technical change and implement customer-oriented service models in health care?

At first we describe our theoretical frame work which is based on social innovation, multi-level perspective and chronic care model. Then we present our case studies and continue to the research results. In the conclusion, we discuss the challenges faced in the two cases when developing customer-oriented services, and end with the conclusions of our research.

2 Theoretical background

The current social, economic, and environmental challenges are too big to be met via individual product and service innovations created in individual organizations. A crucial question is how to combine various innovations effectively and how to disseminate them on the basis of continuous interaction between multiple actor-groups. In other words, examining and developing innovations at the systemic level has come to the fore. In order to analyse the complex system level transformation, it is necessary to understand the whole socio-technical system and the process of the social support and social engagement (Gallouj, 1994, 2002; Geels 2002, 2004; Windrum and García Goñi, 2008; Harrison et al., 2010; Rubalcaba et al., 2011.)

Three theoretical frameworks form our starting point in understanding the broad system level transformation in the health care sector and in analysing both complex interaction in development and implementation and new innovative customer oriented services. The first framework is a multi-level perspective to change. It helps in describing the wide development environment of new solutions and the dynamics in developing and disseminating them. The second perspective, social innovation, forms the meso level: here we focus on the bottom-up and top-down activities that function as an engine for the change. Finally, we examine customer-oriented service models in health care; the chronic care model (CCM) and integrated care models based on it as a manifestation of renewal and change activities in health care.

2.1 A multi-level perspective to understand complex systems

We have applied the multi-level perspective (MLP, see e.g. Geels 2002; Elzen et al. 2008) as the overarching theoretical framework explaining the dynamics of transformation in social and health care system. The multi-level perspective facilitates the analysis of the emergence of a new system as an outcome of interaction of different actors and structures and thus provides understanding of the dynamics of systemic change and system innovation. One of the key features of the MLP is its focus on long-term thinking. Another is its explicit focus on the interconnectedness of technological and social systems, including governance models and institutions.

According to the MLP, a crucial element in a systemic change is the interplay between processes in different system parts in different phases of the development and dissemination of new innovative solutions. It stresses that technological systems change through interplay between landscape, regime and niche level processes. Socio-technical landscape refers to relatively stable, slowly changing factors such as cultural and normative values, long-term economic developments and societal trends. The socio-technical regime refers to established practices in the existing socio-technical system, including the institutions, infrastructure, regulation as well as organisational and social networks to structure and organise a particular societal function such as health care. The set of rules (e.g. agreements, directives, moral codes) are carried by different actors (such as users, policymakers, scientists, and public authorities) and practices and action models based on these rules, and interaction between actors. Niches refer to initiatives and activities in special application areas or bounded geographical areas.

Regimes tend to generate incremental innovations, while radically new innovations are generated in niches which are protected from 'normal' market selection. Radically new innovations need protection because their cost efficiencies, technical performance and usability often need improving. Niches provide locations for experiments and learning processes, and space to build the social networks, which support innovation. (Geels 2004, Geels & Kemp, 2007; Kivisaari et al., 2013.) In practice, well planned and long-term management is rare. Governments are deeply embedded within socio-technical system, and therefore they face difficulties in bringing about radical changes. For this reason,

policies tend to aim towards incremental or conservative innovations. (Lovell 2007) Geels (2004, 37) explain that radical innovations break from the niche-level when the external circumstances are right, that is, when on-going processes at the levels of regime, landscape and timing create a window of opportunity. Particular attention is paid to the involvement of ‘forerunners’, i.e. representatives of innovative solutions that challenge the current unsustainable socio-technical systems.

A multi-level perspective sees that transition only occurs through development at all three levels. Practitioners who participate in transition experiments operate in a multi-level environment. The multi-level environment requires them to act strategically by connecting problems and solutions at different levels. From the practitioners’ point of view, the possibilities for guiding transition are limited, because it depends on actors, developments and events at other levels as well. The distinction between the three levels is useful for understanding socio-technical change and can be seen as a tool (rather than viewing them as real entities). (Raven et al. 2010).

2.2 Social innovation as an engine for a renewal

System level innovations are interlinked with social innovations. In the literature on social innovation, the concept ‘social’ includes two different aspects that are both essential when innovations are pursued at the system level. The first aspect refers to the complex economic and social problems form the starting point of innovation endeavours (Harrison et al., 2010). Social innovations are sought for a wide range of issues in different realms of society: community infrastructures, housing, workplace design, education etc. (Moulaert et al. 2005). The solutions include the simultaneous development of technologies, services, organisations and networks. Regarding the goals, social and systems innovations have much in common. Both tackle prominent societal challenges, among which ageing of the population is primary.

In this paper, we concentrate on the second aspect of ‘social’: the participatory processes which are necessary for the emergence of innovations in a multi-actor environment. Also in the novelties created, new ways of interacting is an important ingredient. Social innovations may emerge at the grassroots level among users and employees; be produced by private, public and third sector organizations; or be initiated by policy and regulatory bodies. In all cases, it is essential to integrate bottom-up and top-down processes (Rubalcaba et al., 2012).

Bottom-up grassroots activities constitute an ‘engine of social innovations’ and are linked to user-driven and employee-driven approaches in innovation (cf. Sundbo and Toivonen, 2011). The creation and implementation of social innovations highlights empowerment: citizens are not passive recipients, but active co-developers (Harrison et al., 2010). When social innovation is studied in terms of empowerment and participation it shares similar qualities with Strategic Niche Management (SNM). SNM is a perspective developed as a part of the transition management approach (Schot & Geels 2008), and it focuses mainly on studying the development and diffusion of innovations as a dynamic learning process between multiple actors.

On the other hand, top-down activities are also necessary for the materialisation and dissemination of social innovations. They are needed both at the organisational and community levels and at the level of policies and regulations. Community decision makers and company managers have to support, recognise and organise bottom-up processes in order to make ideas implementable and scalable (Høyrup, 2010). Policy actors have to enhance society’s innovation capacity by revitalising innovation institutions and by fostering the innovation activities of public, private and third sector organisations (Rubalcaba et al., 2012).

2.3 Integrated care programmes as an answer to challenges in health care sector

Within the health care sector, the current pressure for changes is reflected in the renewal for chronic care. The integrated care programmes have highlighted the need for customer support and education, combined with structured clinical follow-up and case management; a multidisciplinary patient care team; multidisciplinary clinical pathways and feedback, reminders, and education for professionals (Ouwens et al., 2005). These programmes are carried out in various countries and are based on the chronic care model (CCM) developed to improve the management of chronic illnesses through six cornerstones: utilizing community resources, developing health organizations, investing in self-management support, redesigning service delivery, employing decision support for professionals and utilizing clinical information systems. Segmenting the chronic customers according to the intensity of care needs is a part of the model. A three-group division, the so-called Kaiser Permanente Triangle - is typical and consists of customers with multiple diseases, customers with high risks, and customers with a self-manageable disease (Bodenheimer et al., 2002). The elements of CCM in integrated care programmes are summarized in Table 1.

Table 1. Central elements of CCM (Bodenheimer et al., 2002 and Ouwens et al., 2005).

Central elements of CCM	Contents of the element in CCM and in the integrated care programmes
Renewal of health care organization	Ensuring that the health organization is committed to take care of patients with lifestyle and chronic illnesses and structured its activities accordingly.
Identification of customer subgroups	Making a division between customers with multiple illnesses, patients with high risks and patients with self-manageable long-term illnesses.
Self-management support and patient education	Helping patients to acquire skills to manage their own illnesses.
Follow-ups	Monitoring the customer on a regular base, e.g. by utilizing phone calls.
Case management	Allocating care to a small team who takes responsibility for the guidance of the customer in the care processes.
Multi-disciplinary care team	A care team composed of different professions who collaborate in the care of defined customer or customer group.
Multi-disciplinary clinical pathway	Structured multi-disciplinary care plans for professionals with detailed steps in the care of customers.
Professional education	Education provided to professionals about the appropriate care for patients.
Supportive information systems	Registry's for patient information and treatment plans.
Community resources	Creating linkages with community-based resources to support care.

