Design thinking and effectuation in internal corporate venturing: an exploratory study

Thomas Abrell¹, Markus Durstewitz², Falk Uebernickel¹

¹University of St. Gallen, ²Airbus Operations GmbH

This study examines design thinking and effectuation in internal corporate venturing. By researching five internal corporate venturing projects in their early stage from idea to concept to a project that is funded and staffed, we reveal elements of effectuation and design thinking from the viewpoint of the corporate entrepreneur. We find that corporate entrepreneurs work mainly following an effectuation logic, especially through their own means, while elements of prediction are imposed through decision gates in the case company. Furthermore, we find connections to design thinking. We conceptually compare design thinking and effectuation and contribute to the body of knowledge through bridging design thinking and effectuation to internal corporate venturing as well as the connection of design thinking and effectuation.

1 Introduction

Design thinking and effectuation are two concepts related to innovation that recently gained attention of both practitioners and academics. Design thinking is a methodology that “imbues the full spectrum of innovation activities with a human-centered design ethos” (Brown 2008, p.86). In today's economy, change is becoming increasingly important as well as knowledge becomes more significant (Toivonen & Tammela 2013) and business is becoming more entrepreneurial (Sarasvathy 2001). This external change demands also for internal change in established corporations (Kuratko et al. 2011), leading towards a focus on innovation. Corporate entrepreneurship in form of internal corporate venturing is one way to achieve innovation (Guth & Ginsberg 1990). In order to successfully innovate through corporate entrepreneurship, it is necessary to offer the right environment (Ireland et al. 2009) and thus know how corporate entrepreneurs work. Sarasvathy's (2001) logic of effectuation aims to explain the expertise of expert entrepreneurs. Design thinking and effectuation share the same origins rooted in Herbert Simon's (1969) groundbreaking work “The Sciences of the Artificial” (for design thinking see Johansson-Sköldberg et al. 2013; for effectuation see Sarasvathy 2008). There have been recent attempts to compare effectuation to creative approaches such as bricolage (Fisher 2012; Archer et al. 2009). Despite shared origins, effectuation and design thinking have not been compared.

There have been recent attempts to bridge design thinking to corporate entrepreneurship (Abrell & Uebernickel 2014) as well as user involvement in internal corporate venturing (Abrell & Durstewitz 2014). The logic of effectuation has been recently extended to the corporate context through researching effectuation in corporate R&D projects (Brettel et al. 2012) as well as theoretically addressed (Svensrud & Åsvoll 2012; Duening et al. 2012). Nevertheless, design thinking and effectuation have not been researched together in the corporate context.

We utilise a framework from Hassi & Laakso's (2011) literature review of design thinking in the management discourse and conceptually compare design thinking and effectuation. On the basis of this comparison, we research five internal corporate venturing projects from the viewpoint of the corporate entrepreneur in their early stage from idea to a concept until a project which is funded and staffed. We discuss our findings in light of the initial research model and conclude with managerial implications.

2 Background and Conceptual Model

2.1 Design Thinking

Design thinking has been discussed in the design discourse already since Simon's ground-breaking work “The sciences of the artificial” (Simon 1969). Since then, the discourse evolved from the creation of artefacts towards design thinking as reflexive practice, problem-solving activity, a practice-based activity towards the design as creation of meaning (Johansson-Sköldberg et al. 2013). In the managerial literature, design thinking has gained momentum as an approach to innovation (Hassi & Laakso 2011), reflected in a steep increase in the number of publications from year 2000 onwards (Johansson-Sköldberg et al. 2013). Brown (2008, p.86) describes design thinking as “a methodology that imbues the full spectrum of innovation activities with a human-centered design ethos”, with particular emphasis on “thorough understanding, through direct observation, of what people want and need in their lives and what they like or dislike about the way particular products are made, packaged, marketed, sold, and supported”. Besides product innovation, design thinking has been particularly interesting for service innovation (Stickdorn 2010).

Hassi & Laakso (2011) conceptualise design thinking in the management discourse as a combination of practices, thinking styles and mentality aspects. The ‘practices’ encompass a human-centred approach, thinking by doing, visualising, combination of convergent and divergent approaches as well as collaborative work style (Hassi & Laakso

2011). The ‘thinking styles’ category includes abductive reasoning, reflective reframing, a holistic view as well as integrative thinking (Hassi & Laakso 2011). The ‘mentality’ component includes experimental and explorative, ambiguity tolerant, optimistic and future oriented (Hassi & Laakso 2011). The level of analysis is the individual applying design thinking.

2.2 Effectuation

The concept of effectuation has been introduced by Sarasvathy (2001) as a theory explaining entrepreneurial decision-making under uncertainty. She contrasts effectuation with causation, where a certain effect is given and means are selected to achieve this effect (Sarasvathy 2001). Effectuation is described as the logic of entrepreneurial expertise with logic defined as a “consistent set of ideas that forms a clear basis for action upon the world” (Sarasvathy 2008, p.17). Sarasvathy (2001) initially proposed four principles that have been further developed in her subsequent work into five principles of entrepreneurial expertise (Sarasvathy 2008):

1. means-driven in contrast to goal-driven action: to create something new with existing means rather than to select between different means to achieve a given goal;
2. affordable loss: decision-making based on what one is willing to lose in an experiment opposed to calculating expected returns;
3. stakeholder involvement based on pre-commitments to the project to form strategic alliances;
4. exploitation of contingencies through embracing opportunities that develop over time;
5. controlling an unpredictable future: effectuation focuses on the controllable aspects of an unpredictable future, meaning that the entrepreneur him- / herself is the prime driver of opportunity.

2.3 Conceptual model of design thinking and effectuation

The concepts of design thinking and effectuation have a shared origin in Herbert Simon’s *The Sciences of the Artificial* (1969). Effectuators see both firms and markets as human-made artifacts, thus effectual entrepreneurship may be seen as a science of the artificial (Sarasvathy 2008). Design thinking is discussed in the designerly and management context (Johansson-Sköldberg et al. 2013). Johansson-Sköldberg et al. (2013) see the sciences of the artificial as the first of five discourses in the designerly context. However, the concept of design thinking departed since then to the reflection on actions of designers, solving wicked problems, designer’s practice and the creation of meanings (Johansson-Sköldberg et al. 2013). Nevertheless, there may be more similarities between the two concepts.

Hassi & Laakso (2011) distinguish in the management context between practices, thinking styles and mentality. Their model as shown in Table 1 is the base for our conceptual model of design thinking and effectuation. The collaborative work style category corresponds to involving stakeholders in effectuation – who I know in the means category as well as stakeholder involvement. Combination of divergent and convergent approaches may be compared to exploitation of contingencies. Thinking by doing may be compared to experimentation and affordable loss. Effectuation may be the logic behind applying different practices of design thinking. An experimental and explorative approach in design thinking is also comparable to effectuation (Hassi & Laakso 2011; Sarasvathy 2001). Tolerance for ambiguity is necessary in order to deal with uncertain future – one approach is to do small experiments. Optimism and future orientation cannot be directly translated, although belonging to the effectuator. While means are abstract, practices may be the concrete application of means.

Sarasvathy’s definition of logic as “consistent set of ideas that forms a clear basis for action upon the world” (Sarasvathy 2008, p.17) may be comparable with Hassi & Laakso’s thinking styles.

Our conceptual model is based on Hassi & Laakso’s (2011) categorisation of design thinking. For each element delineated by them we looked for insights from effectuation.

Table 1. Elements of Design Thinking (Hassi & Laakso 2011) and Effectuation.

Practices		Thinking Styles		Mentality	
Design Thinking	Effectuation	Design Thinking	Effectuation	Design Thinking	Effectuation
Human-centred approach e.g. people-based, user-centred, ethnography, observation	Means-driven (Sarasvathy 2008) in connection with user involvement (Abrell & Durstewitz 2014) importance of external stakeholders (Toivonen & Tammela 2013) customer-involvement (Brettel et al. 2012)	Abductive reasoning e.g. the logic of „what could be“, finding new opportunities, urge to create something new, challenge the norm	Creation of opportunities through abductive processes (Sarasvathy et al. 2010)	Experimental & explorative e.g. the license to explore possibilities, risking failure, failing fast	Affordable loss (Sarasvathy 2008) Experimentation and means (Chandler et al. 2011; Brettel et al. 2012)

Practices		Thinking Styles		Mentality	
Thinking by doing e.g. early and fast prototyping, fast learning, rapid iterative development cycles	Controlling an unpredictable future (Sarasvathy 2008)	Reflective reframing e.g. rephrasing the problem, going beyond what is obvious to see what lies behind the problem, challenge the given problem	Exploitation of contingencies (Sarasvathy 2008)	Ambiguity tolerant e.g. allowing for ambiguity, tolerance for ambiguity, comfortable with ambiguity, liquid and open process	Expert entrepreneur knows that pursuing opportunity is a process with an unknown end (Wiltbank et al. 2006) Exploitation of contingencies (Sarasvathy 2008) Effectuation way to manage under uncertainty and high ambiguity (Brettel et al. 2012; Duening et al. 2012)
Visualising e.g. visual approach, visualising intangibles, visual thinking		Holistic view e.g. systems thinking, 360 degree view on the issue		Optimistic e.g. viewing constrains as positive, optimism attitude, enjoying problem solving	
Combination of divergent and convergent approaches e.g. ideation, pattern finding, creating multiple alternatives	Experimentation (Chandler et al. 2011)	Integrative thinking e.g. harmonious balance, creative resolution of tension, finding balance between validity and reliability		Future-oriented e.g. orientation towards the future, vision vs. status quo, intuition as driving force	Importance of tacit knowledge and gut feeling in effectuation (Svensrud & Åsvoll 2012)
Collaborative work style e.g. multidisciplinary collab. involving many stakeholders, interdisc. teams	Stakeholder-involvement based on precommitments (Sarasvathy 2008)				

In terms of practices, the importance of external stakeholders and user-based innovation (Toivonen & Tammela 2013) is highlighted as well as partnerships and customer-involvement (Brettel et al. 2012). Also Sarasvathy's (2008) concept of means can be mentioned as Abrell & Durstewitz (2014) found that the means of corporate entrepreneurs are a crucial factor whether users are involved or not. Nevertheless, one main difference between effectuation and design thinking may be in the human-centred approach. Despite the connections outlined here, the concept of effectuation can be characterised more as entrepreneur-centred (Sarasvathy 2001) rather than human-centred.

Thinking by doing may be connected to controlling an unpredictable future (Sarasvathy 2008), as the entrepreneur acts according to his / her set of means to achieve fast learning and iterative development cycles. A combination of divergent and convergent approaches can be described as experimentation (Chandler et al. 2011). In terms of collaborative work style, stakeholder involvement based on pre-commitments (Sarasvathy 2008) can be seen comparable to design thinking.

In the thinking styles category, abductive reasoning can be compared to the creation of opportunities through abductive processes (Sarasvathy et al. 2010), while reflective reframing points towards exploitation of contingencies (Sarasvathy 2008), as the problem may be rephrased when embracing opportunities that develop over time.

In the mentality category, the item experimental and explorative corresponds to Sarasvathy's (2008) principle of affordable loss, which is based on deciding how much one is willing to lose in order to gain new insights. Also the concept of means is mentioned by Chandler et al. (2011) and Brettel et al. (2012). The latter point out, that means alone may not be influential, but how they are enacted in an experimental manner (Brettel et al. 2012).

In terms of ambiguity tolerance, it is mentioned that expert entrepreneurs know that pursuing an opportunity is a process with an unknown end (Wiltbank et al. 2006), pointing towards the exploitation of contingencies (Sarasvathy 2008). Effectuation is seen as a way to manage under uncertainty and high ambiguity (Sarasvathy 2001; Brettel et al. 2012; Duening et al. 2012).

Lastly, effectuation is future-oriented, as the importance of tacit knowledge and gut feeling has been outlined (Svensrud & Åsvoll 2012), corresponding to the importance of intuition as driving force (Hassi & Laakso 2011).

3 Methodology

To study effectuation and design thinking in internal corporate venturing, we conducted a single case study with embedded sub-cases (Yin 2003). Sarasvathy (2001) call for studies examining particular decisions in particular

functional areas inside firms using case studies. Case studies take into account the context in which phenomena occur (Eisenhardt & Graebner 2007) and are specially suitable when the boundaries of phenomena and context are not clearly drawn (Yin 2003), as it can be observed in corporate entrepreneurship (Kuratko et al. 2011).

Despite the limitations of a single case study design, we chose this design due to the unique access we got for this study, i.e. a revelatory case (Yin 2003) as well as that we aim on getting the viewpoint of the corporate entrepreneur in different stages of internal corporate venturing. The research setting provides us with a shared context to be able to draw conclusions for the early stage of internal corporate venturing projects.

The corporation in which the study took place employs over 50.000 people and offers high-tech investment goods in a business-to-business environment. We got the unique access to join the corporation’s support structure for internal corporate venturing for four months in 2013 to conduct the study.

The sub-cases (called sub-case A-E) were chosen due to theoretical sampling based on the current stage the internal corporate venturing project is currently in. We focused on a early stage and derived a classification from Burgelman’s (1980) stage model of internal corporate venturing with the categories idea, concept and project and intermediary stages from idea to concept, as well as concept to project.

Table 2. Overview of the cases.

Sub-case	A	B	C	D	E
Stage	Idea to concept	Concept to project	Concept to project	Project	In service (after project stage)
Data collection method	Interview, document analysis, design-probe, co-creation workshop with lead entrepreneur	Interview, document analysis, design probe, co-creation workshop with lead entrepreneur	Interview, document analysis, co-creation workshop with lead entrepreneur	Interview, design probe, co-creation workshop with lead entrepreneur	Interview, co-creation workshop with entire team

To triangulate our findings, we used four data collection methods: interviews, document analysis, design probes and co-creation workshops. To immerse into the context and gain information on the sub-cases from the perspective of the support structure we conducted ten exploratory expert interviews. In each sub-case, we conducted a semi-structured interview with the lead entrepreneur, lasting from 90 to 240 minutes to grasp the nature and development of the project. In each interview, we asked a set of specific questions to reveal the lead entrepreneurs logic in terms of effectuation and causation. Due to confidentiality reasons, audio recording of the interviews were not possible, therefore we relied on written notes of the interviews and processed them into a structured documentation after each interview.

In addition, we were able to study documents of the sub-cases A-C. We conducted in total three daylong co-creation workshops with similar structure, but changing participants. Before the first workshop was conducted, we did a pilot workshop with students to iterate the tasks. The workshops followed the Lego Serious Play method (LEGO Group 2010) to reveal tacit assumptions of workshop participants through building with Lego bricks and giving them meaning and sharing it with other workshop participants. During each workshop, one moderator as well as one documenting person was present. Both the moderator as well as documenter took structured notes that were supported by rich visual material such as the Lego models and pictures.

Table 3. Participants of the co-creation workshops.

Workshop	Participants
Workshop 1	Five experts from support structure
Workshop 2	Lead entrepreneurs sub-case B and D, one expert support structure
Workshop 3	Lead entrepreneurs sub-case A, C, E, one expert support structure involved in sub-case E, additional entrepreneur sub-case E

Lastly, design probes were given to three lead entrepreneurs to document one week as corporate entrepreneur. Design probes are a method to explore human-centred phenomena and the context of a person (Mattelmäki 2006). Of the three design probes, two probes were returned and taken into account.

We addressed internal validity through a continuous analysis of our data during the data collection (Eisenhardt 1989). We conducted first a within-case analysis of each sub-case, and subsequently compared the findings to identify patterns.

4 Findings

The findings outlined in Table 4 are a combination of the in-depth interviews, co-creation workshops, design probes and document analysis. We centred our questions around the elements that have shown a connection between design thinking and effectuation.

Table 4. Case study findings.

Sub-case Question	A	B	C	D	E
Was your starting point a vision, which you wanted to achieve through own skills or a concrete goal?	Concrete goal, but solution emerged	Vision (starting with a problem and an open end)	Vision (“it happened like this”), building on another idea and taking the principle and applying it to another context	Vision	Concrete goal
How did you conduct activities?					
linear or iterative?	Iterative	Iterative	More linear (one iteration to bring the new idea to the new application)	Strongly iterative	Iterative, used design thinking, agility and sprints
based on your own means?	Yes, learned new skills on the way	Never asked him-/herself the question, just started	Completely, yes	Means-driven (powerpoint-prototype for example)	Yes
through small experiments based on affordable loss? (opposed to expected returns)	Tried various versions, small experiments	Not expected return	Small experiments, prototypes, low-tech, did not acquire any funding (only time invested)	Affordable loss – experiment to share IPR with expert in order to get idea into implementation	(no answer)
Did you ask yourself “What can I do? Who do I know, which resources can I get?”	(no answer)	“Never doubting”, “never reflected if (he/ she) can bring it to end”	(no answer)	Yes	Team member had the skills, was interested, learning, personal time and was able to make a prototype and pitch it to top management
Did people enter the project self-selected?	No, only the support structure showed interest (and his/ her manager)	People interested, but nobody entered the project	One person who first had a competing concept – they gave each other mutual feedback, later worked closer together	No, but hoped for it	Yes
Did the outcomes of the project reshape?	Yes, slightly, but main idea stayed the same	Yes, a lot, and in completely different directions	Yes, the concept got refined and the first idea changed to the second	Yes, strongly because of customer experience	Re-shaped only in details
Did you seek partnerships?	No, worked alone and got feedback from manager	At the beginning yes, but then disappointed	Yes, sought partnership with one fellow corporate entrepreneur	Protection because of bad experiences, but now tries again to seek partnerships	No partnerships
How did you deal with unexpected situations? Did you use uncertainty as a source of opportunity or did you try to avoid it and quickly overcome the situation?	When dealing with unexpected situations take the time to get distance and then work on it	Acknowledged and source of opportunities	(no answer)	Source of inspiration (to invent out of necessity)	Overcome quickly
Did you create a plan? When? What was the reason for it?	No	Only with the support of the support structure to develop the idea further and bring it to the market	No	Yes (beginning)	Yes, with sprints and releases, but not too much planning in the creativity part (more in implementation)

In terms of elements of effectuation, a mixed picture emerged from our results. None of the sub-cases showed only elements of effectuation or causation. Sub-case A shows elements of causation such as having a concrete goal, trying to avoid uncertainty and no partnerships. Sub-case B follows mainly an effectuative approach, although nobody entered the project self-selected. The support structure imposed elements of causation, i.e. writing a plan. Sub-case C combines elements of causation such as linear development with elements of effectuation (iteration, own means, self-selected stakeholders and partnerships). Sub-case D created a plan in the beginning, but worked in a highly effectuative way. Sub-case E started with a concrete goal and avoided uncertainty but worked in an effectuative way. The work was done based on own means and highly iterative. Depending on the educational and professional background and the means of corporate entrepreneurs, activities were emphasised or neglected. Corporate entrepreneurs with a technical background worked first and foremost on feasibility, while those with a business background were more thinking of the customer experience.

Corporate entrepreneurs were working highly iterative. In sub-case E, the lead entrepreneur mentioned that they were following a design thinking approach. All sub-cases agreed that they were developing their idea into an internal corporate venturing project based on their own means and developed new skills on the way. Also small experiments were conducted in all sub-cases except sub-case B and E. In sub-case B, the lead entrepreneur emphasised that the activities were not conducted to get rich. Sub-case D mentioned experiments related to affordable loss in terms of shared intellectual property rights to get the idea implemented. In terms of unexpected situations and uncertainty, we received mixed results. Sub-case A reported that getting distance to unexpected situations helps to overcome the situation. Sub-case D embraces uncertain situations as a source of opportunity. We did not receive an answer on this question in sub-case C. Sub-case D emphasised uncertain situations as a source of inspiration, while sub-case E tries to overcome the situation quickly.

Planning was not conducted at all by sub-case A and C, and only with the support of the support structure or internal corporate venturing in sub-case B. Sub-case D conducted planning in the very beginning, while sub-case E conducted planning in the implementation phase, but not so much in the creative part of the project. When asking about means in the way “What can I do? Who do I know, which resources I can get?”, we did not receive an answer from sub-case A and C. In sub-case B, the lead entrepreneur did not ask himself the question, while sub-case D did. In sub-case E, one team member had the skills, was interested, learned new skills, invested personal time and was able to make a prototype and pitch it to top management.

In terms of self-selected team members, we got mostly negative answers (sub-case A, B, D). In sub-case C and E, entrepreneurs joined the team self-selected. The outcomes of the projects reshaped completely in sub-case B, C, D, slightly in sub-case A and E. Partnerships were not considered in sub-case A and E. Sub-case B and D had disappointing experiences concerning partnerships, and only sub-case C achieved a partnership.

The means of corporate entrepreneurs caught our special attention. Depending on the education and professional background of the corporate entrepreneur, the person possesses a different network as well as different skills. Due to this, activities were conducted or neglected. Corporate entrepreneurs with a business background neglected technical development, while engineers mainly focused on feasibility - all engineers neglected business development activities in the idea phase. In addition, others in the organisation focused on the set of means when arguing against an internal corporate venturing project – such as engineers argued with feasibility arguments against an idea from a corporate entrepreneur with a business background. Such arguments were hard to invalidate by the corporate entrepreneur. Furthermore, the study revealed that the means determine whether a corporate entrepreneur actively develops an idea further or not, i.e. because they are distant from the corporate entrepreneur’s core competency. The activities conducted were conducted to the means of corporate entrepreneurs that are unique to every corporate entrepreneur. Corporate entrepreneurs only engaged in initiatives that were perceived feasible to pursue – this feasibility aspect was strongly connected to the own means. New means were acquired during the project. However, means that were not easy to acquire because of their distance to the corporate entrepreneur’s core competency lead towards a more passive role.

Planning was conducted mostly late – the roughness of the first draft was emphasised as a main difference of the internal corporate venturing track opposed to other channels for innovation in the case company. Corporate entrepreneurs emphasised that a long detailing process should be avoided. In addition, the process was conducted in an iterative, nonlinear way, with intense phases as well as phases when the innovation was not developed further. Prototyping, both in early as well as later stages was regarded important to demonstrate the feasibility of the idea. Small experiments were conducted.

Elements of causation were mostly imposed by the gates in the case company and the planning requirements needed to pass the gate and proceed with getting funding to develop the product / service idea.

5 Discussion

In the discussion, we translate the answers from the findings above to the model introduced in section 2. The base of the discussion is thus Table 5, with the empirical findings of our study in bold letters.

Table 5. Elements of Design Thinking (Hassi & Laakso 2011) and Effectuation with empirical findings (in bold).

Practices		Thinking Styles		Mentality	
Design Thinking	Effectuation	Design Thinking	Effectuation	Design Thinking	Effectuation
Human-centred approach e.g. people-based, user-centred, ethnography, observation	Means-driven (Sarasvathy 2008) in connection with user involvement (Abrell & Durstewitz 2014) means-driven (5/5 cases) importance of external stakeholders (Toivonen & Tammela 2013) customer-involvement (Brettel et al. 2012)	Abductive reasoning e.g. the logic of „what could be“, finding new opportunities, urge to create something new, challenge the norm	Creation of opportunities through abductive processes (Sarasvathy et al. 2010)	Experimental & explorative e.g. the license to explore possibilities, risking failure, failing fast	Affordable loss (Sarasvathy 2008) Experimentation and means (Chandler et al. 2011; Brettel et al. 2012) small experiments and affordable loss (4/5 cases) iterations (5/5 cases)
Thinking by doing e.g. early and fast prototyping, fast learning, rapid iterative development cycles	Controlling an unpredictable future (Sarasvathy 2008)	Reflective reframing e.g. rephrasing the problem, going beyond what is obvious to see what lies behind the problem, challenge the given problem	Exploitation of contingencies (Sarasvathy 2008) Outcomes reshaped (5/5 cases)	Ambiguity tolerant e.g. allowing for ambiguity, tolerance for ambiguity, comfortable with ambiguity, liquid and open process	Expert entrepreneur knows that pursuing opportunity is a process with an unknown end (Wiltbank et al. 2006) Exploitation of contingencies (Sarasvathy 2008) Effectuation way to manage under uncertainty and high ambiguity (Brettel et al. 2012; Duening et al. 2012) Ambiguity source of opportunities (2/5 cases) versus overcoming fast (2/5 cases, 1 no answer)
Visualising e.g. visual approach, visualising intangibles, visual thinking		Holistic view e.g. systems thinking, 360 degree view on the issue		Optimistic e.g. viewing constrains as positive, optimism attitude, enjoying problem solving	
Combination of divergent and convergent approaches e.g. ideation, pattern finding, creating multiple alternatives	Experimentation (Chandler et al. 2011)	Integrative thinking e.g. harmonious balance, creative resolution of tension, finding balance between validity and reliability		Future-oriented e.g. orientation towards the future, vision vs. status quo, intuition as driving force	Importance of tacit knowledge and gut feeling in effectuation (Svensrud & Åsvoll 2012) Vision at the beginning (3/5 cases)
Collaborative work style e.g. multidisciplinary collab. involving many stakeholders, interdisc. teams	Stakeholder-involvement based on precommitments (Sarasvathy 2008) no self-selected stakeholders (3/5 cases) and no partnerships (4/5 cases)				

Our empirical findings suggest a strong relevance of the concept of means as it was mentioned in all of the cases as a central element to the development of the idea towards a project that is funded and staffed. Without funding, the corporate entrepreneurs have to rely largely on their own means. However, as Abrell & Durstewitz (2014) point out, means are crucial to obtain a human-centred approach, as users may not be reachable due to company policies.

Sarasvathy (2008) highlights the importance of stakeholder involvement as one central element of effectuation. Our study suggests that there may be a difference between effectuation in entrepreneurship and corporate entrepreneurship as the corporate entrepreneurs reported no self-selected stakeholders and no partnerships. A collaborative work style as in design thinking (Hassi & Laakso 2011) could not be observed, however would be highly beneficial due to the

possibility to enlarge the means of the project team through different skills. As corporate entrepreneurs in the case company had networks largely in their own functions, interdisciplinary teams and multidisciplinary collaboration would need to be facilitated.

Reflective reframing (Hassi & Laakso 2011) could be observed, as the outcomes reshaped in all cases. An experimental and explorative approach (Hassi & Laakso 2011) could also be observed. The corporate entrepreneurs conducted small experiments and followed the principle of affordable loss as well as worked highly iterative. Lastly, the corporate entrepreneurs worked future-oriented, with a vision at the beginning of their entrepreneurial endeavour.

6 Conclusion

Through this study, we contribute to the body of knowledge by conceptually linking the concepts of design thinking and effectuation and empirically explore the model in the context of internal corporate venturing. Thus, we contribute to the discourse of effectuation through empirical evidence of elements of effectuation in a corporate context, especially connected to the concept of means. Furthermore, we contribute to the discourse of design thinking through first evidence from design thinking in a corporate entrepreneurship context.

Design thinking and effectuation show several conceptual connections – both highlight the importance of involving external stakeholders, experimentation, reflective reframing, ambiguity tolerance and future orientation. In the early stage of internal corporate venturing, we find that the means of corporate entrepreneurs are crucial to successfully develop the idea into a concept. Self-selected stakeholders and ambiguity tolerance have been seen critical, which may be a major difference to effectuation in the entrepreneurship context.

Our study opens important implications for practitioners, especially in support entities for internal corporate venturing. The means of corporate entrepreneurs can be complemented through interdisciplinary team building as well as training.

Inclusive trade: the promise of the global empowerment network

Usman Ahmed, Hanne Melin

eBay Inc. Public Policy Lab

This article presents research results demonstrating how small businesses in emerging and developing markets, making use of the Internet and technology, export to multiple different destinations. We argue that a new system for engaging in globalization now exists, parallel to the Global Value Chains model. We highlight the policy and legal conditions that support this development towards more inclusive global trade.

1 Introduction

Up until now it has only been the few largest players who have been able to take full advantage of trade and globalization. If a small business wished to participate in the global economy it was largely relegated to providing an intermediate product to a large multi-national supply process (the so-called Global Value Chains model). This model for trade is the result of the immense resources that have traditionally been required to develop an international customer base and deliver a product or service efficiently across borders.

A parallel model for trade is emerging. Technology, particularly drawing on the Internet, is now enabling businesses of all sizes to trade directly with consumers around the world. We refer to this emerging model as the “Global Empowerment Network”.

The Global Empowerment Network brings together a set of conditions, such as Internet connectivity, digital services, and logistics solutions. These conditions contribute to an emerging borderless system adaptable to the needs of individual firms. However, the full potential of this model depends on the right policy, legal and administrative solutions.

This article explores the power of the Global Empowerment Network. Using economic analysis to describe what happens when technology meets trade, we look at what this means for businesses in eight developing and emerging markets and we identify the key policy actions that promote, or detract, from the ability of technology-enabled businesses to effectively reach world markets.

Our aim with this article is twofold. We want to raise awareness of the Global Empowerment Network and its power to support exporting by small businesses in emerging and developing markets. We also want to provide concrete proposals for what policy and legal conditions are conducive to building out and strengthening the Global Empowerment Network.

1.1 Data and methodology

This article builds on economic analysis of eBay Marketplaces data carried out in collaboration with Simon Schropp and Andreas Lendle of Sidley Austin LLP. The results presented are based on two different eBay datasets:

1. A global dataset with all global eBay transactions disaggregated by country of buyer and seller and for the years 2008 to 2012.
2. A more detailed dataset for the eight selected countries (Chile, Peru, Ukraine, South Africa, Jordan, India, Indonesia and Thailand) with information on sales conducted by all sellers based in these countries, including the location of the buyer by country and for the years 2008 to 2012.

For the most part, the analysis of these eight countries was done by considering only those eBay sellers with annual sales of at least USD \$10,000. Hereinafter, we refer to those sellers as “Technology-Enabled Small Businesses” (we refer to trade by these businesses over the eBay Marketplace as “Technology-Enabled Trade”).

To allow for comparisons with what we call “traditional trade”, we have used a number of other datasets:

- The World Bank Exporter Dynamics Database for information on exporters based in Chile, Jordan, Peru and South Africa.
- The World Bank Enterprise Surveys for information on the share of firms that are exporting in the eight selected countries.
- The UN Comtrade database for data on exports from about 200 countries.

The comparison with traditional trade is not intended as a perfect comparison between apples and apples. Rather, the traditional trade image provides a reference point that allows us to home in on the different characteristics of Technology-Enabled Trade.

2 Technology meets trade

A key variable that is commonly found to have a large – and negative – impact on trade is geographic distance: countries further apart trade less with each other. One typically finds that a 10% increase in distance reduces trade by 15-20%. Trade over online marketplaces, such as the eBay Marketplace, is much less affected by distance because of how the Internet and digital services facilitate communication and information exchange and, importantly, trust creation. Our research shows that a 10% increase in distance reduces Technology-Enabled Trade by only around 3%, whereas it reduces traditional exports by 18% i.e. by almost six times as much. Significantly, the impact of technology is even more pronounced in the case of trade from developing countries. We find that a 10% increase in distance results in no more than a 1% decrease in Technology-Enabled Trade from developing countries.

3 A look at eight countries

In order to understand the firm-level implications of reducing the negative effects of geographic distance on international trade, we have carried out detailed research into the trade patterns by Technology-Enabled Small Businesses in eight different countries: Chile, Peru, Ukraine, South Africa, Jordan, India, Indonesia and Thailand. These countries were chosen to complement our previous research, which has looked at developed markets.

In this section, we describe the firm-level effects of the Global Empowerment Network in the eight selected emerging and developing markets and discuss what policy efforts help further positive trends.

3.1 Chile

Our research points to a situation of low entry and start-up barriers for technology-enabled trade in Chile. Combined, Chilean newcomers on the eBay Marketplace reach a market share of about 30% in their first year and around 80% survive that critical first year. We also find that the concentration of sales to the largest traders is high in the traditional marketplace with 92% of Chile’s exporting conducted by its 5% largest exporters, whereas in the online marketplace that concentration level is much lower at 16%.

The table above demonstrates the key results for Chile. Our analysis suggests that policy efforts, such as recognizing Small and Medium-sized Enterprises (SME) in trade instruments and upholding strong net neutrality, have contributed to the positive trend our research identifies. Our assessment is furthermore that raising the de minimis (customs relief) thresholds is one type of policy action that could further enhance the ability of Chilean businesses taking advantage of the Global Empowerment Network for exporting.

3.1.1 Recognition in Free Trade Agreements

Recognizing that SMEs engage in international trade and face unique barriers is an important first step to removing the barriers that these businesses face. The Free Trade Agreement (FTA) between the US and Chile contains an important chapter on E-Commerce where Article 15.5 recognizes the global nature of technology-enabled commerce and the importance of adding specific measurable requirements on the governments to remove barriers to technology-enabled SME trade.

3.1.2 Network Neutrality

Small business entities are the most likely to be discriminated against or blocked because they do not have any leverage against Internet Service Providers (ISPs). Larger entities may be able to afford to pay for faster service provision, or utilize their large user bases to exercise leverage against an ISP. Small entities do not have such means. Maintaining an

open playing field on the Internet, where every actor on the edge of the network has an equal opportunity to access a consumer, brings clear benefits to small and medium sized Internet businesses.

Chile was among the first countries to codify the doctrine of net neutrality. An amendment of 2010 to the Telecommunications Act prohibits ISPs from arbitrarily blocking, interfering, discriminating, hindering, or restricting the right of any Internet user to engage in lawful use of the network. This law ensures that the Internet will remain equally open to businesses, and consumers, of all sizes.

3.1.3 Raise the De Minimis Threshold

The de minimis threshold is the monetary level below which an importer of physical goods is exempted from customs duty and paperwork requirements. The Chilean de minimis threshold is currently set at only USD 30. This low de minimis threshold slows down cross border technology-enabled trade for Chilean consumers, but also more importantly, limits the ability of Chilean technology-powered traders to offer returns services to their global customers.

Returns are an essential part of the retail experience. In the current environment, providing cross border returns is difficult for technology enabled businesses because if a good is valued at a level above the de minimis threshold, then upon its return it may be subject to customs duty and paperwork requirements, and the responsibility for those would fall on the seller.

Rather than offering returns, many times a seller from a country with a low de minimis threshold will refuse to offer returns or will simply ship a new product rather than dealing with the hassle of receiving a return.

Chilean sellers that want to offer returns should not be subject to additional burdens. Several members of the Asia Pacific Economic Cooperative (APEC) signed a pathfinder initiative in November of 2011 that recognized the importance of providing higher de minimis levels. Members that signed the pathfinder initiative agreed to raise their de minimis threshold to USD 100 by the end of 2012. Chile is, unfortunately, not one of the participating economies in this initiative; we urge Chile to reconsider raising its de minimis level.

3.2 Peru

Peru is one of the countries where Technology-Enabled Trade is particularly helpful in overcoming the barrier of geographic distance. Traditional trade flows are significantly negatively affected by distance – a 10% increase in distance reduces Peru’s exports by 20%. In contrast, exports over digital services networks such as the eBay Marketplace are about 10 times less affected by distance. The “death of distance” is a reality for Peruvian firms.

Our research also suggests that small Peruvian firms seize this opportunity. We find that all Technology-Enabled Small Businesses in Peru export, reaching on average 25 different foreign markets – in contrast to traditional exporters, who reach three markets on average. In total, these Technology-Enabled Small Businesses export to 100 different foreign markets.

The table above shows the key research results for Peru. Our policy analysis suggests that these results are supported by relatively high de minimis levels in Peru as well as efforts to ensure balanced liability for online intermediaries. The latter is key to cultivating an environment where small firms can build their operations on third party services and platforms. However, and going to the finding of particularly pronounced “death of distance” for Peruvian international trade, we warn that intellectual property rights regimes can have the effect of raising geographical barriers where technology has dismantled them.

3.2.1 *Relatively high De Minimis*

Peru has its de minimis threshold set at USD 200. This enables Peruvian businesses to offer returns on their products and lowers costs and delays for Peruvian consumers. The Peruvian de minimis level is the highest of the countries discussed in this report. But other countries around the world have even higher de minimis levels. Australia has its de minimis level set to USD 1'000. An eBay commissioned report entitled *Enabling Australian Export Opportunities* demonstrated that Australian technology-powered exporters have seen strong growth in the past few years. Moreover, legislation has been introduced in the United States to increase the de minimis threshold from USD 200 to USD 800.

Peru has set the benchmark for other countries in this study with its USD 200 de minimis, but Peru can also see additional cost savings by increasing its current de minimis level.

3.2.2 *Limitations on Liability for Internet Intermediaries*

A well-functioning Internet relies on intermediaries that provide online services and build communication networks for user interaction. The growth of intermediaries is directly correlated to the growth of the digital economy. These intermediaries serve as platforms for large amounts of users; it is not possible for intermediaries to proactively monitor all of the actions of their users. Limitations on liability enable online platforms to host user generated content without risking unmitigated liability

An example on point is the provision that formed part of the US-Peru FTA stipulating limitations in national law regarding the scope of remedies available against service providers for infringements of intellectual property rights that they do not control. Appropriately crafted liability limitations are crucial for the development of the Global Empowerment Network.

3.2.3 *Clarify Scope of Exhaustion of Copyright and Trademark as International*

Intellectual property rights, such as copyright and trademarks, grant a manufacturer the right to control the initial marketing of the product. Once the product has been put on the market – for instance sold to a consumer or to a retailer – the copyright/trademark owner can no longer use the copyright/trademark rights to exercise control over that product: the owner has exhausted that right. The exhaustion doctrine promotes alienability of goods, rewards innovative sourcing methods, provides a backbone for a robust secondary market, and prevents harmful downstream market restrictions.

Some countries apply the international exhaustion doctrine whereby the rights are exhausted irrespective of where the products have been put on the market. Other countries exercise more restrictive doctrines where exhaustion only occurs if the product is placed on the market in that country or within a region.

Here, Peru should clarify that its copyright and trademark laws follow the international exhaustion doctrine – once a good is sold anywhere in the world its distribution can no longer be controlled by the rights owner. For instance, it is unclear under Peru's copyright law when the copyright owner's right to control importation is exhausted; rights owners can exploit this uncertainty to restrict sales of legitimate products into Peru and thus prevent Peruvian consumers and firms from sourcing from world markets. Copyright and trademark law should not be used as a tool to prevent the lawful trade of goods and slow down the "death of distance".

3.3 Ukraine

At the time of writing, the situation in Ukraine with the occupation of Crimea is worsening. Nevertheless, we would like to put forward our research findings and analysis in the belief that facilitating and supporting small business exporting should form part of Ukraine's strategy for economic recovery and participation in the global economy as well as in closer cooperation with the EU.

Indeed, our research points to a huge potential in technology-enabled trade for the Ukraine economy. We find that Ukrainian Technology-Enabled Small Businesses are among those reaching the largest number of foreign markets – on average 36 different markets and in total 152 different markets around the globe.

The table above sets out the key findings for Ukraine. These findings should be read in the context of general Internet trends: according to ITU figures, Ukraine had an Internet penetration of 31% in 2011, up from 5% in 2006 and the use of mobile Internet is also rising as an estimated 16% of urban Ukrainians have access to the mobile Internet.

Pursuant to our policy assessment, we would therefore emphasize initiatives in the area of high-speed mobile broadband as a key for positive developments in technology-enabled trade. Likewise, we suggest that the shift, encouraged in Ukraine, towards electronic documents in administrative procedures is a very important factor in facilitating international trade. However, to further improve the entry and participation of small businesses in trade as well as their competitiveness vis-à-vis large established exporters, we call for continued modernization of national postal systems, which includes strengthened international integration.

3.3.1 High Speed Mobile Broadband Investment

Ukraine’s Open World project is designed to develop a 4G broadband network throughout Ukraine. The initiative promotes educational uses of the Internet and describes how a wide variety of services will be enabled by increased broadband adoption

This program reflects a key understanding of the Internet, namely that value is created at the edge. Moreover, the more users on the network the more valuable the network becomes. The project brief also notes that the state will “create a beneficial regulatory environment.” This statement demonstrates that the Ukrainian government recognizes that deployment of broadband is not enough. Regulatory policies across the board must be updated to foster the digital environment.

3.3.2 Electronic customs processing

Ukraine has a long-standing Law on Electronic Documents, which puts electronic documents on legal par with paper documents. More importantly, however, the new Customs Code of Ukraine, which took effect in June 2012 and is part of steps towards closer EU cooperation, is encouraging the use of electronic declaration forms. The new Customs Code also enables customs rulings to be delivered electronically.