CCM, together with the integrated care programmes based on it, differs greatly from the models of acute care and the expert -led health systems that have earlier been dominant in the health care sector; they are customer-centred (not sickness-centred), their focus is on planned, proactive care (not only on the acute, reactive care) and they provide support to the customer (not only diagnostic information). Treating customers as experts in their own health and empowering them to become partners in care is eventually expected to ease economic constraints in the health care sector (Coulter, 1999). An important insight in the circumstances of an ageing population is that the quality of life can be high even when a person has a chronic disease. Health does not only mean the absence of disease, but it includes the capability to cope and function with everyday physical, emotional and social challenges (Huber et al., 2011). The above-described views have sparked the need to examine how the health systems could be rebalanced from addressing the treatment of acute illness to promoting health, and how the citizens themselves could be engaged in the latter task.

3 Case context and methodology

In the empirical part of our paper we focus on two separate cases in order to study the application of customer-oriented service models in Finland. It has been recognised that health care organisations in Finland struggle with the increased customer pressure and reduced resources of health care professionals, and can no longer ensure health impact in the present system. Challenges faced in health are similar to the ones in other Western countries due to the ageing of the population, rising expenditure and growing inequality in the access to services (OECD, 2005). In addition, it has been claimed that in Finland the problems also relate to the small size of the service providers, current service structure and inefficient management system (Kivisaari et al., 2013)

At the moment, there is an on-going preparation for social and health care reform which will be running from 1 January 2017. The key objective in this reform is to promote health and wellbeing and also to ensure equal access to social and health care services in all parts of the country. One objective is also to promote integration between social and health care services and create a seamless package from primary and specialised services. (Social welfare and health care reform)

Our paper is based on two case studies that focus on different levels of operations and management, but the core questions are the same: how to create and promote the use of customer-oriented service models in a complex socio-technical environment. In the health care sector, the adoption of CCM represents a paradigmatic shift towards customer-oriented service systems, and in our analysis we will examine the central elements of the model from two perspectives: from an integrated care system's point of view and from a municipal primary care organizations. The development of customer-oriented service models in Finnish municipalities can be seen as a niche level innovation. So far, consensus for a customer-oriented health care system has not been accomplished in Finland (Virtanen et.al 2011) Our paper identifies the challenges faced by the two case studies and highlights the barriers to why consensus in Finland hasn't been accomplished yet.

3.1 Developing the customer oriented service model for citizens with cardiovascular diseases

The first case study focuses on developing new customer oriented service models for citizens with cardiovascular diseases. The aim is changing the care of people with cardiovascular diseases by implementing a new customer-oriented integrated service model at a local level. The integrated service model is used in regional and university hospitals as well as in primary care. The goal is to create a generic solution, but at first the emphasis is on cardiovascular diseases and implementing a new integrated service model in use at a local level. A service model is developed in collaboration with multiple regional and national partners including a university hospital, a regional hospital, local health centres, 3-sector organisation, research partners and municipalities.

The new customer-oriented service model aims at supporting the operation of health care and medical treatment, controlling the network of service providers as well as encouraging customers to self care. The development of a new service model is focusses on three specific issues. The first is that the customers should be seen as the expert in their own health and treatment. The second is that the customers should be an equal partner with the health care professionals, and the third is that the care process should be customer-centred. An additional aim in the process is to develop tools that enable customers to participate more actively in their own care. One tool created tool is an online navigator, which integrates to personal health record. Online navigator supports self care and, moreover, gives the health care professionals information about the quality and effectiveness of treatment and gives them the opportunity to manage operations. Development has thus focused on both technological and social service innovations.

An idea behind this development is to empower people to take care of their health and treatment for their illness by giving individual and well-timed support and thus improving health outcomes in a sustainable and cost-effective way. However, the change towards these goals is not easy, because the ideology behind the development is fundamentally different from the mindset of the current service system. The new service model brings changes to professional and customer relationships as it empowers customers to become an active part of their treatment. This also requires new models of operation from the customers. Although the need for new service models is identified by professionals and customers, the change is so paradigmatic, it appears to be ambiguous and difficult to grasp. At the same time the customers need to be empowered by the help of a supporting network and national definitions of policies are needed in order to support the change. A shared vision is essential.

Methodology

Our data collection was conducted between 2011 and 2013 via interviews and workshops. At first, we interviewed ten national and regional welfare and health care experts (see Leväsluoto and Kivisaari, 2012). The interviews were carried out between the autumn of 2011 and the beginning of 2012, and the aim was to map the experts' outlook on customer-oriented service models and their adoption into practice.

After the interviews, empirical work continued in workshops with a large network of stakeholders by using participatory foresight, embedding and stakeholder analysis (see Kivisaari, Kohl, Leväsluoto, 2014). One central aim in the workshops was to create a platform where different perspectives were viewed and discussed in order to promote trust, understanding and a shared vision. As the interviews unfolded that shared understanding is essential to change, the study was based on empirical experiment, which aimed at promoting the creation of a shared understanding of what the change entails and how it can be carried out. We focused on studying how transition from a production-oriented to a customer-oriented chronic care model can be carried out.

The empirical experiment was divided into three workshops. In the first workshop, we developed a shared vision with our partners of what customer-oriented services would look like in the year 2030. Based on this workshop, we started developing vision paths for the change. In the second workshop, with large participation of stakeholder from different organisations and levels, we aimed at creating a shared understanding of necessary stakeholders who are essential for the change. The second workshop gave more information for the development of the vision paths. Based on the interviews and the two workshops, we identified three vision paths which represent different levels. The aim of the third workshop was to deepen the understanding on what local stakeholders can do to foster the change.

3.2 Renewal of a local primary health care system

The second study focuses on the renewal of a primary health care system in a middle-sized city of approximately 67 000 inhabitants. The renewal has been going on since 2010 and is linked to a broader national exercise for social welfare and health care. The efforts have been a part of a national development plan for social welfare and health care (KASTE) supporting the development and implementation of the CCM principals altogether in 61 municipalities. The renewal is led by the city's health organization, which is responsible for organizing the primary care services in 8 health centres.

The health organization has been exceptionally active in learning about the newest developments of the CCM model and integrated care programmes and in testing them in practice. The aim is a systemic change in the health service generation, which is why the renewal activities focus on a comprehensive change in the entire operational model. Primary care in the city is under great development pressure due to reduced resources of health care professionals and the constantly growing customer queues that burden the current health care system and hinder the citizen's access to

services. It was recognized that the old system of primary care functioned for the care of acute illnesses and did not support the increasing number of customers with chronic and lifestyle illnesses. Without development actions the system would eventually collapse.

Moving away from the traditional professional expert – led health system and creating a system that supports the self-efficacy of customers has been identified as the key to the transformation. The current system of primary care has been dominated by the traditional ‘expert professional – passive patient’ –approach, and the role of the customers in the care of chronic and lifestyle illnesses has not been actively supported. The care is reactively rather than proactively organized, the self-management of illness is not supported and the care lacks systematics and planning. This is the challenge of the ‘unfinished patient’, which results in the slowness of care processes and expenses caused by long customer queues (Kivisaari et al., 2009). The problem stems from the lack of process management. To create an empowerment –based system of primary care, the health organization is comprehensively renewing its entire operational model; the delivery of services, management the model and ICT systems. Three goals for the transformation have been set: 1) improving the availability of services to citizens, 2) providing better health impact, and 3) improving productivity by reducing the resources used per customer.

Methodology

Our extensive data, which has already been gathered on the case during 2013 and 2014, consists of primary data based on non-participant observations, action research, interviews, research diaries and documentation. It is supported by secondary data including documentation of the renewal process, reports, and the learning diaries of some personnel representatives. To gain an extensive understanding of the transformation, observation, action-research and interviews have been utilized. The weekly meetings of two management teams responsible for renewal activities of the case organization were observed during February and June 2013. During the first three months, our research group observed without any participation to gain an overall conception of the on-going transformation process. For the final two months, we then adopted an action research strategy: participating in the teams’ conversations and pointing out problems related to the systemic change and solutions development. A detailed memo was created after every meeting. The material gathered from the observations and participations has been further supported by individual face-to-face interviews (15 in total) with all the team members. These interviews were conducted in June and July 2013. The observations and action research carry on until December 2013, and during year 2014 the gathering of the case material has continued in monthly workshops with the management team, which will continue until the end of year 2014. This is seen as necessary in order to gain insight on how the innovative solutions and behaviour has developed throughout the process.

4 Research results

Both cases analysed aimed at developing a new customer-oriented service system where customers are seen as experts, and encouraging them to self-management. The need for systemic change towards customer-oriented services comes from the individual need to manage chronic diseases. In addition, the economic pressure and the need to ensure service quality and health impact motivate the renewal. To create a customer-oriented integrated care system is one step towards a system level customer-oriented service system. National coordination and support is needed so as to promote the change, but the bottom-up innovations are equally important.

The need for paradigmatic change is also acknowledged by health care professionals. However, there are different views on what kind of changes are required towards customer-oriented service models, what the time scale should be, and who the actors are that are needed to promote the change. From the point of view of socio-technical change, it is essential to build a shared understanding of what customer orientation means in the social and health care system. A systemic approach can help people to realise that the comprehensive change requires changes in different practices, processes and levels which happens in parallel processes.

To analyse the elements and challenges of adopting customer-oriented service models, we utilized the approaches of the multi-level perspective, social innovation, CCM and integrated programmes. In table 2 we have summarized our results based on elements adopted from these approaches.

Table 2. Elements and challenges in applying customer oriented service models.

Elements	Renewal of a hospital district; integrated care model for people with a cardiovascular disease	Renewal of a local health care organization; primary health care	Synthesis of the two cases
Organisational renewal	<ul style="list-style-type: none"> • Renewal of operation model through an integrated care model which has been created in a customer-oriented way • Identified problems are a lack of indicators to analyse impacts from new service models; management and care divided into silos, identifying the necessary change, how to proceed, who are needed for change 	<ul style="list-style-type: none"> • Renewal of the entire operational model: setting the management of chronic illnesses as the main goal; simultaneous renewal of the organisational structure, management model, financial structure, health services, working methods and tools; creating <i>new service-oriented positions</i>: service managers, service superiors and service coordinators • Understanding the extent of the development and the systemic nature in transforming the organisation is challenging, as these kinds of developmental activities are new to the personnel and include various stakeholders 	<ul style="list-style-type: none"> • The aim is to develop customer-oriented service system which means changes in current operation models • Professionals agree on the need of new service models for chronic care • New indicators are needed to analyse impacts • The scale of the changes needed is confusing to stakeholders and silos between health care organisation complicates development
Customer subgroups identification	<ul style="list-style-type: none"> • Identify different needs of customers and implement customised health treatment plans • new online navigator to identify customer needs • Implementation of the new online tool to be used in hospitals and health centres requires training and time 	<ul style="list-style-type: none"> • Distinguishing customers with chronic illnesses and multiple diseases from customers requiring acute care. Creating care “channels” for these two sub-groups according to the health situation • Segmenting customers is challenging; the health care professionals have a critical role in identifying customers. Constant hurry and old habits influence the guidance of customer flows. 	<ul style="list-style-type: none"> • Identification of different customerships and needs • Developing new services based on different needs • Implementing these new service takes time and recourses
Self-management support	<ul style="list-style-type: none"> • By identifying different customerships professionals can provide specific information to customers about their chronic disease and self-management and support customers to manage their disease and treatment with individual treatment plans • self-care groups and points available 	<ul style="list-style-type: none"> • Investing in services supporting self-management: group services arranged for educating customers about their illnesses and about the prevention of further problems. • Attending group services is new to customers, who are used to getting guidance in person from a health professional; traditional views on how health is promoted dominate 	<ul style="list-style-type: none"> • New services for customers to support self care • Customers are not used to using group services • Offer different self care options to different customer needs
Follow-ups	<ul style="list-style-type: none"> • Online navigator where the customers and health care professionals can keep in touch. Also, text messages and reminders are being used • Using the online tool is not familiar with customers or health care professionals. How to motivate people to use this tool on a regular basis? 	<ul style="list-style-type: none"> • Empowering customers with target-oriented phone calls by nurses to see how the care is proceeding. Focusing on a coaching approach to support customers in achieving goals. • Coaching requires new skills of facilitation, negotiation, synthesizing information and utilization of customers’ own initiatives from the health care professionals 	<ul style="list-style-type: none"> • Aims at supporting self care by using new methods of follow-ups • New services and methods are not familiar to professionals or to customers
Supportive information system	<ul style="list-style-type: none"> • Online navigator programme is a central part of the integrated care model where the customers can see their health and treatment plans, health record, discuss with peer groups and professionals and allocate support • Unconnected data systems are a challenge 	<ul style="list-style-type: none"> • Utilizing eHealth-system for the communication between customers and professionals: allowing customers to see their test results, treatments and health plans, and to transfer the measurements that they make themselves (e.g. blood pressure). • The system is still seen as a one-way communication tool and not a tool for interaction. There are also some challenges to how the system functions 	<ul style="list-style-type: none"> • New IT services for customers and professionals • Customers can see and create themselves information about their health and thus become more aware of their health status

Elements	Renewal of a hospital district; integrated care model for people with a cardiovascular disease	Renewal of a local health care organization; primary health care	Synthesis of the two cases
Customer management	<ul style="list-style-type: none"> Customers have their own doctor, own nurse, coordinator, case or care manager depending on their need Lack of resources Information doesn't move between different organisations 	<ul style="list-style-type: none"> Assigning of a responsible professional/professional group with whom the customer interacts directly regarding the issues concerning the treatment. 	<ul style="list-style-type: none"> Identifying the professional who is responsible of the care In the first case, the signed professional depends on the identified customership while in the second case the concept is about comprehensive coordination of customers
Multi-disciplinary care team	<ul style="list-style-type: none"> Integrated care model is planned so that the multidisciplinary work is at the centre especially in those cases where the need for professional support is the greatest Established boundaries and attitudes between health care professional is causing problems Silos between organisation in health care 	<ul style="list-style-type: none"> Diminishing professional hierarchy; establishing multi-disciplinary teams to collaborate with the customer; supporting holistic care - not focusing on one disease at a time. Old habits dominate; collaboration still occurs in the form of transferring case to another professional and again to another, rather than basing the care on mutual discussion and interaction around the customers' health issues 	<ul style="list-style-type: none"> Multi-disciplinary care is as an overall aim Established boundaries and attitudes between health care professional and silos between organisation prevent multi-disciplinary work
Multi-disciplinary clinical pathway	<ul style="list-style-type: none"> Health plan for all customers with cardiovascular disease Establishing an integrated care model for customers with cardio vascular Implementation of the integrated care model is sometimes challenging 	<ul style="list-style-type: none"> Creating a systematic health plan in mutual collaboration between the professional and the customer according to goals set by the customer Supporting and coaching customers to set long-term goals is new to both professionals and customers. Traditional transactional views on health care hinder the goal-oriented and holistic care 	<ul style="list-style-type: none"> Health plans are created in collaboration between customers and professionals Establishing new integrated care models Setting goals is new when treating chronic diseases
Professional education	<ul style="list-style-type: none"> Professionals have been participating actively in developing and implementing the new integrated care model. Various workshops have been arranged for discussion and development Customers have all the time more information about health issues A barriers is how to motivate the professionals to participate to the workshops Locked-in's in the current system perspective 	<ul style="list-style-type: none"> Arrangement of workshops for the professionals about the re-organizing of care and new operation models around specific topics. Encouraging learning dialogue between professionals Challenges in getting the personnel to become motivated and participate in the workshops. Open dialogue and co-development still lacking 	<ul style="list-style-type: none"> Both customers and professionals need to change their perspective on how to be a customer or an expert. Customers need to become more of an expert on their own care and health care professionals more of a sparring partner Education for professionals on the new services and models Question about how to motivate professionals to participate in workshops and education events
3 sector	<ul style="list-style-type: none"> 3 sector are an essential part and the customers are given information about peer groups and rehabilitation and health training courses On some occasions, it is difficult to get customers to participate these courses 	<ul style="list-style-type: none"> Collaborating with patient organizations, which can provide information, advocacy, peer support, training, rehabilitation and social events for customers Different interests among groups, active collaboration relationship with the third sector is not yet established 	<ul style="list-style-type: none"> Customers are given opportunities and information about 3 sector courses group meetings
Customer voice and empowerment	<ul style="list-style-type: none"> Perceive customers as experts on their own health, using the knowledge that customers have of their own health Requires changes in customer and professional relationships Change do not happen without a crisis and customers are often forgotten Different attitudes and languages 	<ul style="list-style-type: none"> Treating customers as partners in health promotion; empowering them to take their health into their own hands; changing the power distribution in the care process The shift in the professional identity of health care professionals from being a nurturing expert to becoming a coaching partner does not come easy and should be supported 	<ul style="list-style-type: none"> Point of view that only a crises can change the attitudes and the course of action To encourage customers to self care and using their expertise on their own health by offering new services The shift in customer-professional relationship is needed