Simplifying customs processes by allowing for goods to be declared electronically is an important measure towards facilitating the participation of small businesses in international trade.

3.3.3 Continue to Modernize Ukrainian Post

The Ukrainian postal operator Ukrposhta is a state enterprise, operating as an independent unit since 1994. In 2008, the Minister of Transport and Communications recognized that the Ukrainian postal service needed to improve operations.

Ukraine has met the Universal Postal Services (UPU) “A-Level” rating. A UPU report from 2011 found that Ukraine ranked among the top 25 countries in postal e-services development. Yet, in the World Economic Forum’s Enabling Trade Report of 2012, Ukraine was ranked 74 out of 132 in postal service efficiency.

The Ukrainian postal service could continue to improve by promoting technology services that leverage efficiencies in scale and aggregation to achieve volume discounts. Ukrposhta would also benefit from working with other countries to harmonize shipping platforms between countries. Finally, Ukrposhta could work with the private sector to create interoperable systems that both the public and private sectors can utilize. Creating interoperable tracking systems would enable merchants and consumers to track their packages throughout the shipping process, and thus to improve reliability.

3.4 South Africa

Our economic analysis shows that Technology-Enabled Small Businesses in South Africa sell more to distant markets than to markets closer to home; in contrast, traditional exports decrease with distance. Overall, these Small Businesses

reach 118 different markets worldwide. Adding to the picture, our research shows strong performance by newcomers – with those in the online marketplace accounting for 27% of sales compared to merely 2% in the traditional marketplace.

The table above sets out the key research findings for South Africa. We would attribute some of the positive trends to South Africa’s ambition to harmonize bilaterally and multilaterally both customs processes and postal systems. Pursuant to our policy assessment, we would however urge continued efforts in improving Internet connectivity and access to strengthen the ability of the Global Empowerment Network to facilitate international trade by remote and small firms.

3.4.1 Harmonization and Modernization of Customs Processes

The South African Customs Union (SACU) is the world’s oldest customs union. Its members include Botswana, Lesotho, Namibia, South Africa, and Swaziland. It was designed to encourage the free movement of goods between member countries. In 2009, the SACU in conjunction with the World Customs Organization launched a three-year initiative designed to create harmonized customs policies in the region. The initiative was also designed to improve risk management and information technology aspects of customs in the region.

Small businesses are disproportionately affected by complicated customs procedures. Harmonizing procedures reduces the number of considerations a small business needs to account for when engaging in trade. Modernizing standards, particularly through the introduction of technological solutions, greatly reduces costs for small businesses and reduces barriers to the customs process. Standardization and simplification of customs processes should be a central goal for governments around the world that are interested in seeing an increase in technology-enabled exporting by SMEs.

3.4.2 Harmonization and cooperation on postal

The South Africa-European Union Agreement on Trade, Development and Cooperation Article 56 contains unique language on postal cooperation. It calls for cooperation in the area of postal to include:

- Exchange of information and dialogue on postal matters in relation to, inter alia, regional and international activities, regulatory aspects and policy decisions
- Technical assistance on regulation, operational standards and human resource development
- Promotion and implementation of joint projects, including research, on technological development in this sector

This provision is notable for two reasons. First, postal services are included in the discussion of an FTA. Second, policy, regulation, and technological development are all identified as keys to cooperation.

Harmonization and simplification of policy and regulation, as well as increased technological investment and development of postal services are extremely beneficial for technology-enabled firms that utilize the postal service to deliver their goods around the world.

We would urge moving some of these aspirations from a bilateral discussion to a multilateral context. That would be greatly beneficial as multilateral harmonization would further reduce divergent burdensome standards.

3.4.3 Investing in Broadband Access Proliferation

South Africa has the laudable goal of universal broadband access by 2020. However, in 2013, a report by the Broadband Commission, an international body set up by the ITU and UNESCO, ranked South Africa at 111 out of 183 countries on fixed broadband penetration (2.2 connections per 100 inhabitants). On a positive note, the report noted that South Africa ranked number 62 out of 170 countries on mobile broadband penetration (26 connections per 100 inhabitants).

South Africa does have a national broadband plan, which was drafted in 2010. But there have been delays at the national level and lack of coordination of implementation at the local level, which have impeded the rapid distribution of broadband access.

Needless to say, ensuring that citizens from every economic level and in every part of the country can access a high speed connection is an essential step in creating inclusive participation in and spur the development of global, borderless markets.

3.5 Jordan

Our research confirms that Technology-Enabled Small Businesses from Jordan adopt export strategies similar to those in other countries. These Jordanian Technology-Enabled Small Businesses export and reach customers in on average 28 different markets and in total 93 different countries. In comparison, traditional exporters reach only three different markets on average. We also find that survival rates of newcomers and the concentration level of the largest traders to be similar to the findings for the other countries discussed in this article, including the five developed countries.

However, we note that the market share of newcomers is comparatively low in Jordan. Newcomers in the online marketplace account for 13% of sales, which is the lowest among the eight countries selected for the research. To put this in perspective, 13% is still significantly higher than the 2% found for newcomers in the traditional marketplace.

The table above gives the key research results for Jordan. Studying the Jordanian policy landscape, we have tried to identify policy initiatives that could both explain these results as well as spur further positive development. Here, we believe Jordan’s efforts putting in place a national e-commerce strategy and promoting competition in electronic payments to be key measures already underway. We also believe that measures that derail uptake of new technology must be avoided and runs counter to the ambition of promoting electronic commerce and payments; rather, promoting the usage of smartphones should form part of the national e-commerce strategy.

3.5.1 Comprehensive National E-Commerce Strategy

In 2007, Jordan’s Ministry of Information and Communications Technology launched its National E-Commerce Strategy. The vision behind the Strategy is for Jordan “to become a leading e-commerce centre in the region through the exploitation of its information technology capacity and the creativity of its people.” The Strategy recognizes the relevance to e-commerce of a range of policy areas, such as payments policy, consumer protection, information communications technology, customs, and tax policy. It also draws up specific actions, for example in the area of encouraging SMEs to take up e-commerce.

We support the model of creating a national strategy as it allows a government to holistically, across policy areas, consider the appropriate conditions for technology-enabled trade. We suggest the Global Empowerment Network would make a helpful conceptual framework when constructing such a strategy.

3.5.2 Competition in electronic payments

One of the digital services that is key to a well-functioning Global Empowerment Network is electronic payments. It is therefore encouraging to note that Jordan’s National E-Commerce Strategy recognizes the central role of globally accepted electronic payments. It lays out a specific action plan to increase consumer usage of electronic payment methods.

In addition, the 2001 FTA between the US and Jordan was the world’s first trade agreement to include a chapter on e-commerce. Adjacent to the FTA is a Joint Statement on Electronic Commerce with a number of important principles and recommendations. In particular, the Joint Statement makes a strong declaration on electronic payment systems: “Developments in this area should recognise the importance of private sector leadership and should promote both a competitive market for, and user confidence in electronic payment systems.”

We encourage Jordan, and other countries, to follow down the path of promoting competition in electronic payments in FTAs as well as national e-commerce strategies.

3.5.3 Reconsider the high taxation on mobile phones

A Cabinet decision published in the Jordan Official Gazette in July 2013 raised the special tax on mobile phones to 16% from 8%. The decision also raised the tax on mobile subscriptions –pre- and post-paid – to 24% from 12%.⁴³ This tax not only affects consumers but it also affects businesses of all types that are using mobile devices to optimize processes and develop new mobile services. The Jordanian Consumer Protection Society (CPS) has stated that it plans to file a lawsuit against the government because of the decision to raise taxes on mobile phones and subscription.

The government should reconsider its high tax on a technology that is enabling business innovation and consumer empowerment.

3.6 India

Our research results for India confirm the ability of technology and the Internet to lower entry barriers. In total, Technology-Enabled Small Businesses in India reach 194 different markets and newcomers account for around 32% of exports in the online marketplace and have high survival rates.

The table above presents the key results for India. Our policy assessment suggests that these results are underpinned by efforts to increase and improve Internet connectivity across India and encourage a shift away from cash and towards electronic payment methods. We note that our research suggests that Indian large firms seem to be in a relatively stronger market position than small firms, also when compared with the other countries discussed in this article. Our policy recommendation would be for the Government of India to enact procedural reforms to simplify export processes for SMEs, taking into account their lack of experience and limited resources.

3.6.1 National Optical Fibre Network

Positive policy actions over last several years have resulted in a fast growing mobile telephony and data market with about 870 million subscribers and one of the lowest tariffs in the world. The mobile Internet users in the country are expected to grow from 4.1 million users in 2009 to 164.8 million in 2015 at a CAGR of 85%.

India should continue promoting investments in connectivity. For example, the Government of India approved on 25 October 2011, the setting up of National Optical Fiber Network (NOFN) to provide connectivity to all the 250,000 Gram Panchayats (GPs) in the country. This is to be achieved utilizing the existing optical fiber and extending it to the GPs. This would ensure broadband connectivity with adequate bandwidth. Moreover, in the last 5 - 10 years, India has significantly liberalized and opened up its telecom sector with broadband wireless, 2.3 GHz spectrum and 3G auctions to private sector companies for broadband & wireless services. In 2013, the government allowed Foreign Direct Investment in the telecom sector to 100%.

3.6.2 Encouraging a “Less-Cash” Economy

With the rise of online commerce, it is important that electronic payment methods advance to meet the needs of the consumer. A regulatory policy that encourages a shift towards electronic payment methods will no doubt help the online commerce experience in India continue to thrive.

The Reserve Bank of India’s (RBI) Payments System Vision document 2012 states:

“The overall regulatory policy stance is towards promoting a less cash/less paper society, the ‘green’ initiative, and hence the increased emphasis on the use of electronic payment products and services that can be accessed anywhere and

anytime by all at affordable prices. Embracing new technology and innovation to unveil a bouquet of simple low cost, easy to use modern payment products and services would be the corner stone of this endeavour.”

This is an extremely positive statement as electronic payments methods empower consumers and improve security for the system. Cash and check, however, currently remain major methods of payment in India. RBI’s document recognizes the shortcomings of the current model and calls for a need to substitute cash-on-delivery with non-cash payment modes such as mobile wallets, cards etc.

The RBI has also enhanced the limit for exports processed by an online payment gateway from \$3000 to \$10,000 per transaction. This will no doubt help Indian small business exporters to sell their locally manufactured goods around the world.

3.6.3 Facilitated procedures for technology-enabled trade

In 2012, the Ministry of Commerce recognized the importance of technology-enabled exports for small businesses.⁵¹ The Ministry of Commerce encouraged small businesses in India to begin to take advantage of technology services, and worked with thought leaders like the Federation of Indian Export Organizations to create seminars, incentives, and best practices to help ease the transition for small businesses. Implementation of these aspirations has proven to be difficult.

Now that a high-level commitment to technology enabled small businesses has been made, the government should enact procedural reforms to simplify export processes for small businesses. Currently, export clearance, notifications, VAT, services taxes, and valuation are all issues faced by technology-enabled traders in India. Addressing these challenges through simplified procedures would be of tremendous benefit to the growing sector of technology-enabled businesses.

3.7 Indonesia

Our research finds that Indonesian Technology-Enabled Small Businesses are among those reaching the largest number of foreign markets. They reach on average 36 different foreign countries, and overall they export to 162 different markets. Underscoring this finding of easy access to world markets, newcomers are effective in gaining market shares, accounting for 42% of all sales. There is also a fairly low degree of concentration to the largest firms in the online marketplace: only 23% of sales are conducted by the largest 5% of all Technology-Enabled Small Businesses in India.

The table above gives the key research results for Indonesia. Our policy assessment has identified two separate initiatives, which both support the Global Empowerment Network for Indonesian consumers and businesses and can help explain some of the promising research results. Those are investments in branchless banking and mobile wallets and efforts to develop the logistics industry. In order to not undo the effect of such initiatives, we warn against localization proposals that seek to nationalize otherwise global operations.

3.7.1 Branchless banking pilot programs

Indonesia has a large rural population, and the Internet is an incredible tool for connecting this population to essential financial services. The Indonesian government has recognized this and is investing in branchless banking and mobile wallets through its National Financial Inclusion Strategy. The plan includes improving financial education and facilitating the ability of intermediaries to enter the process of giving consumers access to a variety of financial tools.

The key to the success of these investments will be to ensure openness and competition in the mobile wallet environment. Allowing innovative new players to offer Indonesian consumers a mobile wallet solution will be imperative to ensuring that Indonesian customers are able to enjoy the benefits of a “cash-light” economy

3.7.2 *Reviewing customs with aim of trade facilitation*

In January of 2012 Indonesia signed the ASEAN Australia-New Zealand FTA. Chapter 4 Article 4 of the FTA states: “The customs administration of each Party shall review its customs procedures with a view to their simplification to facilitate trade.”

Frost & Sullivan predicts that the Indonesian logistics industry will grow 14.5% year-over-year in 2013. Frost and Sullivan credit the Government’s initiatives and development of the logistics industry for much of this growth. Yet, Indonesian customs processing is largely still done in paper form, and a move towards paperless trading could further enhance the productivity gains aimed at by the above provision.

3.7.3 *Avoid localization proposals*

The strength of the Internet is that it is an open distributed network enabling information to travel to its destination through the most efficient path. Introducing any additional barriers beyond basic protocols makes the network less efficient. Requiring that all businesses operating in Indonesia acquire a “.id” global top-level domain is an unnecessary burden on the Internet. It limits the potential of the Internet by bifurcating a website operators’ attention, perhaps unnecessarily, to a unique “.id” site. It should be up to the website operator to determine if s/he wishes to setup a “.id” site that is independent from its other sites.

There is an understandable desire for government to have law enforcement authority over websites operating in country. But, good faith corporate citizens will comply with law enforcement requests regardless of whether the corporate citizen has a domestic domain name. Domestic Indonesian businesses that are export-oriented will be harmed by this requirement since they will be forced to operate a “.id” alongside another international-facing global top-level domains even though their products are aimed primarily at international consumers.

3.8 Thailand

Among the countries covered by our research, Thailand is the most effective in reaching a large number of different markets. We find that Technology-Enabled Small Businesses based in Thailand reach in total practically all countries in the world – 198 countries. On average, those Small Businesses trade with 43 different markets. One explanation is to be found in the fact that geographical distance has no statistically significant effect on Technology-Enabled Trade from Thailand. Interestingly, geographical distance has a comparatively very low negative effect also on traditional trade: an increase in distance by 10% reduces traditional trade from Thailand by about 6%, compared to typically 15 – 20%. The consequence is likely the high share of exporting also by traditional traders in Thailand, as shown in the table below.

The table above presents the key results for Thailand. We would attribute the high export share and number of destinations to Thailand’s ambitions in the area of electronic submission of trade administration documents as well as efforts to increase Internet access. However, we emphasize that building an effective digital economy also requires balanced legal regimes for online intermediary liability.

3.8.1 *Electronic submission of trade administration documents*

Small technology-enabled traders are accustomed to conducting business online, and having to obtain paper copies of customs forms and turn them in to a physical location can be a large burden. Facilitating this type of trade therefore includes processes for accessing and managing customs forms and other trade administration documents online.

Working together bilaterally and ideally multilaterally and/or in international fora to enhance the acceptance of electronic trade documents is important as harmonizing rules across the international landscape is key for the global digital economy. For example, the Thailand-Australia Free Trade Agreement (TAFTA) contains a provision on Paperless Trading in its Article 1107. It stipulates as the general rule that the parties shall accept the electronic format of trade administration documents as the legal equivalent of paper documents.

However, we would point out that electronic acceptance is merely the first stage in optimizing customs for the 21st century. Online submission, interoperable systems, and application programming interfaces (APIs) that enable importers and exporters to plug data elements into a customs agency’s back-end system should be aspirations that customs agencies around the world should aspire to.

3.8.2 *Working to increase Internet access*

In 2003, Thailand began in earnest its efforts to bridge the gap between those who benefit from technology and those that do not. The Ministry of Information and Communication Technology has been working hard to provide accessible Internet to the disadvantaged and disabled. For example, the Budget PC project brought millions of computers to Thai citizens.

In a survey of rural Thailand, 60% of respondents reported using the Internet daily for e-mail. Notably, only 24% of those surveyed reported they used the Internet daily for online shopping and only 12% reported using the Internet daily for mobile banking. These figures indicate that while much has been done to increase access to the Internet there is still more that can be done to tie rural Thailand into the global digital economy.

3.8.3 Intermediary liability for offenses of third party users

Thailand’s Computer-Related Offences Commission Act has been the subject of controversy as a result of provisions, which arguably could hold intermediaries liable for content placed on their platforms by third parties. Section 15 of the Act holds service providers liable if they “intentionally support or consents” to an offense of the Act.

There is a need to target the enforcement of Internet crimes in a smart and tailored manner. Intermediaries should not be held responsible so long as they take the content down after receiving valid notice from the relevant authorities and cooperate within a reasonable framework.

Consumer protection and security are legitimate goals for regulation, but regulation must be aimed at the actor that has violated the law rather than the platform that the actor has used. It is neither technically possible nor economically feasible for intermediaries to monitor all of their users’ actions. We propose that Thailand should consider creating a safe harbor provision for intermediaries that exempts them from liability for the actions of their users.

4 When technology is put to use

The research presented in the previous section allows us to conclude that there are stark contrasts between Technology-Enabled Trade and traditional trade in the eight selected markets. Almost all the Technology-Enabled Small Businesses are exporters. In comparison, according to the World Bank survey data, roughly 10–20% of traditional firms across the eight countries report that they export. (Thailand is an outlier, with three out of four firms reporting to export.) Moreover, these businesses reach on average 30 to 40 different markets, whereas traditional traders serve on average three to four different markets.

Data from the World Bank shows that conventional exporting is dominated by established firms, with newcomers accounting for a mere 1–2% of exports. The data also shows that the largest 5% of firms typically account for 80 - 90% of all exports of a country. In contrast, across the eight selected countries, the share of “newcomers” on the eBay Marketplace (defined as sellers that did not make any sales in the previous year) is on average around 26%, and in some countries even more (e.g., 42% in Indonesia). Moreover, these “newcomers” have a much higher chance to remain in the market: we find that 60–80% of newcomers survive their first year, while the respective figure for traditional exporters is significantly lower. Only around 30–50% of such exporters remain active in their second year.

This research also allows us to conclude that Technology-Enabled Small Businesses in developing and emerging markets are remarkably similar to those in developed markets in terms of the share exporting, the number of foreign countries they reach on average as well as survival rates and concentration of sales among the largest of traders. This conclusion can be drawn based on the research presented in this article together with previous economic analysis of eBay data (presented in a number of “Commerce 3.0” reports).

The table compares key research results of developing, emerging and developed markets. We have aggregated the results of the eight countries selected for this article and compared with results for Australia, Germany, France, the UK and the US. Overall, these findings demonstrate that the benefits of new technologies are spread in very similar ways across markets in different regions and at different levels of economic development.

We argue that these findings demonstrate how the Global Empowerment Network supports small traders in developing and emerging markets to reach customers all around the globe. These trade patterns are almost identical to what we have previously identified for developed markets while in stark contrast to traditional trade patterns.

5 Final word

Perhaps the single most important finding from the research presented in this article is that the very same trends and benefits our previous research identified in developed markets are present in developing markets. Firstly, geographic distance has little negative impact on online trade flows. We have found that true for trade flows arising from developed as well as developing markets. Secondly, technology and the Internet foster multi-country exporters. We have found that the large majority of small business traders on eBay in both developed and developing markets reach on average about 30 to 40 different foreign markets.

Against these research findings, we conclude that the Global Value Chains model (i.e., whereby small businesses enter the global market by becoming a part of the production process of a much larger firm) is not the only way for small businesses to reach and service customers in international markets. The combination of the Internet and digital services make it possible for businesses anywhere to reach consumers everywhere. This means that sustainable global operations can spring out of small local establishments.

We argue that our research demonstrates the existence of an alternative, complementary, path to globalization. That path is made up of effective Internet connectivity, adaptable digital services and cross-border logistics; when brought together, these conditions allow also small traders to serve world markets as this article has described. We propose this alternative globalization model be called the “Global Empowerment Network”.

While the Global Empowerment Network is underpinned by technology, its effectiveness also depends on the right legal rules and administrative procedures as the policy assessment presented in this article emphasizes. We have identified the following policy areas as key for creating conditions that enable also small business traders to access and serve foreign markets:

- Investment in open, interconnected broadband and smartphone technology
- Optimized and harmonized shipping and postal regimes
- Robust intermediary liability protections
- Increased and harmonized de minimis thresholds
- International exhaustion of copyright and trademark rights
- Promoting electronic payment methods
- Improved customs processes through increased technology adoption
- Recognition of technology-enabled SMEs and the global empowerment network in free trade agreements

We are excited about the continued growth of the Global Empowerment Network and believe it will be an integral part of global trade in the future.

Development of a Knowledge Management framework to support installed base information management practices in a servitized context

Andrea Alghisi, Nicola Saccani

University of Brescia, Department of Industrial and Mechanical Engineering (Italy)

In the last decades, growing competitive pressures and increased customer expectations have pushed manufacturers to extend their offerings through the provision of value-adding services (i.e. servitization). However, this transition is challenging and risky. The current research, by adopting the lens of Knowledge Management theory, aims to shed a light on how the adoption of procedures and technologies aimed to collect, organize and exploit the information related to the use of the product and services by the customers can act as an enabler of the servitization process.

1. Introduction

Wise & Baumgartner (1999) suggested western manufacturers to go downstream to achieve a steady stream of revenues through the provision of services, given the high installed-base-to-new-units ratio (e.g. 13 to 1 for automobiles, 15 to 1 for civil aircrafts and 22 to 1 for locomotives). In recent years, due to increasing competitive pressures, evolving customer needs and demand stagnation, the *servitization* of manufacturers, defined as the process of creating value by adding services to products (Baines et al. 2009) has become a topic of great interest amid Operations Management scholars. Such transition from products to services that underlies the concept of service orientation described by Oliva & Kallenberg (2003) has been also labelled as Industrial Product-Service System (Meier et al. 2010) and service infusion (Brax 2005; Gebauer 2008; Holmström et al. 2010). Companies undergoing this transition move towards the provision of Product-Service Systems (PSS), i.e. integrated product and service offerings that deliver value in use (Baines et al. 2009). Strategic and organizational patterns through which manufacturers evolve their offerings and increase their service orientation have been investigated (Davies et al. 2006; Gebauer 2008; Gebauer et al. 2010; Mathieu 2001).

This paper presents the preliminary results of a long-term study that aims to increase the understanding of the relationship between manufacturers' service orientation/strategy and the implementation of Knowledge Management practices such as collection, analysis and utilization of data generated from the use and support of industrial equipment (the so-called installed base information management), that can act as enablers of the servitization process (Neely 2009; Ng & Nudurupati 2010; Greenough & Grubic 2010; Ulaga & Reinartz 2011).

Despite multiple evidence presented in literature (such as the Rolls-Royce success case) and practitioners' growing interest in the management of information generated during products' lifecycle (Dutta 2009), what emerged from a preliminary study of the literature is the lack of a comprehensive treatment of the installed base information management topic (Ala-Risku 2009). In particular, a research gap concerns the investigation of the relationships between information management enabling technologies (such as RFID and Wireless Sensor Network), operations management activities related with the provision of PSS and business model addressing the offer of PSS (among the few exceptions are Yang et al. 2009 and Greenough & Grubic 2010). More specifically, the scientific community has not developed yet an interpretative theory of the role and impact of installed base information management practices in the servitization of manufacturing. The present research aims to fill this knowledge gap by adopting a holistic perspective on the topic of installed base information management, investigating the role of installed base information for the provision of PSS through the lens of Knowledge Management theory. This paper, therefore, addresses the question: *How can the role of installed base information in the servitization processes be analysed through the Knowledge Management theoretical approach?*

2. Background

Research and anecdotal evidence suggest that manufacturers undertaking the path towards servitization face several challenges, that may generate inconsistencies, e.g. between strategic intentions and internal organizational arrangements and even more with external elements. Obstacles arise at both the demand and offer sides of the market. Among the most cited obstacles there are customer's psychology, manufacturer's mindset and economic increasing risks. In this challenging context, the adoption of technology and management practices aimed to handle the information related to the use of the product and services by the customers have been addressed by some scholars as enablers of the PSS and as a mean to overcome or mitigate the increasing risks for manufacturers (Wise & Baumgartner 1999; Neely 2009; Oliva & Kallenberg 2003; Auramo & Ala-risku 2005; Cohen et al. 2006). The present study is grounded on the following concepts: i.) Installed Base Information, defined as all technical and commercial data related to installed base and needed for operation or optimization of industrial services, and ii.) Installed Base Information Management as the set of practices that companies adopt to collect, analyse, use and share data concerning installed products and their utilization. Both these definitions are based on the work of Ala-Risku (2009) that defines Installed Base as a collective

noun for currently used individual products sold or serviced by the focal firm, suggesting that *every single product* sold and serviced by the firm can be a valuable source of information. For instance, Jagtap and Johnson (2011) highlight the importance of collecting in-service information in the aerospace industry and draw a comprehensive list of such information, that range from product deterioration level to maintenance, operating, reliability, availability data and also customer information. According to Jagtap and Johnson (2011), the collection and analysis of these of data allows reducing maintenance costs, evaluating and predicting reliability and availability of products, fulfilling and optimizing maintenance requirements.

Other works, however, approach the topic of installed base information management from a strategic perspective. Data generated by products during their lifecycle are unique resources that enable the augmented service offering, mitigating the increasing risks for the manufacturer that this kind of offering implies (Ulaga & Reinartz 2011). Due to the risks mitigating effect, systems such as product condition monitoring technologies, that ease the collection of installed base information, can facilitate the transition to service-based business models such as *pay-per-use* (Greenough & Grubic 2010). In fact, extending the service orientation through more advanced and highly differentiating services entails risks due to "contractual obligations from the customers in terms of performance, availability and reliability" and increased costs for the delivery of such advanced services (Lightfoot et al. 2011). Manufacturers increasing service orientation poses challenges in cost estimation driven by the uncertainties that arise from performance-based contracts (Erkoyuncu et al. 2010).

In this context, the adoption of information and communication technologies to monitor assets remotely can inform and advance actions. Management of information collected from the installed base is fundamental to gain the visibility on installed equipment that is necessary to support effectively an augmented service orientation while real-time field data acquired from products are a main prerequisite for fully exploiting the service potential and develop new value propositions (Allmendinger & Lombreglia 2005; Holmström et al. 2010). Finally, information gathering capabilities about installed equipment is among the enabling factors of outcome-based contracts typically offered by firms with high level of service orientation (Ng & Nudurupati 2010).

Other research works focus their attention on tactical and operational benefits of installed base information management practices. Johnson & Mena (2008) define the information flow as a key process to successfully adopt a servitization strategy. In fact, information flow management links all the processes involved in the delivery of a servitization strategy using for example, real time data from the product, collected through condition monitoring and telemetry equipment. These data are key input for processes such as spare parts management and order delivery (Johnson & Mena 2008). In particular, a highly detailed installed base information obtained through incorporation of the geographic positions of installed equipment and the dynamics of their product life cycles enables a more timely and accurate forecasts of spare parts demand and returns (Dekker et al. 2011). Finally, the robustness of the service delivery process (i.e. the capability to respond to a large variety of service requests) can be increased with reliable service records and installed base data. Analysing past service operations classified by the equipment type provides statistical insight into the variety of different service requests and their requirements for material and technician skills (Agnihotri et al. 2002; Lehtonen & Ala-risku 2005).

As highlighted in the discussion of the research gap, an interpretative theory of the role of installed base information management practices in the servitization of manufacturing is still missing, therefore we adopt the theory of Knowledge Management to overcome this limitation of existent literature.

The knowledge-based theory of the firm suggests that knowledge is the organizational asset that enables sustainable competitive advantage in hypercompetitive environments (Alavi & Leidner, 2001). The knowledge-based perspective postulates that the services rendered by tangible resources depend on how they are combined and applied, which is in turn a function of the firm's know-how (i.e., knowledge). This knowledge is embedded in and carried through multiple entities including organization culture and identity, routines, policies, systems, and documents, as well as individual employees. Because knowledge-based resources are usually difficult to imitate and socially complex, the knowledge based view of the firm posits that these knowledge assets may produce long-term sustainable competitive advantage (Alavi & Leidner, 1999). Modern organizations make knowledge management (KM) an explicit part of their strategy in order to utilize the knowledge and experiences of individuals within the organization. KM is viewed as a broad concept that addresses the full range of processes by which an organization deploys knowledge (Burstein & Linger, 2003).

3. Literature review: knowledge management and servitization

3.1 Methodology

In order to answer to the research question reported in section 1, a two-steps literature review has been set.

In the first step influential papers associated with knowledge management (KM) have been identified through a bibliographic research carried out in several search engines, such as Google Scholar, Science Direct, Scopus, and Web of Science. The search provided a final list of eleven papers, of which eight journal articles and three conference proceedings focusing on the development and study of the KM theory. Years of publication range from 1999 to 2013. These papers were analysed to identify the characteristics that, in the authors' opinion, define a knowledge taxonomy, successful KM practices and knowledge management systems (KMS). These features have been transcribed into summary tables using the exact author's words, in order to prevent misinterpretation. The tables show the bibliographic

references, to maintain a connection to the source article. The classification structure evolved during the literature review: some categories were split into further and more detailed ones, while others features were merged in more comprehensive and general ones. This has led to a creation of a research framework grounded on theory aimed to analyse servitization literature through the lens of knowledge management (see section 3.2 for details).

The second step consisted in the application of the research framework to a set of papers focused on servitization and more generally on service business development. This allows to identify the conceptual relevance and guidelines for knowledge management as a lever supporting the servitization process of manufacturers. In the present paper are reported the preliminary results obtained from the analysis of four recent papers.

3.2 The Research Framework

The first step of the literature review has led to the research framework presented in Table 1. The table should be read starting from left to right, following a structure defined by four levels. Each font style is related to a level in the framework.

Table 1. The Research Framework grounded on Knowledge Management theory.

TOPIC	FIRST LEVEL	Second level	Third level
KNOWLEDGE	HIERARCHY	Data Information Knowledge

	Database management		
	Search		
	Knowledge flow		
	Knowledge mapping		

Features contained in Table 1 are explained below.

3.2.1 Knowledge

According to Alavi, data is raw numbers and facts, information is processed data, and knowledge is information possessed in the mind of individuals: it is personalized information (Alavi & Leidner, 2001). The higher the level in the hierarchy the more structured the understanding required to recognize and comprehend the construct. As one moves up the hierarchy, there is an increasing level of “implicit meaning” or context embedded within the relations, patterns, and principles associated with the various levels. As the structure increases with higher levels of the hierarchy, relations, patterns and principles may confuse rather than inform or provide useful understanding or context. This is very important as time and effort can be wasted paying attention to useless noise rather than to critical information or knowledge (Nunamaker, Romano, & Briggs, 2001).

Knowledge can be either tacit or explicit. The tacit dimension of knowledge is comprised of both cognitive and technical elements. The cognitive element refers to an individual’s mental models consisting of mental maps, beliefs, paradigms, and viewpoints. The technical component consists of concrete know-how, crafts, and skills that apply to a specific context. The explicit dimension of knowledge is articulated, codified, and communicated in symbolic form and/or natural language (Alavi & Leidner, 2001). Tacit knowledge is difficult to extract from the human mind, thus limiting the manipulation and transfer of this type of knowledge. Accordingly, explicit knowledge has become associated with information (and information systems), and tacit knowledge linked to models and behaviours that are considered to aid its expression and transfer (Armistead & Meakins, 2002).

Knowledge can also be viewed as existing in the individual or the collective. Individual knowledge is created by and exists in the individual whereas social knowledge is created by and inherent in the collective actions of a group (Alavi & Leidner, 2001). If managers focus on the knowledge held by individuals they will encourage opportunities for individual learning but potentially at the expense of the needs of the collective knowledge. A concentration mainly on the latter, however, could restrict the creative learning of individuals (Armistead & Meakins, 2002).

The object of knowledge could be external, and thus comprises client information, competitive information, customer information and market information, or internal, and thus comprises activity-based costing, financial information, human resources information and product/services information (Alavi & Leidner, 1999).

Finally, different knowledge typologies were identified: declarative (know-about or knowledge by acquaintance), procedural (know-how), causal (know-why), conditional (know-when), and relational (know-with) (Alavi & Leidner, 2001).

3.2.2 Knowledge management features

Some organizations are associated with formal structure (hierarchy), which suggests that access to some knowledge might be restricted, whereas in other organizations individuals have more informal access to knowledge (Armistead & Meakins, 2002).

The “personalization strategy”, as named by Hahn, recognizing the tacit dimension of knowledge, assumes that knowledge is shared mainly through direct interpersonal communication. On the other hand, the “codification strategy” assumes that knowledge can be effectively extracted and codified and thus uses a document-to-person approach where knowledge artefacts are then stored and indexed in databases that enable easy retrieval (Hahn & Subramani, 2000).

The processes involved in knowledge management are: creation, storage/retrieval, transfer and application. Four modes of knowledge creation have been identified: socialization, externalization, internalization, and combination. The socialization mode refers to conversion of tacit knowledge to new tacit knowledge through social interactions and

shared experience among organizational members (e.g., apprenticeship). The combination mode refers to the creation of new explicit knowledge by merging, categorizing, reclassifying, and synthesizing existing explicit knowledge (e.g., literature survey reports). Externalization refers to converting tacit knowledge to new explicit knowledge (e.g., articulation of best practices or lessons learned). Internalization refers to creation of new tacit knowledge from explicit knowledge (e.g., the learning and understanding that results from reading or discussion) (Alavi & Leidner, 2001).

The approach to knowledge management could be defined as: “technocratic”, i.e. based on information or management technologies, which largely support and, to different degrees, condition employees in their everyday tasks; “economic”, i.e. the most commercial in orientation, explicitly creating revenue streams from the exploitation of knowledge and intellectual capital; “behavioural”, i.e. stimulating and orchestrating managers and managements to be proactive in the creation, sharing, and use of knowledge as a resource (Earl, 2001). According to Armistead, technology can be used alone or in combination with people at an individual or organizational level. Managers do not believe technology could wholly replace people, or that there is no place for technology in approaches to knowledge. The majority of the companies considered that although the role of technology is influential, it is ultimately a facilitator of human knowledge in the organization (Armistead & Meakins, 2002).

3.2.3 Knowledge management critical success factors

KM critical success factors emerged from the literature analysis are as follows:

- It must be stated that even good KMS are not productive if they do not align with business objectives. Knowledge manager’s awareness about strategic priorities, perception of top management of KMS role in supporting business strategies, learning senior managers about importance of KM, applying Knowledge initiatives to strategic changes, and evaluation of strategic importance of KMS are main criteria to evaluate the level of alignment (Mehregan, Jamporzmay, Hosseinzadeh, & Aliyeh, 2012).
- According to Lee, learning and development are important, thus successful knowledge management practices should enable organizational learning (Lee & Choi, 2003).
- Organization has a strong influence on knowledge management outcomes. The first step is establishing new knowledge roles: create a separate organizational unit, create positions or roles responsible for knowledge-related tasks, such as knowledge broker or knowledge engineer, and assign personal responsibility for knowledge (Maier & Remus, 2001) (Alavi & Leidner, 1999).
- Leadership has been recognized as a factor influencing the conduct of KM. This success factor is related to providing the managerial atmosphere that encourages KM initiatives by members of the organization, and providing adequate resources for the KM/KMS initiative (Mehregan, Jamporzmay, Hosseinzadeh, & Aliyeh, 2012) (Holsapple & Joshi, 2002).
- People are one of the most important enabler in knowledge management. There are many factors which are related to people such as personality, cognitive style, self-efficacy, and skills (Lee & Choi, 2003).
- The success of knowledge management practices depends also on the capability of the organization to enable sharing and communication. Maier suggests creating a (virtual) work environment which enables the sharing of tacit knowledge: the issue is to create virtual workspaces, networks of knowledge workers which provide an alternative environment to the co-located workspace, thus enabling the sharing of tacit knowledge (Maier & Remus, 2001).
- In her case study, Alavi reported that managers expressed the need for metrics upon which to demonstrate the value knowledge management. Initiatives should be directly linked to explicit and important aspects of organizational performance (e.g., customer satisfaction, product/service innovations, time to market, cost savings, competitive positioning, and market shares) (Alavi & Leidner, 1999).

3.2.3 Knowledge management systems features

A characteristic describing a knowledge management system is its size. For example, the greater the number of documents in the document repository or the intranet, the higher the chances one would be able to find documents of interest. However, even though greater network size may increase the potential reach of an electronic discussion forum, greater network size would tend to increase information overload. This increases the amount of effort required to follow the discussions. However, if the size of the network is too small, the network may offer insufficient resources (Hahn & Subramani, 2000).

Applications of IT to organizational knowledge management initiatives reveal these common applications: (1) the sharing of best practices and the access to information for IT support functions, (2) the creation of corporate knowledge directories, and (3) the creation of knowledge networks, bringing geographically dispersed workers together to collaborate on team tasks, (4) support for phone-based help desks and (5) reusing and learning from knowledge acquired during previous IT efforts (Alavi & Leidner, 2001) (Nunamaker, Romano, & Briggs, 2001).

Other relevant features are suggested by Alavi: interoperability of existing data systems, security of data on Internet, ensuring customer confidentiality, eliminating wrong/old data and keeping the information current (Alavi & Leidner, 1999).

3.2.4 Knowledge management systems functions

An important function of KMS is communication. Interpersonal contacts enabled by the system results in knowledge sharing and transfer. Instances of such systems include electronic discussion forums where employees may post questions to which other employees with answers or suggestions can post replies. Threaded discussions and e-mail distribution lists are typical technologies used in systems in this class (Hahn & Subramani, 2000). Other systems are desktop video and real-time data conferencing (Synchronous) and non-real-time data conferencing (asynchronous) (Nunamaker, Romano, & Briggs, 2001).

A second function is document management; this factor consists of these criteria: storage, disseminating, searching, document control and reuse. An example is constituted by knowledge repositories (knowledge element management systems): document management systems with added features e.g. with respect to classification and structuring of knowledge elements or with respect to searching with sophisticated filters, user profiles etc. (Maier & Remus, 2001).

Coordination systems are useful in organizing group knowledge and work. Examples include group calendaring and scheduling, electronic meeting systems, workgroup utilities and development tools, groupware services and applications and collaborative Internet-based applications and products (Nunamaker, Romano, & Briggs, 2001).

Another function is navigation: according to Earl, the principal contribution of IT is to connect people via intranets and to help them locate knowledge sources and providers using directories accessed by the intranet. Extranets and the Internet may connect knowledge workers to external knowledge sources and providers (Earl, 2001).

Alavi underlines the importance of advanced computer storage technology and sophisticated retrieval techniques, such as query languages, multimedia databases, and database management systems, can be effective tools in enhancing organizational memory. Document management technology allows knowledge of an organization's past, often dispersed among a variety of retention facilities, to be effectively stored and made accessible (Alavi & Leidner, 2001).

A further function is constituted by intelligent agent technology to filter out irrelevant content and locate potentially useful conversations on Internet relay chat (IRC). The agent builds a profile of the user through a keyword-based model and recommends current chat sessions by sampling IRC channels to find current conversations that match the user's profiles. Employees are required to append appropriate keywords and meta-data to their documents prior to the uploading to the document repository or to fill out extensive skills and expertise questionnaires (Hahn & Subramani, 2000).

IT can also enhance the speed of knowledge integration and application by codifying and automating organizational routines. Workflow automation systems are examples of IT applications that reduce the need for communication and coordination and enable more efficient use of organizational routines through timely and automatic routing of work-related documents, information, rules, and activities. Rule based expert systems are another means of capturing and enforcing well specified organizational procedures (Alavi & Leidner, 2001).

The last proposed application is concerned with knowledge mapping. This activity can be conducted through text mining techniques and techniques for representing knowledge sources (people and information) in a context defined by their relationships reached through clustering, classification and visualization of documents (e.g. IBM Intelligent Miner) (Maier & Remus, 2001). A database of experts is an instance of such a system. The contents of the KMS are created by employees filling out a questionnaire to describe their level of expertise in a predefined list of skill categories (e.g., Java programming, project management, vibration dampening, etc.). The Experts database is intended to be useful for users to locate people with specific skills in domains where the user has a problem to contact them for help (Hahn & Subramani, 2000).