Elements	Renewal of a hospital district; integrated care model for people with a cardiovascular disease	Renewal of a local health care organization; primary health care	Synthesis of the two cases
Governance, legislation and policy instruments	<ul style="list-style-type: none"> • Shared vision of the future is missing • Investments over sectorial borders • New improvements in Finnish health care legislation • Point of views of politicians' are narrow and divided into silos • Development projects are divided into small projects; continuity is a problem • Hybrid actors are needed to promote change in multiple levels 	<ul style="list-style-type: none"> • Creation of collaborative networks with municipal decision makers; creating partnerships with other Finnish primary health care units • Networking with stakeholders is challenging, as it is new to the organisation and there are no established ways of collaborating; true operational collaboration within the municipality has been missing; confusion of who has the overall coordination responsibility of the transformation 	<ul style="list-style-type: none"> • Supporting health should be seen as a as an overall goal which needs actions from different sectors • A shared vision is needed to promote change towards customer-oriented service models • Who are the responsible stakeholders to promote change?
Pilots and experiments	<ul style="list-style-type: none"> • New service models are needed • Professionals cannot promote change by themselves, customers need to be involved • Diffusion of service innovation is difficult 	<ul style="list-style-type: none"> • Piloting activities are carried out in implementing new services • The feedback-loop from customers and professionals to the development team is missing. Customers are not an active part of the development 	<ul style="list-style-type: none"> • Project needs to be more coordinated so that they support each other and thus new innovation can spread • Customer need to be involved when developing new services

5 Discussion

Both cases analysed aimed at developing new customer-oriented services. Supporting self-care has been promoted by offering services and new tools where customers can see and create for themselves information about their health. This has been done in our first case study by implementing a new online navigator, whereas our second case study has focused more on personal follow-ups by professionals. In the second study, self-care is supported by implementing new services, such as the eHealth system, group services and target oriented contacts from health professionals. In both case studies, the aim was to identify the professionals responsible for the care. In the first case study, the professional is assigned based on identified customership and the needs of the customer. In the second study the idea is to assign a professional responsible for the whole care of the customer. Identifying different needs of customers was one of the key aspects in our first study and it was not emphasized the second study. However, this is most likely because in our first case study the focus was on one disease and its integrated care model, and in our second case study the emphasis was on renewal of the entire primary health care services and investing in holistic care rather than focusing on one disease group. Multi-disciplinary care and clinical pathways are an aim in both our cases. Education of professionals has been offered, and it is seen as an important tool in affecting the attitudes of health care professionals. 3 sector services are also offered to customers as a tool for support self-care.

From the results we were able to identify the key requirements and factors that are needed in pursuing a system level transition in the health care sector. The focus in the renewals should be on strengthening service-thinking in health organizations and care processes. Making the change from the traditional reactive and expert-centred approach to care towards empowering customers in care processes requires creating new service solutions that better serve the needs of customers. From the point of view of ensuring economically sustainable and high quality health care, it is essential to recognise customers' own recourse to self care and to offer extra support for those customers who need help from the professionals. To monitor the success of developed solutions and the extent of health impact, new indicators are also required. Identifying key stakeholders and establishing collaboration networks where hybrid actors can act as a link between regime and niche levels are essential during the development of customer oriented service- models. A shared vision among actors is needed to promote change towards customer-oriented service models. For example, strengthening collaboration with the third sector so that they become an active part of the health system is required so that the care of customers is supported by the provision of information, services and support enhancing health promotion more holistically. The silos between health care organisations are seen as a barrier to implementing services where the customer is seen as a subject and not an object of treatment. Supporting health should be as an overall goal needing actions on the part of different sectors which also highlights the need for stronger coordination of renewal activities.

The collaborative network approach should also reach the health professionals implementing new health services and work activities, as the profound change in health care provision requires a stronger multi-disciplinary team work in treating customers. Forums that enable interaction should be developed and provided so as to support the new ways of collaboration. In health care, established routines are not easy to break down. The transition is also greatly dependent on the transformation of the professional identity from being a nurturing expert to becoming a coaching partner. The willingness and attitudes of both the customers and the health professionals are crucial factors in adopting new practices, and are greatly influenced by prevailing attitudes and values. Adopting new forms and practises of care depends on factors linked to human behaviour and interaction; one significant challenge is the cultural mindset change in the customer – doctor/nurse relationship, which requires a reformation of power distribution – both customers and

health care professionals need to change their perspective on how to be a customer or an expert. The health professionals have to see the customers as partners in care, and the customers need to take a stronger role in promoting their health (see Ouwens et al. 2005). Professional identity does not change overnight, and investing in support, guidelines and education for health professionals as well as for customers in adopting new ways of collaborating is essential, as adopting new practices also requires new skills of facilitation, negotiation, synthesizing information and utilization of customers' own initiatives. The availability of information and the possibility of preparing for the care is a significant development, as the customers have the possibility to access and utilize their own health information.

Another significant factor arising from both our studies is the need for stronger customer participation in developing and implementing customer-oriented service models. Though the language used is changing towards customer orientation (patients are seen as customers, see also Langergaard, 2011), the reality of utilizing customer views in the renewal activities is lacking. The culture developing in health organisations should change from seeing customers only as targets to seeing them as resources for innovation. The lack of customer participation in the health care sector can partly be explained by the fact that innovations in public sector usually originate from disconnected impulses from employees interacting with customers at the grassroots and from managers implementing policy requirements (Sørensen et al., 2013). These two approaches are difficult to merge. However, we argue that in order to achieve true customer-orientation in service models in health, the voice of customers need to be heard and utilized.

6 Conclusion

This paper has examined the challenges of implementing an integrated care model and thus understanding the challenges of socio-technical change in the Finnish health care service system. A multi-level perspective, social innovation and a chronic care model were used as a theoretical framework in understanding the broad system level transformation in health care sector and in analysing both complex interaction in development and implementation and new innovative customer oriented services. Our paper was based on two case studies. The case studies represented first a renewal of a hospital district in developing an integrated care model for cardiovascular disease, and second a study based on the renewal of a local health care organisation focusing on primary health care.

Making the change from the traditional reactive and expert-centred approach to care towards empowering customers in care processes requires creating new service solutions that better serve the needs of customers. Collaboration networks and coordination in development activities are needed to be strengthened and identifying and supporting hybrid actors is one solution to this. A shared vision among actors is needed to promote change towards customer-oriented service models and breaking the silos inside health care is essential. All in all, supporting health should be seen as a as an overall goal which needs actions from different sectors.

Changing the attitudes of both the customers and the health professionals are crucial factors in adopting new practices as well as changing the cultural mindset in the customer – doctor/nurse relationship. Support, education and guidelines are needed to health care professionals and customers in adopting new ways of collaborating. Another significant factor arising from both our studies is the need for stronger customer participation in developing and implementing customer-oriented service models. In order to achieve true customer-orientation in service models in health, the voice of customers need to be heard and utilized.

Travel Experience creation in the context of mobile technologies

Chaoren Lu¹, Wei Geng², Iris Wang²

¹SAMOT, Karlstad University, Sweden, ²Southwest Jiaotong University, China,

The purpose of this paper is to understand how travel experience emerged in distinct context of mobile technologies. Study results show that the combination of characteristics of personal, virtual, networked, and variety functions of mobile technologies enables customers have more initiative to manage and create their travel experience. These findings indicate public transport operators should design different service platforms to let customers create experience by their own initiative. The record emerged through such service platforms can be helpful to have broaden understanding of customer behaviour.

1 Introduction

The customer experience is important for all kinds of services, both scholars and practitioners (Pralhad; Ramaswamy, 2004b; Helkkula et al., 2012) view the creation of such phenomena as an imperative component of the service firm's success. It is vital to not only experience-centric services (Zomerdijk; Voss, 2009), but even non experience-centric ones, such as public transportation.

Yet despite the recognition of the importance of developing superior customer experience in service sector, the academic literature has not considered customer experience as a separate construct. Traditionally, customer experience studies has usually centered on consumption during the service encounter (Zomerdijk; Voss, 2009; Berry et al., 2006; Meyer; Schwager, 2007), focusing on understanding how the firm should create and manage superior experiences for its customers. More recent researches, following service-dominant logic (Vargo; Lusch, 2004), contemplating on both customer and company co-create experiences together (Teixeira et al., 2012; Prahalad; Ramaswamy, 2004b). Lately, service researchers have also begun to explore experiences from customers' daily lives, arguing important component of social context in the customers experience creation (Helkkula et al., 2012).

However, in public transport service, there still exists the confusion of who create experience, the service operator or the customer? The academic literature also exist fragment of when and where customer experience emerged. Especially by given the context of mobile technologies, which enable customer and company have innovative way of interaction in experience creation process.

In this paper, I reviewed the existing service literature of customer experience and expend to public transport service sector to examine whether customer experience creation differs in the context of mobile technologies. This would be done by answering two following research questions:

1. How to understand the different perspective of experience creation in public transport service?
2. What is the scope and temporal of customer experience creation in public transport service? Whether the use of mobile device changes such scope and temporal?

2 Customer experience

Customer experience can be defined as "the internal and subjective response customers have to any direct or indirect contact with a company" (Meyer; Schwager, 2007, p.118). Customer experience has received increased attention since Pine and Gilmore (1998) advocated a new era of experience economy came. Its focus has further developed to a more multi-dimensional and holistic view (Gentile et al., 2007; Verhoef et al., 2009; Carreira et al., 2013).

The holistic customer experience, according to Verhoef et al. (2009), formed through the search, purchase, consumption and after-sale phrases; involved different experience factors (e.g. social environment, service interface, retail atmosphere, assortment and price). Such experience factors can be defined as customer perceptions of all aspects of service that contribute to the customer experience (Carreira et al., 2013). Table 1 synthesizes factors found in the literature that can potentially be associated with travelling.

2.1 Three main perspectives of customer experience creation

After identifying the experience factors that may potentially form customer experience, it is essential to understand the subject who facilitates customer experience creation.

The traditional approach to customer experience creation mainly emerged from management practice and service design literature, which refers to management-oriented perspective (Berry et al., 2006; Zomerdijk and Voss, 2009; Meyer; Schwager, 2007; Edvardsson et al., 2005). This perspective focuses on service providers' experience design, implementation and management capabilities. Accordingly, customers are invited to engage into the pre-designed customer experience stage to purchase experience subjectively. Therefore, firms need to create experience clues within the service process to attract customers' cognitions and responses to certain service. Such clues involves functional,

mechanic and humanic ones, according to Berry et al. (2006). From the point, customer experience creation is controlled under the service providers' capabilities.

The collaborative perspective argues experience has been co-created by both customer and service provider (Pralhad; Ramaswamy, 2004a), much in accordance with S-D logic (Vargo; Lusch, 2004). In this perspective, Teixeira et al. (2012) argue customer experience is not designed; rather it is co-created through customer interactions with service providers and the several service elements. Customer co-create unique experiences through their interactions with a service provider across different touch points, responding to the different designed elements, along with other elements that are not under an organization control, such as the social environment (ibid). Although this perspective confirms the customer initiative within the experience creation process, customer is argued still as invited to join company's value co-creation process.

The customer-oriented perspective posits the customers create their own experience with a service (Helkkula et al., 2012; Verhoef et al., 2009). This perspective, coherent with customer-dominant logic, views customers actively create their own service process and experience landscape by selecting service elements to achieve which experience they looking forward (Heinonen et al., 2010). Inline with this, customer experience is labelled as lived experience emerged from customers' daily life rather than pre-designed by company. Customers invite service providers to join their own value co-creation process rather than opposite.

2.2 Encounter and temporal scope of customer experience creation

The traditional management-oriented perspective views customer experience emerges within the customer-company encounters, where customer experience created at the interaction and purchasing stages (Berry et al., 2006). Such customer-company encounters include all major levels of one's consumption chains. The temporal scope of such experience creation based on all encounters with the service providers, both present and past (Zomerdijk; Voss, 2009).

The collaborative perspective widens the experience creation boundary through pre-, core- and post service encounters. The customer experience is co-created directly with the firm, or/and the other service elements and stakeholders within the service system (Teixeira et al., 2012). The temporal scope of customer experience creation has been viewed over the lifecycle of customer relationship, aggregated all previous and present experiences, rather than only service activities.

The customer-oriented perspective further broadens the scope of customer experience creation that takes into account of not only core service-related experience, but also non-related phenomena, such as social context (Helkkula et al., 2012; Verhoef et al., 2009). This perspective views the customer experiences in a customer context, based on past, present experiences and even future experience, which assumes experience as an ongoing flow of interrelated (Helkkula et al., 2012).

2.3 Customer experience creation in context of mobile technological

Inline with service-dominant logic, travellers create and perceive unique value and experience with close interactions with service providers (Vargo; Lusch, 2004; Kristensson et al., 2004). The combination of portable, personal, networked, textual/visual and converged characteristics of mobile devices enable customer to have closer interaction with service provider and other customers in real-time, and facilitate the customized travel experience (Lariviere et al., 2013).

The converged of technologies enables travels to check online time table before entering or standing at bus station (pre-service activities), get expectation of overall time and transfer methods before or during the journey (imaginary), keep in touch with friends through social network (social interactions), share positive or negative travel experience with friends or social people (post-activities), and do some personal work or read e-book (entertainment), to name a few.

The networked characteristic of mobile devices enable customer purchase multi-channel (online and offline) travel experience simultaneously. Users can optimize their journey by comparison of multiple travel routes or transfer methods together with real situation (multi-channel), or just forms an understanding of current situation.

The ability to communicate with text and visual content, somehow even audio and video information, enable users purchase better imaginary experience, and gaining insight into the circumstances of others, as well as sharing attractive experience.

With the label of personal assets, mobile enable customers to store large amounts of personal information. For instance, customers can create favourites to collect travel routes or bus stations to facilitate faster purchase previous travel information, which create value proposition for future experience (pre-service activities and post-service activities).

Last but not the least, portability characteristic of mobile device enables customer to practically carry out anywhere and use whenever it is needed. Therefore, customer can pick the service elements to choose experience to purchase.

3 Method

This study aimed at an in-depth understanding of customer perceptions and responses to address travel experience in the distinct context of mobile technologies, and as such, a qualitative approach was adopted. The qualitative method is

developed in the social sciences to enable researcher to understand certain social and cultural phenomena with a holistic view, which emphasis the researcher’s opinions and explanations (Berg; Lune, 2004).

3.1 Data collection

Following the qualitative research strategy, interviews and focus group discussion are appropriate method to identifying factors that customers are able to verbalize. Before collecting the data with the passengers, I undertook several interviews with department managers and employees within a public transport operation corporate. The categorize of each journey route, transport operation process, customer reply process, mobile service platform design and other travel variables was made at this stage, in order to consider all factor of variability in each setting of customer observation and customer interviews. The customer interviews were done main at the metro station with the tool of Ipad. The semi-structured interview questions were uploaded online and downloaded through Ipad. The advantage of using Ipad as an instrument is its portable and auto-record function. Observation continued even during the interviews to notice every relevant aspect and non-verbal behaviour. The internal data about customer complaints and feedbacks were collected from the public transport operation company to have broaden view of customer feeling and experiencing even somehow mostly from negative aspects.

3.2 Data analysis

The process of data preparation and collection previously described which contributed to better understand about customer behaviour and emotional process that facilitate further data analysis. The interview texts were analysed line by-line and assigned provisional conceptual codes. The next step is the iterative search to bundle the codes into categories. The goal of such inductive and deductive process is systematic creating appropriate codes and categories. During this process the theory is allowed to emerge from the empirical data to have better understanding about travel experience.

4 Results

To get an in-depth understanding of travel experience based on distinct context of mobile technologies and social media, the study chosen three mobile apps addressing public transport service (Table 2). The main focus of the study is to understand whether the usage of such mobile device influences the scope and time boundary of travel experience. The interview samples comprised 19 passengers with the age of 20s and 30s, which were frequent transport users and transport-related mobile app users.

Table 2. Travel experience factors touched by selected mobile service.

Travel experience factors		Changzhou Pocket Bus	Kuaidi Taxi	Weibo
Related service (Supplementary service)	Information provision	X	X	X
	Intangible artifacts (e.g. mental images, brand)	X	X	X
	Multi-channel	X	X	X
	Staff’s professional skills			
	Pre-service activities	X	X	X
	Post-service activities		X	X
Non-related phenomena (Non-travel service)	Entertainment			X
	Social interactions			X

To explore how mobile technologies influence travel experience creation through the lifelong period, I coded the interview results based on customer feelings and behaviours. After the comparison of passengers’ travel experience in the context of whether or not using the mobile technologies, I coded the interview records while only discussed the difference factors or activities by using or not using mobile technologies. Results of three samples of mobile services were provided as following.