3.3 Findings: the knowledge management framework

In this chapter the research framework presented in previous section is used to identify knowledge management practices necessary to develop a successful service business. The framework is applied to a list of papers focused on service business development and presented in Table 2.

Table 2. List of papers used to apply the Research Framework.

FIRST AUTHOR	TITLE	YEAR
Baxter	A knowledge management framework to support product-service systems design	2009
Grant	Capturing and measuring technology based service innovation – A case analysis within theory and practice	2013
Kowalkowski	ICT as a catalyst for service business orientation	2013
Rämänen	Human role in industrial installed base information gathering	2013

The application of framework comprised the carefully reading and analysis through tables of the papers. All the relevant KM practices were transcribed and compared to the features described in the framework, in order to assess if there was an actual correspondence. In Table 3 a synthesis of the results is presented.

Table 3. Result of research framework application to selected servitization papers (*= dimension added to the original Research Framework in order to consider specific application of the KM practices in a servitized context).

TOPIC	FIRST LEVEL	Second level	Results
KNOWLEDGE	HIERARCHY		All authors use the terms “data” and “information” as synonymous, with no regard to hierarchy.
	OBJECT	Customer	Data about customer satisfaction on product and services are seen as relevant as input of a feedback system that aims to continuously improve products and services.
		Product/service	In all the papers the importance of Installed Base Information is stressed; it comprises all technical and commercial data related to installed base and needed for operation or optimization of industrial services. Typologies of data collected from the Installed base are: product technical and spare parts history, degree of utilization (working hours, number of working cycle, etc.), geographical position, product modes of use, functioning parameters (temperature, vibration, etc.), resource and consumable consumption. Sensors provide technical data via remote monitoring, but some data have to be collected manually. This manually collected data typically include operational and cost related data from service operations, such as hours spent at the site and spare parts used (Rämänen et al., 2013).
	TYPOLOGIES	Declarative	In a technical PSS, detailed descriptions of design, manufacturing and service are required. Baxter proposes a knowledge-based system, where the central class ‘life cycle system’ is principally comprised of three classes: product, process and resource. The system also comprises various descriptive classes: requirements, behaviour, logistics, operating methods, and installation environment. Examples of service features include uptime, response, and capability to quickly address problems. The product class is comprised of architecture and requirements (Baxter et al., 2009).
		Procedural	In Baxter’s knowledge-based system proposal, the process class is comprised of activities and resources. This is developed in line with the Process Specification Language (PSL) core, which defines processes in terms of activities, objects and time points. Time is a requirement for process execution, however is has not been included as part of the proposed framework. The resource class, in a similar manner to the PSL ‘object’ class, refers to any resource that is used by a process. Resource subclasses include facilities (e.g. manufacturing; service), equipment (e.g. tools; office equipment), person, and material and information resource. The information resource class contains drawings, standards, detailed machining features, tolerance data, materials data, and others (Baxter et al., 2009).
		Causal	Indication of failure cause is necessary for a full appraisal of a product failure. ‘Failure cause’ is not a simple issue. There is some risk associated with service technicians assigning root cause to product failures, since the cause is not always clear from the symptoms. In Baxter’s case study, for every product service carried out, symptoms are recorded but root cause is not investigated. For every warranty claim, an investigation is carried out to identify root cause in order to assign the cost of repair. Where unusual or repeat failures occur, detailed investigations are carried out at the customer site by applications specialists to identify and rectify the root cause and improve system performance. Data from all three types of investigation, including the reports produced and the photos taken during machine disassembly, should be available to the design team in case they want to investigate any given product failure in more detail.

TOPIC	FIRST LEVEL	Second level	Results
KNOWLEDGE MANAGEMENT	FEATURES	Approach	<i>Technological:</i> information systems are required to manage Installed Base Information. Examples are ad hoc system developed in-house (e.g. spreadsheets, Access database, etc.), ERP, CRM (Customer relationship management), PDM (Product data management), PLM (Product lifecycle management)
			<i>Behavioural:</i> although a trend to replace humans with sensors as the diagnostic element has been widespread, certain elements of the failure diagnostic process cannot be easily handled without the presence of human actors. Sensors only provide discrete data regarding variables (e.g., temperature) that can indicate failures but human observation is needed to form a deeper understanding of the failure cause (Rämänen et al., 2013).
		Processes	<i>Creation (socialization, externalization, internalization, combination):</i> The focus is, in particular, on combination process, which is referred to as “integration”. Rämänen in fact affirms that it is important to have a system that effectively integrates the information pieces received from the different data collector groups so that the information is easily utilizable in different business functions (Rämänen et al., 2013).
			<i>Storage/retrieval:</i> IBI can be derived from various information systems (manufacture, sales, etc.) (Rämänen et al., 2013). <i>Transfer:</i> IBI can be collected automatically through sensors (remote monitoring) or manually (Rämänen et al., 2013). <i>Application:</i> IBI plays an essential role in a number of functions. Firstly, this information can serve as a key source for making correct and accurate preventive maintenance plans. Furthermore, sales personnel may utilize up-to-date IBI as they make decisions on where to sell modernization packages or new substitutive equipment. Correct and timely information can also be invaluable in order to provide customers with the best possible service level. For instance, one of the companies involved in Rämänen’s research uses IBI to optimize the operation of equipment installed in their customers’ site (Rämänen et al., 2013).
	CRITICAL SUCCESS FACTORS	User skills	Insufficient training and deficient data collection guidelines can negatively affect the quality of manual data gathering. Problems can also occur due to people’s manifold interpretations of complex equipment involved in the data collection. Elaborate, comprehensible and uniform data gathering training and guidelines should be provided to all workers that are or could be involved in the IBI gathering process (Rämänen et al., 2013).
		Organization	<i>Knowledge roles:</i> 1) Dedicated data collectors. By dedicated data collectors is meant persons whose primary task on a site is to collect IBI. However, they may also have other off-site work duties. The practices of having dedicated information gatherers may vary depending on, e.g., the country. These workers have no other tasks that would interfere with information gathering so they can fully concentrate on it and they have enough time to do the task well. What comes to motivation for collecting good quality information, it is likely to be naturally high because the evaluation of the worker performance is based on the quality of information gathering. 2) Workers with other primary tasks. They include all workers that, in one way or another, perform work tasks with the installed base but whose primary work tasks do not include IBI gathering. This group includes skilled technicians and the manufacturer’s maintenance staff. These persons could collect IBI alongside their primary work tasks while they are at the site. 3) The customer needs to gather and provide information, such as usage data, environment information and location data, to enable value added services provided by the manufacturer or a third party service provider. The data collector group of customers encloses a variety of different people working for the customer, which means that people with varying job roles are involved.

TOPIC	FIRST LEVEL	Second level	Results
			<p>4) Equipment users. By equipment users Rämänen refers to ordinary citizens who have no particular tie to the company at issue but who use the products or services provided by the company. Whether companies have users amongst ordinary citizens depends on the product and service offering of the company. Among industrial companies this is less common compared to companies providing consumer products and services, but these kinds of companies do exist. If an industrial company has users among ordinary citizens, these equipment users can, in practice, provide the company with IBI. In his research, Rämänen has used the term industrial crowdsourcing when discussing ordinary citizens as IBI gatherers. The job can be performed either collaboratively by many people or by single individuals.</p> <p>5) In certain business domains, it is possible that external inspection agencies gather information regarding the installed equipment while they are making inspection reports. They may also have own databases where this equipment information is being stored. Hence, these authorities can be considered as one potential source of IBI. According to Rämänen company contacts, a representative from the own personnel can also sometimes be sent to accompany the person from the inspection agency, which provides an opportunity for gathering IBI.</p> <p>6) Insurance companies collect IBI and use it in estimating risks. They also provide information to their customers when pointing out risks in customer operations. Vice versa, if customers can show that they manage their risks, for example, by collecting and analysing IBI, insurance companies may be willing to lower insurance payments due to lower risk levels (Rämänen et al., 2013).</p> <p><i>Top management commitment:</i> The quality of data can also be negatively affected by poor management structures that do not promote accuracy, completeness and timeliness of data reporting. Management's commitment to data quality as well as data quality awareness are important factors in the pursuit of high-quality data. The importance of effective management and operator feedback as well as fluent communication amongst involved stakeholders has been also brought up (Rämänen et al., 2013).</p>
		Measurement	<p><i>User satisfaction:</i> the knowledge contributors require motivation to spend time populating the system. Both manufacturing and service managers aim to keep data recording to a minimum. Therefore two important aspects contribute to this motivation: minimal time required for inputting data, and maximum potential for the system to support the activities of the knowledge provider (Baxter et al., 2009).</p> <p>Usability of the tools used for entering information affects both the quality and quantity of provided information. Bad usability causes confusion and leads to mistakes when providing information as well as leads to frustration and reduces motivation to provide data (Rämänen et al., 2013).</p>
		Enabling communication / sharing	<p><i>Incentives:</i> Firstly, motivation towards data gathering is low if data collectors do not consider data gathering as being part of their job. Data collection can also be considered as additional paperwork, hence not being fascinating. Further, data collectors may feel incompetent what comes to data gathering, and therefore be unwilling to participate. Lastly, some workers may fear that the gathered data could somehow be used against them, which makes them reluctant to collect data. Also, the important role of education regarding the importance of good quality data has been highlighted. The person gathering the information may not benefit from the use of that information which can result in a diminished motivation to collect data. In the case of the group of workers with other primary tasks, Baxter has found out that integration with other work tasks is crucial. Workers are not motivated to perform an additional task if it causes significant deviation to their current workflow. According to Baxter's findings, the motivation for information gathering can be generated through at least three alternative ways. Firstly, direct monetary compensation or some other kind of reward (e.g., vouchers) can be used to whet</p>

TOPIC	FIRST LEVEL	Second level	Results
			workers' appetite for gathering information. Secondly, information gathering may bring intangible benefits for the information collector, which can positively affect attitude and motivation. An example of such benefits is something that eases the person's other tasks. The benefit can either result directly from the worker's actions regarding information gathering, or another party can grant the worker certain benefits as a reward. Lastly, the workers' motivation may be improved by promoting the meaningfulness of information gathering through effective communication, hence making workers feel themselves important (Baxter et al., 2009).
		Alignment with strategy	Managers should have in mind that a strategic move to increase service business orientation through investments in ICT requires a business rationale and strategic congruence as well as the critical resources and capabilities needed (Kowalkowski, Kindström, & Gebauer, 2013). Firms with high Service orientation have a higher maturity level in terms of installed base information management practices due to a wider breadth of data collected from their installed base and implementation of more specialized and integrated information systems to manage this information, and experience a wider number of benefits from this kind of practices.
		Environment	Regarding the potential effects of work environment and the nature of work tasks, it has been suggested that operator time pressures are likely to affect the quality of collected data (Rämänen et al., 2013).
	FEATURES	Size	The set of information that is truly needed needs to be defined. We claim that it is not reasonable to collect large amount of information just in case it might be utilized at some point - the true usefulness of most of it may end up being debatable. Smaller set of information also increases the likelihood of actually getting all of the needed information (Rämänen et al., 2013).
		Data management:	<i>Consistency:</i> In certain service business domains, equipment turnover in the service base can cause problems with keeping IBI up-to date. When a service contract is lost to a competitor, the visibility to the equipment is lost. During that time the competitor may make changes to the equipment, and when the service contract is at some point won back the IBI at hand may be outdated. Therefore, trying to find means for keeping the IBI up-to-date is of great importance (Rämänen et al., 2013)
		Aims	ICT is an important asset for creating superior customer value based on explicit service quality, proactive and integrated solutions as well as timely, empathic design of new services. According to previous research, new services can be introduced more rapidly into the market when having a significantly better control over the IT infrastructure. Controlling the IT infrastructure is necessary for building a service system and enhancing service quality excellence. Hence, ICT enables better service delivery and leads to improved cross-functional communication and service-oriented business strategies (Kowalkowski, Kindström, & Gebauer, 2013).
	FUNCTIONS	Communication	1) The adoption of information and communication technologies to monitor assets remotely. Due to the risks mitigating effect, systems such as product condition monitoring technologies, that ease the collection of installed base information, can facilitate the transition to service-based business models such as pay-per-use. 2) Mobile devices for service employees. Such initiatives involve relatively low risks, do not require a comprehensive understanding of the technology among top management, and the cost reductions allow a rather straightforward and measurable return on investment. Since 2002, in Toyota Material Handling Europe, the service organization is using a mobile business system and service technicians are using handheld computers to receive and report work orders and access customer fleet data and spare parts information. In this way, value can be created by offering process analysis and consulting services. Customers can view the real-time utilization of their fleet and see how the trucks are driven, set driver access and shock levels remotely, and manage all production sites centrally. (Kowalkowski, Kindström, & Gebauer, 2013).

TOPIC	FIRST LEVEL	Second level	Results
		Document management	Direct billing and transaction-efficient service order handling (Kowalkowski, Kindström, & Gebauer, 2013).
		Search	Baxter defines a scenario, in his case study, where designers have to access machining capability data. Designers reported that the system provides too much irrelevant information, that they had to ‘drill down’ through too many levels to access to the data relevant to them, and that this would prevent them from accessing the system. This recognizes that with an increasing amount of content available in a knowledge management system, there is a requirement to ensure that people are able to access knowledge relevant to their work function. The approach taken to ensure that appropriate knowledge can be delivered is to provide an activity level mechanism, which links knowledge resources with activities. The precise mechanism is the inclusion of a ‘knowledge resource’ slot in the activity class. This slot enables any instance from any class in the knowledge base to be associated with an activity. Whilst the system limits the content of the knowledge resources to alphanumeric inputs, the class structure supports the extension of the principle to include hypermedia links, attached files, and links to other systems (Baxter et al., 2009).
		Knowledge flow	The information flow is a key process to successfully adopt a servitization strategy. In fact, information flow management links all the processes involved in the delivery of a servitization strategy using for example, real time data from the product, collected through condition monitoring and telemetry equipment. These data are key input for processes such as spare parts management and order delivery. In particular, highly detailed installed base information obtained through incorporation of the geographic positions of installed equipment and the dynamics of their product life cycles enables a timelier and accurate forecast of spare parts demand and returns.
APPLICATIONS *	DESIGN SUPPORT		<p><i>Product design:</i> One important element of design knowledge capture, particularly in the design of mature products, is process modelling. A prescriptive design process model shows the best practice sequence of tasks which contribute towards the creation of the final product. The process is divided into two main stages: conceptual and detailed design. The conceptual design activity begins with the creation of a project team. In parallel, the requirements specification, product family definition, module structure definition and service package design activities are carried out. The recognition of an integrated product and services sales strategy brought about the requirement to design the service package concept at this early stage. this model proposes a manufacturing analysis activity to take place within the conceptual design stage in order to verify the commercial validity of the project. The requirements specification activity is one of the first activities to take place in the design project. The purpose of the activity is to identify and document the requirements in order to develop an engineering specification for the product or system. Concurrent activities include product family definition, module definition (defining the strategy for common modules across the range), and service package design (the outline strategy for service delivery).</p> <p>In the knowledge base, the requirements specification activity includes various knowledge resources, including requirements specifications from previous products. The detailed reference to the requirements specification from previous projects supports the design team in developing specifications for the new design project where they are not explicitly indicated by the market analysis activity by giving them a clearly defined starting position. Various personnel are involved at this stage, including engineering, manufacturing, marketing, sales, and customer application specialists (Baxter, Roy, Doultsinou, Gao, & Kalta, 2009).</p> <p><i>Service design:</i> The first activity relates to defining the product. Inputs from the knowledge framework include the product architecture class (BOM, modules) and inputs from the resource class (e.g. drawing). The product description is likely, in practice, to represent a family of products with multiple variants. A further critical</p>

TOPIC	FIRST LEVEL	Second level	<i>Results</i>
			<p>element is the intended customer application, defined using the ‘installation environment’ class. This includes references to resources including equipment and personnel. This process will have been evaluated by service personnel at the prototype stage. In combination with the projected volume, this input is applied to the development of the service process. Activities and resources (personnel, information, tooling) required by the process are compared against the existing facility. Tooling, training, and test procedures are developed according to the existing facility, in line with the volume of products expected (Baxter, Roy, Doultsinou, Gao, & Kalta, 2009).</p>
	<p>SERVICE SUPPORT</p>		<p>There is a wide range of generic SSP that are enabled and facilitated by ICT, for example remote monitoring and control, product utilization report packages, preventive maintenance agreements, and fleet management systems. As more and more information about product usage is possible to collect wireless in real time, firms have a more accurate foundation for proactive, higher-quality maintenance and operational services. ICT enables the development of new SSP but these are not necessarily new stand-alone services. Customer benefits enabled by SSP, such as reduced operational costs through process automation, better predictability, and information on product performance and usage in customer operations, lead to more attractive value propositions (Kowalkowski, Kindström, & Gebauer, 2013).</p> <p>Baxter provides examples of knowledge management systems supporting service such as spare parts and training and feedback from service to design. Spares are a designation for components available to the after-market as replacement parts. Spares definitions may dictate that certain parts replacements are carried out in groups. For example, a single seal may only be available as part of a kit. That kit may include several washers, seals ‘o’-rings or gaskets, according to the expected requirement for a full or partial rebuild. Other rebuild parts kits may also be available, containing various wear parts according to the recommendation for parts which should be replaced as part of every product rebuild.</p> <p>Training refers to the requirements for procedures and documentation as well as project planning to support product launch. Documentation describing service and maintenance procedures is a key part of the training requirement. Hands-on training also takes place: a service technician trained by the NPI team may travel to the various service centres to train key personnel, or service technicians from the various global sites may travel to a central location to receive hands-on training.</p> <p>Serviceability is indicated through feedback from service personnel to designers. Feedback may include actual time taken in the service process, problems encountered, ideas for improvement, and design change requests. (Baxter, Roy, Doultsinou, Gao, & Kalta, 2009).</p>

4 Conclusion

Although the research attention towards servitization has been very high in recent years, the role of installed base information management as an enabler of this transformation of manufacturers has not been approached comprehensively. This paper presents a preliminary work meant to support the development of a theory about this topic. To do so, we addressed the role of installed base information for the provision of PSS through the lens of Knowledge Management theory.

The contribution of this paper is therefore twofold. First, a research framework was developed based on the knowledge management literature, which identifies the characteristics of three entities: i.) Knowledge; ii.) Knowledge management; iii.) Knowledge management systems.

Second, this framework is tested by applying it to four papers dealing with knowledge and successful service business development in manufacturing. This generates a preliminary understanding of knowledge management features in the servitization process, which are listed in Table 4.

Acknowledgments

The research presented in this paper stems from the activity of the ASAP Service Management Forum (www.asapmf.org), a research and dissemination initiative involving researchers from five Italian universities and several companies, about product-service systems, servitization of manufacturing and service management.

The authors would also express their gratefulness to Federica Valzelli, a former student at the University of Brescia who greatly contributes to the work presented in this paper.

Remember to identify what your service network partners value

Maaren Ali-Marttila, Salla Marttonen, Timo Kärri

Lappeenranta University of Technology

The traditional view of value in exchange has increasingly shifted to value in use where the customer and provider interact in long-term relationships by sharing and integrating resources. In addition, the outsourcing of industrial services (e.g. maintenance services) has increased inter-organizational co-operation and networking in many companies. This has created a need for models and tools to identify what the different partners value in the service. The specific objective of this paper is to present a conceptual framework for a collaborative value analysis model built to identify what the network partners value in industrial services. The framework is based on a systematic literature review considering value analysis models in the business-to-business context. In the previous research, the value discussion has been mainly about customer perceived value and relationship value. Service provider value has garnered scant attention. Our framework aims to present a collaborative model, which considers multiple operators in the industrial service network: the customer, the service providers and the equipment providers. To make business networks successful, the company partners need common goals and expectations, the value of all network members should be taken into account. The paper contributes to industrial service decision making by providing a conceptual framework for collaborative value analysis based on research gaps identified in the previous literature.

1 Introduction

Value creation is the essence of service relationships (Lindgreen & Wynstra 2005; Möller 2006; Vargo & Lusch 2008; Walter et al. 2001). In order to be able to create value, the partners need to identify the value of the service. This paper presents an overview of different value analysis models employed in B2B services, based on a systematic literature review. We use the term model to mean implementations (e.g. frameworks, equation models and conceptual models) that can be used for decision making, and should also be independent of a single case. Based on the identified models and the literature, a conceptual framework for collaborative value analysis with a specific focus on maintenance services is presented.

Better integrated and more knowledge intensive solutions provided for industrial service customers, and the outsourcing of support services, has increased the inter-organizational collaboration between many companies operating in industrial maintenance and other service networks (Kremic et al. 2006; Redondo-Cano & Canet-Giner 2010). Ford & McDowell (1999) state that the network context is highly complex and this hampers, for example, marketing and purchasing management. This emphasises the need for collaborative value analysis, cost analysis and pricing models to identify what each partner values in the service relationship and support decision making. Many of the extant value analysis models do not take the new collaborative context into account, so updated models are needed to improve decision making between network partners and strengthen the relationship and trust (e.g. Ahonen et al. 2010; MacCarthy & Jayarathne 2012; Panesar & Markeset 2008; Werner Reinartz 2008; Sinkkonen et al. 2013).

Maintenance has shifted from what could be described as a necessary evil to being a part of the business which creates additional value (Parida & Kumar 2006). The current literature supports the value of maintenance services, which e.g. for customers can be surprisingly high (e.g. Komonen 2002; Sinkkonen et al. 2013; Al-Turki 2011). Especially if the customer operates in the process industry and insufficient resources are put into maintenance, this can result in major losses through lost production (Knapp & Mahajan 1998). In addition, maintenance is highly case specific due to the different strategies employed to maintain critical and non-critical systems. Increasingly complex assets have grown knowledge intensity and attracted specialisation in the field (e.g. Al-Turki 2011). The value of maintenance comprises both tangible and intangible value elements (Ali-Marttila et al. 2013; Ojanen et al. 2012; Toossi et al. 2013).

The strategic importance of maintenance has increased the number of inter-organizational partnerships and led to the creation of more maintenance networks. These comprise customer companies, i.e. maintenance purchasers, and a variety of supplier companies such as maintenance service providers and equipment manufacturers (Marttonen et al. 2013). Maintenance operations are often at least partly outsourced (Ali-Marttila et al. 2013). We know that maintenance can create additional value and that the nature of the business has changed; maintenance service suppliers are now an important part of the landscape. But service-dominant logic that says value is created throughout the relationship not just in the exchange has to date received less attention (Vargo & Lusch 2008). The importance of the price of the service is often still emphasised, although especially for complicated services functionality should be the deal breaker. In addition, due to case specific contracts, it is essential to know the specific value elements for each case. To engage in true collaborative relationships, the value elements of the service provider should be considered. Also collaborative value analysis is needed in order to be able to improve the service networks and make them successful.

The concept of modelling the key elements and dimensions that constitute value creation in maintenance service relationships and overall in B2B relationships has attracted relatively little research interest (e.g. Corsaro & Snehota 2010; Ulaga & Eggert 2006). But the B2B marketing literature is already further ahead in considering service value and relationships than the maintenance literature (e.g. Aarikka-Stenroos & Jaakkola 2012; Grönroos & Helle 2010). In order to gain insights from the marketing literature, the extant literature is systematically analysed to identify the current models employed for value analysis in B2B services, and to see how they have been used. Based on the findings and by taking into account the special characteristics of industrial maintenance services, a conceptual framework for a model to identify the value elements of the network partners is proposed.

Our research questions are:

- What kind of value analysis models have been presented in academic journal publications relating to B2B services?
- What kind of building blocks for the collaborative value analysis framework can be identified in the extant literature?
- What elements should the collaborative value analysis model of industrial services include?

The current models do not consider all the partners in service networks. In order to improve the competitiveness of the service relationships, the partners need to understand what elements create value in the service for each member. We contribute by providing a conceptual framework for collaborative value analysis to support decision making. Collaborative tools are needed to improve network level co-operation between members in maintenance and other services. Appropriate models and their implementation strengthen the networks and help them compete with others.

The paper is structured as follows. First, the relevant value theory is described. Then the methodology of the literature selection is described in detail, after which the selected literature is analysed and the framework presented. Finally, the conclusions and avenues for future research are presented.

2 Value creation in business relationships

Payne et al. (2008) explains that the value creation process in business relationships comprises what value the customer receives, what value the service provider receives, and how the partners can manage the value exchange successfully to maximise the received total value. Although this sounds clear, the value has multiple dimensions and the value literature has focused significantly on exploring what the dimensions and drivers are that create value in business relationships (e.g. (Corsaro & Snehota 2010; Menon et al. 2005; Ulaga & Eggert 2006)).

Customer value is generally defined as the trade-off between the benefits and sacrifices (or cost) in an exchange (Ulaga & Eggert 2006; Zeithaml 1988). The benefits can include, for example, quality or cost savings, and price can be seen as a sacrifice (Dumond 2000; Grönroos 2011). In this paper, in analysing the identified models we consider customer value a value perspective that discusses only the value and benefits relating to what the customer gains from the service relationship.

The marketing literature has focused predominantly on customer value, so supplier value is studied markedly less (e.g. Purchase et al. 2009; Ramsay & Wagner 2009; Walter et al. 2001). Purchase et al. (2009) and Ramsay & Wagner (2009) describe supplier value as the benefit the supplier receives when interacting with the customer. The benefit can be, for example, profit or new customers. We see supplier value as a perspective where only the benefits from the supplier are considered.

The traditional value-in-exchange view (goods-dominant logic) has been challenged by value-in-use (service-dominant logic). Value is not only created with the object of exchange (e.g. product, service offering), but also in the whole value delivery process during which resources, skills and knowledge are shared when the customer and supplier interact (Lindgreen & Wynstra 2005; Payne et al. 2008; Vargo & Lusch 2004). In industrial services, the value delivery process can last for several years through long-term contracts. In persistent relationships, value is also created through interactions over time because the customer and provider continuously learn from each other as the relationship develops (e.g. (Ford & McDowell 1999; Hammervoll 2012). Relationships create synergies that benefit network partners, and thus can be considered to have value for both the customer and service providers (Smals & Smits 2012; Ulaga 2003).

The value of the relationship can take in factors such as reputation, the innovativeness of the supplier, and access to networks of partners (Möller & Törrönen 2003; Walter et al. 2001). Thus, companies must consider also other elements that create value in business relationships rather than just the current offering (Ravald & Grönroos 1996; Lindgreen & Wynstra 2005). This has shifted the broader focus of value research from individual transaction processes to the ongoing interactions between the firm, its customers and network partners over time (Payne & Holt 2001).

The value experienced in relationships can be both tangible and intangible, and derived from multiple dimensions such as increased profits, increased reputation, access to new partners, and trust (e.g. (Baxter & Matear 2004; Biggemann & Buttle 2012; Grönroos 2011; Ulaga & Eggert 2006). However, partners in the same relationship might have different perceptions of the elements that create value (Corsaro & Snehota 2010). In order to be able to discuss and gain a mutual understanding of the created value and improve the value creating elements, what each partner values in the service and relationship should be identified (e.g. Aarikka-Stenroos & Jaakkola 2012). In this paper, we see the

relationship value perspective as one where the value of two or more parties is considered and value is created in collaboration.

While actively involving suppliers in the value creation process can increase value creation potential, it can also make the partners increasingly dependent on each other, as Möller (2006) points out. Therefore, striving for value creation through relationships is not always the best solution. In this paper, however, we focus especially on situations where industrial service networks are created, and supplier, customer and equipment provider are actively involved in the value creation process. The research has not been able to keep pace with changes in the industry, so this paper provides a conceptual framework to identify the value elements of industrial maintenance service partners, and thereby to support decision making in industrial service networks.

3 Methodology for the literature selection

A systematic literature review was conducted to study the current value analysis models for B2B services that can be found in the academic journal publications. This section presents the literature sample selection process in more detail.

As we wanted the literature sample to include articles that consider value analysis models used in the service context, we defined three main categories – value, models and services – for keywords used in the search strings (Table 1).

Table 1. Keywords used in the search strings.

1 Value	2 Model	3 Service
value	model*	"business service"
	tool	B2B ¹ service
	framework	"industrial service"
	method	"maintenance service"

¹also business-to-business

All the category keywords are quite common so more specifications were applied in order to work through the material in reasonable time. The first category, and the keyword *value*, goes to the heart of this study and is therefore included in all search strings. The second category focuses on the modelling aspect and includes the specific keywords *model*, *tool*, *framework* and *method*. They are all constructs for decision making and to cover the analysis process adequately should be included in the search strings as well. In addition, different keywords should be employed to identify the appropriate models, because for example some argue that model and method are often used interchangeably. The third category is for services and contains the keywords *business service*, *B2B service*, *industrial service*, and *maintenance service*. “Business service” can be considered the most upper case, and the other services come down to more specific fields and finally to the specific theme of this paper, namely “maintenance service”. Thus the models identified in the literature sample must include also the service aspect.

Keywords were then combined from each category into 16 (1x4x4) search strings that were applied to the databases. Since Scopus (Elsevier) and ISI Web of Science (Thomson Reuters) may be considered both leading and competing databases in business research, they were employed to ensure the availability of a large, comprehensive literature pool (e.g. Gavel & Iselid 2008). We collected the literature sample in July 2014 and no time distribution limitations were set for the search.

In order to find the relevant articles, the following criteria based on Newbert (2007) were applied when considering the inclusion or exclusion of a paper:

- Include only peer reviewed scientific journal articles
- Ensure relevance by selecting articles that contain at least one keyword in their title or abstract
- Exclude articles with very narrow aspects or context (e.g. suitable only for a single case)
- Read remaining abstracts and ensure their relevance to the subject
- Further, read remaining articles in their entirety to ensure relevance of content

In addition, the following criteria were used for the content:

- The selected articles should consider value from multiple aspects (not just one element such as trust or quality) or similar aspects (if modelling does not consider value directly, the paper should still be associated with the concept of value) and this should be a significant part of the paper.
- The selected articles should consider modelling in the sense that the model is separable from a single case and can be used for decision making
- The selected articles should consider value analysis from a service perspective; they should be appropriate for the B2B context so that they are also viable for the specific focus on maintenance

We chose to omit articles examining new service development, branding, specific strategy formulation, and improving innovativeness, unless they considered especially the value modelling concept.

The different combinations of search strings produced 548 potentially relevant articles. Employing the exclusion and inclusion criteria described above, 24 papers were selected as the literature sample for more specific revision. The selection process is depicted in more detail in Figure 1 and the selected articles in Appendix 1.

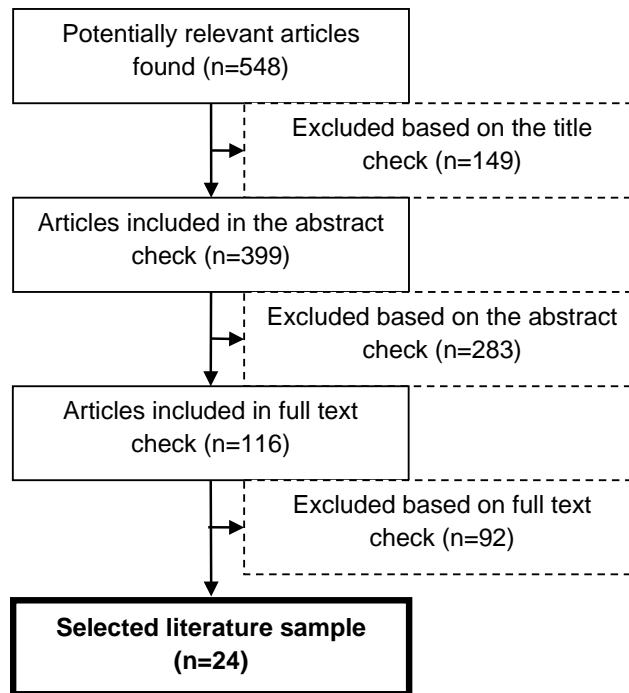

Figure 1. Literature sample selection process.

4 Results

4.1 Time distribution

Figure 2. Time distribution of the sample.

The time distribution of articles considering value analysis models of services is shown in Figure 2. Interestingly, it is clear that the number of journal publications has increased significantly in the last nine years. Some interest in researching the area started after 1995, by Lapierre (1997, 2000) and Lynne Bennington & Cummane (1998), but after a few years there were no publications for a while, until now a rising trend towards and need for value analysis models can be seen published by several researchers.

4.2 Industry

The main industries specified in the articles are shown in Figure 3. The most researched industries were industrial services and information technology (IT) services. Especially in industrial services it has been noted that value analysis is important in order to create value and remain competitive by providing solutions for the customer. Two articles considering maintenance services were also found (Macdonald et al. 2011; Ojanen et al. 2012). Interestingly, articles considering maintenance services were found even more in the earlier stages of the process, before final exclusion (e.g. Chang & Lo, 2011; Finne & Holmström, 2013; Holmström et al., 2010; Ahonen et al., 2010; Lam, 2008). These articles were ultimately excluded from the final sample because they examined a specific problem other than value analysis (e.g. selection of the best consultant, modularization, communities).

Figure 3. Distribution by industry in the reviewed articles.

4.3 Value perspective

As can be seen in Figure 4, the focus in the value analysis models is still on the customer side, as the majority considered customer value assessment or similar aspects. Supplier value in the service was considered in only two of the models.

Figure 4. Value perspectives in the sample.

The relationship value perspective was identified in seven of the models. It is a positive development that at least some are focusing on mutual value creation, especially concerning B2B services where it is important to consider both parties in the value creation process. But none of the models considered more than two actors (customer and supplier).

Figure 5 depicts the value elements used in the models. The majority of the value analysis models use both tangible (e.g. profit, price, speed) and intangible (e.g. reputation, trust, commitment) value elements in assessing the value of the service (e.g. Songailiene et al., 2011; Logožar et al., 2006; Sole & Carlucci 2010; Lapierre 2000). This supports the view that value is multidimensional and comprises both monetary and non-monetary elements that need to be considered in its analysis. Five models considered primarily one dimension of value, and most of these articles recognised in their conclusions that the unevaluated elements should be taken into account in further research.

Figure 5. Measured value elements.

4.4 Managerial implications of the models

The identified models were mainly frameworks or models developed through equation modelling. As the use of equation based models is often complicated, the managerial implications of what the researches felt the model could be used for were reviewed. The majority of the managerial implications did not consider particularly versatile implications but mainly suggested that the tested model or framework should be employed for evaluation purposes in improving a party's own services or considering the value of the partner. Also other implications were suggested on a few occasions such as customer segmentation, marketing purposes, analysis in greater depth, management, prediction, comprehensive value assessment and identification purposes. As the identification of the important value elements of the service for each partner is the first step in mutual value creation, it is surprising that it was not considered in more models as a managerial implication in addition to evaluation. Even though actors are in the same relationship they might have different perceptions of the service value and therefore the differences should be identified (e.g. Corsaro & Snehota 2010; Aarikka-Stenroos & Jaakkola 2012).

The identification of value elements was mainly considered in the models for comprehensive value assessment as a first step. Only one of the models also provided value elements that could be employed to assist in value identification. Therefore, we conclude that simpler models and tools should be provided to support the first step in the value assessment process. Based on the literature review, we propose four different building blocks for inclusion in the conceptual framework: identify case specific characteristics, different dimensions of value (tangible and intangible), network partners, and creating a mutual understanding of value creating elements.

4.5 Conceptual framework

Based on the identified models and literature considering value creation in relationships, the building blocks for a conceptual framework for collaborative value analysis are now presented. Since we are focusing especially on situations where there are multiple partners (e.g. customer, supplier, service provider and equipment provider in a maintenance network) operating and actively involved in the value creation process, we can see from the literature review results that a model for the identification of service value in service networks is needed because there is a clear research gap that needs to be filled. We propose a conceptual framework and its building blocks for the identification of value elements in a collaborative service network (Figure 6).

The first part of the framework proposes identification of the case specific characteristics of the required and provided service, and which partners should be involved. Especially maintenance services are highly case specific and

therefore the characteristics need to be identified for example if a critical or non-critical item needs to be maintained (e.g. Al-Turki 2011). Often network partners have no common language and concepts are used broadly, and this emphasises the specification of a special case and its value elements.

The second part of the framework presents the different value elements of the service. It has been recognised that in maintenance services value is both tangible and intangible (e.g. Ali-Marttila et al. 2013; Ojanen et al. 2012; Toossi et al. 2013), and the literature review results support this as the majority of the service analysis models considered both. The value elements should include both tangible and intangible elements that can be chosen by the partners (Songailiene et al. 2011; Macdonald et al. 2011; La et al. 2008; Huntley 2006; Fiol et al. 2011; Ng et al. 2012; Barry & Terry 2008; Biggemann & Buttle 2012; Lynne Bennington & Cummane 1998; Logožar et al. 2006; Komulainen et al. 2007; Ojanen et al. 2012; Sole & Carlucci 2010; Aarikka-Stenroos & Jaakkola 2012; Lapierre 1997).

The third part of the framework considers the network view of industrial services. All major members of the service network identify their value elements in the service. The literature review pointed up a lack of models that considered more partners than just the customer and supplier. The framework suggests the main members of the maintenance network, as described by Marttonen et al. (2013), are the service customer, the service provider and the equipment provider. But also other partners can be added to the framework.

The fourth part of the framework proposes that once each service network member has evaluated the elements that create value, the value profiles are brought together so that the member's profiles can be identified and discussed. This is important because even though the actors are working in the same relationship they might have different perceptions of the created value (Corsaro & Snehota 2010). This leads to the fifth part of the framework, where finally the value creating elements for each party are diagnosed and discussed between practitioners to gain a mutual understanding of those elements (e.g. Aarikka-Stenroos & Jaakkola, 2012; Keränen & Jalkala, 2013; Songailiene et al., 2011). All partners should gain insights and together comment on the value process.

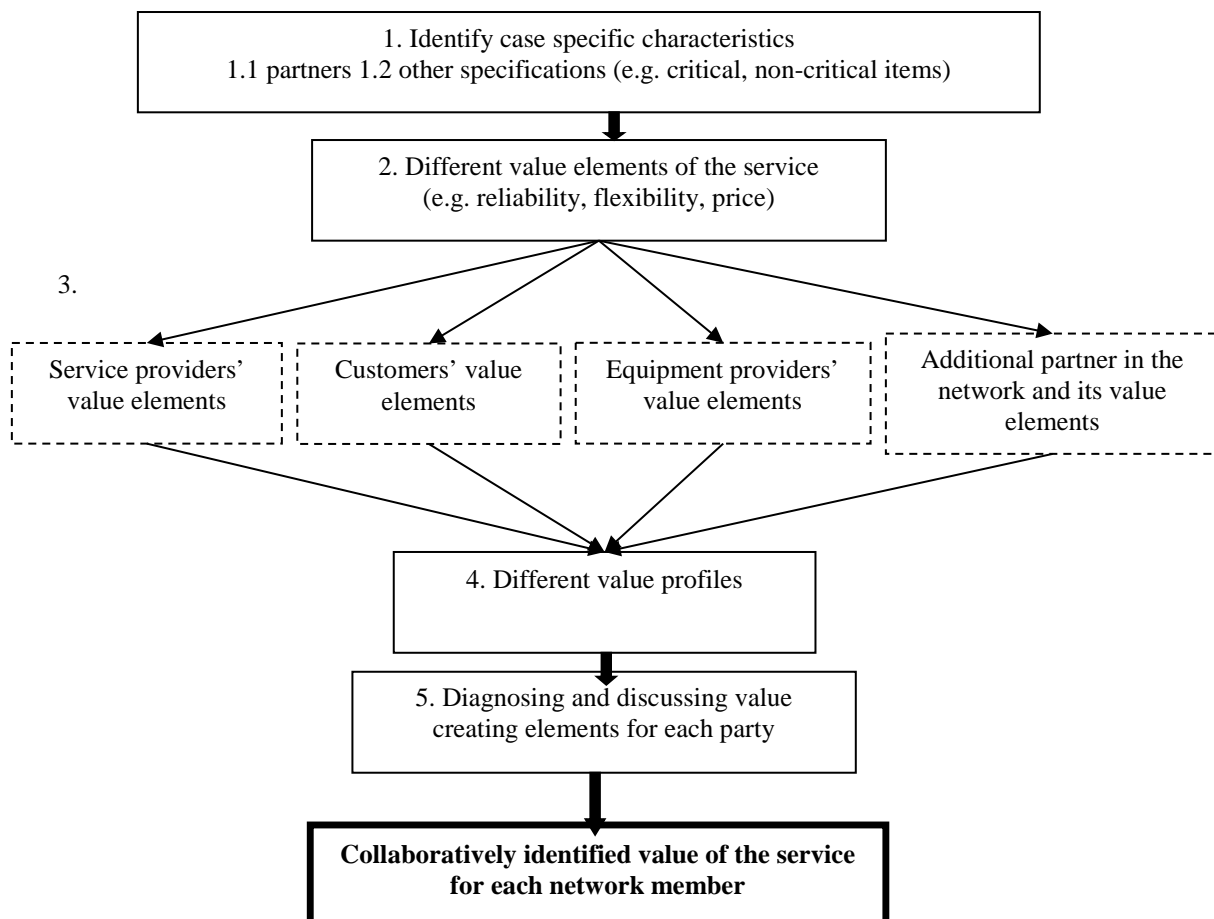

Figure 6. Conceptual framework for collaborative identification of the value elements of the industrial service.