ChangZhou Pocket Bus is developed with the aim to increase the use of public transportation through access to real-time bus and BRT information (See Table 3). By searching from current location to destination, on one hand, passengers can select the suitable solutions for their travel need. The multiple travel routes transfer information and real-time table helps passengers to have better time management and have imaginary experience before entering the travel service. Alarm setting based on bus location provides reliable experience to, especially, office worker, who may sleep on the bus. Storing favorite bus lines and stations is like making key note after reading articles, which provide convenience for further experience purchase. The usage of mobile service let previous travel experience make sense to future experience.

Table 3. Travel experience enhancement based on Changzhou Pocket Bus Mobile service.

Within the context of mobile technology	Past experience	Pre-service	Service encounter	Post-service	Future
No	Bus travel experience.	Check the available bus lines at the bus station.			
Yes	Time saving. Smart decision making.	Check the available bus lines before or after entering the bus station. Multiple alternative travel routes. Automatic positioning.	Set alarm. Customer complaints and suggestions.	Add favorite bus station. Add favorite transfer method. Add favorite bus line.	Time saving. Personal travel setting.

Kuaidi Taxi is a crowdsourcing/service ordering mobile app, the location based service platform is helpful for citizen and taxi driver to have a mutual awareness of each other (See Table 4). It changes the interactive method between customers and company within taxi ordering method, therefore passengers could have an imaginary expectation about the time and location of taxi service. Passengers have more initiative to let taxi to join the passengers’ travel plan rather than any other ways. The online payment method let passengers break the traditional taxi paying boundary, which is more suitable for passengers’ personal behavior. Travel data history sometimes has other functions, such as searching for lost property. This mobile service providers the closer interaction platform between passengers and taxi drivers, compare to traditional taxi order method.

Table 4. Travel experience enhancement based on KuaiDi Mobile service.

Within the context of mobile technology	Past experience	Pre-service	Service encounter	Post-service	Future
No	Taxi calling experience.	Go to taxi rank and wait for taxi.	Payment time: Leave after paying. Pay as the Taximeter shows.		
Yes	Social Identity: Credit record. Travel cost reduces.	Accessibility: Taxi goes to customer. Convenience: Book a time. Imaginary: Make sense of the location of taxi.	Convenience: Payment time. Monetary value: using voucher.	Monetary value: get vouchers to use for next time.	Higher credit record. Taxi ordering knowledge. Review taxi ordering record (lost property).

Sina Weibo is a crowdsourcing microblogging website, has been widely used by public in China. Sina Weibo provides a large variety of information relate to customers’ daily life, through the information source of text, visual, audio and video. Since most people use transport are not going to experience the transport but use it as a tool, many people would like to best use of the travel time to do some personal work or enjoy the on-boarding entertainment (See Table 6). The news and other information provided from Sina Weibo is chosen by each individual customer, which is more valuable than bus on board media based to the users. Rather than receiving information, customers themselves play as the we-media that generate information and sharing with others, especially during the travel time. This platform not only provides the channel for customer to complaint or gives feedback to service company, but let public open to assess such events. The both passive and negative participation into the social interaction let customer enjoy the travel experience, for the reasons of learning knowledge, achieve social identity and so on.

Table 6. Travel experience enhancement based on Sina Weibo Mobile service.

Within the context of mobile technology	Past experience	Pre-service	Service encounter	Post-service	Future
No	On board entertainment: mass media.	Collecting free newspapers.	On board entertainment: information source chosen by media company; already chosen.		
Yes	Enjoyable and fun. Knowledge increasing.		On board entertainment: information source chosen by customer.		Recommended news based on previous using record.

5 Discussion and conclusion

The combination of characteristics of personal, virtual, networked, and variety functions of mobile technologies enables customers and service providers to interact and communicate, produce and consume benefits and create experience in new ways.

a. Transform towards customer-oriented travel experience creation

Travel experience cannot pre-designed by service providers, but constructed varieties of service elements and platforms. From the customer-oriented perspective, passengers create their own travel experience through close interactive with all moments of contact with transport service, as well as some elements that outside the passengers' control (Verhoef et al., 2009; Carreira et al., 2013). In the transport sector, since the core service elements (e.g. service interface, assortment and price) are pre-designed by the service providers, which is uncontrolled by the customers, therefore the travel-related service (e.g. time and location information provision) and non-travel related elements (e.g. social and purpose of travel) plays important role in forming better travel experience. Among the large volume of information resource available online, customer have initiative to pick the service elements as they wish. Therefore, service providers' responsibility to support passengers' travel experience formulation is to provide structured service information, and attract customers' cognitive, affective, emotional, social and physical response to such travel service elements.

One important way to attract and motivate customers to engage in the travel experience is to provide more service elements that previously cannot be controlled now available to the customers. Further, let customer get such awareness. For most passengers, travel experience is based on the utilitarian trip (Carreira et al., 2013), provide convenient interface platform, multiple channel and interactive with other service of customers' daily life can enhance passengers' travel experience. Rather than emphasis humanic element to cultivate customer experience in other service sectors (e.g. retail), in transport service, the shorter waiting time, or in other words, optimize the linkage between transport service to others can maintain travel experience level.

b. Scope and temporal changes in the context of mobile technologies

With the help of mobile technologies, the scope of travel experience was expended compare to traditional travel method. Based on the mobile technologies, passengers can purchase of imaginary and lived travel experience simultaneously through multi-channels (online and offline). For instance, customer monitor the taxi's real-time moving route on the taxi to check whether the taxi driver chosen the detours. Moreover, mobile technologies extend the customers' social interaction scope. Such social interaction can be not only active information searching, but also passive information receiving. The sharing experience of real-time experience with society can somehow benefit passengers' travel experience, vice versa.

The temporal boundary of holistic travel experience is expanded into the customers' life-long context (Helkkula et al., 2012). However, this ongoing flow of travel experience mainly based on feelings, understandings and such emotions components (Verhoef et al., 2009; Helkkula et al., 2012), which is hard to identify by others. By using the mobile technologies, travel experience track can be recorded within a history fold. At least, some intangible travel experience becomes tangible, that provides certain clues to service providers for smart decision making recommendation.

6 Practical implications

Transport practitioners should design different service platforms to let customers create experience by their own initiative. The record emerged through such service platforms can be helpful to have broaden understanding of customer behaviour.

The role of Public-Private Innovation Networks in the development of smart city services: an exploratory analysis in Europe

Alessandra Marasco, Luisa Errichiello

National Research Council – Institute for Service Industry Research

This paper contributes to the understanding of networked innovation for the development of smart city services by leveraging the interpretive potential of Public-Private Innovation Networks in Services (ServPPINs). A conceptual framework is proposed to explore the structure, process and dynamics of “smartServPPINs” and the drivers influencing their functioning and role in realizing technological and non-technological innovations for cities’ smart development. Then a comparative analysis of two European case studies of smart projects and their related service innovation networks is conducted based on the framework, showing its contribution in disentangling the complexity of these collaborative arrangements.

1 Introduction

Recent years witnessed an increasing interest in cities’ strategies and efforts to become smart in response to the societal challenges of sustainable socio-economic and urban development, global competitiveness and improved quality of life. Smart city initiatives involve innovative approaches to develop advanced services in various areas of the city life that are relevant to the needs of the users and the urban environment (Paskaleva, 2011; Nam; Pardo, 2011b). In this direction, several studies point to the importance of partnerships and networks involving private firms, non-market organisations and citizens for the development of smart city innovations (a.o. Komminos, 2006; Schaffers *et al.*, 2011a, 2012; European Parliament, 2014). However, theoretically grounded efforts to understand these complex collaborative arrangements at the crossroad of urban, social and service innovation are still limited. This paper aims at providing a contribution in this direction by leveraging the interpretive potential of the service innovation perspective, namely the concept of Public-Private Innovation Networks in Services (ServPPINs). Recent literature on innovation in services emphasizes the role of these flexible inter-organisational structures between public, private and third-sector organisations for the development of new or improved services, also within the context of public services (Gallouj *et al.*, 2013a; Djellal *et al.*, 2013; Weber *et al.*, 2014). We argue that ServPPINs can provide a useful lens to advance the understanding of collaborative innovation within the complex landscape of smart cities, by properly addressing the complexity of interactions between public and non-profit stakeholders, private firms and users/citizens communities for the development of innovative solutions in response to urban and social needs. Based on research on collaborative innovation in smart cities and on ServPPINs, a conceptual framework is proposed for exploring the nature and role of ‘smartServPPINs’ in realizing opportunities for technological as well as non-technological innovations in the smart city context and the factors influencing their operation and performance. Specifically, the framework identifies a set of nested components for understanding the drivers, structure, dynamics and outcomes of smartServPPINs. On the basis of this framework, a qualitative exploratory analysis of successful public-private service innovation networks in European smart cities is conducted. The empirical analysis aims at shedding light on their features and at identifying the conditions influencing their role in the development of innovations for cities’ smart development. The paper is structured as follows. The next section examines the literature on innovation in the smart city context, highlighting the importance of collaborative arrangements based on the interaction among a variety of stakeholders for developing new and improved city services. Moreover, the main issues and gaps are considered in relation to the analysis of collaborative arrangements in the smart city context. Section 3 introduces the service innovation perspective, notably the ServPPIN concept, as a useful lens to advance the understanding of the complex nature and functioning of public-private innovation networks in smart cities. Against this background, Section 4 presents a conceptual framework for exploring smartServPPINs, which identifies the key components to be investigated for understanding the role of innovation networks to realize new smart city services and the factors influencing their effective functioning. Section 5 presents the results of a comparative analysis of two European case studies of smart innovation projects and the networks associated to them, which is aimed at validating our framework as well as at providing an empirical contribution to existing (but still scanty) knowledge about the characteristics and role of what we labelled smartServPPINs. Finally, in the last Section some conclusions and directions for future research are provided.

2 Enabling the smart city: the role of collaborative innovation

In recent years, the concept of ‘smart city’ has attracted an increasing attention as many cities worldwide have started to develop strategies and initiatives to manage in a more effective way the complexity of urban living and development within the social, economic and environmental domains. Notwithstanding the multiple uses of the term and the lack of a shared definition, a smart city is quintessentially enabled by innovative approaches in urban areas that are based on the symbiotic connection of people, businesses, institutions, technologies, infrastructures and spaces (Nam; Pardo, 2011a;

European Parliament, 2014). Indeed, many studies in this area point to the importance of embracing an open perspective to city innovation, emphasizing a wide range of collaborative models and approaches (e.g. districts, clusters, public-private-people partnerships, living labs, open data, e-governance), which links local government, research institutions, universities, companies, third-sector organizations and citizens into an innovation ecosystem for developing more inclusive, higher quality and efficient services (Paskaleva, 2011; Zygiaris, 2013; Komninou *et al.*, 2013; Schaffers *et al.*, 2011a). Also the current European Commission programs FP7-ICT and CIP ICT-PSP stimulate experimentation into smart cities as open and user-driven innovation ecosystems for designing and piloting innovative solutions based on the collaboration between citizens, firms and local governments (Schaffers *et al.*, 2012). In this respect, Schaffers *et al.* (2011a) distinguish two different layers of collaboration in smart city innovation ecosystems. The first concerns collaboration within the innovation process between research, development, validation and utilisation, with the innovation projects carried out within smart cities being the typical arenas to explore these interactions. The latter concerns collaboration at the territorial level, significantly driven by urban and regional development policies aiming at strengthening the “urban value creation system”. At this level, the creation of effective conditions for innovation is affected by a number of factors, including physical and immaterial infrastructures, entrepreneurial climate, demand for services, policy interventions aimed at stimulating the enhancement of innovation capabilities and the creation of sustainable partnerships among the main stakeholders from business, research, policy and citizen groups. Clearly, both levels of collaboration and their interaction are important to foster the development towards open innovation for smart cities. However, available studies seem to focus either on collaborative approaches at the second level, stressing above all the key role of public-private partnerships (PPP) in urban planning and infrastructure development (e.g. Bevilacqua *et al.*, 2012; Ng *et al.*, 2013; Bakici *et al.*, 2013), or on interactive and user-driven models of innovation, with a particular emphasis on the potential of living labs for co-creating new city services (e.g. Schaffers *et al.*, 2011b; Pallot *et al.*, 2011; Paskaleva, 2011). Moreover, available studies on collaboration for innovation within smart cities are mostly technology-oriented, focusing on its outcomes in terms of new technologies and e-service applications. While technological innovation is a necessary condition to make a city smart, the development and adoption of up-to-date technologies *per se* does not guarantee the success of smart cities initiatives. Indeed, as Nam and Pardo (2011b, 190) underline, the challenge of smart city innovation is not primarily on technology, but on service transformation and improvement, since “the ultimate goal of a smart city is to enhance the overall quality of city services”. This calls for a more comprehensive view of innovation, including also the non-technological human, organizational and political changes associated with the innovative fulfilment of city’s service demands (Nam;Pardo, 2011b). Such a broader view is in line with the concept of social innovation, which is increasingly emphasized within current smart city programs and initiatives (e.g. URBACT II, Periphèria, Human Smart City movement). A core concept to social innovation for smarter cities is the co-production of socially innovative solutions to urban problems with a strong involvement of citizens and non-governmental associations and the diffusion of innovative models of cooperation and social relationships to improve service quality (Ramsden, 2012). By this brief review, it appears that further understanding of the complex nature and role of collaborative innovation in the smart city context would benefit from additional efforts to better take into account the interplay between the different layers of collaboration, the collaborative arrangements involved in innovation processes and the non-technological, social dimensions of smart city innovation.

3 Public-Private Innovation Networks in Services: advancing the understanding of smart city innovation

Recent literature on innovation in services has focused on the role of interactive structures and processes in relation to a general open innovation perspective covering a range of cooperative models (Gallouj; Djellal, 2010). These include Public-Private Innovation Networks in Services (ServPPINs), which involve collaborative partnerships between public, private and third-sector actors for developing, producing and delivering new and/or improved services. ServPPINs are flexible collaborative structures that support the exploitation of complementarities and synergies among different organisations, the integration and sharing of dispersed knowledge, technology, competences and potential risks in uncertain innovation processes. These inter-organizational arrangements are a specific type of innovation networks, being characterised by three fundamental features (Gallouj *et al.*, 2013a): firstly, the interaction between public and non-market actors and private actors occupies a central role; secondly, service providers act as the main actors in the networks; and, finally, they build upon a broad conceptualization of innovation, including also non-technological forms (i.e. organizational, process, cognitive, conceptual, network-based). Moreover, they are ‘naturally’ characterized by customer/user interactivity and involvement in innovation processes, given the endogenous role of customers in service co-production. The relational configuration of ServPPINs can widely vary depending on the actors involved, their role and the degree of formality of relationships among them. Further, it is subject to change during the networks’ lifecycle, which can be described in terms of the three main phases of initiation, emergence and wider implementation or uptake (Green *et al.*, 2013; Weber *et al.*, 2014). Empirical research on the structure and operation of these networks in transport, health, tourism, knowledge-intensive services highlights that their success is determined by four main interrelated sources (Rubalcaba *et al.*, 2011): a) the role of both internal and external drivers, including trust, pro-innovation culture, leadership, a right strategy between bottom-up or top-bottom approaches, financial and political support, technological opportunities and policies concerning innovation, public procurement, employment and skills, sectoral development; b) the integration within wider systemic and social networks; c) the ability to overcome barriers

in areas such as the rigidity of public administrations, the existence of different interests and incentive systems, free riding, asymmetric information and networking competences, appropriability; d) the reduction of evolutionary inefficiencies, concerning the risk of not being efficient enough to adapt to the changing phases of networks' lifecycle. Recent studies have emphasised ServPPINs as a viable means for approaching, from a network-based perspective, a field of innovation that is still largely underexploited, namely innovation in public services (Djellal *et al.*, 2013; Weber *et al.*, 2014). Indeed, research in this area pays a growing attention to innovation models for the public sector, given the increasing complexity underlying the goal of public value creation for service users, citizens and society as a whole in an era of economic and financial crisis where traditional mechanisms of public provision such as the State and the Market are no more adequate. In particular, it is highlighted that innovative solutions to modern challenges can be effectively developed, promoted and maintained through multi-actor collaborative structures that enable public, private, third-sector and civil society actors to interact in a complementary and synergistic way in joint innovation processes (Weber *et al.*, 2014). In this viewpoint, ServPPINs have been suggested as a viable alternative for realising innovations to existing models, such as outsourcing of public service provision and contractual PPPs. Moreover, it has been shown that these structures represent a suitable organisational mode for social innovation, facilitating the collective creation process necessary for the development of new solutions to societal needs (Djellal; Gallouj, 2011; Rubalcaba *et al.*, 2013). For their features, ServPPINs can thus be as a valuable concept to explore innovation networks in smart cities and advance the understanding of key factors influencing their effective operation and their role in realising innovations for cities' smart development. Indeed, these new inter-organizational arrangements describe the way in which multiple public, private, third-sector and civic actors interact to produce not only technological innovations but also social innovations. Thus, they allow to address public-private collaboration for innovation through a more holistic view, by taking into account the complexity of networked innovation processes in the context under examination in terms of actors' heterogeneity, relationships' dynamism and variety of innovation outcomes.