The proposed framework can be employed as a first step in negotiations but also later for the evaluation of current and future services. The evaluation and control of the value elements is also important because the perceptions of benefits and costs may change over time (Corsaro & Snehota 2010)

5 Conclusions

The value elements of all major service network members should be identified because value is co-created. However, there is a lack of easy-to-use models that take into account the value elements of multiple network members. The growing trend for value analysis research shows that there is a need for value analysis models. But the existing models do not as yet take the collaborative context into account and therefore new models are needed to support decision making between network partners (e.g. Ahonen et al., 2010; Lapierre, 2000; MacCarthy & Jayrathe, 2012; Olsson & Espling, 2004; Panesar & Markeset, 2008; Reinartz & Ulaga, 2008).

The current value analysis models found in the systematic literature review considered mainly the customer value perspective, and suggested evaluation tools. It seems that the marketing literature is still focusing on customer value as Purchase et al. (2009) and Ramsay & Wagner (2009) earlier suggested. Supplier views are still rare and none of the identified models considered the collaborative service context where multiple partners (more than just the customer and supplier) operate; this can be considered the main research gap. Future research should also focus on easy-to-use identification models as the models uncovered did not address this. At this point, the identification process was only concluded in a few models where comprehensive value assessment was considered. Comprehensive value assessment is an important practice, but it might be too blunt a tool for some relationships. Also it was not specified how the identification process should run despite mutual discussions.

We propose a collaborative value analysis framework for industrial services which comprises five stages that conclude in a collaboratively identified value of the service. The first stage is to specify the case specific characteristics; the second provides the value elements; the third includes the different network partners; and the fourth and fifth stages present the value profiles and ensure that mutual understanding is achieved on what are the value creating elements in the service for each network partner.

We contribute to the extant value literature by presenting research gaps in the current value analysis models for B2B services. In addition, we present a conceptual framework for a collaborative value analysis model. It shows how the value for each network member can be identified.

Collaborative models and tools are needed to improve network level cooperation between members in maintenance and other B2B services, to build trust and competitive advantage. Appropriate models and their implementation strengthen the service networks and help them compete with other networks.

The systematic literature review has some limitations. Due to its focus on specific keywords, some relevant articles may have been missed. Future research should address this, and for example the reference lists and citation maps of the literature review articles could be checked to make the sample more comprehensive. Also the framework provided is only conceptual and derived from the systematic literature analysis. Empirical analysis based on the proposed concept should be conducted to complete the theoretical findings.

Customer service requirements and co-creation: Empirical study

Argyro Almpantopoulou¹, Jukka Hallikas¹, Mikko Pynnönen²

¹School of business, Lappeenranta University of Technology

²School of Industrial Engineering and Management, Lappeenranta University of Technology

The aim of this study is to empirically test how customer service requirements influence the probability and extent of customer collaboration with the service provider in value creation process. Our results indicate that customer requirements affect the likelihood and intensity of customer-provider collaboration in value creation process. Our findings carry important implications for both service research and service practitioners. Understanding such relationships will enable service providers to optimize their operational strategies according to customers' diverse needs and thus enhance their profitability.

1 Introduction

The rapid development of the service sector is a result of intense global competition, which pressures companies to innovate and excel operationally, so they can address swiftly evolving customer needs and wants by all-inclusive offerings and achieve customer intimacy (Rai; Sambamurthy, 2006; Agndal et al., 2007). In fact, value creation in the service sector is explicitly customer-driven because customers' wants and needs are the actual base of designing the offerings of companies and determining factors in their competitiveness (Howden; Pressey, 2008; Vargo; Lusch, 2008). Thus, it is becoming increasingly important that service providers learn to adjust their offerings to meet divergent customers' needs successfully and interact with customers effectively. It has been suggested that value is collaboratively created with the customer and other stakeholders in a constellation of interactions that generate and form the value split among the actors in a value creating system, which, based on customers' needs, enables the choice of certain complementary elements and their bundling (Normann; Ramirez, 1993; Ramirez; Wallin, 2000; Lusch et al., 2010; Pynnönen et al., 2011).

Research on customer value (co-) creation is not new in the literature. However, there is still a need to understand the factors that affect the customers' level of engagement in value creation (e.g., Epp; Price, 2011; Lusch et al., 2010; Pynnönen et al., 2014). In this study, we focus on customer-related factors (see Kalaignanam; Varadarajan, 2006; Van Doorn; Lemon; Mittal; Nab; Pick; Pirner; Verhoef, 2010) and specifically customer service requirements. The research problem of this paper is to understand how customers' service requirements predict the likelihood of their participation in value creation processes. Specifically, we investigate how much the need for integrated services, information sharing and systemic purchasing orientation explains the probability of intensity of collaboration being high or moderate. In answering these questions, two main methods are used: cluster analysis and logistic regression analysis. In particular, empirical evidence is gathered by means of a structured questionnaire survey. Our results indicate that customers with a disposition towards integrated services are more likely to engage in intense collaboration with the service provider.

The paper is structured as follows. First, on theoretical and conceptual levels we discuss customers' participation in value co-creation. Next, we review the literature of customer service requirements focusing on systemic purchasing, integration of services and information sharing before describing the methodology and presenting the data analysis and the results. Finally, we discuss the findings and present our conclusions.

2 Theoretical background

2.1 Customers participation as co-creators

The fundamental idea in customer value creation is that the firm utilises its resource profile to optimize its product-market activities (Wernerfelt, 1984), thus creating value for its customers, which can be enhanced by identifying any links between a certain resource and a particular product in a specified market (Clulow; Barry; Gerstman, 2007). However, the customer is no longer just a target but primarily a co-producer who can be involved in the entire value creation process acting on operand resources (Vargo; Lusch, 2004). Accordingly, the customer's role in the creation of value in service offerings is central (see e.g., Normann; Ramirez, 1993; Bettencourt, Ostrom; Brown; Roundtree, 2002; Grönroos; Ravald, 2011). Thus, direct interactions with the customer's value creation processes become essential. However, in industrial business-to-business context the depth and intensity of these relationships can vary from conventional transaction-based relationships to closer contractual relationship or even to advanced value partnerships and full-service contracts and solutions (see Stremersch et al., 2001). The deeper the partnership, the more important is the need for an in depth analysis and understanding of the value co-creation process.

The co-creation process can comprise the co-development (see Brax; Jonsson, 2009) and co-production of an offering (see Thomke; von Hippel, 2002). Further it has been argued that co-creation "involves the (customer) participation in the creation of the core offering itself. It can occur through shared inventiveness, co-design, or shared

production of related goods.”(Lusch; Vargo, 2006, 284). Aarikka-Stenroos and Jaakkola (2012) have identified five value co-creation activities: diagnosing needs, designing and producing the solution, organizing the process and resources, managing value conflicts, and implementing the solution; and they argue that the co-creation process can occur in parallel and in diverse order through a dialogical, hermeneutical process that includes the participation of the customer in the formulation of the value proposition.

Customer involvement discusses the opportunity for customers to fully engage themselves in the process of developing a solution which will suit their needs. The extent of customers’ participation or involvement appears to be influenced by a host of factors. According to Literature (see Kalaignanam; Varadarajan, 2006; Van Doorn; Lemon; Mittal; Nab; Pick; Pirner; Verhoef, 2010) these factors can be customer-related, product-related, firm-related and context-related. Environmental trends and developments arising from the political/legal, economic, social and technological context within which customers and providers operate seem to enable companies to engage customer in numerous processes and activities to an even greater extent (Ibid). Further, competitors and their actions also affect customer engagement (Van Doorn; Lemon; Mittal; Nab; Pick; Pirner; Verhoef, 2010). Further, product characteristics e.g. good or service, digital or non-digital etc. may influence the intensity of customer engaging in specific activities and in the whole process. Firm- related factors include issues related to the provider’s ability to increase customer participation e.g. its information resources and skills (Kalaignanam; Varadarajan, 2006).

The customer-related factors can include customer satisfaction, knowledge structure, receptivity toward the provider, and resources such as time, effort, and money (Kalaignanam; Varadarajan, 2006; Van Doorn; Lemon; Mittal; Nab; Pick; Pirner; Verhoef, 2010). Furthermore, customers’ motivation towards engaging in deep partnerships seem to be boosted when they anticipate benefits like enriched knowledge, social benefits, and economic benefits such as cost savings (Nambisan; Baron 2009; Füller, 2010). Thus, there is a need for effective platforms for information exchange and interaction as well as rewards for customers’ contributions (Baron; Warnaby 2011; Dholakia; Blazevic; Wiertz; Algesheimer, 2009; Füller 2010). In addition, customer goals as well as their needs, wants and dispositions can also affect the probability and intensity of their participation in co-creating activities (Van Doorn; Lemon; Mittal; Nab; Pick; Pirner; Verhoef, 2010). Therefore, based on the above the following hypothesis is posed:

H1. Customers’ requirements predict the likelihood of their participation in the value creation process.

2.2 Customer service requirements

2.2.1 Systemic purchasing orientation and integration

An important strategic choice of the purchasing function is associated to the distribution of the purchase entity to its supplier network. This often relates to bidding every part and service separately or buying larger entities. An advantage of the purchasing smaller entities can be recognized as market price efficiency and increased competition among suppliers. This approach is often most advantageous if organizations emphasize direct purchasing price as a measure of purchasing value. Another option is to stress the total value or cost of purchase and include the value of the whole system into consideration (Hallikas et al., 2014). This refers to the integration advantages of the system parts and services. Systemic advantages are often gained when one supplier is responsible of integrating several parts and service together. In this approach firm purchases systems rather than individual parts. This is rather similar than in the network sourcing approach (Hines, 1994) where larger entities reduces the number of direct suppliers, increases degree of supplier innovation in both new processes and processes, and involves high degree of trust, openness and profit sharing between supply network members.

Value creation is a complex phenomenon that has a strong linkage to the characteristics of the purchased service (Anderson; Narus, 1998). In the cases when the value creation is connected to the integrated and systemic features, the customers are also more willing to buy integrated systems rather than separate goods and items. An important element in the value creation is related to the phenomena of systemic value creation, which can be explained by the concepts of product bundle and integration value. The benefit of the integration can be defined as a process of bringing together potentially diverse products and services in ways that create value (Epp; Price, 2011). Systemic purchasing is also buying of material and service together. Here, buyers prefer to purchase entities as a whole package.

It has been investigated in the previous studies that systemic features may have significant role in customer purchasing orientation in the industrial service supply chains (Hallikas et al., 2013). Identified benefits of expected monetary savings, increased convenience and reduced compatibility risk are mentioned as reason to purchase bundles (Harris; Blair, 2012, Sarin et al. 2003). This implies that the customer is often likely to choose an offer which provides better systemic functionalities. Companies purchase services from different reasons, but the common denominator here is that the services procured are expected to solve some of their specific problem in somewhat collaborative way between the buyer and provider (Ulaga; Chacour, 2001; Vargo; Lusch, 2008). The customer expectation is that the provider can provide the services as a solution to the problems in hand but the relationship is bipolar i.e. the customer has also a role in the service execution (Tuli et al., 2007). The customer requirements towards the service provider can be related to customization benefits, deployment process, integration benefits and life-cycle cost advantage (Tuli et al., 2007, Worm et al., 2009).

As service providers increasingly replace single offerings with integrated solutions, their connections with their customers become stronger (Hax; Wilde, 1999; Gudergan, 2010). This is because of the greater depth of the customer-provider relationship in integrated service provision (Davies; Brady; Hobday, 2007). Specifically, these stronger bonds are enhanced by close proximity to the customer, which makes it possible for providers to foresee their needs and successfully collaborate to develop and configure new technology, products and services that fulfil these needs (Davies, 2004). In fact, it has been widely argued that companies should be able to understand the customer's perspective on value creation in order to provide solutions that link optimally to the customer's priorities (Wise; Baumgartner, 1999; Galbraith, 2002; Davies, 2004). Previous studies (e.g. Oliva; Kallenberg, 2003; Matthyssens; Vandembemt; Weyns, 2009) have recognized that customer involvement and close collaboration with a leading customer is followed by successful industrial service development. However, further investigation is needed regarding the need for the close collaboration and participation of customers (Windahl; Lakemond, 2006). Since different customer goals and integration requirements demand diverse collaborative strategies.

2.2.2 Information sharing

Information sharing has been regarded as an essential element in an effective supply chain relationship between buyer and supplier. For example the study of Lee et al. (2000) illustrates that the value of demand information sharing can be quite high in the case of buyers and their upstream suppliers. Other reported information sharing benefits derived from the research include that supply chain members can gain benefits in terms of reductions in inventory levels and cost savings from forming partnerships with one another (Yu et al. 2001). Additionally, information sharing allows companies to make reliable delivery and introduce products to the market fast (Li; Lin, 2006) which leads to high levels of integration among partners in the supply chain (Jarrell, 1998).

However, making the information accessible is not enough as the significance of its impact on customer-provider relationships highly depends on what information is shared, when and how it is shared. The quality of information shared (e.g. the accuracy, timeliness, adequacy, and credibility) has a positive effect on customer satisfaction and partnership quality (Monczka; Petersen; Handfield; Ragatz, 1998; Spekman; Kamauff; Myhr, 1998. Lee; Kim, 1999). According to Van Doorn et al. (2010) when customer has all the necessary information about the provider is more likely to participate in value creating activities and processes. It follows that information sharing has value creation potential in terms of collaboration with customer (Hallikas et al., 2014), meaning that the provision of real-time, customer-level information and interaction enable the creation of long-term profitable customer relationships (Massey; Montoya-Weiss; Holcom, 2001).

3. Methodology

3.1. Sample and data collection

The method of data collection includes a structured questionnaire survey. As our target group we selected customers of the B-to-B infrastructure service provider whose purchases related mainly to the IT network and the energy infrastructure. Data were collected through a web survey and the link was sent to the customers via the CRM system of the infrastructure service provider. Two weeks after the original posting we sent a reminder to the same respondent list. The general survey instrument included measures covering background information, systemic purchasing orientation, collaboration between the focal firm and its customers, as well reflections on the importance of integrating separate services. We classified the respondents as knowledge workers, managers or specialists. The respondent ratio was 17 per cent that is; there were 149 responses to the 864 emails sent. A T-test was conducted to assess the existence of a non-response bias on all variables. Based on Armstrong and Overton (1977) we compared the early respondent groups to those that responded after a reminder. Since no statistically significant differences were revealed, we concluded that non-response bias did not affect the results of the study.

3.2. Measures and descriptive statistics

The measurement included multi-item scales that were mainly gathered from the previous literature and modified to fit the scope of this study. All items were statements measured with a seven-point Likert-scale ranging from 1 = not very important to 7 = very important or from 1 = strongly disagree to 7 = strongly agree.

First, we mapped the provider's service offering in workshops with a group of experts and specialists from the provider. They described the service attributes and evaluated the service offering. Table 1 lists the service functions. To measure the customer's need for integrated services, we then asked them to evaluate the importance of the integration of a service in a total service package. Intensity of collaboration comprises measures related to the intensity of co-development (Brax; Jonsson, 2009) and co-production of the service offering (Thomke; von Hippel, 2002).

Table 1. Services.

Service	Description
Helping in network development	Network-present-state studies, planning and developing networks
Network design	Implementation plan for network-development strategies
Field planning	Planning network routing and resolving land-usage issues
Work planning	Planning the network structures and the execution of the construction
Excavation work	Digging trenches and burying cables, Installing fibers, wires and pipelines
Connecting networks	Scheduling start-up with the network operator and other customers, connecting cables
Quality inspection	Inspecting the operability of the network and removing possible problems/faults
Preventive maintenance	Monitoring the network condition and introducing measures to ensure its functioning
Spare-part management	Ensuring the supply of spare parts for standby situations
Fault-situation management	Receiving alerts, Locating the site, Forming repair plans, Arranging fault separation
Fault separation	Arranging back-up connections and on-line reserve power
Fault locating (on-site)	Locating faults on site by visual means or with special equipment
Fault repairing	Bringing out damaged network parts, repairing indicated faults at the site
Automation	Creating interfaces between customer databases and the service provider's systems
Logistics	Managing stock and ordering supplies as a complete service
Aligning processes with the customer	Defining interactions between customer and service provider
Reporting	Services for sharing documents and reports between customer and service provider

Furthermore, systemic purchasing orientation reflects buying behavior that is service dominant when the purchased system consists of both goods and services. Generally, integration is defined as the process of gathering together potentially diverse products and services in order to create value (Epp; Price, 2011). When the definition is applied to purchasing and supply management, services and products can be purchased from one supplier and system suppliers are preferred (Davies et al., 2007). Provider information sharing on network level is considered an important aspect of customer-provider relationships (Lancastre; Lages, 2006). Communication can be defined as the formal or informal sharing of meaningful and timely information between firms (Anderson; Narus, 1990). One essential feature is availability and consistency of the shared information in the interests of speed and convenience at the general-solution level (Mikkonen, 2011). Table 2 reports the descriptive statistics and Alpha scores.

Table 2. Descriptive statistics.

Measures	N	Mean	St. Dev	Alpha
Intensity of collaboration	139	5,95	0,83	0,912
The service offering is continuously developed in collaboration with our personnel.				
We co-operate extensively with service provider with respect to service design.				
We co-operate extensively with service provider with respect to service process design.				
We co-operate extensively with service provider with respect to forecasting and production planning.				
We co-operate extensively with service provider with respect to quality practices.				
Intention to systemic purchasing	139	4,60	1,22	0,733

<i>Measures</i>	<i>N</i>	<i>Mean</i>	<i>St. Dev</i>	<i>Alpha</i>
We appreciate that whole service package can be purchased from one supplier. Our aim is at purchasing whole service systems rather than separate service elements. We pay much attention to that purchased services are integrated in a way that they work smoothly together.	141	5,42	0,84	0,781
Information sharing				
Information is tailored for my task Information matches with the information from other sources Information is online Provider offers information about ongoing performance				
Need for integration				
See Table 1	135	5,18	1,03	0,907

3.3 Data analysis and findings

Two research methods were utilized. First, cluster analysis was used to classify the respondents based on the extent of their collaboration with the service provider in the value creation process. The results of the cluster analysis were used to transform our dependent variable (intensity of collaboration) into binary for the needs of logistic regression analysis (LR). The binary variable was made using mean as the cut point. Thus, in the new variable, 0 represents moderate collaboration and 1 high collaboration (see table 3). The independent variables of the analysis are the need for integrated services, information sharing and systemic purchasing orientation. Analysis for both cluster analysis and logistic regression was performed using IBM SPSS Package.

Table 3. Clusters.

Cluster	1	2
Description	Moderate collaboration	High collaboration
Size	 51,8% (72)	 48,2% (67)
Mean	3,71	5,56

Logistic regression analysis was used because it can assist in profiling the intergroup characteristics of the subjects and in allocating them to their appropriate groups. Specifically, LR enables the understanding and explanation of research problems that involve a single categorical dependent variable and numerous metric independent variables. The outcomes of logistic regression can assist in profiling the intergroup characteristics of the subjects and in allocating them to their appropriate groups (Hair; Black; Babin; Anderson, 1998). Unlike in the linear regression, a logistic regression model is based on predicting probabilities between two cases. Further, compared to other research methods, logistic regression is more flexible since it does not make any assumptions about the distributions of the variables (Landau; Everitt, 2004; Tabachnick; Fidell, 2013).

A test of the full model against a constant only model was statistically significant (Table 4), indicating that the predictors as a set reliably distinguished between those engaging in moderate co-creation and those of in high co-creation (chi square = 14,664, $p < .05$ with $df = 3$). Nagelkerke's R Square (Table 5) of 0,150 indicated a moderate relationship between prediction and grouping. The classification results (see table 7) shows that inclusion of the need for integrated services, information sharing and systemic purchasing orientation factors increase the percentage of correct classification by 0,7 to 73,1%-compared to the 72,4% for the step 0 when only the intercept was included into the model-. According to the Hosmer and Lemeshow (H&L) value (see Table 6), which measures the correspondence of the actual and predicted values of the dependent variable (Hair; Black; Babin; Anderson, 1998), we have a non-significant chi-square value ($p > 0, 05$) indicating a smaller difference in the observed and predicted classification, meaning that our model is good.

Table 4. Omnibus Tests of Model Coefficients.

		Chi-square	df	Sig.
Step 1	Step	14,664	3	0,002
	Block	14,664	3	0,002
	Model	14,664	3	0,002

Table 5. Model Summary.

Step	-2 Log likelihood	Cox & Snell R Square	Nagelkerke R Square
1	143,256	0,104	0,150

^a. Estimation terminated at iteration number 4 because parameter estimates changed by less than ,001.

Table 6. Hosmer and Lemeshow Test.

Step	Chi-square	df	Sig.
1	3,918	8	0,864

Table 7. Classification Table.

Observed		Predicted		
		Collaboration		Percentage Correct
		Moderate	High	
Collaboration	Moderate	7	30	18,9
	High	6	91	93,8
Overall Percentage				73,1

The Wald criterion demonstrated (see table 8) that the only factor having a statistically significant ($p=0,004$) effect on the dependent variable, intensity of collaboration, is the factor of need for integration. When analyzing the Exp(B) column, it indicates that the customers with a disposition towards integrated services are 1,917 times more likely to engage in intense collaboration with the service provider. The p-values for the other factors are quite high (SPO: $p=0,134$, IS: $p= 0,494$), indicating that they are not significantly predictable for co-creation.

Table 8. Results of the binary logistic regression analysis.

	B	S.Error	Wald Chi-square	Df	Sig.	Exp (B)
Systemic purchasing orientation	0,381	0,254	2,245	1	0,134	1,464
Information sharing	-0,184	0,269	0,467	1	0,494	0,832
Need for integration	0,651	0,224	8,472	1	0,004	1,917
Constant	-3,586	1,775	4,081	1	0,043	0,028

Finally, we calculated the values for standardized residuals and Cook's distance, and save them to the data set. To eliminate the outliers and influential cases, we request the cases that are not outliers or influential cases. Namely, we utilized a formula that specifies that we should include cases if the absolute value of standardized residuals is less than 3 and the Cook's distance value is less than 1.0. Our results showed that there is no outlier effect and no case need to be removed; therefore we do not remove any of the observations.

4 Discussion and conclusions

The aim of this study was to empirically test how customer service requirements (i.e. the need for integrated services, information sharing and systemic purchasing orientation) influence the probability and extent of customer collaboration with the service provider in value creation processes. Our results indicate that customer requirements affect the likelihood and intensity of customer participation as co-producers, so our hypothesis is accepted. This result contributes to literature regarding customer participation (e.g Kalaignanam; Varadarajan, 2006); customer engagement behavior

(e.g. Van Doorn; Lemon; Mittal; Nab; Pick; Pirner; Verhoef, 2010) and the generic service-dominant logic (see Vargo & Lusch, 2004; Vargo & Lusch, 2008; Hallikas et al., 2014). These streams of research have highlighted the importance of customer's role in value creation and have provided frameworks that help in understanding the different aspects of customer participation in this process. However, there is still need to go deeper in these aspects and empirically test their relationships and our study contributes in that part.

Previous studies (e.g., Windahl & Lakemond, 2006; Vargo & Lusch, 2008; Hallikas et al., 2014) argued that the customer is always involved as a co-creator of value and the intense collaboration and key development responsibilities of the provider are fundamental elements of integrated purchasing. Additionally, the previous literature (e.g., Morgan & Hunt, 1994; Davies et al., 2007; Caldwell et al., 2009) found that the customer-provider relationship in integrated service provision does not end with the purchase and is in effect a partnership, implying that customers in need for integrated services are inclined to participate more intensively as co-producers. Our results largely support these arguments; as it seems that customers in need of integration are more likely to engage in strong collaboration. Interestingly, our findings indicate that information sharing and systemic purchasing orientation do not significantly predict the extent of collaboration. Firstly, the result for information sharing could be explained by the fact that today reliable information are openly available and from various sources, hence access to information does not necessarily need intense participatory behavior. Secondly, the result concerning systemic purchasing orientation could be explained by the fact that customers that prefer purchasing seamless-functioning whole service packages from one service provider expect that their participation in the development of the offerings is the least possible.

The results of this study also have interesting implications for service providers. First, our results clearly indicate a growing need for service providers to be able to adjust their cooperative resources, capabilities, and processes according to the diverse requirements of their customers' needs. Specifically, providers of integrated service offerings should be capable of intense collaboration and interaction with the customer. Further, it is no more enough for service providers to segment their customers based on their perceptions of the brand or other demographic criteria. Other factors such as customers' propensity to participate in value creation activities should be considered as they can help to form more thorough segmentation strategies and boost the efficiency of their operations with the ultimate goal to maximize profitability.

4.1 Limitations and further research

The following limitations of our study will serve as the basis for further research. First, the degree of Nagelkerke's R (0,150) in our model seems moderate to low. This result indicates that other factors could better predict the likelihood of intense collaboration. Further research could strive to identify such factors in order to create a more comprehensive view of the influences on the probability and extent of customers' engagement in value creation activities. For example, customer satisfaction, perceived costs and benefits etc. (see Van Doorn; Lemon; Mittal; Nab; Pick; Pirner; Verhoef, 2010) are potential customer related factors. However, apart from customer related factors, literature (Kalaigianam; Varadarajan, 2006; Van Doorn; Lemon; Mittal; Nab; Pick; Pirner; Verhoef, 2010) has identified factors related to the firm, environment and product. Hence, an interesting future study could search for how much such factors (e.g. firm reputation, provider's informational skills, digital vs. non-digital products etc.) predict the intensity of customer participation. Such findings would further contribute to the research on customer engagement, customer participation and value co-creation. In addition, future research could also investigate how different factors interact with each other to influence the customers' participatory behavior.

The measures were explored within the customer base of one service firm, which limited the generalizability of the results. Further studies could focus on a larger number of firms, including those in other industries, thereby increasing the generalizability of the results. Additionally, even though the analysis showed that a non-response bias did not influence the results, a larger sample would have strengthened our findings. Finally, further in-depth qualitative and quantitative studies are needed to investigate these phenomena and determine why and how they occur.

Service Productivity: Evaluation of Concepts from Literature

Schafiq Amini, Roland Jochem

Department of Quality Science, Technische Universitaet Berlin, Germany

Abstract

Reviewing the literature you will find high level concepts to measure service productivity. The purpose of this paper is to point out that there is a need of a practical approach to measure service productivity. Common service productivity concepts from literature are introduced and evaluated with the aid of a structured criteria model. The criteria model will especially evaluate the practical application of the concepts in service companies with high interactions between customers and suppliers. A lot of concepts point out that there is a correlation between service quality and service productivity. But these concepts do not consider how to measure this correlation between service quality and service productivity. Service productivity concepts from the literature consider either the “what” but not the “how”.

1 Introduction

The measurement and evaluation of service productivity is quite different than for industrial processes. Especially services with high interaction between customer and supplier are characterized by process performance and product output performance. Customers not only evaluate service product but also service process. Therefore measurement and evaluation concepts have to consider not only process output figures but also process performance figures. Process performance figures are characterized by three dimensions: quality, time and cost (Magnusson et al., 2001). All these three dimensions need to be taken into consideration for the measurement and evaluation of service productivity. These figures interrelates which each other. Service productivity concepts have to show the relationship between the figures.

Reviewing the literature you will find high level service productivity concepts, which are neither practically applicable nor show the interrelationship between service process and service product. This paper will introduce widely known service productivity concepts from literature. Afterwards these concepts will be evaluated with the aid of a criteria catalogue to point out the need of a practical approach to measure and evaluate service productivity.

2 Approach

A lot of concepts of productivity measurement in manufacturing were introduced years ago and are based on the relationship between outputs and inputs. Concepts of service productivity measurement are quite rare and at the moment a very important research field (Johnston/Jones, 2003; Biege et al., 2013). The biggest challenge is that you especially have to consider the interaction of the customer during the service production process if you want to measure service productivity. Therefore it is impossible to simply transform traditional manufacturing productivity measurement approaches to services (Biege et al., 2013). Furthermore you have to deal with quality issues during service productivity measurement. The customer not only evaluates service product but also service process performance. It is a dynamic evaluation of the customer, which has to be taken into consideration during the service productivity measurement. In the following sections of this paper widely known service productivity concepts from literature will be introduced. Next step will be the evaluation of the concepts concerning their practical application.

2.1 Service productivity concept of Parasuraman

The concept of Parasuraman describes service productivity from the viewpoint of the customer and the service supplier. Service quality is one major fact in this concept, as it is the connection point between customer and service supplier (Parasuraman, 2010; Parasuraman, 2002).

Figure 1. Service Productivity Concept of Parasuraman (Parasuraman, 2002).

The productivities stand in relation with each other. On the one hand the inputs from customers and suppliers are substitutable. There is a need of an effective allocation of resource on the input side. On the other hand outputs also stand in relationship. Customer's output (e.g. customer satisfaction) has a positive effect of suppliers output. The concept of Parasuraman takes the service quality into account. Service quality is here neither an input nor an output of service productivity. It is rather a separate variable, which is influenced by input factors from customer and supplier and which influence their output factors (Parasuraman, 2010; Parasuraman, 2002).

2.2 Service Productivity Concept of Grönroos and Ojasalo

In the concept of Grönroos and Ojasalo the integration of customers in the service process is a significant factor. Grönroos and Ojasalo make a distinction between three different service processes (Grönroos/Ojasalo, 2004; Grönroos, 2007):

- Service process which is solely created by the service provider
- Service process which is created from customer and service provider
- Service process which is solely created by the customer

The following figure shows the concept of Grönroos and Ojasalo.

Figure 2. Service Productivity Concept of Grönroos and Ojasalo (Grönroos/Ojasalo, 2004).

Like other concepts Grönroos and Ojasalo differ between objective and subjective outputs. They point out the importance of quality aspects in service processes, either as output parameter or during the service process. Further the concept of Grönroos and Ojasalo makes a difference between several types of efficiency (Grönroos, 2007):

- Internal efficiency
- External efficiency
- Capacity efficiency

Internal efficiency describes the relationship between produced output and used resources. External efficiency is the ability to achieve a certain degree of quality in the context of service offering. Capacity efficiency reflects the degree of capacity utilization. Grönroos and Ojasalo point out that there could be a negative relationship between quality and capacity utilization. A high degree of capacity utilization can result in a degradation of quality perception (e.g. a company reduces its staff capacity to optimize the utilization ratio. Result is a higher waiting time for customers and a reduction of perceived quality (Grönroos, 2007).

2.3 Service Productivity Concept of Johnston et al.

The concept from Johnston et al. makes a difference between operational productivity and customer productivity, which overlap to some extent (Johnston/Jones, 2003; Johnston/Clark, 2001).

Figure 3. Service Productivity Concept of Johnston et al. (Johnston/Clark, 2001).

Operational productivity is the quotation of operational outputs to inputs over a certain time period. In this context inputs are materials, customers, employees and costs. Outputs are customers, used resources, revenues. Customer productivity is the quotation of customer inputs (e.g. time, cost, efforts) and outputs (like experiences und benefits). Service quality is not a separate figure in the concept of Johnston and Jones but one output between lots of output parameters. For Johnston and Jones the biggest challenge is the definition of the relationship between operational productivity and customer productivity (Johnston/Jones, 2003).

2.4 Service Productivity Concept of Corsten

The concept of Corsten distinguishes two service productivities (Corsten, 1994; Corsten, 2007):

- Internal developed willingness to produce (potential phase)
- Productivity of end combination (production phase)

Figure 4. Service Productivity Concept of Corsten (Corsten, 2007).

The potential phase is that part of service production process, which is independent from customer. In the potential phase the service provider reveals the potential of his service offerings. For example a hairdresser makes his premises and work utilities available to state his potential to implement the service. In the second phase, the productivity of end

combination, the potential of service is used to generate the service output. In the hair dresser example this would be the process of hair cutting. Due to the differentiation between potential phase and production phase there is separation of productivity measurement. The measurement of productivity in the potential phase is equivalent to the traditional industrial productivity concept. The productivity of the potential phase is an input of the productivity of the production phase. During the production phase there is an interaction between customer and service provider. Therefore there are three different factors, which influence the productivity of the production phase (Corsten, 1994):

- the productivity of the potential phase
- the interaction between customer and service provider
- the performance of the service provider during the production phase

2.5 Service Productivity Concept of Kleinaltenkamp et al.

The concept of Kleinaltenkamp et al. differs between two productivities (Kleinaltenkamp et al., 2008). In the first phase, the potential phase, the non-current and current assets are the basis for the service production process. The combination of assets and the capabilities and resources of service provider constitute the internal factor and define the service potential. In the second phase the internal factors and the external factors, e.g. the consumer, are combined with each other to produce the service. The integration of external factor is the main difference between the first and the second phase. In this context Kleinaltenkamp et al. point out, that the integration of external factors during the service production process can optimize but also reduce the efficiency of the service provider. That depends on the capability of the customer (Kleinaltenkamp et al. 2008).

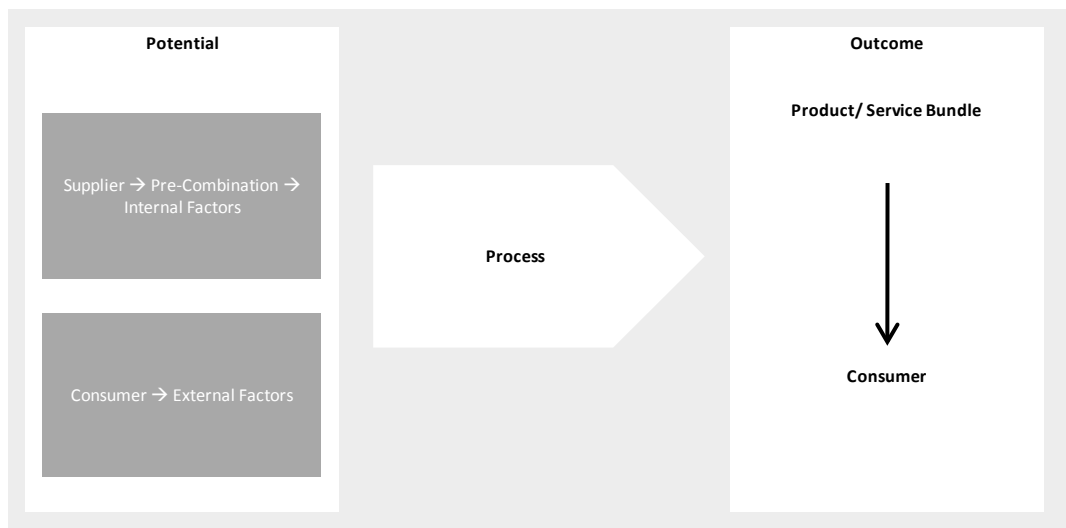

Figure 5. Service Productivity Concept of Kleinaltenkamp et al. (Kleinaltenkamp et al., 2004).

2.6 Service Productivity Concept of McLaughlin and Coffey

McLaughlin and Coffey define a classification scheme with the following dimensions (McLaughlin/Coffey, 1990):

- complexity of inputs and outputs
- degree of aggregation
- customization

Complexity of inputs and outputs means first of all how many inputs and outputs characterize the service process. McLaughlin and Coffey point out, that the complexity depends on the service mix (number and type of service offered).

Degree of aggregation differs between the measurement of outputs and inputs on an aggregate (e.g. firm level) or disaggregate (e.g. process level) basis (McLaughlin and Coffey, 1990).

Customization refers to the degree of variability in the output of the process. This variability depends on the degree of consumer involvement during the service production process.

McLaughlin and Coffey use this classification scheme to position common methods of productivity measurement, like output/input ratios, Data Enveloped Analysis or Quality plus techniques (Quality plus techniques describes the recognition of quality during the service productivity measurement). They integrated this classification scheme into their procedure for Service productivity analysis, which is illustrated in the following figure.

Figure 6. Service Productivity Concept of McLaughlin and Coffey (McLaughlin/Coffey, 1990).

2.7 Evaluation of the concepts

In the following the service productivity concepts will be evaluated especially concerning their practical application. Therefore there is a need to define the criteria which are characteristic for the practical application. The main requirement for the criteria is that they describe the “how” and not only the “what” of the measurement of service productivity.

The main question in this context is: How can we measure and evaluate service productivity and what do we need therefore? The authors define main criteria to evaluate service productivity concepts concerning their practical application:

- Service productivity measurement needs key performance indicators on input and output side. So there is a need of a methodology to generate key performance indicators.
- The performance measurements indicators should also cover the whole process performance. That means that they have to be derived from the dimensions quality, time and cost.
- Key performance indicators have to be in relationship with each other on the input and output side. The service productivity concept has to consider the relationship between the key performance indicators.
- Service productivity concepts should have a method to aggregate service productivities to an overall productivity.
- There is a need of the definition of concrete measurement points in the service process to measure service productivity.
- Service productivity has to recognize service quality during the service production process and as output parameter. The customer not only evaluates the output of a service but also the service production process.
- Service productivity concepts has to take into account that the overall service productivity consists of customer part of productivity and operational productivity

- There has to be a systematic to define the concrete relationship between customer part of productivity and operational productivity.

The following figure shows the result of the evaluation of the introduced service productivity measurement concepts.

Figure 7. Evaluation overview of introduced service productivity concepts.

Figure 7 illustrates that none of the service productivity concepts are fully suitable for practical application. The main deficits are the recognition of performance indicators, the coverage of whole process performance, the definition of the relationship of key performance indicators and the definition of an aggregation approach for an overall productivity. The concepts mainly make clear what we have to do to measure service productivity but they have deficits in the definition of the how.

3 Summary and Outlook

Service productivity measurement is quite different than industrial productivity measurement. There is a need of the consideration of customer's influences during service processes and that customers not only evaluate the service product but also the service process. Therefore it is impossible to adapt industrial productivity measurement concepts for services.

It has been shown, that the illustrated service productivity concepts are not fully suitable for practical application. The main focus of the presented service productivity concepts is to illustrate service productivity measurement from a high-level view but not from operational view. There is a need of a generic approach to concretely measure service productivity. In this concept you especially have to deal with key performance indicators and their concrete relationship, with aggregation approaches to define overall productivity. You also have to consider the whole process performance and therefore the dimensions quality, time and cost with the definition of their relationship. The introduced service productivity concepts provide a solid framework for further research and development of practically applicable approaches.

Eco-innovative construction business models for social development

Carmen Antuña Rozado¹, Pekka Huovila¹, Aapo Huovila¹, Álvaro Corredor Ochoa²
¹VTT Technical Research Centre of Finland, ²SYKE The Finnish Environment Institute

Abstract

ecobim project has already identified a number of business opportunities for eco-innovation within the construction sector. Opportunities related to BIM, PLM, LCA and Monitoring are being developed through real case studies in Finland, France and Germany. Other opportunities not related to BIMs and ICTs are explored through co-creation workshops with different stakeholder groups supported by ecobim networking platform.

This paper focuses on the findings of the methodology followed in the workshops to develop eco-innovative services for social development and their corresponding business models, seen from the perspective of service research theory and in terms of service development.

1 Introduction: ecobim context

The main expected outcome of ecobim, Value Driven Life Cycle Based Sustainable Business Models (Eco-Innova 1st Call) is the development of a set of guidelines based on indicators for sustainable eco-innovative construction business models. As a result, this process will also provide a roadmap for enterprises, particularly SMEs, at a European level, and easy-to-understand recommendations for policy makers. It has also established an online networking platform with SMEs to discover new innovation fields within the construction sector and develop the required methodologies and tools to serve the whole value network.

ecobim project has already identified a number of opportunities for eco-innovation within the construction sector and is currently working on the following: BIM checkers and assessment, Product Life Management (PLM), Life Cycle Analysis and Production of Eco-Indicators, Monitoring of Buildings and other business opportunities not necessarily related to BIMs and ICTs. Opportunities related to BIM, PLM, LCA and Monitoring are being developed through real case studies in Finland, France and Germany. However, other opportunities not related to BIMs and ICTs are being explored through co-creation workshops with different stakeholder groups supported by ecobim networking platform (see Figure 1).

This paper focuses on the findings of the methodology followed in the workshops to develop eco-innovative services for social development and their corresponding business models, seen from the perspective of service research theory and in terms of service development.

Figure 1. Opportunities for eco-innovation identified by ecobim project. (Pekka Huovila & Carmen Antuña, VTT).

2 Innovation models

2.1 Innovation systems

Innovation systems analysis has been performed by several authors in recent decades (Freeman, 1987; Lundvall, 1992; Nelson, 1993; Edquist; Johnson, 1997). Currently one of the most well-known international innovation systems is SRI International's *Five disciplines of innovation*® (Carlson, Wilmot, 2006). VTT has also developed its own *3i Innovation System*. Both systems have been analysed for the development of proposals in the ecobim project. SRI International system offers 5 basic starting points for a market success. These five points are:

- Important Customer and Market Needs
- Value Creation
- Innovation Champions
- Innovation Teams
- Organizational Alignment

“Knowing the Important Customer Needs” represents about 50% of SRI Enterprise Innovation Index; although the numerous workshops made with governments, universities and investors have shown that only 10–20% of the key actors have had a clear idea of the customer needs. “Value Creation” is the most important point for SRI International and represents 60% of their Enterprise Innovation Index. The process for value creation of the product or service does not follow a straight timeline, and in the end always a lower value product/service is obtained instead of the desired one. How to measure value creation is critical to business success. Carlson and Wilmot (2006) proposed a series of concepts easy to understand but difficult to perform to achieve business success. One of the concepts is to have a toolbox of best practices, which focus on the customer's needs, both internal and external, that creates using a common language, a set of tools for the value creation in a process to rapidly develop customer value. Few leading companies use these types of practices as an important source of competitive advantage (e.g. Medtronic, IDEO, Baldor, P&G, etc.), but their results are impressive. “Innovation Champions” represents 60% of the Index and the correct choice of Innovative Team 70%. It is very important to choose good partners who have unique capabilities for better value creation. Finally, Organizational Alignment represents another 60% of the Index for a total of innovativeness of 7.56%.

VTT's *3i Innovation System* is similar to SRI International's *Five disciplines of innovation*®, though it is a system based on continuous learning by doing and developing their own Innovation System. The 3 “i” are Identification, Invention and Implementation.

To identify an important need, VTT proposes to use the customer whenever is possible, create a Market Map, target the potential customer segments for the product/service and try to identify the important needs of those. When it comes to inventing or proposing services or products to the customer, VTT considers doing it together with the customers whenever possible. VTT also promotes value creation through the NCBA system, using a unique approach to meet the important needs of the customer, locate the benefits that will result as well as the differentiation between competitors and disruptive elements. Also the implementation phase is meant to be done together with the customer whenever possible. During the implementation, it is considered of major importance to create value for the customer according to the value proposition. It is important to have a champion team and find out if there is a need of support from other organizations to implement the product or service.

2.2 Eco-innovation

Innovation processes have suffered a change since the Earth Summit in Rio in 1992 (Rennings, 2000, 319-320) and accelerated a shift in mentality so that innovation would be used for sustainable development. In 1996 Claude and Peter James Fussler defined for the first time eco-innovation as “*the process of developing new products, processes or services which provide customer and business value but significantly decrease environmental impact*” (Fussler; James, 1966). If the definition of innovation is fairly neutral on the content of change and open to all directions, the eco-innovation goes on a one-way progress through sustainable development. There is a recent European programme, more strictly focused on eco-innovation, namely the Eco-Innovation Action Plan (EcoAP) that pursues also reducing pressure on the environment through innovation within the framework of the Europe 2020 strategy. This programme will help to mobilize financial instruments and support services for small and medium-sized enterprises (SMEs) to improve investment readiness and networking opportunities related to eco-innovation (Triguero et al., 2013, 25)

The eco-innovations can be developed by firms or non-governmental organizations, can be traded on markets or not, their nature can be technological, organizational, social, or institutional (Rennings, 2000, 322). Changes in lifestyle and consumption behaviour (Scherhorn et al., 1997, 16), a shift in the modal split from private car transport toward bicycling or the creation of environmental awareness in firms (Rennings, 2000, 324) could be considered as social eco-innovations.

The need for eco-innovation is increasingly recognised and viewed as becoming even more urgent in a world of a growing population and changing consumption patterns (The Royal Society, 2012), and the construction sector can be considered as one of the most responsible for material and energy consumption and emissions in the environment (Allione, 2007, 1).

“There is limited understanding of how initial new ideas and concepts develop..., and how these ideas become the basis for product development. Moreover, there is little understanding of organisational mechanisms, tools, activities and techniques employed within innovation projects, which enable environmental-specific innovation to arise and commercialise in particular in the early stages of the innovation process”. (Bocken et al., 2014, 44)

After analysing different innovative systems and based on the results of the SRI International’s workshops showing that only 10-20% of the key actors clearly knew which were the customer needs (Carlson; Wilmot, 2006), and that customers are the most important source of innovation (Von Hippel, 1988), it was appropriate to then locate groups of key actors in order to obtain a clear idea of the needs they might have in the construction sector and thus to develop an eco-innovative social service.

For ecobim project, the initial standpoint was that paradigm change towards eco-innovation within the construction sector means more than technological innovation. Systemic approaches including LCA and ICTs are needed to cover social, environmental and economic aspects. Novel business models are needed to create clear advantages for all actors (particularly SMEs) in the value network. Effective and easy-to-use tools are needed for the implementation of the developed model.

2.3 Life cycle of a building

Different phases during the building life cycle may typically have differently defined, even changing objectives, different data management processes and formats, and most of the time they also involve different actors (see Figure 2).

The phases of the life cycle of a building considered by ecobim project are: brief phase, design phase, construction phase, commissioning phase and operation and maintenance phase. These phases are seen to overlap concurrently. Different actors as structured in ecobim project can be seen to contribute to these phases as follows:

- Brief phase: regulators, city planners, professional associations, real estate developers, owners, building occupants, neighbourhood associations, universities and research centres.
- Design phase: engineering and architecture firms and service providers.
- Construction phase: construction companies, system suppliers, manufacturers and services providers.
- Commissioning phase: construction firms, system suppliers, manufacturers, engineering and architecture firms and services providers.
- Operation and Maintenance phase: regulators, city planners, professional associations, construction firms, owners, building occupants, neighbourhood associations, universities and research centres.

Figure 2. Key actors in the different phases of the building’s life cycle. (Pekka Huovila & Carmen Antuña, VTT).

Results from different research studies show the importance of bringing the environmental concerns at the initial phase or Front End of Eco-innovation (FEEI) process (Bocken et al.,2014), which for building’s life cycle are the brief and design phases, when the parameters are still flexible.

Eco-innovative business models as identified in ecobim at this stage may address different life cycle phases, e.g. BIM checkers in design, PLM in construction, LCA and indicators in commissioning, monitoring during operation and maintenance, but all of them could be considered already in the brief phase. It is also important to keep seamless continuity of data management across phases and actors. Core indicators assist in succeeding with this challenge.

2.4 Business model development

The construction sector is traditionally focused on minimizing the investment costs of buildings at an acceptable quality level, primarily regulated by authorities from the health and safety aspects, instead of maximizing the value over service life, i.e. improving the performance against whole life costs and environmental impacts. This leaves very little space for innovation if the client’s business model focuses on competing who delivers “the same product” at a lowest price.

When agreeing on the definition and defining aspects of business models in ecobim context, one may use well-known approaches for the development, such as business model canvas by Osterwalder (Osterwalder et al.,2005, see Figure 3) that was used in ecobim workshops.

Figure 3. ecobim focus on business model canvas (adapted from Osterwalder & Pigneur, 2010).

In the core of the business model canvas method is the value proposition that explains how the service provider aims to solve a problem of its customer with a given service, fulfil a need or create value. However, how to prove that such value would be created with the given service and how to monitor if such value is actually created is often a more difficult task. Such methods are needed to promote service providers that are willing to provide services that help to achieve higher performance than the minimum requirements or that promote life cycle approach instead of only short-term profits. Huovila, P. et al (2013) propose a more thorough analysis of what value actually is in construction projects and how it manifests and can be verified at different phases (see Figure 2) of building’s life cycle. Performance indicators can be used to promote the value to be created and to monitor at later stages to which extent the promised value is actually achieved. That approach is also adopted in ecobim project. In order to create true benefits to all committed value network actors, the value propositions need to be written in the contracts in a construction project. Performance indicators help assessing the value propositions in different procurement models spanning up to life cycle contracts (Huovila, P., et al., 2013). Such approach should be part of future construction business models of different service providers to promote sustainable and profitable construction business development.

2.5 Principles of service development

The change from goods based manufacturing economy to service oriented economy – that has been called “servitization of business” (Vandermerwe & Rada, 1988) – is a trend that has been seen since long time. Goods suppliers become service providers and services account already for around 70% of total employment in Europe (Pro Inno Europe, 2010; Kettunen et al. 2012). In the core of the new way of doing business is the customer instead of the product. Companies tend to outsource their upstream activities (e.g. sourcing, production, logistics) and network with key partners. The downstream activities, instead, are becoming the main source of competitive advantage. The main focus of today’s successful companies is on customers’ needs and the company’s position relative to customers’ purchase criteria. The competitive advantage is often embedded in the processes for interacting with customers, in marketplace information, and in customer behaviour. (Dawar, 2013, 100-102) For services this trend means a shift from “operand resources” (value in property) to “operant resources” (value in use) (Kettunen et al., 2012, 26). For companies the change from goods provision to service provision is huge since services are about facilitating and supporting a customer’s everyday processes, and through that the customer’s goals in life and in business in a value creating way, i.e. helping customers to successfully reach their goals (Grönroos, 2012).

Service science aims to create a basis for systematic service innovation (Maglio & Spohrer, 2007, 18). A key foundation (Kettunen et al., 2012, 26) underpinning the previously mentioned customer and value oriented business logic for services is Service-Dominant-Logic (SDL) (Vargo & Lusch, 2004; Vargo, 2009). SDL theory explains why and based on which principles today’s economy and society are concerned with exchange of services rather than goods. Being widely acknowledged, this theory is used here as the premise for service development. In this approach value is co-created with customers and partners instead of the company marketing to the customer. According to Vargo (2013, 9), service-driven innovation provides input into customers’ value-creation processes by linking firm-available resources to peoples’ purposes. Innovation is then about finding novel and useful ways of enhancing own value co-creation activities by participating in ecosystems through resource integration and service provision to assist other actors in their value-co-creation (Vargo, 2013, 10).

SDL is based on ten foundational premises (FPs) (Vargo, 2009, 375):

1. Service is the fundamental basis of exchange.
2. Indirect exchange masks the fundamental basis of exchange.
3. Goods are distribution mechanisms for service provision.
4. Operant resources are the fundamental source of competitive advantage.
5. All economies are service economies.
6. The customer is always a co-creator of value.
7. The enterprise cannot deliver value, but only offer value propositions.
8. A service-centered view is inherently customer-oriented and relational.
9. All economic and social actors are resource integrators.
10. Value is always uniquely and phenomenologically determined by the beneficiary.

Most of these premises (FPs 1, 4, 6, 7, 8, 9, 10) have guided the approach taken in the different ecobim project’s co-creation workshops to develop social services together with end-users (see chapters 4-5). Citizen involvement and collaborative workshops have lately proven to be successful (if not necessary) methods in urban service development and innovation (Ahvenniemi et al. 2013; Huovila, A. & Nykänen, 2013).

A method that has inspired the approach used in ecobim workshops is Service Blueprinting which is commonly used in service innovation (Bitner et al., 2008). It is a practical method to concretely analyse the service interface from the customer’s point of view. In ecobim workshops, the participants started by defining user profiles. After that customer journeys (Nenonen et al., 2008) were developed for the user profiles in order to understand the aims, frustrations and needs related to different service interfaces during a typical day.

3 Co-creation workshops around eco-innovation: from idea to business models

In order to discover other business opportunities for eco-innovation, ecobim project has organized a number of co-creation workshops in Finland and Germany in collaboration with the following partners:

- White Lobster GmbH (Germany), an agency for sustainable communication based in Berlin. **Workshop 1**
- ARTOVA (Finland), a very active neighbourhood association based in Helsinki. **Workshop 2**
- Mattliden School in Espoo (Finland), interested in introducing sustainable development as part of their curricular activities. **Workshop 3**
- SYKE (Finland), the Finnish Environment Institute. **Workshop 3**

The aim of the workshops was to identify and map opportunities for eco-innovation and social development. The ideas proposed were discussed and categorized. The most promising ones were further developed into eco-innovative services along with the corresponding business models, including the definition of business model canvases. The stakeholders taking part in the workshops represent ecobim’s main target groups:

- Policy makers, practitioners (SMEs and large companies) and researchers. **Workshop 1**
- Users. **Workshops 2 and 3**

Workshop 1 was conducted in several phases, face to face and online, and supported by an e-networking platform. Workshop 2 was carried out in two evenings (from 17.00 to 21.00) with the same participants, whereas Workshop 3 was carried out in one day (from 8.15 to 14.30). In Workshop 1 some of the participants already knew each other, in Workshop 2 none of the participants knew each other and in Workshop 3 all the participants knew each other.

3.1 Co-creation set-up

As already explained, the aim of the workshops was to identify opportunities for eco-innovation and social development within the built environment leading to new services that in turn would lead to new businesses. Preparatory discussions with ARTOVA, ecobim project's collaboration partner for Workshop 2, focused the attention on the importance of social development and the potential offered by this area based on their experience. Linking social development and eco-innovation was perceived as a novel approach capable of yielding promising results and therefore worth trying through the workshops.

For the sake of consistency and comparison, the three workshops followed the same set-up with slight variations in relation to the content and the programme. The common steps shared by the three workshops were:

- Presentation of ecobim project's objectives
- Introduction of the participants
- Description of the programme and objectives of the workshop
- Definition of user profiles
- Definition of customer needs through customer journeys
- Service idea selection through identification of common needs
- Business model canvas for the selected service idea (see Figure 4)
- Eco-innovation in the service provision

Variations related to the content

- Workshop 1 focused on the sustainable neighbourhood of the future trying to identify existing gaps for sustainable social development and eco-innovation.
- Workshop 2 focused on innovative services, businesses and spaces for social development that are environmentally friendly and economically viable.
- Workshop 3 focused on the development of eco-innovative services specifically for the youth.

Business model canvas for:

Figure 4. Osterwalder's business model canvas adapted for ecobim project to include social & environmental costs and benefits of the service (Aapo Huovila & Carmen Antuña, VTT).

Variations related to the programme

- Workshop 1/Phase I included the development of the showcase outline previous to the definition of the user profiles. Phase III included development of services and businesses within a sustainable neighbourhood so that the different user profiles or professionals acted either as service provider or customer.
- Workshop 2/Evening 1 included the description of the participants' ideal neighbourhood in terms of personal, social and physical structure. Workshop 2/Evening 2 included a final discussion about opportunities for research on social innovation.
- Workshop 3 included a final group discussion about the developed businesses and their feasibility. In this case, the customer journeys were described through a very detailed day schedule and track-mapping of the user profiles defined.

3.2 Practical realization

The differences in the practical realization of the workshops depended on the different number, background, age of the participants and their availability:

Workshop 1

- Developed in 3 phases: Phase I face to face in Espoo; Phase II online through Owela for ecobim networking platform; Phase III face to face in Berlin.
- 6 participants in Phases I and II from the Ministry of the Environment (policy maker), minigram Studio für Markendesign GmbH (SME), VVO Group Plc. (large company), YIT (large company), VTT (researcher) and Aalto University (researcher), and 5 participants in Phase III from VTT (researchers), White Lobster GmbH (SME), Ingenieurbüro Trinius GmbH (SME) and Federal Ministry of Education and Research (German research funding organisation) / ECO-INNOVERA (European research programme) (policy maker).
- Phase II online allowed the participants to review and refine the user profiles defined in Phase I, and also to compared them with the research findings of Prof. Marketta Kytä from YTK Land Use and Urban Studies Group at Aalto University (Kytä et al.,2013).

Workshop 2

- 7 participants representing the users of different age and professional background.
- Developed in 2 evenings with the same participants.

Workshop 3

- 12 participants from Mattliden School in Espoo (8th and 9th grades). During the first part of the workshop they were divided in 3 groups, and during the second part in 2 groups.
- The user profiles developed were their same age.

3.3 Main outcomes

User profiles

- In Workshops 1 and 2 the definition of the user profiles included: name, gender, age, occupation, story/background, goals and frustrations.
- In Workshop 1/Phase II (online), the user profiles defined were compared against the “tribes” found by Marketta Kyttä’s research on the human aspects of urban planning and the methodology of participatory planning. Those “tribes” were the Neighbourer, the Busybody and the Homebody. The user profiles/tribes were also mapped against the developed neighbourhood services by specifying the service provider and the customer.
- In Workshop 3, since the eco-innovative services to be developed were meant for the youth, in particular for teenagers, the definition of the user profiles was slightly different and included: name, gender, age, family, type of house (the family lived in), living neighbourhood and hobbies.

Customer journeys

- In Workshops 1 and 2, the goals and frustrations of the user profiles defined were used to determine the services that those user profiles could need or provide.
- In Workshop 3, the definition of the customer journeys consisted of a typical day of the user profile described hour by hour focusing on the itinerary followed, services used and problems encountered. Positive and negative feelings related to the activities described in the customer journeys.

Service idea selection

- In Workshop 1, one service idea was selected for further development.
- In Workshop 2, two service ideas were selected for further development, one of them being particularly promising. Given their numerous touch points, it was decided to combine them in one service idea.
- In Workshop 3, two service ideas were selected for further development.

Business model canvas

- All the service ideas selected were developed further through Osterwalder’s business model canvas adapted for ecobim project (see Figure 4).

4 Lessons learned

Participants

- Finnish participants in Workshop 1 knew each other beforehand and even collaborated in the past at some point. However, the interaction with the German participants attending the workshop, who brought a different perspective, enabled a “new” approach towards “old” problems.
- Workshop 2 gathered a quite heterogeneous group of users in terms of age, origin, personal and professional background, etc. As a result, the discussion leading to the definition of user profiles and customer journeys was full of nuances and in-depth analysis. The good atmosphere created among the participants helped the communication.
- Workshop 3 was carried out with a group of teenagers, not typically chosen for this type of workshop. Even though (or perhaps due to) they were not familiar with the substance of ecobim project or some concepts related to the tasks they were asked to perform, they were not scared by the challenge and showed great willingness to contribute. They clearly valued their opinion being heard.

User profiles and customer journeys

- In all the workshops, the definition of user profiles and customer journeys was very detailed and showed considerable observation skills and understanding of the motivations of different types of customer groups. This was even more the case of the students taking part in Workshop 3.

Service ideas

- The service ideas selected for development seem to respond to clear gaps in social development.
- Enormous eco-innovation potential can be unlocked through collaboration with non-experts, normal users, different age groups, etc.
- Developing solutions “together with” instead of just “for”, or even worse “despite of” those affected by them, may be a better way to solve complex problems in the future. This approach should be more consistently used by companies, policy makers and researchers.

Business models

- Workshops 1 and 2 proved the difficulty of finding the right business models for the novel service ideas developed. This coincides with Curt Carlson’s opinion. When discussing innovation, the CEO and President of SRI International believes that the stress should be on sustainable business models. In his own words “people have lots of ideas and those ideas morph and go through transformations. Oftentimes the hardest part is coming up with that business model“ (Carlson & Mark, 2013).
- The young participants in Workshop 3 (14 and 15 years old) showed a fresh approach to all the tasks, and succeeded even when developing the business models for their selected service ideas.

Acknowledgements

ecobim project team wishes to thank all the participants and partners that have collaborated in the realization of the workshops.

Workshop 1

- Co-organizer and facilitator: Nils Bader, Managing Director at White Lobster GmbH (Germany)
- Participants: Holger Grünwald, Scientific Officer Responsible for Research on Eco-Innovation, Projektträger Jülich; Harri Hakaste, Senior Architect at the Ministry of the Environment (Finland); Samy Hamadeh, Managing Director at Minigram Studio für Markendesign (Germany); Juha Kostiaainen, Senior Vice President for Urban Development and Corporate Relations at YIT Corporation (Finland); Marketta Kyttä, Associate Professor in Land Use Planning at Aalto University School of Science and Technology (Finland); Niina Savolainen, Research Manager at VVO Group Plc (Finland); Wolfram Trinius, Managing Director at Ingenieurbüro Trinius GmbH (Germany)

Workshop 2

- Co-organizer: Janne Kareinen, Manager at ARTOVA (Finland)
- Participants: Rob van der Capellen, Software Engineer at eCraft Oy (Finland); Álvaro Corredor Ochoa, Research Assistant at SYKE (Finland); Anna-Kaarina Kairamo, Training Manager at Aalto University (Finland); Anna Kääriäinen, Owner at Vilnis (Finland); Riitta Korhonen, Geologist emerita at Geological Survey (Finland); Lassi Raunio, Teacher in Adult Education (Finland); Kristina Westerholm, Safety Coordinator at City of Helsinki (Finland)

Workshop 3

- Co-organizers: Álvaro Corredor Ochoa, Research Assistant at SYKE (Finland); Susanne Bergström-Nyberg, Teacher at Mattliden School (Finland); Katja Wide, Teacher at Mattliden School (Finland)
- Participants: Victoria Ahlstedt, Kristina Causton, Anna Helin, Maria Krogius, Lola Lerche, Johanna Lindstedt, Valmire Mlinaku, Nathalie Nyström, Frida Oinonen, Amanda Porko, Sabina Siren, Maria Trendafilova, Benina Uotinen. All students at Mattliden School (Finland)

Speed of New Service Development among Finnish ‘low-tech’ SMEs

Juha Arrasvuori, Juha Vänskä, Liting Liang

University of Vaasa, Department of Production, SC-Research, Finland

This explorative study examined aspects of speed of New Service Development (NSD) in ‘low-tech’ service SMEs. Focal questions were how these companies perceived service development speed and the impacts of accelerated NSD. A parallel research topic was how these firms used Service Design tools and methods in their service development activities. 300 respondents from Finnish SMEs participated in the study through a telephone survey. The findings give insight on how speed in New Service Development is perceived among Finnish ‘low-tech’ SMEs. Some indicative advantages and disadvantages of accelerated NSD were identified. Potential enablers for accelerating NSD were recognized. Utilization of Service Design was found to be low among the majority of respondents.

1 Introduction

Services have an essential role in the global economy. For example in the European Union, services contribute to 73.5% of the total gross value (EU-28 in 2013; Eurostat, 2014) and in Finland to 70.4% (preliminary data for 2013; Statistics Finland, 2014). A majority of service businesses are small and medium-sized enterprises (SMEs) that, according to the EU definition, employ fewer than 250 people and have an annual turnover below 50 million euro. For example in Finland in 2009, 94% of service sector firms had less than 10 employees each, and these firms employed 27% of the service sector workforce (Statistics Finland). Competition on the market is an apparent driver for the firms to continuously renew their current service offering and to develop entirely new services.

New Service Development (NSD) has been defined as the process of making of service products that are new to the supplier (Johne; Storey, 1998). According to Umashankar et al. (2011), accelerating the design process is a primary means for obtaining competitive advantage in NSD. Accelerating the speed of service development could have an impact for example on the time-to-market, responsiveness to customer needs, quality of service, development costs, cash flow, profitability, and the firm’s innovation capability (some similar outcomes of development speed in New Product Development have been proposed by Cankurtaran et al., 2013). If NSD is successfully accelerated, or even attempted to be accelerated, it will no longer be ‘business as usual’ for the firm. Obviously, the impact can be different – positive or negative – in the short run (e.g. immediate cash flow during accelerated service development work) than in the long run (e.g. annual profit).

When considering it on a generic level, service development can be accelerated by service suppliers, for example, by investing more resources (e.g., amount of working hours, number of people working simultaneously or consecutively during a day on the development activity, assigning the firm’s top talent on the work), or performing some steps of the service development process (e.g. ideation, prototyping, testing, iterating) in less time than previously, by skipping some of the steps altogether, or by progressing between the steps faster than previously (i.e. leaving less time to reflect on the learnings from each previous step).

Against this background, we are interested to explore how speed in NSD is perceived by ‘low-tech’ service SMEs. Such focus is most relevant as the majority of service sector firms are SMEs delivering long-established services like hospitality, maintenance, and construction. Following Hirsch-Kreinsen et al. (2003), we base our definition on ‘low-tech’ service suppliers on the OECD classification, which defines industries that have an R&D/Turnover ratio of less than one per cent as ‘low-tech’ (see also Nuns et al., 2010). Following den Hertog et al. (2011), we emphasize that ‘low-tech’ does not imply that the firms would be low in innovation so they wouldn’t be able to develop services innovatively. For instance, den Hertog et al. (ibid.) found many examples of innovative entrepreneurship in the ‘low-tech’ hospitality service business they studied. ‘Low-tech’ SMEs have no (or have very small) formalized Research & Development operations (e.g., personnel dedicated to R&D activities) for service development, so New Service Development is done in parallel with the daily operations of supplying the current service offering.

Service Design (SD) is an emerging discipline, which offers practical tools and methods that can assist the development of new services and the renewal of existing services. There is some indication that SD tools such as service blueprinting have the potential to speed up future service innovations (Bitner et al., 2008). On the other hand, if the service development activities in a firm have been incrementally developed to perfection over the years (e.g. when the company has little employee turnover or when the supplied service is of a very specific nature), the introduction of formal SD tools and methods may not accelerate the NSD process in a firm. Case studies on successful Service Design projects describe the use of SD tools by ‘high-tech’ companies or the public sector, or their use in the development of services that have digital/online service elements as major component (e.g. Meroni; Sangiorgi, 2011; Enninga et al., 2013). However, there has been little research in to what extent Service Design tools and methods are utilized in long-established service areas where IT-elements have no role or play just a minor role (e.g. in the online promotion of the service).

The intent of the study presented in this article is twofold. First, we want to explore how Finnish ‘low-tech’ service SMEs perceive the factor of speed in New Service Development, and how they see the possibilities and consequences of accelerating their service development activities. Second, we want to explore to what extent the potential of the Service Design discipline is used by these firms in their NSD activities. To better understand the responses, we also inquire about the current market circumstances the firms operate in.

The structure of this article is as follows. In Section 2 we summarize previous research on Service Design, and speed as a factor in New Service Development. In Section 3 we present the methodology of this study, followed by the presentation of results in Section 4. In Section 5 we discuss the findings and their possible implications, and wrap up the paper with conclusions presented in Section 6.

2 Previous research

New Service Development has been defined by Johne and Storey (1998, 185) as “[...] *development of service products which are new to the supplier*”. Following this definition, the scope of NSD activities also includes renewing (e.g., augmenting or streamlining) an existing service or its delivery (Johnson et al., 1999). Froehle et al. (2000) argue that NSD is vital to success in service operations, so the factors contributing to NSD speed and effectiveness must be completely understood and better implemented by the service firms.

In their study on the enablers of NSD effectiveness in 182 U.S. service firms (of which 28% had fewer than 200 employees and thus constitute as SMEs), Froehle et al. (2000) found that formalized NSD processes indirectly influenced a firm’s ability to develop new services by increasing the speed of NSD. Additionally, the researchers found that a firm’s IT sophistication (in terms of facilitating communication and feedback, reducing error and redundancy, and streamlining the service design process) directly effected the speed of NSD. Froehle et al. found strong positive relationship between the speed of NSD process and the general effectiveness of the firm’s NSD efforts. However, the researchers emphasise that the general effectiveness of NSD is influenced also by other factors such as product strategy, project definition, and clear organizational roles. Froehle et al. conclude that speed does aid a firm’s NSD initiatives, but speed should not be the firm’s single development goal. (Froehle et al., 2000.)

Development speed has been one focal point in the field of agile service development of ‘service systems’ that combine IT and business elements (Lankhorst et al., 2012), in other words, in the development of ‘digital’, ‘online’ or ‘Internet’ services. A related concept is Rapid Service Development, which Janssen & Steen (2001) describe as an engineering methodology for developing e-business services. Lankhorst et al. (2012) describe agile service development as a solution for service development organisations to tackle the increasing speed of change in the business environment. According to Lankhorst et al. (ibid.), an agile service is a service that has the ability to rapidly accommodate changes. Lankhorst et al. (ibid.) address three kinds of agility, namely ‘Business agility’ (aiming for faster time-to-market, more effective partnering strategies, decreased development costs, increased customer satisfaction, and using change as an essential part of the firm’s strategy), ‘Process agility’ (using agile practices for design and development, placing focus on people and interactions, aiming for more rapid value delivery and improved responsiveness to change) and ‘System agility’ (aiming for organizational and technical systems that can be more easily reconfigured when necessary). Agile service development practices have been developed for and their use have been studied in the context of ‘service systems’ (i.e., ‘online’ or ‘digital’ services), and as far as the authors of this article are aware, the use of agile practices have not been studied in the context of ‘traditional’ service development or by ‘low-tech’ service firms. Thus, there is a lack of understanding of how development speed and the possibility of accelerating NSD are perceived by ‘low-tech’ SMEs.

Service Design is a rapidly emerging discipline that is argued to have a great potential to make an impact in the development of new services (Tether, 2008). Service Design involves systematically applying design methods and principles to the design of services (Holmlid; Evenson, 2008). Johnson et al. (1999) differentiate SD from NSD by suggesting that Service Design involves specifying the detailed structure, infrastructure, and integration content of a services operations strategy, while NSD refers to the overall process of developing novel service offerings. Holmlid and Evenson (ibid.) argue that the Service Design discipline should be viewed as complementary to service development, as SD activities take place throughout a service development process. Ostrom et al. (2010) suggest that the design of a service can have a significant impact on key metrics, such as costs, revenues, customer satisfaction and brand perceptions of the firm supplying the service. Service Design practices have been widely applied in different service sectors (Mager, 2009).

The research of Service Design has begun to take shape (Kimbell, 2011). The body of literature on SD draws on contributions from multiple research fields, such as service marketing (Shostack, 1982), innovation management (Bessant; Maher, 2009), service operations management (Goldstein et al., 2002), and New Service Development (Bitner et al., 2008). SD research literature describes a variety of practice-oriented tools and methods that can be utilized in the different phases of service development, e.g., service blueprinting (Shostack, 1984), customer journey (Kimbell, 2011), storyboarding (van Oosterrom, 2009), touch-points (Clatworthy, 2011), exemplars (Blomkvist; Holmlid, 2009), and service prototyping and piloting (Neyer et al., 2009; Passera et al., 2012). Rontti et al. (2012) have developed a service prototyping laboratory (‘SINCO’) that collects a variety of SD tools into a holistic approach to designing services. Another service prototyping and simulation environment is ‘ServLab’ (Meiren; Burger, 2008). Miettinen and Koivisto (2009) have collected several viewpoints on how design thinking and innovative methods work as tools for developing

services in co-creation with users. In addition to research literature, several practical books on Service Design have been published, for example, by Curedale (2013) who summarizes around 250 SD tools and methods. Furthermore, established idea generation and organizing tools and techniques, such as mindmap and affinity diagram, can be used in Service Design. Thus, there is a good availability of “pen and paper”-based SD tools, IT-based SD tools, and conceptual SD tools and methods, but an interesting – and so far largely unaddressed – question is to what extent these tools are used in practice by ‘low-tech’ service SMEs?

Increasing the speed of NSD and utilizing Service Design can be a means for a firm to pursue competitive advantage; in other words, to derive profit by setting up a strategy for providing value to customers that is not used by competitors. As addressed by Weerawardena and McColl-Kennedy (2002, 14), “[c]ompetitive advantage grows out of the way a firm organises and performs discrete and connected activities of the value-chain.” Competitive advantage can be gained by creating superior value for customers, and can be achieved by performing service delivery related activities in an innovative manner. When competitors are unable to duplicate a firm’s value-creating strategy, the firm can achieve sustainable competitive advantage. Weerawardena and McColl-Kennedy (2002)’s capability-based model of NSD suggests that to obtain sustained competitive advantage, a service firm should build up distinctive capabilities that enable it to perform organizational routines for delivering services in a way that outperforms competitors. A firm’s value-creating strategy may involve accelerating the speed of and/or utilizing Service Design in its service development and delivery. Ways of speeding up service development and using SD tools and methods in NSD can be a part of a firm’s distinctive capabilities. Thus, we want to examine how Finnish ‘low-tech’ SMEs perceive the possibility of accelerating NSD as a source for obtaining competitive advantage, and how beneficial they see Service Design for their business.

3 Methodology

We developed an exploratory survey to collect data on ‘low-tech’ service SME businesses’ perceptions on the various aspects of speed in New Service Development. Additionally, we set out to collect data on how aware the firms were of the potential of the Service Design discipline and how beneficial they considered SD for their business. The survey included both quantitative (multiple selection) questions and qualitative (open-ended) questions for more in-depth data capture.

We explored the following three main topics through the survey:

1. *Respondents’ current circumstances*: respondent firms’ background; market situation; seek for growth; current speed and frequency of NSD; use of systematic design processes in NSD; use of service trials and seeking learning from the trials in NSD; use of specific tools and methods in NSD.
2. *Outcomes of accelerated NSD speed*: respondents’ perceived competitive advantage obtained from faster time-to-market; business impacts of halving the current speed of time-to-market; enabling criteria for accelerating NSD; disadvantages of accelerated NSD.
3. *Utilization of Service Design in NSD*: respondents’ awareness of the potential of Service Design; availability of internal SD competence; use of external SD competence; perceived favourability of SD for business; SD tools and methods used by the respondents in service development.

The survey was implemented between March and April 2014 as a series of telephone interviews of employees representing ‘low-tech’ service SMEs residing all over Finland. Potential respondents were chosen randomly from an enterprise database of 1,478 ‘low-tech’ companies employing fewer than 250 people and having annual turnover below 20 million euro. Senior managers at the companies were targeted as respondents. Altogether 487 people from these firms were contacted to participate in the survey. 300 people representing different firms responded to the survey. 272 of the respondents were CEOs of their respective companies.

4 Results

The results are reported below grouped into the following main topics: Background of respondent firms, Seek for growth, Engagement in New Service Development, Speed of New Service Development, and Utilization of Service Design. Quotes from the respondents have been translated from Finnish to English by one of the authors.

4.1 Background of respondent firms

The 300 respondent firms represent altogether 70 service activities (classification based on the Finnish Standard Industrial Classification ‘TOL2008’; Statistics Finland, 2008). Examples of these service activities include food and beverage services (e.g., restaurants, cafeterias, catering), accommodation, maintenance (of property, motor vehicles), real estate management, cleaning, waste collection, specialized construction (e.g. site preparation), bookkeeping, installation (of electricity, HVAC, industrial apparatus), and retail sales (of motor vehicles, small retail stores).

Most of the businesses operated locally (60.2%) or nationally (29.8%). 85% of the respondent companies had 20–49 employees; 11.3% employed 50–99 people, and the remaining 3.7% had 100–249 employees.

The perceived competitiveness of the markets was as follows. According to 48.8% of the respondents, the markets their firms operate in were aggressively competitive. 43.8% of the respondents described their markets as moderately competitive. Only 7.4% of the respondent companies reported to operate in markets that were marginally competitive.

4.2 Seek for growth

Through a set of three questions, we wanted to find out the respondent firms' drive to seek growth (Figure 1), if the firms have renewed their service development activities (Figure 2), and if the firms have brought new or renewed services to the market (Figure 3).

Figure 1. Distribution of responses to the question: "How would you describe your firm with regard to growth?".

Figure 2. Distribution of responses to the question: "Has your firm significantly renewed its service development activities during the past two years?".

Figure 3. Distribution of responses to the question: "Has your firm brought to the market entirely new or significantly renewed services during the past two years?".

As the data in Figure 1 indicates, nearly two-thirds of the respondents reported that their firms were seeking at least a moderate growth in their business (12% reported to seek strong growth, 53% reported to seek moderate growth). The responses in Figure 2 suggest that around one third (29%) of the businesses were seeking growth by renewing their service development activities. Furthermore, the data in Figure 3 indicates that around one third (35.3%) of the firms have introduced a new or renewed service to the market within the past two years.

On the other hand, 69% of the respondent firms reported to not have renewed their service development activities during the past two years (Figure 2) and 62.3% have not brought any new or renewed services to the market (Figure 3) during the past two years.

4.3 Engagement in New Service Development

An important area we wanted to explore was the respondents' current engagement in New Service Development. To learn about this topic, we devised a pair of questions presented to the respondents as arguments (Figure 4).

Figure 4. Distribution of responses to the question: “Please estimate how accurately or inaccurately the following two arguments describe New Service Development in your firm.” Note that only 213 and 207 study participants responded to these two questions.

Looking at the data in Figure 4, roughly a third of the respondents considered as very accurate the proposed descriptions that NSD in their firms is based on a systematic and predefined design process (30%), and rapidly piloting new ideas and seeking learning from the experiments (36.2%). On the other hand, more than one tenth of the respondents (13.6%) stated that the proposition of NSD being based on a systematic and predefined design process as a very inaccurate description of their firm. More than one fifth (22.2%) of the respondents considered it very inaccurate to describe NSD in their firms as being based on making rapid trials and seeking learning from the trials.

Next, we asked the respondents if their firms used specific tools or methods in the different stages of developing a new service. Their combined responses are reported in Figure 5.

Figure 5. Distribution of combined responses to a set of questions inquiring if the respondent's firm used specific tools or methods when developing new services.

As the responses show in Figure 5, nearly three-quarters (73.2%) of the respondents indicated that they have not used any formal tools or methods when developing new services. Only 13.8% of the respondents reported to have used some specific tool or method. The specific tools and methods the respondents mentioned are reported later in this article.

4.4 Speed of New Service Development

To obtain an overview of the current speed of service development in the respondents' companies, we inquired them about the time it typically takes to develop and introduce a new service to the market (Figure 6).

Figure 6. Distribution of responses to the question: “How long does it typically take your firm to develop and bring a new service to the market?” Note that only 230 study participants responded to this question.

As the data in Figure 6 indicates, the average speed of NSD varied considerably between the companies. For nearly one fourth (23.5%) of the respondents it took less than one month to develop and bring a new service to the market, whereas for more than half (57.4%) of the companies it took between six and twelve months. It should be noted that 9.6% of the study participants responded that it took for them less than a week to bring a new service the market. Thus, New Service Development could be characterized as fast in almost one tenth of the respondent companies.

Next, we asked the respondents if they considered that a shorter time-to-market would bring significant competitive advantage (Figure 7).

Figure 7. Distribution of responses to the question: “Would a shorter time-to-market bring significant competitive advantage to your firm?”.

More than half (55.7%) of the respondents considered that the possibility of bringing a new service to the market faster than currently would not entail significant competitive advantage to their businesses. A mere 16% of the respondents thought that their businesses would obtain a significant competitive advantage from a faster time-to-market of a new service. Nearly a third (28.3%) of the respondents could not give an estimate on what kind of impact a shorter time-to-market would make on the competitive advantage of their firms.

4.4.1 Business impacts of accelerated NSD

To find out the respondents’ opinions about what accelerated time-to-market speed would entail, we asked them to respond in their own words to the proposition: “If your firm could bring a new service to the market twice as fast as currently, the impact on your business would be...”

Some responses described clear business impacts – both positive and negative – that accelerated service development would make. The most illustrative responses are reported in Table 1. The responses are grouped based on common themes.

Table 1. Example responses to the proposition “If your firm could bring a new service to the market twice as fast as currently, the impact on your business would be...”