4 A Framework for Exploring Public-Private Service Innovation Networks in smart cities

Drawing on studies in the field of collaborative innovation in smart cities, ServPPINs and previous research (Errichiello; Marasco, 2014), a conceptual framework is proposed for disentangling the complexity of smart service innovation networks (smartServPPINs) and understanding their role in realizing opportunities for service innovations. The framework (Figure 1) identifies a set of nested components that include: 1) the structural features, processes and dynamics of the network; 2) the innovation outcomes produced at various levels; 3) the broader smart city innovation context; 4) the networking regime related to a given smartServPPIN.

Figure 1. The conceptual framework.

The first component concerns the *smart city innovation context*, which creates opportunities and constraints for networked innovation influencing the general features and properties within which specific ServPPINs develop and operate. Major components of this broader context include (Schaffers *et al.*, 2011a; Rubalcaba *et al.*, 2011; Weber *et al.*,

2014): features of the general political and institutional environment at the city level, i.e. laws, regulations, policy interventions and government investments, which can shape and foster infrastructural/technological development, employment and skills, entrepreneurship, innovative conditions, collaboration; cultural and social norms, in terms of business climate, entrepreneurial spirit or the diffusion of a pro-innovation culture at the urban level; level of commitment and strategic action along one or more smartness areas (i.e. smart economy, smart mobility, smart environment, smart living, smart governance, smart people) directly affecting the overall “endowments” of a smart city (Giffinger; Pichler-Milanovic, 2007) and reflecting different degree of integration, coordination and interaction capabilities of local stakeholders (and the public actors in particular) in managing smart initiatives and projects (Achaerandio *et al.*, 2012). The smart city innovation context influences the evolution and performance of smartServPPINs from their outset and over time, providing the key external drivers for the initiation of a given project and the related collaborative network, its development along a specific trajectory and its effective operation. In this respect, empirical research on ServPPINs has identified a number of key driving forces that, according to our framework, can be considered as emerging from the broader smart city innovation context. These include (Gallouj *et al.*, 2013a): technological and market opportunities, customer demands, environmental concerns, concrete actions from public or semi-public institutions in the form of programmes, institutional/political support, semi-public coordination, financial incentives and funding opportunities for specific projects. In the smart city context, in particular, the ‘public mission’, i.e. the intention to improve the quality and efficiency of city services, can be viewed as a key driver in all those cities actively involved in the implementation of a smart development plan. Next to city-level conditions, the smart city innovation context also includes ‘inter-city’ factors that reflect the positioning of a city in a broader arena where other cities are actively engaged in implementing smart development programmes. In this respect, an important factor is represented by the level of rivalry among cities aspiring to become ‘valuable practices’ of smart city development. Indeed, this factor can directly influence cities’ capability and effort to access financial or knowledge resources that are assigned to specific smart initiatives and projects through competitive schemes.

The second component, namely the *networking regime*, includes the set of relational conditions that can foster or hamper networked collaboration at the project-level. This can be connected to the overall atmosphere of the relationships¹⁷⁶ (among network members) *à la* Håkansson (1982), which arises from the overall state of closeness or distance, power-dependence, conflict or cooperation and mutual expectations of the parties involved in a specific smartServPPIN. On the one hand, this component is embedded in (and thus is conditioned by) the broader smart city innovation context, which actually influences the openness of firms’ towards collaboration and their innovation capabilities; on the other hand, it includes a number of internal conditions that influence the dynamics and performance of the innovation network with variable intensity and often in combination. The networking regime provides key drivers for the initiation of a smartServPPIN that can be considered sine qua non conditions of collaboration, but remain essential throughout the innovation process. These include (Bryson; Crosby, 2006; Emerson *et al.*, 2011; Gallouj *et al.*, 2013a; Weber *et al.*, 2014): leadership, commensurability and non-rivalry of needs and interests, complementarity of competences. As for mutual trust, although it is widely recognized as a precondition for initiating collaboration at the inter-organizational level, innovation networks can also start with low degree of mutual trust. Indeed, what is crucial for successful collaboration is the capability of trust building along the innovation development process (Ring; Van de Ven, 1994; Vange; Huxham, 2003). Similarly, prior relationships or integration in existing social networks at both local and extra-local level (*structural embeddedness*) - though not always required for the initiation of a smart city project - can facilitate the formation and maintenance of collaborative innovation networks since it is often through them that actors can judge the trustworthiness of other potential partners (Ring; Van de Ven, 1994; Bryson; Crosby, 2006), increase their attitude towards risk-taking and a pro-innovation orientation. However, the influence of the collaborative regime on the smartServPPINs dynamics and performance is not unidirectional. Indeed, over time, the network itself affects the emergent features of the collaborative innovation regime, since it contributes, for example, to accruing the capability of the parts to exploit complementary skills, to maintaining commitment towards a common goal, to reducing unbalance between firms (e.g. large firm dominating), to conciliating different culture, interests and competences (e.g. among public and private actors).

The third dimension relates to the *structure and process* of smartServPPINs, which can be described in terms of actors’ roles, their competencies and contribution to the different stages/activities of the innovation process, the forms of arrangements, the governance and interaction mechanisms. These arrangements can vary widely, for example, depending on the number and type of actors involved, which can be from the public administration, the policy-making area, the research system, the private business sectors, the third-sector, the civil society. It is to be noted that often smartServPPINs have an open ‘geographical’ character that goes beyond the boundaries of the city, because they include actors from other cities and regions that are gathered together by the same transnational project and funding. For

¹⁷⁶ The concept of atmosphere is part of the Interaction Model developed by the Industrial Marketing and Purchasing (IMP) Group to understand the interaction process in dyadic relationships and the embeddedness of these in industrial networks. In this model, the interaction occurs within an atmosphere arising from the closeness, dependency, expectations and cooperation of the parties, and is further contained in a larger environmental system. In his seminal work on the Interaction Model, Håkansson (1982, 29) notes that the variables related to the atmosphere “are not measured in a direct way in this study. Instead, the atmosphere is considered as a group of intervening variables, defined by various combinations of environmental, company specific, and interaction process characteristics. The atmosphere is a product of the relationship, and it also mediates the influence of the groups of variables”.

example, this is the case of the transnational innovation networks that participate to the several European smart city projects aimed at transferring and testing innovative solutions in each of the partner cities (e.g. Genius Open – URBACT; CitySDK – ICT PSP; Open Cities - ICT PSP). Moreover, their initiation can be based on a top-down approach, driven by public action, as well as by bottom-up initiative, based on the voluntary engagement of other actors. Further, these arrangements can be characterized by a ‘caretaker’ mode, in which one actor plays the role of conductor, hub actor or systems integrator, or by a ‘distributed’ nature, in which responsibilities are more diffused among the actors (Galloway *et al.*, 2013a). Overall, the structure and process of smartServPPINs need to be considered in a dynamic way, in order to take into account the evolution of the network over time that can be described as a life-cycle (Green *et al.*, 2013; Weber *et al.*, 2014), distinguishing between the three main phases of initiation, emergence and uptake. The first one is characterised by the development of a shared vision among partners of needs, benefits, contributions as well as of the basic operating mechanisms; the second phase involves the full operationalization of the network along with the finalisation of agreements, the establishment of more sophisticated and practical structures and processes, agreed roles, lines of communication, milestones, leadership, and decision-making; in the third phase, the goals of the network have been achieved in the case of successful network formation and the network could be terminated or continued in a further project where opportunities exist. Throughout these phases, smartServPPINs are likely to change and evolve along most of their dimensions, including composition, roles of actors, governance/communication mechanisms, networking regime, external and internal enablers.