Theme	Responses
IMPROVED COMPETITIVENESS	We would get a head start over the other companies (Respondent 52); We would be ahead of the competitors (Respondent 14); Being able to produce a service faster would increase our competitiveness (Respondent 77); Competitors wouldn’t have time to copy [our service] (Respondent 186); It improves notably the competition situation if you are the first on the market. The first one sticks on the minds of people (Respondent 68); It is always good to be the first one on the market, to be the forerunner (Respondent 119); It always improves competitiveness, when you are at the forefront of the development (Respondent 124).
IMPROVED VALUE DELIVERY TO CUSTOMERS	We would be able to better meet customers’ expectations (Respondent 195); Customers would feel increased value towards our business or the product (Respondent 194); Extended service offering for customers is probably the greatest benefit (Respondent 58); The faster services are produced, the faster they provide benefit to customers (Respondent 261, Respondent 285).
IMPROVED CUSTOMER CONTACTS	We would get new customers (Respondent 177); Contacts with customers would be made faster (Respondent 255); [We would get an] extended contact interface to customers (Respondent 295); Customers would get the service faster from us than from other companies (Respondent 130).
INCREASED OPERATIONS	Increased profit (Respondent 4); Faster cash flow (Respondent 7, Respondent 104); Increased revenue (Respondent 39, Respondent 72); Increased production and operations (Respondent 105); Increased sales (Respondent 282); Increased market share (174); Faster growth (Respondent 299); Increase in quality and profitability (Respondent 173); Improved company image (Respondent 122).
FASTER RESPONSIVENESS	We would be able to respond faster to the markets (Respondent 183); The obtained benefit is in being able to react to the situation, so not to fall out of the competition (Respondent 118); A possible benefit is that the service would be brought on time or on the right season (Respondent 97); It would enable faster testing of the new service (Respondent 103); It would diminish the impact of economic fluctuation (Respondent 196).

Theme	Responses
SAVED RESOURCES	<i>It would save resources (Respondent 265); It would free resources for other activities (Respondent 103); If new service models are to be invented, it is for the purpose of seeking cost savings (Respondent 284); Cost savings (Respondent 122).</i>
RENEWAL	<i>Renewal would be faster and it would improve our position on the market. (Respondent 276); The message of renewal could keep up the interest [in our business], when there is something happening all the time. (Respondent 69).</i>

On the other hand, in addition to these positive effects that were mentioned, several respondents considered that faster time-to-market would not be possible in their business or it would not have any benefits. One respondent noted sceptically, *“The turnover would grow, but I doubt if the profit would”* (Respondent 39). Another respondent considered that accelerating service development would imply that the resulting service would be half-baked: *“I see no benefits [in accelerating our service development]. I see just disadvantages if incomplete services are brought to the market.”* (Respondent 251) One respondent considered the service area so established that accelerating service development would make little difference: *“Restauranting is one of the oldest services; I don’t see any benefit in [developing a new service twice as fast].”* (Respondent 44)

Some respondents stated that New Service Development is not even possible in their particular business area, for example: *“In our business [electric installation services] it is difficult to invent anything new.”* (Respondent 290). In addition to electric installation services, other service activities where respondents considered it to be difficult to develop anything new were cafeteria, catering, specialized construction, HVAC installation, and maintenance.

4.4.2 Enablers for accelerating NSD

To find out the respondents’ views on the feasibility of speeding up NSD, we asked them to complete in their own words the sentence: *“Increasing significantly the speed of New Service Development is possible when...”* The most illustrative responses are reported in Table 2. The responses are grouped based on common themes.

Table 2. Example responses to the question *“Increasing significantly the speed of New Service Development is possible when...”*

Theme	Responses
THERE ARE SUFFICIENT RESOURCES	<i>There would be time and money available. And that there would immediately be networks and help available, if there is a lack in own competences (Respondent 55); There would be personnel involved, in other words, resources available (Respondent 180); There are enough of external resources and funding available (Respondent 186); We would get funding (Respondent 196); There would be more time available (Respondent 194); A new service brings expenses and so forth, so would have to make those fit within our activities. We cannot speed up service development without interfering our other activities (Respondent 92).</i>
THERE IS SUPPORT FROM THE ORGANIZATION	<i>The entire organization is involved as effectively as possible (Respondent 178); There is enough know-how, or someone would drive things forward (Respondent 287); The leadership would be more involved (Respondent 189).</i>
DEVELOPMENT WORK IS SYSTEMATIC	<i>It is a systematic activity (Respondent 167); Our development work would be more systematic (Respondent 191); Our other activities would better organized (Respondent 163); When we are able to make rapid decisions (Respondent 159).</i>
CUSTOMERS ENABLE IT	<i>When there are good interactions with and trust in our customers (Respondent 192); When our businesses customers are able to move faster (Respondent 164).</i>

In addition, the following enabling criteria for accelerating New Service Development were mentioned by at least one respondent: *“When a good idea [for the service] has been identified”* (Respondent 4); *“When there is an acute need for the new service”* (Respondent 59); *“When we find new ways to operate”* (Respondent 176).

4.4.3 Disadvantages of accelerated NSD

To learn about the respondents’ insights on the possible disadvantages of accelerated NSD, we asked them to complete in their own words the sentence: *“The most significant disadvantage of increasing the speed of service development is that...”* The most illustrative responses are reported in Table 3. The responses are grouped based on common themes.

Table 3. Example responses to the question “The most significant disadvantage of increasing the speed of service development is that...”

Theme	Responses
MISTAKES MAY BE MADE	<i>Rush introduces easily mistakes (Respondent 106); When developing services, the faster you proceed, the more things get unnoticed. You cannot see the disadvantages, if you do development work in a too short time frame (Respondent 114); Grave mistakes may be made. There are so many stakeholders to consider, so the risks grow considerably (Respondent 273); Perhaps there would be rushed judgements and something unconsidered (Respondent 118); If it is not studied carefully, it may turn out to be a bad investment (Respondent 270); We might do hasty decisions (Respondent 4); My only concern would be if every angle or opportunity will be considered (Respondent 265).</i>
THE SERVICE MAY BE INCOMPLETE OR OF INFERIOR QUALITY	<i>Based on my experience, very quickly produced services do not work. Their functionality is not as good as in services that have been developed for a long time and have been tested (Respondent 37); An untested service would bring lots of problems, if it is brought to the market too quickly (Respondent 41); The service would be incomplete (Respondent 252); The service may not be complete and tested (Respondent 14); The service may not be of high quality (Respondent 22, Respondent 269); The service has to be perfect, before it is ready for launch (Respondent 26).</i>
IT MAY HURT CUSTOMER SATISFACTION	<i>Getting current customers accustomed to new services is the greatest challenge (Respondent 69); When the quality does not meet customer expectations (Respondent 87); It hurts customer satisfaction (Respondent 27); When incomplete service models are introduced, they disrupt the clientele (Respondent 44); When you cannot be sure what the customers want (Respondent 188); An adverse effect is getting the service to the market and how customers will react to it (Respondent 254).</i>
WORKFORCE AND PROCESSES ARE DIFFICULT TO ADAPT TO ACCELERATED SPEED	<i>How to get the personnel involved (Respondent 176); When the personnel cannot embrace it (Respondent 266); How to keep the personnel on par with in the change: through information and learning (Respondent 72); When the organization is inflexible (Respondent 189); Getting our processes into the new service is the biggest challenge, as well as adapting with the other service producers (Respondent 59); The structures of old services are hinders (Respondent 93); When old attitudes slow things down (Respondent 178); When we have to move ahead within the schedule given by a customer (Respondent 164).</i>
IT REQUIRES EXCESSIVE RESOURCES	<i>Getting workforce is the greatest challenge (Respondent 58); Resources, because we are a small firm (Respondent 123); It takes away from own personnel resources (Respondent 173); Resourcing is the most significant challenge (Respondent 38).</i>
IT BECOMES EXPENSIVE	<i>Expenses get out of hand (Respondent 167); It is expensive (Respondent 170); It increases expenses (Respondent 235); Expenses are of course always the gravest adverse effect (Respondent 84).</i>

Additionally, one respondent operating in waste collection services provided an interesting comment concerning the disadvantages of accelerated NSD: “Our business is based on public fares. If new services are introduced to the market too rapidly, the public authorities defining the fares cannot keep up because the fare adjustments are made annually. This causes misunderstanding and confusion, and causes problems in market communication. Furthermore, we wouldn’t have time to induct the employees sufficiently.” (Respondent 122). This response gives an example of the external complexities of introducing new services at accelerated speed: if the service fees are based on public fares, then the authorities have to keep in pace with defining fares for the new services.

4.5 Utilization of Service Design

To begin exploring the topic of utilization of Service Design in the respondent firms, we first inquired the respondents’ awareness of the potential that the Service Design discipline may have for them (Figure 8).

Figure 8. Distribution of responses to the question: “Are you aware of the possibilities of Service Design?”

Looking at the data in Figure 8, it appears that the potential of the Service Design discipline was not well known in the surveyed SMEs: almost two-thirds (60.3%) of the respondents reported to be unaware of the possibilities. 27.7% of the respondents reported to be aware of the possibilities of Service Design.

Next, we inquired about the internal Service Design competence (Figure 9) and the use of external Service Design competence (Figure 10) in the respondent firms.

Figure 9. Distribution of responses to the question: “Does your firm have internal competence in Service Design?”

Figure 10. Distribution of responses to the question: “Has your firm used external Service Design consultants?”

As the responses indicate, the potential of the Service Design discipline was not broadly utilized in the surveyed SMEs: just 14.3% of the companies reported to have internal competence in Service Design, while 61% have not. One fifth of the companies have used external Service Design consultants, while the remaining 4/5 have not used or could not say.

Next we asked the respondents if they perceived Service Design as favourable for their business (Figure 11).

Figure 11. Distribution of responses to the question: “Do you see Service Design as beneficial for your business?”

26.3% of the respondents considered Service Design to be favourable for their business, 28.7% of the respondents considered Service Design not to be beneficial, and 45% could not say one way or the other. The latter response may be the reason of such a large percentage (60.3%, cf. Figure 8) of the respondents being unaware of the possibilities of Service Design.

Through a set of open-ended questions, we inquired what specific tools and methods the respondents had used in the different stages of developing a new service. E.g., the following tools and methods were mentioned by at least one

respondent: Market research; Customer feedback; Input and ideas from customers; Customer interviews; Test customers; Electronic feedback; Web analytics; Observing consumers and finding out what they want; Trying out what works and what doesn't; Service pilots; Mindmap; Process charts; Freeform idea creation; Formal brainstorming sessions; Idea creation workshops; A specific tool for developing ideas further.

As can be seen from these responses, different ways of obtaining input from customers seems to be a common set of methods. Different ways of testing a service before bringing it to the market were also used by some respondents. The respondents mentioned specifically only a few Service Design tools and methods (e.g., mindmap, service pilots, process charts, and test customers). Only two of the mentioned tools (i.e., Electronic feedback and Web analytics) were obvious IT-based tools (some of the other mentioned tools may be supported by IT). Interestingly, none of the respondents explicitly mentioned co-design or co-development as methods of developing services with customers. Instead, customers were seen in the responses as sources of ideas and feedback.

5 Discussion

Our exploratory study sampled employees of 300 Finnish 'low-tech' SMEs representing 70 service areas. This sample appears adequate to give at least some insight in the studied topics in Finnish 'low-tech' service companies. 272 out of the 300 respondents were CEOs. Thus, their responses represent a senior manager's perspective to the studied topics. A majority of the sampled firms, 85% to be exact, had 20-49 employees and thus were small-size companies.

The markets the firms operate in were described as competed: according to 92.6% of the respondents, the markets were at least moderately competitive (and furthermore, nearly half of the respondents described the markets as aggressively competitive). Thus, it can be interpreted that the competitiveness of the markets puts pressure on a majority of the respondent firms for renewal or increasing their competitiveness, rather than passively expecting the business to remain as usual. This interpretation is supported by the data that almost two-thirds of the firms reported to seek at least a moderate growth in their business.

The current speed of NSD varied notably between the respondent companies. 9.6% of the respondents reported that it takes for them less than a week to develop and bring a new service the market, so these firms can be interpreted to have a rapid approach to NSD. However, for more than half (57.4%) of the respondent companies it took between six and twelve months, and for almost one fifth of the firms (19.1%) it took more than a year to develop and bring a new service the market. Obviously, the sampled firms cannot be directly compared across service activities because what exactly constitutes 'bringing a new service to the market' may vary greatly between, for example, a restaurant compared to a vehicle maintenance service. A topic for further research is to compare the different service activities with regard to their average speed of developing and introducing a new service.

The frequency of service offering renewal also varied notably between the respondent firms. Almost one third (29%) of the surveyed businesses reported to have renewed significantly their service development activities during the past two years. Furthermore, around one third (35.3%) of the firms reported to have brought a new or significantly renewed service to the market within the past two years. However, the data indicates that the majority of the respondent firms have not recently implemented renewal or launched new services: around two thirds of the respondent firms reported not to have renewed their service development activities and have not brought any new or renewed service to the market during the past two years.

Formal service development tools seemed not to be used by the majority of the surveyed companies: almost 3/4 of the respondents stated that their firm have not used formal tools or methods in NSD. Only 13.8% of the respondents reported to have used specific tools or methods. However, nearly one third (30%) of the respondents firmly agreed with the proposed description that NSD in the firms was based on a systematic and predefined design process. Thus, the systematic design process in these 30% of the respondent firms is not based on the use of formal tools or methods, or the respondents were unable to identify and report their use of such tools.

A number of respondents considered that accelerating service development by halving the current development speed would make an impact on their business. The following examples from the responses of such impacts can be interpreted as positive effects on the business and thus be considered tentatively as examples of advantages of accelerated NSD. According to some respondents, the immediate business operations would be impacted positively (e.g., increased sales, faster cash flow, improved revenue, and increased market share). A number of positional and resource-based competitive advantages could be obtained, e.g. cost savings, saved resources that can be allocated to other activities, differentiation ('being the first on market'), improved value delivery to customers, and the competitors wouldn't have time to duplicate the new service. Furthermore, the firm would be able to renew faster, respond faster to changes, and obtain new customer contacts. Some of these impacts are similar to what Lankhorst et al. (2012) described as characteristics of agile development of digital services, including *renewal* (i.e., using change as an essential part of the enterprise strategy), *faster time-to-market* to outmanoeuvre competitors, *decreased development costs*, *increased customer satisfaction*, *more rapid value delivery* and *improved responsiveness to change*. This suggests that a fruitful topic of further research is to examine if certain agile practices of 'digital' service development could be adapted to facilitate 'traditional' service development in 'low-tech' companies.

One finding of this study is that NSD can be accelerated in the 'low-tech' SMEs when certain criteria are met. From the responses to open-ended questions, e.g. the following enabling criteria for accelerated service development were identified: there has to be adequate resources available (such as having a key person driving the acceleration effort);

there has to be sufficient support from the company organization; customers have to give support (e.g., the necessary trust and interactions have to be established with customers; or the business customers have to be able to move faster); and the service development work has to be systematic. The latter finding, that service development work needs to be systematic so service development can be accelerated, is along the lines of the finding by Froehle et al. (2000) that formalized NSD processes increased the speed of NSD and thus indirectly influenced a firm's ability to develop new services.

Conversely, it may be hypothesized that if one or some of these enabling criteria are not met, NSD cannot be accelerated. This is an important topic for further research. Some indication on this from the present study is that according to some respondents, accelerating service development is not possible when necessary resources are not available, or when the firm's workforce and processes cannot be adapted to develop services at an increased speed. Furthermore, accelerating service development was not considered possible by a number of respondents involved in the following services activities: electricity and HVAC installation services, cafeteria, catering, construction, and maintenance.

The respondents mentioned several potential disadvantages that accelerating NSD may have. One concern was that if service development is accelerated, mistakes can be made and the quality of the service may suffer, which will in turn hurt customer satisfaction. In other words, some respondents associated speeding up negatively with haste, where every aspect and opportunity relevant to developing the service may not be considered because of lack of time or progressing too fast. Furthermore, some respondents thought that accelerated development would result in the launch of incomplete or untested services. An additional potential disadvantage mentioned by some respondents was that accelerating service development would not lower development costs, but may turn out to be expensive or to require excessive resources, and thus have a negative influence on the firm's competitive advantage. A topic of further research is to identify accelerated service development projects that have failed or produced incomplete or badly received services, and find the reasons for these failures (i.e., to find out to what extent the failures were caused by an accelerated development speed).

With regard to utilization of Service Design, our findings suggest largely an unawareness of its potential among the respondents. Nearly one-third (27.7%) of the respondents reported to be aware of the possibilities offered by Service Design. This proportion is consistent with the data that 26.3% of the respondents considered Service Design to be favourable to their business. At the same time, almost two-thirds (60.3%) of the respondents reported to be unaware of the possibilities of Service Design. In a similar vein, the respondents reported to have used only a few SD tools and methods. Nearly two-thirds (61%) of the respondents reported that their firms had no internal competence in Service Design. These are indications for Service Design consultancy companies and research organizations working with Service Design to raise the awareness of Service Design, at least in Finland.

6 Conclusions

The findings of this exploratory study give some insight on how speed in New Service Development is perceived among Finnish 'low-tech' service sector SMEs. A number of indicative benefits and disadvantages of accelerating NSD were identified. The main advantages were that accelerating NSD could improve competitiveness, operations, value delivery, responsiveness, and renewal. The primary concern of speeding up NSD was that the resulting service could be of inferior quality, and thus impact customer satisfaction negatively. Additional concerns of accelerated NSD were that it would require excessive resources, turn out to be expensive, or that grave mistakes could be made during development process. Furthermore, some concern was raised whether or not the workforce and firm processes could adapt to accommodate accelerated service development speed.

A surprising finding was that nearly one tenth of the respondent firms were already engaged in fast service development, as they reported to typically develop and launch a new service in less than a week. At the same time, for more than half of the respondent companies developing a new service it took between six and twelve months, and for nearly one fifth of the companies it took more than a year. Thus, there is clearly room for accelerating service development in many Finnish SMEs. For Service Design practitioners, one indication from the study is that the potential of Service Design discipline is not yet well recognized in Finnish 'low-tech' service sector SMEs. Furthermore, it is a topic of future study how SD practitioners and researchers perceive the situation, e.g., what challenges they see in 'low-tech' service firms adopting SD practices, and how the service designers perceive the possibilities of accelerating NSD through SD tools and methods.

The findings suggest also other areas of further research of speed in NSD, including a detailed comparison between firms operating in distinct service areas, of different sizes, and in different countries. Weerawardena and McColl-Kennedy (2002) have emphasised the significance of distinctive capabilities to obtain sustained competitive advantage in NSD. With regard to NSD speed, a future research question is what kind of distinctive capabilities do firms need to be able to accelerate their service development activities, and what can the firm's strategic leaders do to develop these capabilities in the organization? For example, in what ways can traditional and IT-based Service Design tools be adapted by an organization to facilitate speeding up NSD? Furthermore, it seems fruitful to build upon the work by Lankhorst et al. (2012) and explore how agile practices of 'digital' service development can be adapted to facilitate accelerating 'traditional' service development in 'low-tech' companies.

The authors wish to acknowledge Tekes (the Finnish Funding Agency for Technology and Innovation) for funding this research.

Consumer value journey with pet in multiple service touchpoints

Jaakko Autio¹, Ari Kuismin¹, Minna Autio¹, Henna Syrjälä^{1,2}, Eliisa Kylkilähti¹

¹University of Helsinki, ²University of Vaasa

Our paper explores how consumer value is negotiated in pet-related services. We combine the discussion on value with the standpoint of service design; the approaches of consumer journey and service touchpoints. The contribution lies in discussing how consumer value is experienced in pet-related services through and by the pet, not only within dyadic interaction between consumer and service provider. We argue that applying a consumer value journey gives a comprehensive understanding of experienced value in several touchpoints with multiple service providers.

1 Introduction

In service research, the value creation has traditionally focused on service provider and its processes for customers (see Johns, 1999; Osborne; Ballantyne, 2012). The approaches have emphasized the dyadic interaction between consumer and service provider starting from the early work of Nordic school of service marketing (Grönroos, 1978; Gummesson, 1979). More recently, the idea of co-creation of value (Prahalad; Ramaswamy, 2002) in philosophical level, and activities of service design in more practical level have underlined, firstly, the importance of service provider–consumer interaction, and secondly, understanding the integratable resources of these two actors (Lusch; Vargo, 2006). In these discussions consumer interaction is seen directed by service design (Mickelsson, 2013, 536) and the examinations have focused on the consumer’s engagement in the value-creation process (Vargo; Lusch, 2004).

However, consumer value emerges not only in interaction with a firm, but also together with and in relation to other actors of everyday life (Heinonen et al., 2010; Mickelsson, 2013) such as other firms, communities and co-consumers. Many of the actors and their behaviours may not be manageable by the service providers (e.g. Gabriel; Lang, 2006). Since our empirical study takes place within context of consumption for and with pets, let’s consider an example that your dog is having hip dysplasia and needs treatment. You may have a dyadic 15 minutes service encounter with your veterinarian, but before, during and after the encounter you are also in contact with physiotherapist, dog agility community and the breeder of the dog. Different actors contribute to the service experience (Tax et al., 2013). Consumers may also use service in a way the service provider did not plan for. In other words, consumers face multiple touchpoints (Patrício et al., 2011) with several different service providers even at the same time and therefore consumer journey (Tax et al., 2013; Shove et al., 2012, 132) is layered, sometimes scattered. In this paper consumer journeys are not assumed to have a predetermined or designed order. Instead, we see consumer actively constructing her journey with companies, commercial actors, and also products, services, persons or other communities (Cova; Dalli, 2009).

Where service research has traditionally focused on dyadic interaction between the consumer and service provider, the previous research on consumers and their animal companions has to a great extent concentrated on pet owners’ relationships to their pets. This line of research originates from Human-Animal-Bond (HAB) studies, starting in 1970’s (Hines, 2003). The focus has been, for instance, on how pets are part or extensions of their owners’ selves (e.g. Belk, 1988; Hirschman, 1994; Bettany; Daly, 2008; Dotson; Hyatt, 2008). Studies seem to share an interest to endeavour how pets have been considered as objects of consumers’ love and attachment (e.g. Beck; Katcher, 1983; Belk, 1996; Voith, 1981). Jyrinki (2012) claims that attachment should be seen as multidimensional phenomenon that is constructed dynamically; thus, the pet owner does not have just one kind of relationship to her pet, but the pet may be regarded simultaneously for example as a friend and as an equipment for avocation.

As prior research has concentrated on examining the consumer-pet -relationship, it has ended up neglecting a large area of pet-related consumption. However, taken a more holistic view, it is obvious that experiences in pet-related consumption are not constructed in an isolated relationship between the owner and her pet, but several other actors, such as service providers, sellers and producers participate in constructing the consumer value too. As Prahalad and Ramaswamy (2002; 2004) have argued, value is co-created with consumers and other actors in networks (also Vargo; Akaka, 2009). However, few exceptions to this shortage in pet-related research exist; for instance the interaction between pet owner and vet has been studied (Brockman et al., 2008; Harrison-Walker, 2001). Yet, there are no studies on how interaction between the pet and the service provider influences pet owner’s consumption experience (except, see report by Coe; Adams; Bonnet, 2007; Rötzmeier-Keuper; Wunderlich, 2014).

In the current paper, we aim to argue through our qualitative material that the experienced value in pet-related service consumption is constructed contextually in tripartite relationship between pet owner/consumer, pet and service provider (Syrjälä et al., 2014). Our viewpoint is consumer-centric, and departs from the traditional firm-centric perspective of service research (see Osborne; Ballantyne, 2012). From this viewpoint pet owner appears in a two-fold role: consuming various products and services to the pet (Brockman et al., 2008; Harrison-Walker, 2001), and creating value journey in interaction with service providers (Teixeira et al., 2012, 364). Even though we adopt consumer’s point of view, the pet is also seen as an independent actor, who interacts and influences consumer’s feelings, activities and the value experiences.

2 Theoretical framework

2.1 Consumer value

Among the various discussions on consumer value (see e.g. Gummerus, 2013; Sánchez-Fernández; Iniesta-Bonillo, 2007), we lean on Holbrook's (1999, 5) definition of value as 'an interactive relativistic preference experience'. This means that value is constructed between the consumer subject and an object, for example a product (Holbrook, 1999). As Holt (1995) argues, products are not just carriers of meanings, instead meanings are created when we are using, valuing, understanding and experiencing consumption objects within various social contexts. In current research, the interest is in how consumer experiences value. However, we argue that the value experience should be seen as interactively formed. Similarly, Helkkula et al. (2012) see that value in the experience is intra- and intersubjective, the experience is individual and subjective, yet created jointly, for example in the manners that pet owners share and evaluate various consumption objects in the hobby communities.

According to Holbrook (1999) relativistic value experience refers to the subjectivity of experience and to its relation to other products, services and situations. The value experience gets structured also along consumption experiences of other consumers (Helkkula et al., 2012): when they compare the experiences of products and services with each other. To illustrate, pets' grooming services are valued in regards to previous, best and other pet owners' experiences.

Preference in experienced value in turn means favouring of certain products or services, and accordingly the value reflects for example consumer's attitude toward, or attractiveness of the experienced service. Preference may be directed towards the whole service experience, part of it or the result. (Boksberger; Melsen, 2011.) It should be taken into account that experienced value includes several types of preferences, not just economic but also for example emotional (Gummerus, 2013; Karababa; Kjeldgaard, 2013). Thus, for instance when different dog training services are sequenced, the value experiences get constructed along multidimensional preferences with emotional meanings.

The experiential nature of consumption brings feelings, emotions, play, images and other consumption related aspects meaningful to consumption (Holbrook, 2006). Consumption experience is not restricted to marketplace or buying situation, but experience may take place outside markets, still in relation to market-created products and/or services (Carù; Cova, 2003, 276). Thus, consumption experience may be carried out in dog park (outside actual markets), where dog owners share their recommendations of, say, dog collars (product in the market). This is in line with the idea that consumers experience services as journeys.

2.2 Consumer value journey

Alongside with the concept of experienced value, we use concepts derived from service design approach to describe the construction of consumer value in pet-related services. By service touchpoint we refer to the ways of interaction between consumer and service across multiple channels (Bitner; Brown; Meuter, 2000; Patrício et al., 2011). People, encounters, tangible elements, spaces and objects can all be seen as touchpoints (Clatworthy, 2011). A series of digital or real life touchpoints form a consumer journey that includes all the events and activities related to service, product or problem solving from the consumer's perspective (Patrício et al., 2011). The consumer journey may therefore extend over different channels, physical place and period of time (e.g. Shove et al., 2012). It may be designed (e.g. Zomerdijk; Voss, 2010), but consumers do not necessarily follow or face the journey as intended.

We set the concepts of service touchpoint and journey into context of variety of service providers, where combination of multiple interdependent services is involved in contributing to consumer's value experience (van Riel et al., 2013, 316). We take consumer-centric perspective to analyze, how consumers construct their journeys with different firms, and also with products, services, persons, co-consumers and communities (Cova; Dalli, 2009). Tax, McCutcheon and Wilkinson (2013, 2) have pointed out that service delivery is increasingly fragmented and consumers encounter several providers when using services.

In our study, the consumer value journey depicts all the experiences with different actors (e.g. vet, pet shop, insurance company) and service touchpoints (digital, real life) in time and in space. Thus, we do not restrict our exploration to any singular service or provider. As Johns (1999, 966) suggests the idea of service as a journey is not limited only in time and space but it denotes also an adventurous service odyssey. In order to grasp the journey and the touchpoints of consumer and the pet as a co-consumer we apply the concept of value wheel. The wheel illustrates what and how consumers encounter touchpoints along the service journey (Lee et al., 2013).

3 Data and methodology

The empirical material of this study consists of 53 personal pet owner interviews. In three of the interviews two persons from the same household participated. Research participants were recruited through snowball sampling (Merriam, 1998, 63) and during fieldwork in pet supply stores, vet clinics and communal dog parks. Altogether 38 women and 15 men took part to the interviews. The age of the respondents varies from 21 to 75 and the majority of the participants (12) are aged between 30 and 39 years. Participants are either dog or cat owners and almost everyone has at least one dog. The interviews were carried out between December 2012 and January 2014 in Southern and Western Finland by four different researchers.

In recruitment, our aim was to find different kinds of pet owners, such as pet-related hobby enthusiasts that train actively e.g. agility, dog or cat shows and obedience trials as well as pet owners, who do not have any avocations or specific devotions with their pets. The participants were also recruited on the basis of dog or cat breed so that owners of different breeds would be presented. Three (3) of the interviewees are also working as professional veterinarians in private clinics and four (4) are working in a pet shop chain. Some of the interviewees are, or have been, also breeders or small kennel owners.

The interviews were guided by a semi-structured but flexible interview framework. The framework was customized to each participant depending on his or her responses (Eriksson; Kovalainen, 2008). This allowed new questions and directions to be brought up during the discussion. The interview themes covered pet owners' everyday life and pet-related (service) consumption from several angles. Interviewees were asked and encouraged to tell freely about their daily routines, possible problematic situations, service encounters and products, but also about pet-related hobbies and hobby communities. The aim was to provide in-depth understanding of pet-related consumer market (Moisander; Valtonen 2012, 249).

The research participants are seen as active subjects that actively take part to creating social meanings concerning pet-related consumption. In this sense the interviewees – as well as the interviewer – are not seen as passive objects but subjects shaping the contextual understanding of pet-related consumption (see Moisander; Valtonen, 2006). The experiences of the interviewees are understood as personal, but constructed and shaped by social interaction.

The analysis was an iterative process where data and theory driven stages altered (Thompson, 1997). In the first stage, before the actual analysis, the researchers got to know all the material gathered without specific questions in mind. At this stage we were interested in pet-related consumption in general. In the second stage, two researchers applied the Holbrook's (2006) definition of value as 'an interactive relativistic preference experience' as an analytical tool. In addition to this, consumer journey maps (Patrício et al., 2011) were used as a visualization tool to recognize and understand the actors and functions reproduced in the interviews. The analysis was deepened by discussions between all the researchers.

The article is positioned within the interpretative research paradigm (Shankar; Goulding, 2001; Moisander; Valtonen, 2012) and the interviews are interpreted as narrative stories. Whitebrook (2001, 9) has argued, that narrating is a basic human activity since persons understand their own lives as stories. We believe that consumers express something about their own way of thinking as well as the cultural norms of society through storytelling. In service design storytelling is used both as an informative and inspirational method for design (Kankainen et al., 2012), and as an approach from the company side to create stories for communicating with the consumer/customer (Vollmer, 2013).

Kankainen et al. (2012, 221) combine storytelling with customer journey by reading the consumer/customer stories, and defining the service touchpoints. The authors define that service journey is often structured on multiple service providers, networks where service providers together or without knowing each other create the consumer service experience. In this multi-channel service ecosystem, a consumer can create and influence on her own service journey. On the other hand, service provider may influence on the service experience by developing the service, prototyping it, and managing the context in which experience is happening. (Kankainen et al., 2012). Narrative stories thus enlighten how consumer arrives at a particular service journey with certain touchpoints (Vollmer, 2013, 52).

In the following chapters we analyze: 1) how consumer experience value with pet, and 2) how consumer creates value journey in a case of multiple touchpoints with multiple service providers.

4 The pet co-creating consumer value

In pet-related consumption the pet itself plays a significant role: it has been seen, for instance, as a co-consumer (Vänskä, 2014). However, the presence of this third party at the construction of consumer value varies. To analyze the multidimensional and dynamic position of the pet, we operationalize a touchpoint wheel (see e.g. Lee et al., 2013) as an analytical tool to explore consumer value. Therefore we conceptualize the wheel as a consumer value wheel. The wheel illustrates the variable position of the pet that shapes the way pet owner encounters service touchpoints and experiences value. Thus, the wheel spins. The idea of variable position of the pet is in line with the argument that the pet owner does not have just one kind of relationship to her pet but the relationship is constructed dynamically (Jyrinki, 2012).

Thus, the value wheel is usually used to make sense about customer touchpoints between a customer and a company or a brand. We contextualize the wheel to analyze the touchpoints from the perspective of value experienced by consumer during the value journey through multiple service touchpoints in regards to pet-related consumption. We follow the argument of Syrjälä et al. (2014) and situate the pet in the core of consumer value wheel as a value creator, a mediator of value (between consumer and service provider), and as an experiencer of value.

Figure 1. The consumer value wheel: Pet as a value creator, as a mediator of value, and as an experimenter of value.

Next, we study the value experience in the relation between the pet owner/consumer and the pet (Figure 1). First, (i) the pet acts as a value creator, when the value experienced by the consumer is created in the interaction between the pet and the service-provider. Second, we focus on the relationship between the pet owner and the service provider, where (ii) the pet acts as a mediator of value. Third, the pet is positioned as (iii) an active subject that experiences value. The agency, meanings and the position of the pet in the family shape the value experienced by the consumer. In chapter 5, we conceptualize and contextualize the three-dimensional (Figure 1) value experience as a value journey including multiple touchpoints with several firms and other actors.

4.1 The pet as a value creator

Pet owners' descriptions of a tight-knit and close relationship to their pet speak of the consumer's value experience which is constructed in looking after the animal's wellbeing and affection toward the pet. The relationship between pet owner and pet is outlined by emotional factors linked to the pet's wellbeing: *"It makes no, you know having an animal in the first place makes no sense, unless you care about it"* [Interview 17]. When the value experience is outlined through the pet, the owner's own agency is placed in the second position and the pet's significance takes priority when the owner considers consumption decisions and use of time (Ridgway et al., 2008). An informant states: *"for wellbeing I absolutely do spend more money on the animal than on myself"* [Interview 20]. Looking after the animal's wellbeing and succeeding at it hence create value for the owner (Dotson; Hyatt, 2008). Consumers assign a separate agency for the pet, represented as independent of the owner. The pet owner constructs the position of the pet as an active subject as follows: *"(N)othing is as much fun, as watching them be so happy when they get out there to run around a bit and roughhouse with their friends"*. [Interview 22] The consumer perceives the pet as a sentient and experiencing actor. The pet as a subject of its own has resources that shape the value experienced by the owner.

The pet's active status is meaningful to the owner, as the pet is depicted as a playful actor, bringing the owner fun and joy (Holbrook, 2006). Following and interpreting the pet's actions and living with a pet create value (Beck; Katcher, 1983), making detached actors superfluous. A pet owner describes a relationship with the pet, where the owner's sense of wellbeing is essential:

It's also been kind of a lifeline, like if you're really stressed out, it's really great to see the dog having fun, rolling around in the snow or whatever. Because it can't help but it can make you feel better, because the dog is never really in a bad mood. It's pretty much in that sense, like all you have to do is go home, there's a happy dog waiting for you there, so that does make you feel good. [Interview 21]

Positioning the pet as a subject that shows affection towards its owner would appear to be pivotal to the value experience: *"Well if I think of my own pet, it loves me exactly as I am, completely like unconditionally, and loyally."* [Interview 3]. The consumer's experience of the relationship between pet and owner forms as reciprocal: both in turn are active subjects, and objects. The pet as a subject is built upon interpreting behaviour and being, and humanizing the pet (Beck; Katcher, 1983), but also of its natural aspect and qualities as an animal.

4.2 The pet as a mediator of value

Above, we have examined how the relationship between consumer and pet enables the formation of a value experience. Now, we examine the relationship between service provider and pet owner, where the pet plays a pivotal role in value creation. Here, the consumer's value experience results from her interpretation of the pet's experience from the interaction with service provider.

The consumer gives and receives recommendations, and eventually decides which products and services are acquired to the pet. Thus, the pet owner defines the value experience – in relation to the service provider and through the pet. In the following quote, the consumer explains how pet's food-related choices are formed in interaction with both social media and a service provider:

He ate, when he was a puppy it was something like Royal Canin food and I, you know, when I had time I went and read all the online chat forums for what's in them and what's good and what's bad and then I came up, talking at the pet shop about what's good. So then they said that that's got the worst nutritional values like it doesn't even say what the meat content is and, then after that, I made or you know they recommended some different options where the meat content at least is really good and then the kibble, I used those but so other than that it's raw food [i.e. BARF Biologically Appropriate Raw Food] so that it's.. [Interview 32]

The service provider gives the pet owner diet recommendations, which the owner approves of, because she has 'the best interest' of the pet at heart. A pet shop does not simply sell products; it creates value for the customer through expertise – instructions, advices and recommendations.

In the relationship between service provider and the pet owner, value creation is negotiated via the pet, however involving also social networks and communities of the owner. Consumption objects and actions are employed as vehicles to join enthusiasts of a given hobby or a certain dog breed, to those that favour a specific retail outlet or a specific breeder. For instance, communities formed around enthusiasts of a specific breed or around a breeder are comparable to brand communities (e.g. Muniz; O'Guinn, 2001). The qualities of a pet – a given breed – or status within the family are significant when a consumer justifies the profitability of insurance:

For a puppy I'd say it's pretty important, or if for some really hard-core racing dog, then it's probably really important. But maybe for just your normal house pet, then it's not necessarily quite as important. [Interview 21]

Thus, it is not just affection towards the pet, but also the financial risk is taken into account when deciding whether to insure the pet. Getting and keeping a pet involves the threat of financial loss. Awareness of available insurance policies may also reinforce awareness of the risks, for example the conditions of puppy insurance may pinpoint the health-related insecurities such as possibility for hip dysplasia. In this manner, the insurance appears as a way externalise the risk related to acquiring a puppy. Similarly, comparing insurance quotes, acquainting oneself with indemnification regulations or picking a veterinary surgeon may be challenging decisions for a pet owner. So, in this case, the value is constructed in relationship between consumer and service provider, and the pet is positioned as a negotiating instrument.

When a consumer justifies choices such as a recommendations concerning pet food, selecting an insurance company, or purchasing dog collars from a flea market, a pet constructs as a mediator of value. The agency, which a pet owner has posited to her-/himself (e.g. as an active enthusiast) and the status that the pet owner has produced for the service provider (e.g. a speciality retailer) define the value, alongside the status given to the pet (e.g. family dog).

4.3 The pet as an experienter of value

In this chapter, we show how pet owner's consumption experience in relation to the producer of pet services is created indirectly through the pet's experience. When the consumer takes the pet's experience under evaluation, pet's 'dual role' is outlined, both as a consuming subject as well as an object transmitting the experience to the consumer. For instance, pet's emotions and proper treatment are of primary importance when the consumer uses veterinary services. The pet takes central role in experiencing value; so, the consumer experiences the relationship with a veterinary surgeon through the pet as the following excerpt highlights:

Everything's gone well and I've felt good about it and it's left a very positive experience for the dog, too. Not that it would matter a whole lot, but so with us it's actually a joke because it's in Munkkivuori really near us, so Hertta always goes on a walk, she walks there [laughs], to the door of the veterinary clinic because the ladies always come and give her treats out the door. [Interview 5]

The quote sums up the three-dimensional nature of relationships in pet service consumption: in addition to the relationship between consumer and service provider, understanding the consumption experience and the value experienced by the consumer requires taking into account the interpretations and evaluations made through the pet. The experience is not analyzed as separate from the pet; instead the pet is positioned 'between' the consumer and the service provider. The interview reveals how the pet is positioned as an active subject that experiences the service. It is the consumer's interpretation of the pet's experience that structures the perception of the relationship with the service provider. This functions as a resource for experiencing value in the relationship between pet owner and service provider. The consumer describes the value experienced in a service encounter through the pet: "*We go to canine massage. (...) the pleasure you feel yourself, when it looks like the dog's enjoying it, makes it worth it.*" [Interview 20]

Pet-related consumption experiences are also analyzed according to which product or service the consumer perceives as worthy of her pet. Owners highlight that not all objects of consumptions are "*good enough for my pet*".

This is related to a view, prominent in prior research, of the pet relation as an extension of the owner's self (Belk, 1988, 1996; Hirschman, 1994). The value experience occurring through the relationship between the service provider and the pet may be difficult to recognize, as the significances linked to the pet merge into the owner's self and on the other hand the owner constructs experiences of value for the pet. When the service succeeds, the social relationships between people and factors focused on the animal become hard to distinguish. An informant describes veterinary services: "We were treated well there, the dog very well". In the same spirit, value experiences regarding veterinary services are comparable to experiences of public and private health care services for people:

Hell no, not public. I use private. Because in the private sector, the differences are very similar to human health care, but in animal health care (...) the differences become more marked, so that I think in the public sector they are in a way more indifferent. [Interview 7]

The consumer describes the negative experience and the unpleasant service as indifferent. This goes against the pet owner's assumption that the relationship between pet and service provider should reflect altruistic concern for the pet (Coe; Adams; Bonnett, 2007). The technical quality and the efficiency of procedures are secondary evaluation criteria if the service is not interpreted as primarily considerate towards the pet specifically. The pet is entitled to caring service just as a human being would be. Thus, the service that is considered unpleasant in relationships between people is also considered the same in pet services.

5 Consumer value journey with pet

Above, we examined the value experienced in pet-related services through the changing position of a pet in relation to pet owner/consumer and service provider. All the positions define pet as a kind of co-consumer (see Vänskä, 2014) next to or sometimes even equal to the pet owner/consumer. Pet may create value to the pet owner as such e.g. bringing joy and fun, pet may negotiate or mediate value experience to the owner e.g. status in a breed community or dietary decision-making, or pet has its own, active value experience e.g. pet feels good, enjoys playing.

As a consumer, the pet owner generally seeks the most appropriate available solution for the pet, and wants to be a 'good parent' for the pet. 'Parenthood' can be reached through choosing a service journey that result in desired aim, e.g. a recovered dog. As a co-consumer, the value position of the pet differs depending on individual touchpoints during the journey or even depending on the whole service journey. According to Rawson et al. (2013, 4) consumers, however, do not care about singular touchpoints but they value more the experience across multiple touchpoints and multiple channels over time. Sometimes the pet is in the frontline of value experience (recovered, happy dog), creating value for the pet owner (joy about a recovery of the dog) or standing aside but having a mediating role in value experience (the value from choosing a good expert). Consumers also structure their service journey culturally and in network with other consumers.

Pet ownership, activities with and consumption for the pet have different contents in relation to various touchpoints of different providers, e.g. together with organizations, communities and networks (Figure 2). The pet owner's relationship with a service, such as a community of enthusiasts, brings out the social aspects of experience and its multi-faceted unfolding. The understanding 'of the right kind and essential' pet-related consumption is constructed socially within one's own reference group or through expert advice from breeders or vets, for example. The shared traditions of the community, the sense of belonging, the value structure and a moral obligation towards group members become apparent when observing the instrumental role of the pet in the value experience (Muniz; O'Guinn, 2001).

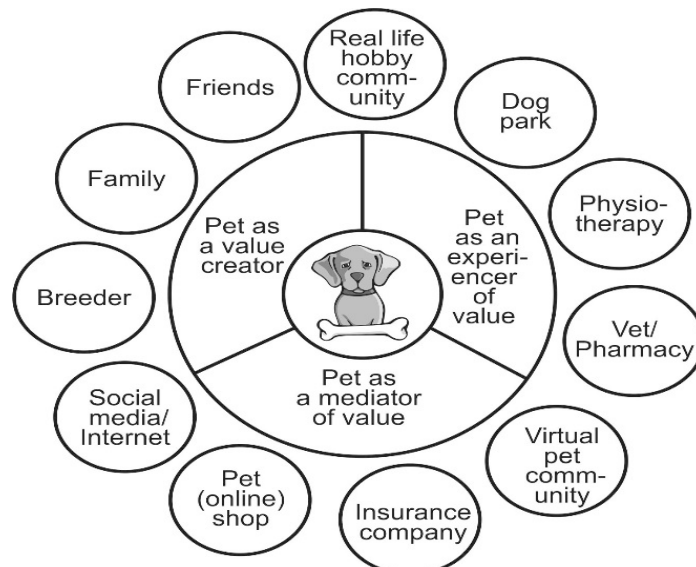

Figure 2. Consumer value wheel through pet and service touchpoints.

As the spinning value wheel (figure 2) reveals, touchpoints in pet-related consumption show fragmentation of active actors in the service delivery (see Tax et al., 2013, 454–455), and we may reckon opposing interests between the actors. Certain actors are not, however, locked to certain position of the pet when experienced, but actors in the figure and their places present an illustration of possible relations. If we consider a case of a dog with a leg injury the obvious starting point of consumer journey would be to meet the vet, probably the one that has been sending you advertisement regularly. However, the interest of a pet owner/consumer is to make the journey from sickness to health suitable for her needs, wealth, use of time, and taking the dog's 'wishes' and previous experiences into consideration. The journey may, thus, start by contacting the breeder, a friend from pet-related hobby club or pet shop, googling or asking the Facebook community about the best expert in dog leg injuries (see Patrício et al., 2011). Owner may also contact an insurance company, a pharmacy, a physiotherapist etc. before even meeting the vet.

Thus, the consumer value journey consists of events, actors, and activities which occur in different channels, physical places and time (e.g. Shove et al., 2012). Tax et al. (2013) discuss that some companies actively leave it to consumers to create their own combined service offering, their own journey. Below, we can read a story, how an owner of a Rottweiler creates his and his dog's journey concerning well-being, health, and medication:

Pet owner: We do look at them **websites, discussion forums**, although there's no such forum left where some idiot's are not trying to stir things up, but when you always leave those out you do have proper ones, plus one great thing is of course the fact that we have a good **breeder**, where we got ours from, a wonderful person, and we're good friends with her, so we can always get good advice from there, and of course we know **a lot of Rott people**, we're in the local **Rottweiler club** so, there's a whole bunch, and you know with **social media**, you do it so fast, you don't even have to **call**, so you can just type up a message and...

Researcher: And someone responds there then.

Pet owner: Someone responds, there are common sites, or then you can go there, like **Facebook** has totally, like incredibly useful, Facebook's great with all this.

Researcher: What would be your primary source of information, what would you use if you needed some information on a health-related issue?

Pet owner: If I ... you know I am such a web person, I could **check it out on the web** but, not for that long I wouldn't... I'll call, and I'd call the breeder, who's had Rotts for 30 years, and then I have... [Interview 2]

In the citation multiple persons, communities and actors come to play together and have intertwined effect to the value experience, even though they may not be designed to do so. In this manner, the citation gives voice to the fragmented nature of consumer experience concerning pet's wellbeing. However, it also shows how a narrative can act as an organizer for the fragments (Deighton, 1992). Similar to a narrative the concept of service journey gives order and structure to incidents (touchpoints) that may otherwise seem even chaotic (Kankainen et al., 2012). The journey is not predetermined, but rules of thumb and previous experiences do exist. They help, when consumer e.g. has to evaluate, what is relevant and irrelevant information and from where to get it.

During the journey different actors and influencers interact with each other, when consumer links them together and to other everyday life activities of pet owner. Consumer has a decisive role in creating or sometimes also co-creating the service provider network (see Tax et al., 2013, 456). However, consumer has also a possibility to discard the expected or supposed journey: in the story above, the Rottweiler owner might be indifferent to the existing health information by e.g. trusting the breed's general healthiness. Some consumers may also choose a journey planned by some service provider on the way of the journey, such as breeder who has tight recommendations concerning the food, or an insurance company that obliges its customers to use particular veterinarian. Narratives understood as told service journeys thus enlighten how consumer arrives at particular solution or stage (Vollmer, 2013, 52).

To illustrate the layered nature of consumer service journey with pet as a co-consumer, we draw Figure 3 on the basis of the Interview 3 that unfolds the value journey with pet in multiple service touchpoints. The journey depicts a case of a sick pet that requires actions from the pet owner. To the figure we have summarized the touchpoints with actors having influence on the progression of consumer journey and contributing to the overall value experience. The black line connects these actors in the figure. In addition, we have listed actors that are mentioned but somehow rejected or ignored – they however shape the significance of the actors included in the journey. This confirms our argument that service encounters or touchpoints do not take place in isolation but always in relation to other actors and actions of everyday life (see Mickelsson, 2013).

Figure 3. Consumer value journey: recovery of a sick pet.

The consumer value journey with pet is contextual and has a history. The journey does not begin from a blank slate: “When Daisy was small, she did not have anything special; however it did suffer from ear infections few times”. [Interview 3] The pet has been sick before, and the journey takes shape in relation to previous experiences. By choosing or accepting certain touchpoints with providers, the pet owner and pet as a co-consumer construct or repeat a journey that serves best at the aim to heal the pet. The value-creating journey can be defined as a set of interlinked actions that are having a shared purpose or unifying factor, and which consumers apply to create value to themselves or to co-consumers. For instance, the figure 3 shows how opinion seeking is linked to choosing the best veterinarian, using the medicine, and selecting the specialized physiotherapist, asking advices from the breeder, friends, close salesperson at pet shop, and browsing the social media. The actors may be separate, but they are not experienced separately.

In our case of a sick pet, the pet owner/consumer tries to be as good and responsible ‘parent’ as possible to her pet. Constructing or repeating journey that creates value then equates with executing proper ‘pet parenthood’. Like Johns (1999, 966) points out, from consumer perspective the concept of journey denotes more than just a passage through space or time. The journey may, for instance have a nature of an adventure that allows consumer a position of an explorer that hunts for bargains (see Gabriel; Lang, 2006). Applying a value journey as a temporal sequence hereby gives more comprehensive understanding of experienced value in several virtual and real life touchpoints, and with multiple service providers.

6 Conclusions

We have explored consumers’ experienced value in, firstly, through and by the pet, and, secondly, as a value journey in time and space. Article participates to the discussion on experienced consumer value in Holbrook’s (1999; 2006) theoretical framework. Our findings show how pet owner/consumer experiences value through the pet along consumer journey in series of multiple service touchpoints with different service providers. We argue that understanding consumer value requires expanding the traditional focus of service research on service provider and dyadic interaction between consumer and firm. According to our study, also other actors and activities of everyday life play a significant role in how value emerges and consumers experience it. In particular, in the current context, pet becomes a pivotal actor, taking variable positions along the consumer value journey.

In other words, consumer value journeys are complex and often unplanned including touchpoints with several providers, services, communities and people even at the same time. This reflects that consumers are actively constructing their journeys by using, sometimes misusing, choosing and refusing services. Service design can shape the journeys, but activities and relations beyond the scope of service provider can have a major impact. From provider-centric perspective there may be a certain ‘moment of truth’ of experiencing the service in service encounter (e.g. Lewis; Mitchell, 1990), but from consumer perspective ‘the moment’ extends over a prominent period of time and with variety of actors like other providers (Johns, 1999, 966–967).

Further, our findings support that the concept of service touchpoint referring to dyadic interaction between consumer and service provider (Patrício et al., 2011) should be reconsidered. According to our findings, touchpoints in the context of pet-related consumption represent rather a tripartite relationship between pet owner/consumer, pet and service provider. The pet has a role as an active co-consumer (also Vänskä, 2014): it participates in the negotiations and experiences on consumer value. In our study, three active positions of the pet are recognized: pet as a value creator, pet as a mediator of value and pet as an experiencer of value. The pet is a co-creator of consumer value, though it may not be included in the service design or concept. The tripartite relationship in service touchpoints show that service interaction and value experience is as much about the actors (including other people and animal companions) who are not taking part to the immediate interaction as those that are.

Even though our findings are context-specific (Moisander; Valtonen, 2012) they give a reason to consider also other contexts than pet-related consumption to hold tripartite relations. For instance, tripartite relationship has analogies to

consumption for elderly or children, as they can also be seen as vulnerable co-consumers (Rötzmeier-Keuper; Wunderlich, 2014). Similarities can also be found from car-related consumption: also cars need to be fed, cleaned and taken care of, but they can also be loved (Huefner; Hunt, 1994). Cars are sometimes described as ‘reliable, and a good partner’. Our study and these few samples from different contexts point out that consumer-centric ways of exploring consumer value are needed as they may considerably differ from procedural approaches like ‘blueprint’ or ‘service script’. In everyday life, consumers do not meet a consistent chain of service stages along the time axis in isolation but the journey appears as a layered, sometimes scattered set of touchpoints experienced inseparably.

New Replicating Organizations on the Rise? The Case of Local Manual Services on the B2B market

Richard Backteman, Eric Giertz, Niklas Arvidsson

KTH Royal Institute of Technology (INDEK)

The paper aims to shed a light on significant Nordic-born corporations in today's service society, namely large organizations providing B2B local manual services (B2B LMS). These firms have grown to significant sizes, partly by acquisitions. Their services need to be performed on-site by people, and are dependent on individual skills gained through experience as well as structural capital. B2B LMS seems underrepresented in the current management literature however. The success of these corporations might be explained in part by their use of managerial principles similar to those in replicating organizations, as they share general characteristics. Related theory and on replicating organizations is reviewed and juxtaposed. In conclusion, multiple case studies on the management of B2B LMS are recommended.

1 Introduction

In 2010, almost 85 percent of the working population in Sweden was employed at some kind of service producing organization, including retailing and public services. This is just one indication of the multifaceted post-industrial society where "services" is a wide concept. It includes activities with very different business logics. Some services can be produced online over the internet, while others must still be produced manually and locally. Some services are concentrated to fewer and larger workplaces but an increasing number of people in the industrial world are in fact working at small, local workplaces. Some services require highly educated or skilled staff while others may serve as temporary jobs, when staff can be swiftly trained and put to work, regardless of prior knowledge and experience.

As services are conceptually multifaceted, it ultimately results in different conditions regarding business development and successful management principles, based on different business logics. It becomes obvious that management principles and success factors will differ from one business logic to another. Such as those of a network operator, a consulting firm, a retail store or a call center. Thus, it is hardly possible to speak in general terms of what characterizes successful business development or successful management principles in all types of services, a problem that has been discussed before (Lovell, 1983; Silvestro, Fitzgerald, & Johnston, 1992).

A considerable proportion of the growing service sector is aimed at consumers. Health care, child care and elderly care are among the expansive sectors in our part of the world. But B2B-services are growing even faster. One of the reasons is that companies and organizations are increasingly choosing to outsource professional services instead of supplying them internally. One big and expanding sub-sector is knowledge-intensive services, or consulting. Another one is the contracting of manual services, such as maintenance and repair work as well as janitorial and security services.

The focus of this paper, inspired by the contents of the reports by Giertz (2011; 2012), is to start understanding the organization and management of *local manual services* in the B2B-sector. In our definition, local manual service provision entail services that are provided by workers performing manual services locally at a client's location, e.g. carpenters, plumbers, glaziers, installers, repairmen, janitors and security guards (Giertz, 2000). Some distinguishing characteristics identified by Giertz (2000, 88) are:

- The nature of the work is local in the sense that it must be performed at the designated location. Workers cannot be separated from the workplace.
- The efficiency of the operation is directly related to the individual provider's work methods, vocational know-how and manual skills.
- The work is extremely labor-intensive. It is expanding and becoming increasingly professionalized as a result of outsourcing, exposure of in-house services to competition and the creation of customer-supplier relationship.
- Maintaining a high and even workload for the employees is necessary in order to provide cost-efficient services, as work hours cannot be stored.
- Standardization of best practice (tools and work methods) combined with learning and upgrading of skills, can yield major quality and cost advantages.
- Important competitive parameters are price, delivery time and delivery reliability, labor productivity, thoroughness and customer service level.
- The local operation can be part of a replicating organization that offers uniform service at many different locations.

If one were to contrast with two other modern industries such as Information and Communication Technology (ICT) or consulting, there are some similarities and significant differences. Most importantly, ICT and consulting services are

often, but not always, absorbed and stored into deliverable systems and can thus be performed without great dependency on location and time of services rendered, which has consequences in regards to what the business looks like geographically and operationally. As Hansen, Nohria & Tierney (1999) discussed, consultancies have seen the different advantages of focusing on codifying knowledge or focusing on retaining high performing individuals or codifying knowledge for wider use.

Similar to some consultancies, several of the local manual service professions, employers seek labor with great professional knowledge and good manual skills. In others it is possible to train new staff in a short time, making subsectors ripe with temporary jobs that attract students and others looking for extra work. Akin to what Hansen et al (1999) note as codification and personalization strategies, there are differences in how knowledge can be managed. The B2B local manual services sector is growing and we believe that it is probably becoming increasingly "industrialized", organized and rationalized. But it does not seem to have been studied at great length by researchers. In Sweden, the amount of people employed within local manual services has increased significantly over the last 15 years – from 300 000 in 1993 to roughly 480 000 in 2010. In other words, about 11 percent of all working people in Sweden are employed by companies focusing on the production of local manual services. In this aspect, the standardization of best practice and more efficient ways of managing the knowledge and people within this service sector, could have significant impacts on our economy considering the sheer number of people. As mentioned earlier, one reason behind the growing development is that many companies and organizations have outsourced certain support services instead of running them in-house (Fixler & Siegel, 1999). Specialized service industries providing local manual services, have expanded through outsourcing since the middle of the 1980's. The landscape is still changing, as it is in a considerable consolidation- and internationalization phase. Initially, the structural changes were largely about splitting up large organizations and establishing several new local or domestic service companies. Today some of the service providers, many with origins in the Nordic countries, are expanding through acquisitions of existing independent spun-off competitors. Some of them have grown into multinational enterprises competing on a global market.

An example of a service provider that has a strategy of systematically expanding on local markets in the wake of the increased outsourcing is ISS, a company within facility management and janitorial services. They have grown both organically and by acquisitions, and in 2013 the group had a turnover of over SEK 90 billion and over 530 000 employees in more than 50 countries, being one of the largest private employers in the world¹. The Swedish subsidiary of ISS had 42 000 employees, of which 12 000 were located in Sweden. Another Swedish company, having expanded internationally by acquisitions, is Securitas AB. In 2010 the group had over 280 000 employees in 45 countries, with a turnover of SEK 61 billion. There are many more examples of local manual service providers, with infra-services as an example, where many tele-operators and energy companies outsource installation and repairs. Eltel Networks is specialized in building and maintaining electrical- and telecom installations in the Nordic countries, with approximately 8 000 employees of which 2 500 were active in Sweden. Dalkia, specializing in energy and facility management has 1 200 employees at 70 branch offices in Sweden and are part of Veolia Environment, a leading global provider of environmental services on local markets, with over 320 000 employees in about 70 countries. An additional example is Finnish Caverion (formerly YIT). Caverion offers energy efficiency services for facilities. Caverion has expanded in Sweden through acquisitions of ABB Building Systems, among others. In 2010 the group employed 25 000 and 4 400 employees were active at 100 branch offices in Sweden. Companies offering local manual services on the B2B-market are a fast growing part of the post-industrial service society, becoming increasingly important employers in modern societies.

2 Purpose

An important question is how these large growing multinational companies are organized and how they manage work and motivate people – both local managers and workers. We tentatively believe to a large extent that they are managed like replicating organizations - setting up more or less identical operations on many different locations. But before studying these organizations, we will examine in what theoretical context these organizations exist. The aim of this article is to review literature and theory linked to service management and management of replicating organizations. What relevance does existing research have on understanding management in companies offering local manual services on the B2B-market? To address the issues at hand, we have formulated the following research questions:

RQ1: In regards to service concepts and management how well does the literature represent B2B local manual services?

RQ2: What does the theory and rationale of replicating organizations look like, and how well do they correspond to local manual service providers on the B2B market?

3 Method

Viewing the literature as a network of nodes with various related developments presented in each publication, we adopted an approach similar to that of Ryan, Scapens & Theobald (2002) in searching and organizing the literary sources. This paper is concerned with finding the fit of local manual service providers in the literature, and juxtaposing

¹ ISS Global A/S Annual Report 2013

them to other replicating organizations. We have made literature search based on search terms related to services, service management and management of firms with a multitude of local units. Furthermore, literature surrounding management issues, history and organization, around chain organizations in for example retailing were delved into. Searches were conducted in the search engines of Google Scholar and that of the Web of Science, using various key words that relate to our issue.

Keywords that were used included:

chain, company, company-owned, federat, franchis*, local, management, manual, multi-unit, network, organization, retail*, replicat*, service*, system, versus, wholly-owned.*²

The above keywords were combined in different fashions using Boolean operators in order to get several and more narrow sets of results. Keywords (such as *replicat**) were also added as the research progressed. Some of the authors provided further understanding with their research and terminology in their articles, which we in turn built our theoretical framework upon.

In a staged review, the abstracts of the articles resulting from the search were scanned and several interesting articles were selected. A full list was then created in a spreadsheet with all the data presented and comparable in and ordered in categories as recommended by Collis & Hussey (2009). The articles that were deemed to have a good combination or in the least a fair balance between impact factor and relevance, were read through to explore and answer research questions at hand. Books were generally judged by author impact, and were chosen only when they were an original source of knowledge and theory. Checking cited articles as well as citing articles created further literary pathways. Industry data from public sources have been used when appropriate to do so in order to illustrate certain points in the article. The companies chosen as examples in this review fit well as they fulfill the criteria of a replicating service organization with several local units governed by a central body. The central factors underlying replication theory is that an organization that has some processes and/or products that can be standardized and applied in many different locations will aim to do so, generating several advantages. The so called multi-unit companies within pure manufacturing, with differing divisions and functional units are consequently not of interest in this paper.

4 Services – Definition and Management Principles

As we have initially touched upon, services today are indeed multifaceted. As a result, the explicit definition of a service is not as straightforward as one may think. Zeithaml, Parasuraman & Berry (1985) condensed several streams of service research that had taken place until the mid-1980's and listed four dimensions (IHIP) of what defines a service; (1) *intangibility* which refers to the notion of services as performances rather than products; (2) *heterogeneity* relating to the variability in performances; (3) *inseparability* due to production and consumption being simultaneous; and (4) *perishability* as services cannot be saved or stored. Services according to Bitner, Brown and Meuter (2000) have claimed that services have previously been exclusively in a "low-tech, high touch paradigm" (p. 146-147), which to some extent changed with the advent of information technology (IT), challenging the IHIP concept considerably. Experts interviewed by Edvardsson, Gustafsson, & Roos (2005) critique IHIP, with some of them mentioning technology as a reason. B2B local manual services themselves do not quite apply in this context. Information Technology does not enable the work to be "electronically" performed remotely, stored, or completely standardized. Although, as much as technology is changing the playing field in many ways, especially in regards to many modern high-tech services, they are not a significant topic in regards to B2B local manual services.

Edvardsson, Gustafsson & Roos (2005) as well as Vargo & Lusch (2004) also argue that the aforementioned characteristics of intangibility, heterogeneity, inseparability and perishability are obsolete in the sense that they are too producer- and goods-oriented and that the customer is the center of interpretation. We do acknowledge that the recent customer perspective is a valid interpretation in its own way, and that IHIP the correct paradigm of all services today. Yet, to objectively describe these services from the eyes of any third party observer, IHIP cannot be fully dismissed. Some of the "old-fashioned" manual services that are still required today, and that will not be automated in the nearest future such as cleaning, maintenance and repairs, stand as examples in this matter. A clean workspace or a set of connected circuitry, and the processes behind these results cannot be defined as a tangible *object*, and they are heterogeneous and perishable for both customer and provider.

The possible exception nevertheless, would be inseparability which can be questioned in a B2B-setting, where the business customer rarely needs be present to consume during production. In the Nordic School of Service, alongside the service marketing profiles of Evert Gummesson and Christian Grönroos, Richard Normann is a notable profile with a consulting background in corporate strategy and organization theory (Gummesson & Grönroos, 2012). In his work *Service Management: Strategy and Leadership in Service Business*, he set the foundation of many longstanding service-related concepts. The perhaps most recognized one however, is an important foundation of his and Grönroos' (2007) perspective on service management, namely, *the moment of truth*. According to Normann (2001, 21) it can be defined as the moment when "... *the service provider and the service customer confront one another in the arena*", and when "... *the skill, the motivation and the tools [of] the firm's representative [meets] the expectations and behavior of the*

² Stars [*] indicate a truncated word. All words pluralized when possible.

client which together will create the service delivery process". What constitutes the moment of truth between service employee and customer varies between different types of customers, and among different types of services. Within local manual service production on the B2B-market, it is more difficult to identify where the moment of truth occurs. Between whom lies the primary interaction? The purchasing manager of the client firm, his colleagues that work in the vicinity of the local manual service employees, or the colleagues that primarily benefit from the service? The workers in service companies may run into employees in some of the client companies, but they very often perform their duties without interacting with the client company employees, at least not systematically with a value creating purpose. On the B2C service markets, there is often more or less a direct contact, as service providers often simultaneously interact with the buyer and primary beneficiary of the service, as they are commonly the same individual. In a B2B setting however, where many of the larger providers of local manual service can be found, the picture is somewhat different, which is a first of many reasons of why these organizations are interesting objects of research. Having touched upon the matters of services themselves we will in the following section discuss the organizational aspects and structures that enable the provision of services.

5 Replication

Large and growing B2B local manual service providers share organizational characteristics analogous to *replicating organizations*, with several local independent units arranged around a central governing node. Therefore, we will in the following sections study the theoretical aspects of these. The theory on replication of routines has been discussed for some time, with *replicating organizations* and *replication as strategy* being coined by Winter & Szulanski (2001). Today the terms often pertain retailing and chain restaurants when discussed in the literature.

5.1 Replication as strategy

Replication of organizational routines implies that routines "... *play the role that genes play in organizational theory*" (Nelson & Winter, 1982, 14), which Bengtsson (2008) interprets as building blocks that characterize a firm and what it can do, and thereby determines possible behavior. Replicating routines would thus be to follow the logic of any life form that wishes to procreate, carrying on the genes to new "organisms." Nelson and Winter (1982, 118) on the other hand also describe replication as a "*costly, time consuming process of copying an existing pattern of productive activity*". In fact they question whether replication of routines is a fruitful exercise citing Polanyi's (1962) observation of a light bulb blowing machine identical to another that failed to produce light bulbs at a different location for a whole year.

Winter and Szulanski (2001, 730) define replication as strategy as "... *the creation of a large number of similar outlets that deliver a product or perform a service*", or as they define it in layman's terms, "*the McDonald's approach*." The underlying goal is to attain economies of scale and leverage brand recognition. In this setting, not just one routine is replicated but a multitude – as many as it takes to independently run a local operation. Organizations may benefit from applying their routines in more than one setting, stretching their life cycle as Helfat & Petaraf (2003) argue. As a replicating organization expands to further locations, its centre or node develops its replication capabilities, or its dynamic capabilities. Winter and Szulanski (2001, 733) refer to these as the *arrow core* – the essence of "*what, how and where*" the replicator should try to replicate its business model.

Winter & Szulanski (2001) indicate that during expansion, or creation of a local unit, there is a broad scope of knowledge transfer from the centre, or great modification of a target outlet, i.e. creating a local unit that can sustain itself via local production of products and/or services. In other words, a new McDonald's outlet has enough routines transferred to it that it may produce meals and create value for customers independently and geographically separated from other McDonald outlets. Again, this is very similar to local manual services providers where local units are able to perform services independently under local leadership. A so called faux-replication strategy, according to Winter and Szulanski (2001), would apply to retailing, or simply where producing products are of primary concern, or where on-site idiosyncratic services is non-existent or subordinate to the simple distribution of goods.

In the light of replication and services, Richard Normann points out a less recognized element in service management. He points out that scale advantages does not only belong to the domain of manufacturing industry of tangibles, but it is evident that "bigness" can be a benefit to service firms as well. Such advantages may come in the form of brand, culture, network effects of systems and scale effects of purchasing and knowledge management (Normann, 2001). Normann further discusses the reproduction of a service management system, as means of growth for a firm by multiplying through a reproduction formula (similar to the Arrow Core discussed by Winter & Szulanski (2001)), in effect transferring a service management system and its social innovations from one place to another. According to Normann (2001,174) replicating a service management system requires: (1) an analysis in order to find "the single logic" that contains the necessary functional characteristics; (2) a conceptualization of these so that they may be fully formulated and controlled; and (3) establishing central management, policies, as well as information and support functions. One could argue that this is at least partly related to the Arrow Core and its principles. A challenge Normann (2001) brings up regarding the replication of a service system, which is similar to what Winter and Szulanski (2001) argue, is the process of discerning what is replicable or not. An idiosyncratic local phenomenon may not necessarily transferrable to another location. Interestingly there are some similarities between the two theory bases, yet

no formal theoretical connection exists between them in the literature. Treading into the realm of replication, we will in the next section focus on the theoretical concept of replication and replication as strategy.

5.2 Origins and Notable Examples

Replicating organizations have become a dominant type of organization in our time, but their history dates back at least 200 years according to Lebharr (1952). It is possible they have done so even longer than that, nonetheless it stands in contrast to Nelson and Winter's (1982) perspective on replication. One of the origins of replicating organizations can be found in the retailing sector (albeit faux-replicating organizations.) Ambitions of increased volumes and economies of scale manifested themselves through attempts to closer link suppliers with many local outlets through which to distribute the products to the end consumers. In the post-Civil War United States, as retailers were growing exponentially larger in the urban environments and mail-order companies were also gaining considerable market shares, the *chain stores* emerged in smaller cities and suburbs (Chandler, 1977). They began forming in trades where retailers were not already strongly established, such as within groceries, drugs and furniture, as single store merchants wanted to increase their sales volume, escaping their single-store limitations through franchising (Lebharr, 1952). As such, the growth was initially regional rather than national. By the 1920's the chain stores were the fastest growing type of mass marketer and eventually became the standard instrument for mass retailing in the United States (Chandler, 1977). The wholesaler-retailer system was initially very well entrenched to the point that manufacturers refused to sell directly to the chain stores (Lebharr, 1952). Control over an efficient supply chain is naturally important (Vida, Reardon, & Fairhurst, 2000), but equally important is the ability to distribute the goods to as many customers as possible, which requires a presence (Lebharr, 1952) at and mastery (Greenwald & Kahn, 2005) of several local markets. The chain-stores had stores in many locations, fulfilling the distributive criteria, and thus worked towards securing a better and more direct connection at the supplier/manufacturer side. This led to two distinct channels of distribution during the growth of American chain-stores: the wholesaler-retailer system and the chain-store system.

Today as well, many of the largest replicating organizations (by its core definition) can be found among retailers. Among them, Walmart – even though it is not the first in its cadre - is a well-known chain-store system and an operationally successful example among American (and international) retailers. It is the largest retailer and private employer of the world with over 2,200,000 employees worldwide and wholly owns their entire chain of stores. In the same vein as that of the post-Civil War chain-stores, Sam Walton established his network of Walmart stores in what he called “one-horse-towns”, and has heavily invested in information technology and efficient logistics. The information technology investments began in 1969 with a computer at their first distribution center, and by the late 1970's there was a computer at each distribution center and store, forming a network. With it, Walmart eventually took the notion of getting closer to the suppliers to a completely different level in 1990, by connecting their suppliers to their network through the software Retail Link. Walmart was also an early adopter of barcodes. Technology created a basis for growth and growth in turn brought further advantages through amplified economies of scale as well as scope (Basker, 2007). In Sweden, federation-type grocery chains were prevalent with the old consumer cooperatives (Giertz & Strömberg, 1999). In similar principle as with Walmart, Albin Johansson propagated the benefits of industrialization and scale economies towards consumer cooperatives to provide products with good quality and low cost towards consumers (Giertz, 2008). These cooperatives have however mostly transformed into franchised chains with a central node that directs overall strategy and build the brand, while still maintaining a large scale purchasing base.

Other large retailers come from different backgrounds such as IKEA which started out as a furniture manufacturer that later on integrated forward towards retailing their products. The Swedish clothing retailer H&M started out as a single store company in 1947 today having 3 100 stores in 53 markets. Just as IKEA, they work with independent manufacturers, focusing their in-house resources mainly on designing, logistics and retailing. Both companies also franchise stores in some emerging markets, and where attaining the best store location can be a difficult matter. An in-depth study of H&M's replication process is provided by Bengtsson (2008), where she portrays fashion as a volatile industry where exact replication from a template is not always an optimal approach, in contrast to Winter & Szulanski (2001) prescribe, and that the replication process in itself enables internal career opportunities.

Besides retailing, the most common example of replication in local consumer services is restaurants with McDonald's being a text-book example, described in detail by Love (1995). McDonald's started as a restaurant by the brothers Dick and Mac McDonald in the year 1940. With the intention of increasing their service levels they created a slimmed down and static menu in 1948, with only eight courses and a cooking process according to line production principles. It became a success story observed by Ray Kroc, whom sold milkshake machines to the brothers McDonald. Kroc saw the possibility of starting similar restaurants at other locations in the United States, and 1955 he himself became the first franchisee, purchasing the full rights in 1961. Sweden has 230 McDonald's restaurants of which 80 percent are run by franchisees, all together serving 430 000 guests every day. Having mentioned franchising, we will now elaborate on the main type of governing structures in the following section.

5.3 Franchises

It is a common organizational form among replicating organizations. Oftentimes a predominant franchise organization such as McDonalds is referred to when discussing replication as strategy. As a term, a *franchise* can be defined as:

“a long-term contractual agreement between two types of firms – a franchisor who has recognized opportunity and created a new venture to exploit it and a group of franchisees who see the value in the opportunity and purchase the right to replicate the venture in new geographic markets” (Combs, Ketchen, & Short, 2011, p. 413).

Franchise organizations often originate from a business that develops a successful concept on one local market, their brand providing a quality assurance for potential customers, especially in their unfamiliar geographic settings (Brickley & Dark, 1987). The *franchisors* define the concept, package it and license it to other independent entrepreneurs on different local markets, as a quick growth strategy to catch market shares in many places. The entrepreneurs, or *franchisees*, approach the franchisor on their own accord, with a commitment to make significant investments of their own. In turn they are trained, gain support and take on a well-known brand while accepting to offer a well-defined service on a well-defined local market. The franchisees are contracted and thus have no real safety net; should the business not be able to sustain itself in its location, its costs will not be carried by another entity in the franchising network.

A risk that the franchisor takes, should a franchisee fail, is arguably that the brand perception of consumers may be negatively affected; however in a direct financial perspective the only one at risk is the franchisee; which reduces the agency costs for the franchisor, as the franchisee's motivation exceeds that of hired employees (Caves & Murphy, 1976; Lafontaine, 1992). While franchisees do enjoy some independence as a contracted separate business owner, they are often bound to adhere to quality standards, determined product offerings, marketing principles or other constraints. Depending on the nature of the business, the value chain and franchisor revenue model may differ as in a percentage of the franchisees' revenue or a fixed fee.

Other sources of income for the franchisor can come from wholesaling to the franchisees. Mekonomen Group, a car parts retailer, and by extension through their franchisees an auto maintenance service provider, recognized that car parts are not only sold in retail stores but also through repair shops. To increase their market share they integrated forward through franchising. *Sibylla*, a fast-food chain in the Nordics grew by forward integration, expanding from selling to grocery stores to franchising hot dog stands in the 1930s. In both cases, franchisees must also agree to the certain terms of the contract in order to become a sales outlet and take advantage of the attractive wholesale prices.

While these organizational forms of franchising and company owned systems seem clear and distinct from one another, it is worth noting that firms having combinations of more than one category are in fact quite common. Even within the same form of arrangement there may be differences in how they are managed and what the value chain looks like. Oxenfeldt and Kelley (1968) theorized that franchising might be a temporary form allowing for rapid expansion for a young firm, and that firm ownership of all local units is a final goal that all organizations perhaps strive towards. A large, concrete and current example that stands opposite to Oxenfeldt and Kelley's (2008) premise would be Burger King, that divested almost every single company owned outlet in 2013, and became an almost complete franchise based organization. Furthermore, we still see replicating organizations with franchised local units alongside wholly owned local, units in the same districts. Bradach (1997) and Sorenson and Sørensen (2001) both argue that a mix of both franchising and firm ownership of local units, a *plural form*, has intrinsic value as it leverages the benefits of both organizational forms which creates an even stronger organization than if operating with one structure alone. But what makes plural forms so effective? Bradach (1997) explains that it keeps control processes fresh and enables an organization to better learn and innovate, while Sorenson and Sørensen (2001) similarly argue that a mix provides a trade-off between exploitation of wholly owned units and exploration of franchised units, explaining that Oxenfeldt and Kelley (1969) do not take into consideration the learning needs of a chain. Bradach (1998) outlines four main premises of a plural form; it (1) allows wide expansion with little needed oversight; (2) helps maintain uniformity of the concept (3) provides local responsiveness through knowledgeable and motivated franchisees; and (4) enables innovation from motivated franchisees that can be tried and transferred through wholly-owned units. His theory was later empirically tested by Cliquet & Penard (2012) to some extent confirming his notions. Relatedly, Kidwell & Nygaard (2011) have also proposed strategic deviance theory, the basis being that all agents within a system have access to information about each other, such as benchmarks indicating each other's business performance. In a plural form it would further lessen the agency costs of monitoring both franchisees and hired managers, with all types of local units competing with each other within the benchmarking system.

Figure 1. Member firms' sectors share of all franchisors. Adapted from *Franchising in Sweden 2013* (The Swedish Franchising Association).

Franchising has seen a considerable growth in Sweden and has contributed to the growth of replicating organizations in general. In 2012 Swedish franchises employed 110 000 and generated turnover of SEK 200 billion, having almost tripled and increased five-fold respectively since 2002, numbers that correspond to 2.6 percent of total employment and a 5.6 percent of GDP.³ Figure 1 above illustrates the share of each sector based on the data of its members, with sectors such as retail, restaurants and various brokers representing slightly more than half of the total members of franchisors. Most of these firms represented are predominantly within sectors where service is directed at consumers. Secondly, a significant part and top two of the sectors in this chart revolve around the delivery of some type of physical good at the core of the service. At the very surface it would seem as if franchising is an attractive organizational concept mainly for delivering product-based services B2C markets.

5.4 Federations

Federations, as defined by Johnstad (1997) "are formed when two or more actors join in creating a common unit to promote common interests on contracted issues while keeping autonomy on others" (p. 48). They are comprised of existing independent member units, which may or may not be registered firms, and agree upon a form of cooperation. They may in principle compete with each other, although they are often geographically separated. In this collusion, a central type of node firm may be created; one possible path is that the member-firms elect a board that in turn appoints a CEO within the node to run the federation (Edgren & Skärvad, 2014). The logic behind this is to organize and attain economies of scale in several matters by pooling purchasing power for bulk procurements and centralizing administrative functions that are expensive to run in each single member firm. Other benefits include a consistent marketing message, a strong brand value and the possibility of forming standardized training programs to increase competence and quality. The firms entrust the central node organization with directing the collective, but in the long term they are not bound to remain within the federation, as opposed to franchisees who are contractually bound and obligated in many ways. Then again, a member-firm owner that is unsatisfied with the federation executive management does not necessarily have to leave. He or she has the ability to affect the board members and vote for ones that will enforce their opinion regarding what services they want to pay for and how, if the executive team should put restrictions on members or if they should continue to run the node of the federation (Edgren & Skärvad, 2014). As it stands, Johnstad (1997) declares that federations are not common in organizational research, yet they are a fair part of the service industry in Sweden. An example of a federation system is the Swedish company Praktikertjänst AB, a small scale business in dentistry and health care, employing almost 9 000 people at nearly 2 000 clinics. It is owned by 2 150 shareholders or partners that act as operating managers at their respective clinic. The managers and their employees at every local unit all share the same employer, in practice however it is more of a chain of independent businesses. Together they fund a central node in the organization, and every local unit or clinic more or less functions as a firm within the firm. Each shareholder is responsible for their respective clinic's profitability and must adapt their expenses, investments, salaries and pension benefits to the revenues of their clinic. A similar setup to that of franchising, where local managers are motivated through some degree, yet more decentralized in terms of power in the long run.

5.5 Are B2B Local manual service providers replicating organizations?

We have seen that an important capability in replicating organizations such as retailing is to integrate several factors. In retailing, for example, possessing a supplier advantage must be coupled with a distribution advantage at several different geographical locations or electronic channels if the organization is to maximize its sales. This is often combined with scale advantages in purchasing since large quantities of products are sold through these channels. The course of action for many actors has consequently been to replicate its unique business concept across several retail outlets. In the case of local manual service providers on the B2B market, being large and having many local units spread out geographically enables them to serve very big client firms whom also may have offices or factories at many locations in different cities. This implies that one important factor behind the development of large corporations providing local manual services on the B2B market is that their customers want to buy services at different locations from the same vendor. On the B2C markets individual customers act independently from customers on other locations. In B2C markets growth is perhaps more related to the creation of globally similar consumption patterns.

Franchising allows for fast growth, aiding to this purpose of spreading distribution channels on a wide geographical market, and as we have seen, franchising is a growing phenomenon mainly in B2C markets. In regards to local manual service production on the B2B market however, the large service companies have not expanded by franchising but rather through organic growth and mergers and acquisitions. The acquiring companies have very often taken over both local managers and workers from their future customers, subsequently run these (and other) local units as wholly-owned ones rather than critically handpicking the new local managers and having them invest in the unit itself.

Much of the literature focuses on either product distribution sectors, or sectors where a product is a core part of the service offering, or on franchising on the B2C market. With franchising, as well as with federations the literature identifies several benefits of a franchising system such as reduced capital investments and reduction of moral hazards resulting a reduced agency cost (Caves & Murphy, 1976; Lafontaine, 1992; Edgren & Skärvad, 2014). There are also several further benefits granted when combining organizational forms (Bradach, 1997). These are however benefits that wholly-owned organizations may not reap, along with little obvious scale economies, at least to the naked eye. This raises the question as to why large service companies within the B2B market are growing on such a scale despite no obvious advantages related to size. They cannot motivate a local manager with ownership of a unit, their nodes do not wholesale products to local units as a sole income source. For the organization to generate profit, there must be a high focus on human productivity, and human productivity requires competent leadership and well defined work methods, as well as the proper mechanisms that develop both. This leads to new questions such as whether these firms share similar management models and methods as more traditional and common replicating organizations, such as retail chains and franchising organizations? Can they enhance their organization by integrating IT systems the way Walmart does? Are they able to enjoy scale economies in the same way as the other replicating organizations? Do they have tournament-like ranking between local units, as Kidwell & Nygaard (2011) propose for franchises? The questions are numerous, and so far the answers are few.

6 Conclusions

Different to some foundational concepts of service management such as the moment of truth, and aged compared to newer definitions of services that criticize IHIP, local manual services within the B2B sector seems to reside in a category of its own. Yet their organizational characteristics are strikingly similar to that of replicating organizations, which highlights some gaps in the literature of service management. We have also seen that local manual services have not left an imprint on the existing theory, implicitly or explicitly. The field, however, share a similar backdrop as retailers and chain restaurants in the theory of replication as strategy. Some questions that arise from this organizational similarity is if these large local manual service providers are attempting to realize economy of scale, establishing standardized working methods, routinely improving and diffusing best practice, developing systems for quality assurance, and systematically streamlining offers and routines. Alternatively, how do such efforts manifest themselves in a pure service firm?

Given the relatively little research we have found in the literature study on wholly-owned international local manual service providers on the B2B market, and that they are becoming increasingly significant employers, we argue that there is a great need for research aiming at understanding these organizations. More specifically, we strongly call for studies upon the management of these replicating organizations. Including but not limited to: usage of key performance indicators, service process development, leadership development, ranking systems, incentive and compensation systems, creation and diffusion of best practice etc. In short, how management harnesses productivity within the large replicating organizations providing local manual services on B2B markets.

Another stream of research should aim at providing better understanding of how and why these forms of organizations are able to grow. This research will apply replication theory and theories on service management to study factors related to standardization and growth. As we studied the service management theories we also saw that this research to a large extent has been focusing on B2C-services and there is a need to pursue research on B2B-service providers.

Lastly, research may also be focused on the transformation of the industrial society to a post-industrial society, in which the organizational forms we have studied play an important role. As we have discussed, an explanation as to why

these forms develop is that corporations outsource some activities they deem to be outside their core business. Specialized replicating organizations are then able to perform these activities as a core business and use replication strategies to grow not only nationally but also internationally.

Given the uncharted nature of the area, we propose in-depth case studies focusing on different aspects such as the ones listed above, in order to better understand and explain the nature of these emergent organizations and how they are managed.

Development of Cultural and Creative Industries in China

Sen Bao, Marja Toivonen

VTT Technical Research Centre of Finland

This paper focuses on the development of cultural and creative industries in China. The concept of this industry is much later origin than in the Western countries, but it has raised high attention from the central government recently. It developed very rapidly during past decade when China is experiencing the economy transition from 'manufacturing' to 'services'. Our study aims to distinguish China's specific concepts and characteristics, to learn current situational factors and drivers, and to target the challenges and future trend of cultural and creative industries in China. In addition to the established Western literature, we utilize a number of studies, including literature and documentary materials in both English and Chinese, carried out by Chinese scholars. Our empirical study is mainly based on the experience of a Western 3D company which is actively looking for business opportunities in the cultural and creative industries in China. This experience has been illustrated through interviews in the company and among its partners and potential clients.

1 Introduction

Cultural and creative industries, closely linked to KIBS, have attracted the interest of an increasing number of researchers in the field of innovative economics (Müller, et al., 2009). They have had a significant contribution to the economy over the past two decades, particularly in terms of employment, regional development and urban dynamics (Andari et al., 2007). The concept of cultural and creative industries has gained popularity in Western countries since 1990s, but arrived in China later: during the 2000s (Banks and O'Connor, 2009; Keane, 2009). Currently, China is experiencing a transition from an investment-led economy into a consumption- and service-driven economy. The Chinese government starts to regard cultural and creative industries as part of its long-term economic vision (O'Connor and Gu, 2006). The developed cities in the Eastern part of China, such as Beijing, Shanghai and Guangzhou, have especially become interested in this industry to build the 'knowledge economy' (O'Connor and Gu, 2006). Cultural and creative industries are also considered as new growth opportunities for this huge emerging market, to meet the growing demand of the 13 billion populations, especially the younger generation. In the Chinese government's 12th Five-Year (2011-2015) Plan (NDRC, 2011), the average annual growth rate of this industry is supposed to be around 20%, much higher than the general GDP growth.

However, cultural and creative industries in China have their unique characteristics and development trends when compared to Western countries. Our paper focuses on this topic to distinguish these specific factors in China's socio and culture context. We proposes the following research questions: 1) what are the specific concepts and characteristics of Chinese cultural and creative industries compared to the development in the Western countries; 2) what are the current situational factors and drivers of cultural and creative industries in China; and 3) what kinds of factors influence the development of Chinese cultural and creative industries and their future trends in China.

The structure of this paper is as follows. After this introduction, we open up the concepts and characteristics of cultural industries, creative industries, and cultural and creative industries from both Western and Chinese perspectives. Thereafter we tackle the detail of China's current situation and drivers in this industry. It is in the early stage but government support and large consumer demand mainly drive its rapid development. Then we continue our discussion with the challenges and future trend of cultural and creative industries in China. Piracy and censorship are the barriers for its future development. Chinese traditional Confucian culture may also hinder creativity in this industry. All these parts are based on the literature study from both Western and Chinese scholars, as well as policy documentation reports. Before final concluding discussion, we also supplement our study with practitioner's view in a small-scale case study via interviews and discussions among different stakeholders in the 3D field.

2 Concept and characteristic differences

The term *cultural industries* has been frequently used in cultural analysis and policy for many decades, and recently it has been joined by another popular phrase *creative industries* (Hesmondhalgh, 2008). Since there is little clarity or official explanation of the differences between cultural and creative industries, they are often used interchangeably (Galloway and Dunlop, 2007). The concept of cultural industries was first coined by Theodor Adorno and Max Horkheimer in 1947 with their essay 'The Cultural Industry: Enlightenment as Mass Deception' (Adorno and Horkheimer, 1979). They used this term to refer to *industrially produced commercial entertainment*, including broadcasting, film, publishing, recorded music, visual and performing arts, museums and galleries, etc (Horkheimer and Adorno, 2002). This understanding underpinned the cultural industries policy initiatives of the United Educational, Scientific, and Cultural Organisation (UNESCO) (Galloway and Dunlop, 2007).

The concept of creative industries emerged in 1990s primarily as a policy discourse (Flew and Cunningham, 2010). The Creative Industries Mapping Document (CIMD, 1998) in the UK has first defined creative industries as *'activities which have their origin in individual creativity, skill and talent and which have the potential for wealth and job creation through generation and exploitation of intellectual property.'* It not only refers to traditional cultural industries including resolutely analogue (arts, crafts, antiques, architecture) and established commercial business sectors (TV, radio, film) in the modern society, but it also extends portfolios to emerging digital sectors (e.g. interactive leisure software) in order to capture significant 'new economy' enterprise dynamics (Cunningham, 2002).

Cultural and creative industries have been interpreted differently in the international markets. For instance, Germany, the Netherlands and Korea prefer to use the term of culture industries, whereas the UK used to adopt the concept of creative industries. Spain used to refer it to culture and leisure industries. In addition, the U.S. addresses the similar industries as copyright industries, whose primary purpose is to create, produce, distribute or exhibit copyright materials, including videogames, books, newspapers, periodicals and journals, motion pictures, recorded music, radio and television broadcasting, and even computer software (Siwek, 2013). Japan prefers to call it as content industries, which highlight video games, animation, cinema, music, broadcasting, book and newspaper industries (Xu, et al., 2011). They all represent the domain of cultural and creative industries, even though there is no uniform name or definition in different countries.

In China, both cultural industries and creative industries are of much later origin and have developed later than in the Western countries. The term of *culture institutions* is more suitable to characterise the nature of China's cultural development in the socialist orthodoxy from 1949 to 1979, since culture during this period was mainly described in conventional Marxist terms as the superstructure reflecting the base or the economic reality (Keane, 2004). The *industrialization of culture* starts right after Deng Xiaoping's 'open door' policy. The concept of *culture market* has existed since the early 1990s in policy discourse when China was deepening the reform to a market economy (Keane, 2004). Thus, a turn towards the term *culture industries* has been witnessed in the late 1990s in China. The booming economy and large consumer market in China have also generated a huge demand of culture industries, especially in new media and value added services after 2000s.

The concept of creative industries has come to China somewhat late in 2004 (Keane, 2009). It is in the right time going through the transition trend in China from 'manufacturing' to 'services' for the industry upgrade, with the mindset 'create or design in China' instead of previous only 'made in China'. The key term of creativity has also matched with the Chinese policy concept of 'innovative nation' during this period, when many Chinese scholars have exploited the significance of creative industries on China (Keane, 2009). For instance, Li (2008) defines creative industries in his book 'Creative Industries are Changing China' as *'those industries that rely upon creative ideas, skill and advanced technology as core elements, increase value in production and consumption and create wealth and provide extensive jobs for the society through a series of activities'* (Li, 2008, pp. 3). In his definition, advanced technology has been regarded as one of the core elements, which may not be considered as a necessity in traditional cultural industries in China.

Since creative industries has a natural link with cultural industries in the international markets, China has even combined these two terms together as the *cultural creative industries* (*Wenhua Chuangyi Chanye*), which is a combination of culture, creativity, and information technology, with the characteristics of high added value, high intelligence, and strong convergence (Xu and Yao, 2012). However, it is not that common way to express such terms in the West. In order to match Western expression, this combinatory term has adopted an official English translation '*cultural and creative industries*' in the policy discourse (Zhang, 2011 b). The concept of cultural and creative industries has been first time written into China's 11th Five-Year (2006-2010) Plan in 2006 (NDRC, 2006), whereas it was defined in Taiwan earlier in 2002, as *'the industry to enhance the overall quality of life, with the potential to create wealth and employment opportunities from the creative or cultural accumulation and use of different forms of intellectual property'* (CCA, 2004).

Although there are still divergent views on the detailed definitions of cultural and creative industries after it arrived in china, many Chinese scholars believe this is a driver of regional growth based on modern science & technology and cultural resources (Deng, 2007). As we mentioned earlier, this industry has various names in different countries, which reflects their economy reality and development focus. For instance, the UK focuses on branding of creative products and the U.S is keen patent development and protection of intellectual property; In Japan, game, animation and other entertainment are the major parts of its content industries (Xu and Yao, 2012). However, cultural and creative industries in China emphasize on both the heritage of traditional Chinese culture and the utilization of advanced technology (Li, 2008; Xu and Yao 2012).

3 Current situation and drivers in China

Different from many Western countries, cultural and creative industries in China is still at the exploratory stage, and it has not formed a comprehensive industrial chain yet (Xu and Yao, 2012). Although China has abundant cultural resources, it is relatively small as the provider of cultural and creative products in both domestic and international markets due to slow development in this field before 2000s. Cultural and creative industries has recently become a hot topic in China only after it has been raised by the central government in 2006 (Xu and Yao, 2012). Since then, more than half of provinces in China start to include cultural and creative industries in their local economy development

planning (Zhang, 2010). The production of cultural and creative industries in China has grown by 60 times in only 10 years to 1,807 billion RMB, accounting for around 4% of GDP (NBS, 2013).

Many of cities in China are interested in learning the successful experience in content industries from Japan, and regard animation as a key part in the development of cultural and creative industries (Zhang 2011 b). China produced domestic cartoons in TV about 400,000 minutes, more than in Japan, in 2009; however, the quality and profitability are questionable, because government's financial support in this field is even able to buy all these domestic cartoons based on current production cost (SARFT, 2010). The excessive protection and support policy leads to the dependence on government business - many enterprises even use their 'guanxi' network to turn the government as a client (Zhang, 2011 b). This phenomenon causes unfair competition and lower the effectiveness of financial resources.

At the same time, numerous cultural and creative industry parks have been built in different regions in China (Zhang, 2011 a). The emerging cultural and creative industries in many parts of China, especially in less developed areas, still lack contents, in terms of the entry of enterprises and experts. Some local governments in these regions only follow the trend to build industrial parks, without a complete follow-up planning. So far, China has three cultural and creative industry clusters mainly in the relatively economy developed regions in the Eastern part: Beijing, Shanghai and Guangzhou area (Zhang, 2011 a). Cultural and creative industry development meets the economy transition requirement in these regions.

Both grassroots and elites have realized that traditional industrialization with high-consumption and high-pollution model cannot continue for long, but low-carbon and green economy will become an important direction for China's future development (Zhao and Huang, 2011). Following the success in the exploitation of the 'World Factory', China is now attempting to explore new possibilities: cultural and creative industries can be defined as a transition project for its national policies and services (Cai and Cai, 2011). On the one hand, Chinese consumers' non-material needs are growing along with the economic booming during the past three decades and there are huge demand for constant renewal of knowledge and ideas. On the other hand, economic globalization increases the international competition and drives China to enhance core competitiveness by added value of products and services (Hu, 2007). This industry also plays a key role for China to demonstrate its soft power in the global market, even though it is still very weak at this stage.

4 Challenges and future trend in China

At the policy level, the government's promotion of 'cultural and creative industries' aims at a transition from 'manufacturing' to 'services'. However, there are certain practical barriers against creativity in China. First of all, the piracy phenomenon is still popular. Although China has enacted its first copyright law in the early 1990s, the implementation of this law has been very poor so far (Montgomery and Fitzgerald, 2006). For instance, pirated DVDs and CDs are hampering the development of China's domestic marketplace and creating ambivalence to international investors (Keane, 2004). China's illegal distribution channel is well established, offering a full range of high level services (Montgomery and Fitzgerald, 2006). It is estimated that the piracy rate in film and music accounts more than 80% of the market share (Montgomery and Fitzgerald, 2006). The consumers are used to get free access to those cultural and creative products.

In addition, the strict censorship regulation from the traditional cultural industry has restricted individual's creativity and enthusiasm (Montgomery, 2010). The strict censorship regulation origins from the ideology control of previous cultural institution since the establishment of the Chinese Film Bureau (Montgomery, 2010). The censorship committee was set up in this bureau to decide if the film, animation and documentary scripts were suitable for production to the public (Zhang, 2004). Although the economy reform has carried out for more than three decades, the political reform in China has still been lagged behind. The censorship on cultural and creative industries continues by the State Administration of Press, Publication, Radio, Film and Television of the People's Republic of China (SAPPRFT).

Interestingly, Chinese traditional Confucian culture may eschew innovation without breaking 'the patterns of the past' (Keane, 2009). The Confucian view was that a sage does not create but merely transmits (Makeham, 2003). This might be another angle to explain why there is much less radical innovation than incremental innovation in China. While the copyright cannot be well protected and there is a risk to pass the strict censorship, many local culture and creative producer may hesitate to put many efforts and high cost to realize the innovation. On the contrary, they are more willing to 'Shanzhai', "to copy" and "to parody" as self-aware, casual, and public behaviour (Hennessey, 2012).

The economic development of a country will increasingly rely on cultural and creative industries when it reaches a certain level from past experiences of world economic development (CPMJ, 2014). As we mentioned earlier, current rapid development of cultural and creative industries mainly concentrates in the Eastern part of China due to their better economic development level. However, there is a huge potential in Western part when China starts to balance the regional differences in the near future. From the whole China perspective, national citizens' average culture consumption, also including imported cultural and creative products, only takes up about 7% in their family expenditure, which is much less than the U.S. and Western Europe's 30% (CPMJ, 2014). There is a large room for improvement at least in the domestic market.

Currently, there are only less than 1 million talents, who are working on cultural and creative industries in China, but the talent needs in this industry during the 12th Five Year (2011-2015) Plan (NDRC, 2012) is more than 10 million based on the industry growth and consumer demands (Su, 2011). The shortage of domestic talents indicates that

homogenous cultural and creative products may not meet the growing demand of domestic consumers. There are huge opportunities for Western providers in this industry to sell their products and services, some of them with strong Chinese culture elements, to China. The Chinese government has also realized this reality and utilize strong financial support to encourage young talents to start with this industry. Recently, the ‘going out’ of Chinese culture has even become an important part of China’s reform and opening-up policy, with the hope to improve China’s international impact (CPMJ, 2014).

5 Illustration from practitioners’ experience

In order to illustrate the experience of practitioners involved in cultural and creative industries in China, we have conducted a small-scale case study in a Nordic 3D company which is actively looking for collaborations and opportunities for 3D content and display solution business in China. We have interviewed three members from the case company (two of them from the top management and one of them with Chinese working experience) and six of its potential partner representatives. In addition to these formal semi-structured interviews, we have also participated three exhibitions and two seminars in 3D areas. These activities offered us the platforms and opportunities to discuss with different stakeholders in this industry, including potential customers, solution providers, 3D experts, etc. Since cultural and creative industries has a broad range of portfolios, the interviews and discussions on 3D business in China supplements our views on challenges and opportunities in this industry from a specific segment perspective.

Our case company is in the very early stage to enter 3D business in China. In order to reduce the internationalization investment risk, the company prefers to first deliver 3D services that do not require physical transportation of goods (e.g. 2D to 3D conversion services). Since the company does not have any physical presence in China yet, they want to work closely with local partners, as one of the representatives from the case company mentioned that:

“In China we recognize that we cannot get anywhere without well-connected local partners, so screening and finding the right partners is vital in order to penetrate the Chinese market.”

In this less matured industry, collaboration with partners is very important. The company have sent the experts to travel and work in China in order to build local networks, and identified suitable partner candidates. They prefer to have such partners with certain government background or access due to a large amount of government related business and influence in this industry. However, this process goes somewhat slow when it takes time for the case company, as a SME (Small and Medium Enterprise), to prove their capability and credibility and win satisfactory partners’ trust.

Although Chinese traditional Confucianism, to some extent, hinders radical innovation or creativity, the Chinese are keen on learning the new technology, and adapt it to the local needs incrementally. It is very important for our case company to introduce new and high technologies in 3D field to the partners, and work together with them to adapt the local clients’ requirements. This co-creation process with partners not only adds value of offerings to clients but also gains government’s preference. One of the potential partners emphasized that:

“Role of technology has been crucial in China. We have constantly screened the market for new technological developments, especially when the technology acts as a limiting factor in some platforms in the local business.”

China has been regarded as a huge 3D markets, since it has the largest number of 3D cinema screens at the moment and the Chinese government has planned to launch at least five 3DTV channels by the end of 2015. However, 3DTV channels have only been made a slow progress so far in the practice. Current operation model of CCTV 3D channel has a serious problem. The government set up the rule to request six local TV channels to provide certain 3D contents for free or with a very low purchasing budget. Thus, there is lack of excellent programs due to the government’s planning economy mindset on this issue. The related companies are not willing to put advertisements on this niche distribution 3DTV channel when audiences have been driven away. One of 3DTV officials and experts also raised that:

“The most important thing in 3D is the contents. When audiences left because of the poor contents, it is much more difficult to attract them back in the future. We have realized this issue and need to improve our budget to make better contents.”

It is not difficult to make the 3D contents, but it is a challenge to produce high quality contents with impressed stories. Current 3D markets in China are mixed with much more low quality and much less high quality 3D contents. There is a lack of capable talents and related technologies to meet local consumers’ growing demand when many of their attitudes towards 3D have been changed from “fresh and interesting things” to “excellent experience”. This provides a good opportunity for our case company in this niche premium market, as one of the case company representatives perceived that:

“We have a good chance to sell our high-quality but cost-effective 2D to 3D conversion services to the Chinese market. We are also interested in joint concept development with local partners to suit Chinese consumers’ preferences.”

6 Concluding discussions

Cultural and creative industries is quite a recent category in academic, policy and industry discourses in China. The industrialization of culture after 'open door' policy in 1979 makes China experiencing a transition from culture institutions to culture industries. Culture products not only reflect national socialist orthodoxy, but also become commodities in the culture markets where the citizens can purchase and consume it freely. Creative industries has arrived in China even late in 2000s. This term matches its national policy to create an innovation country when China is at the stage of industry upgrade. Soon after, China has combined both terms together and created its own words 'cultural creative industries' (Wen Hua Chuang Yi Chanye) in order to emphasize the creativity and utilization of technology in traditional cultural industries on the policy level. Although it has been officially translate into 'cultural and creative' industries in English, the Chinese way to express 'cultural creative industries' integrate culture and creativity much more firmly as a whole.

Cultural and creative industries has developed impressively rapid since it gets popular in China in 2000s. It is not only driven by the central government's policy and financial support during the economy transition process, but also due to the growing demands from the large consumer markets along with increasingly improvement of living standard and mindset change in life style. Numerous cultural and creative parks, especially with animation theme, have been built in a very short time in different regions in China. However, it also causes certain problems. For instance, some of these fast-built industrial parks are lack of entry enterprises and experts; some of these parks are part of reconstruction projects – incapable animation enterprises only produce simple and repetitive cartoons by using government financial support.

Besides, some practical barriers also exist and hinder the development of cultural and creative industries in China. The piracy phenomenon is still common after 2000s. It is understandable that the legal copy of films (DVDs) or music (CDs) were too expensive for normal Chinese consumers one or two decades ago when they still had very low income. Nowadays, these consumers still keep previous behaviour to enjoy free of charge access to pirated copies from the internet. The copyright consciousness in Confucian culture might be less visible than in the Western culture, when the Confucianism views a sage does not create but merely transmits. In addition, the Chinese government support in cultural and creative industries is also debatable. On one hand, the government does offer the financial support; on the other hand, the strict censorship regulation, to a large extent, hinders the key element 'creativity' in this industry.

There is still a large potential for the development of cultural and creative industries in the whole regions of China. In the Eastern part, three clusters (Shanghai, Beijing, Guangzhou) in cultural and creative industries have attract many young talents and start to form certain levels of the industry chain based on the strong consumption power in these regions. In the Western part, although no such clusters have been formed yet, they keep better original culture resources. The government's on-going 'West development' policy will definitely benefit their development in this filed in the near future. Moreover, the demand of cultural and creative industry talents in China is at least 10 times more than the existing capable ones. It leaves an excellent opportunity for both domestic and foreign providers in this industry.

The case study illustrates the experience of practitioners and supplements our views on challenges and opportunities from the perspective of a specific segment, 3D business as an emerging part of cultural and creative industries. In the unmaturing industry, the connection with a broad network is very important. Especially in China's business context - 'guanxi' before business, finding a right partners is vital to penetrate the markets. Advanced technology has been highlighted as a significant brand in China's 3D industry, and it can even be acted as a 'door knock' when dealing with both partners and customers. Along with the economy booming, local consumers' demands on high quality 3D contents are dramatically increasing. The premium market in cultural and creative industries in terms of 3D business at least is more prosperous than traditional industries, such as manufacturing. However, this empirical study is only based on a small-scale Nordic case in 3D industry. It requires more broad research on other fields in cultural and creative industries to tackle China's contemporary situation and future trend. In addition, the influence of Chinese traditional Confucianism on cultural and creative industries is an interesting topic and worth to do further research.

A Classification of Skills and Competencies for the Domain of Renewable Energies⁴

Michael Becker, Michael Sonnenberg, Stephan Klingner

University of Leipzig, Department of Business Information Systems

Human resources are an essential factor for providing services. For an optimal match between employees' capabilities and service activities, it is necessary to precisely define skills, competencies, and qualifications that are required. This paper presents findings of an investigation of competencies in the domain of renewable energies. Based on a unified classification system, it is presented how to use this classification for describing service activities and for mapping employees.

1 Introduction

The description and formalisation of competencies required for service provision is a challenge in a variety of industrial domains. This is caused mainly by a lack of terminological standards of central concepts. As a result, it is possible that organisations have problems in creating an appropriate allocation of human resources to services. Furthermore, job offers cannot be formulated clearly enough to address proper applicants.

The focus of this work is on the domain of renewable energies. Besides terminological inconsistencies, this domain is also characterized by a large number of legal regulations and certifications. Service providers usually need to adhere to several regulations using different terminologies at the same time.

The aim of this work is to present a theoretical and structural basis for developing a harmonized terminology of skills, competencies, and qualifications⁵ in the domain of renewable energies. The terminology is hierarchically structured and embedded in the existing classification system *ESCO*. Thus, interoperability can be ensured.

As a result of this work, a classification of skills, competencies, and qualifications to provide renewable energy services was established. This classification scheme can be used as a reference model regarding terminology and hierarchical structuring of key domain concepts. Using the classification has two main benefits. First, companies are able to publish improved job offers, since the standardized terminology reduces ambiguity. Accordingly, companies are able to appoint suitable employees for the vacant position what can result in a higher service provision quality.

In a more advanced setting, the classification can be used company internally for supporting service provision. It is possible to record competencies of existing employees. Based on this, service processes can be assigned with appropriate employees.

A notable service provision performance enhancement can be achieved by complementing reference processes (e.g. in terms of a standardised portfolio) with reference competencies. In doing so, uncertainty about whether companies may provide additional services can be reduced. Furthermore, it is possible to assess costs for providing services by comparing necessary competencies with costs of particular employees. Additionally, the classification provides an optimal basis for the more detailed description of resources by extended attributes.

For providing an overview about the research outcomes, this paper is structured as follows. In the next section, additional motivation for the research is given by presenting competency management approaches. The data collection process is presented in more detail in Sect. 0. Based on these data, a structure was established and is shown in Sect. 0. Section 0 gives an overview on how to apply the classification in praxis using the structured data. Finally, the paper is concluded in Sect. 0.

2 Motivation

It is a long-known fact that resources play an important role for business success (Barney, 1991), i.e. a company using its resources in an optimal way has a competitive advantage compared to its competitors (Peteraf, 1993). Besides technical resources (e.g. a measuring device), human resources (e.g. a purchaser) are an integral part of service provision and, thus, need to be planned according to the skills, competencies, and qualifications they possess and can offer for executing specific activities.

The term *competency-based management* is used to describe an organisational approach for identifying knowledge that is necessary for performing specific activities (Draganidis & Mentzas, 2006). Competency-based management has a variety of application areas, e.g. workforce planning, recruitment management, learning management, performance management, career development, and succession planning (Draganidis & Mentzas, 2006). To be helpful in these

⁴ The project EUMONIS (www.eumonis.org) on which this report is based was funded by the German Federal Ministry of Education and Research (BMBF), funding codes 01IS10033D and 01IS10033K. EUMONIS was supervised by the project sponsor German Aerospace Centre (PT-DLR). The BPMN models were created using the web-based software Signavio as part of the Signavio BPM academic alliance.

⁵ At some points of the text the denotation competency is representative used for skill, competency and qualification.

application areas, the competency-based management process consists of the following steps that can be supported by a *competence management system* (Lindgren, et al., 2004): specification of competency needs, identification of competency gaps, competence sourcing, competence development, and project staffing.

On the one hand, a company needs to be aware of the competencies different employees possess. On the other hand, clearly defined competencies are a means for creating precise job offers and for hiring new employees. For doing so, it is necessary that the company has a clear understanding about the meaning of different competencies. In this direction, Winterton, et al. (2006) provides an aggregative study about definitions of relevant concepts. While knowledge can be defined as the “result of an interaction between intelligence (capacity to learn) and situation (opportunity to learn)” (Winterton, et al., 2006, p. 25), skills are “used to refer to a level of performance, in the sense of accuracy and speed in performing particular tasks” (Winterton, et al., 2006, p. 26).

Though this type of meta-research is important for laying theoretical foundations regarding skills, competencies, and qualifications, practically applicable methods and tools need to be made available for companies. That is, companies must be provided with insights about how to apply a set of competencies for their daily work. To facilitate this activity, several company-specific competency dictionaries have been established. For example, the “NASA competency management system”⁶ provides a structured overview classified according to different domains.

However, company-specific competency lists are not sufficient due to two reasons. First, an increasing amount of work is outsourced to other companies. To find suitable partners, a precise description of necessary competencies is required. Second, a clear description of competencies is necessary for job offers, too.

Domains like renewable energies are still in their infancy regarding clear and precise job descriptions. This is based on the fact that a variety of companies uses non-standardised names, thus, resulting in different names for equal competencies. The problem is further complicated since a variety of different standards for describing product-related facts but only a handful of preliminary standardisation approaches for service provision exist. Thus, the activities conducted in this area are described in different diverse ways that might not be compatible with each other. Sonnenberg, et al. (2013) presents a survey in the renewable energies sectors identifying a strong demand for supporting the provision of services by optimizing resource planning, selection, and use. To overcome an aspect of this problem, in this work a proposal for structuring skills, competencies, and qualifications in the domain of renewable energies is presented.

3 Data Collection

The collection of relevant skills, competencies, and qualifications was established by analysing different information sources from the domain renewable energies. First of all, company specific concepts were extracted from job offers, description of existing services, workshops with service providers, and documentation of service processes. Furthermore, it was possible to extract necessary competencies by role descriptions of companies. Competencies that are not bound to a specific organization were identified by scanning existing training materials for certificates in the domain renewable energies. Existing classifications, thesauri, and taxonomies of skills, competencies, and qualifications that are the result of several standardisation approaches were used as complementary sources. In the following, the extraction process for the different information sources is presented in more detail.

Job Offers: Companies in the sector of renewable energies are continuously searching for qualified employees. Due to this fact, a multitude of job offers from companies were analysed for skills, competencies, and qualifications. Besides identification of relevant concepts, the job offers can also be used to establish relations between concepts. This is due to the fact that job offers usually consist of a job name (e.g. head of quality management), responsibilities (e.g. auditing), and necessary qualifications (e.g. graduation in economics).

Workshops: During workshops with several representatives of renewable energies companies, the whole classification was improved iteratively. Thus, the results of these workshops were twofold. First, the companies verbally described competencies necessary during a discussion. These competencies were then integrated into the existing ones. Second, the companies evaluated existing previously found competencies according to their practical relevance.

Service Descriptions: Various service descriptions of different service providers were analysed. There are two types of descriptions. On the one hand, services are described for internal employees to support the provision. On the other hand, descriptions for a customer-oriented presentation of the services are provided.

Based on these descriptions, it is also possible to derive service characteristics. For example, Verma (2000) defines four types of services based on the dimensions degree of customer contact/customisation and labour intensity. According to the specific value of a dimension, different competencies are necessary, e.g. a service with a high degree of customer contact must be provided by employees that can interact with customers in a suitable manner.

Service Process Documentation: Due to the growing complexity of services, more and more companies use Business Process Management (BPM) for managing their service processes. In doing so, a variety of different process models was established in the last years. These process models contain rich information about necessary skills, competencies, and qualifications for services.

Existing notations like Business Process Model and Notation (BPMN), Event Driven Process Chains (EPC), or UML Activity Diagrams (AD) allow for defining the activities that need to be performed to provide a service process.

⁶ <http://ohr.gsfc.nasa.gov/cms/home.htm>

Figure depicts a process snippet from a company using BPMN. The presented process specifies an alert management service. After receiving an alert message, the operational manager has to login to the specific program of the plant manufacturer that was source of the message. This might either be a so-called Condition Monitoring System (CMS) or a Particle Sensor. She then has to check the status of every installation using the company-internal *GreyTime*⁷ database or a specific manufacturer program. If fielding is necessary, a separate process (failure management) needs to be started using the IT system *ROTORsoft* and the process ends. Otherwise, the operational manager needs to check whether a documentation of the incident is necessary. If documentation is required, she writes it into the event database and the process ends.

Figure 1. Sample process as source for skills, competencies, and qualifications.

In addition, it is possible to assign a role to an activity to specify who is responsible for performing this activity. A role might be a specific employee, an employee group, or a division of the company. The role names can be used as an indicator for required skills. For the process shown in Figure , the role *Operational Management* might indicate skills that are defined in a role description (see below in paragraph Role Descriptions). Similar to job offers, it is possible to define relations between roles and competencies by analysing which roles have to perform which activities. Besides roles, the depicted IT systems and databases can be used as an indicator for required skills and competencies of the role *Operational Management*. For example, executing the first activity *Login to manufacturer program* requires using (and, thus, knowledge in) the *Condition Monitoring System*.

In addition to explicitly stated information like role names and IT systems, it is also possible to extract necessary competencies from activity names. For example, the activity *Login to manufacturer program* requires general knowledge on how to use IT systems. Using these information sources, a detailed overview about necessary skills and competencies can be extracted. Additional information might be found by using (semi-)automated techniques for retrieving business process resources, e.g. Cabanillas, et al. (2014).

Role Descriptions: As stated above, several companies have established a framework for describing employee roles. In doing so, it is possible to provide additional information for specific roles that can be used in process models. Usually a role can be described similar to the examples shown in Table . It consists of the role name as an identifier, a precise summary about the purpose of the job, e.g. the activities that are usually performed by this role. In addition, several requirements for employees that are assigned to this role can be defined, e.g. necessary certificates (cf. training materials below). Besides internal usage for assigning roles to activities, role descriptions can also be used for creating job offers.

Table 1. Role descriptions, gathered within the research project EUMONIS.

Role	Description	Duties and Responsibilities
Plant Operator	Is the owner of a plant and responsible for the correct plant operation.	Operational processes Managerial authority Legally responsible
Plant Manager	Is in charge of the technical operation of a plant.	Technical operation Coordination of tasks and resources Optimisation of appointments

⁷ Due to intellectual property reasons, the name of this company-specific tool was anonymised.

Role	Description	Duties and Responsibilities
Planer	Is in charge of planning the complete plant or components thereof.	Construct, design, and planning of the plant Monitor construction Define technical parameters
Purchaser	Is in charge of all operational activities which are associated with the order within the supply of materials, goods and equipment.	Purchase materials, goods, equipment Handle ordering processes Determine purchasing policy, procurement market research
Installer	Is in charge of building the complete plant or components thereof.	Build plant Put plant in operation
Service Employee	Is in charge of providing miscellaneous services for technical activities.	Maintenance services Documentation of work steps Perform remote access

The textual description of roles is an initial helpful step for identifying who is able to perform specific activities. This can be extended by the hierarchical structuring of different roles as shown in Figure 2. Based on this figure, roles can be distinguished from each other in more detail. While there are two roles with the name *Sales Representative* in the example role model, these roles do not specify the exact same roles. Instead, both roles are located in different departments and require slightly different competencies.

Figure 2. Role hierarchy.

Guidelines and Standards: Different international and national organisations like the *International Organization for Standardisation (ISO)* or the *Deutsches Institut für Normung (German Institute for Standardisation, DIN)* release standards and guidelines for products and services. These often normative documents contain information about legal requirements on how to perform specific activities and the necessary qualifications of employees. In recent years, a variety of different standards in the domain of renewable energies were released, cf. (IRENA, 2013) for an overview about 573 standards. While most of these standards address product-related issues, service related issues are not in the focus of standards as of now. A first approach for classifying technical operation services of renewable energy plants is presented in DIN (2014). Furthermore, Hirschl & Weiß (2009) analyses strategies for renewable energies and can be seen as a preparatory basis for additional standards.

Similar to the company-specific service descriptions (see above), guidelines and standards provide a valuable source for information of required skills, competencies, and qualifications for providing specific services. For example, necessary competencies can be extracted based on description of classified services. In addition, these standards can also serve as a valuable basis for referenced certificates that are legally required for performing specific activities.

Training Materials: Today’s economy is characterised by ever-increasing complexity and continuous change. To keep pace with these changes, responsible employees need to participate in advanced vocational training. Several organisations, both public and private, provide different seminars also in the domain of renewable energies. Using the descriptions of these seminars, it is possible to extract relevant skills, competencies, and qualifications. The seminars usually provide an overview about expected outcomes. In addition to this information, it is also possible to scan the seminar descriptions for prerequisites for attending which is also a valuable source.

For the majority of seminars, a certificate is offered for successful participation. Due to this fact, it is possible to establish links between certificates and skills, competencies, and qualifications, i.e. employees that can verify the possession of a specific certificate have the respective competencies. This is of special relevance when structuring the list of skills, competencies, and qualifications as shown in Section 0.

4 Data Structure

As a result of the collection of data about skills, competencies, and qualifications as presented in the last section, an unstructured list was established. However, there is no reasonable way to use this list without any structuring. To overcome this problem, the terms were structured as concepts of an existing ontology. For being able to do so, the following steps were performed and are described in more detail in the next sections:

1. Grouping of obvious synonyms into one concept
2. Extraction of abstract concepts
3. Classification of concepts according to an existing system

4.1 Synonym Identification and Concept Abstraction

Before insights about the synonym identification and concept abstraction are presented, a small prospect about the differences between terms and concepts should be given. A term is a sequence of characters shaping a word of a specific language. A term might have different meanings (i.e. be a homonym), e.g. the term *bank* might refer to a “raised shelf or ridge” or an “establishment which deal in money”⁸. Due to different possible meanings, terms can be used subjectively in different jargons or different companies. Furthermore, different terms might have the same meaning (synonyms), e.g. the terms *quality* and *characteristic* both might refer to a property of an object. The problem of different terms with one meaning is further extended due to different languages, e.g. the English term *quality* has the same meaning as the German term *Qualität*.

Contrary to terms, a concept has exactly one meaning and is, thus, precisely and unambiguously determined. A concept might be defined by using several terms, e.g. translations. Though the philosophical debate about the definition of the concept “concept” is still ongoing (Margolis & Laurence, 1999), this work follows a Platonist approach, defining a concept as an abstract object (Kraut, 2013). Thus, the concept competency represents an abstract competency that might group different concrete instances of this competency. For example, the concrete competencies *readiness for working on construction sites*, *readiness for field installation*, *readiness for travel activity*, and *readiness to travel within Germany* are aggregated into the abstract competency *readiness to travel*.

By extracting abstract concepts from specific terms, obvious synonyms were grouped into one concept, too. For example, the terms *accept responsibility* and *sense of responsibility* were aggregated and the concept *readiness to accept responsibility* was created. In doing so, the list of unstructured terms was cleaned up resulting in a set of unique competency concepts.

4.2 Concept Classification

The terms that were extracted from the different sources were grouped as concepts according to the European Skills, Competencies, Qualifications and Occupations (ESCO) classification systems. ESCO is currently under development by the European Union. A first draft was presented in 2013; the final version is scheduled for 2017⁹. The core of ESCO is established by the three pillars *Occupations*, *Skills and Competencies*, and *Qualifications* that are presented below. To allow for representing dependencies between different pillars, it is possible to establish relations from one concept to another. In doing so, it is, for example, possible to define which competencies are required for or related to a specific occupation.

For interoperability reasons, ESCO is based on semantic technologies RDF (Resource Description Framework), SKOS (Simple Knowledge Organisation System), and LOD (Linked Open Data). Due to these semantic technologies, the ESCO classification can be integrated into company-specific taxonomies more easily. The ESCO data can be imported into a taxonomy management system. In addition, the ESCO portal¹⁰ allows for browsing and searching concepts.

4.2.1 ESCO Pillars

Each of the three ESCO pillars is characterised by a set of hierarchically ordered concepts in a tree-like structure. While leafs of these trees represent actual concepts (occupations, skills/competencies, qualifications), the higher abstraction levels form concept groups. The ESCO data model is presented in Figure 3. As can be seen in this figure, the skills/competencies and the qualifications pillar consist of two levels (the essential skill/competency and qualification and groups of skills/competencies and qualifications). Contrary, the occupation pillar has five levels; the four abstract levels are composed of elements from the International Standard Classification of Occupations (ISCO) enabling the reuse of an existing standard.

⁹ https://ec.europa.eu/esco/escopedia/-/escopedia/ESCO_versions

¹⁰ <https://ec.europa.eu/esco/hierarchybrowser>

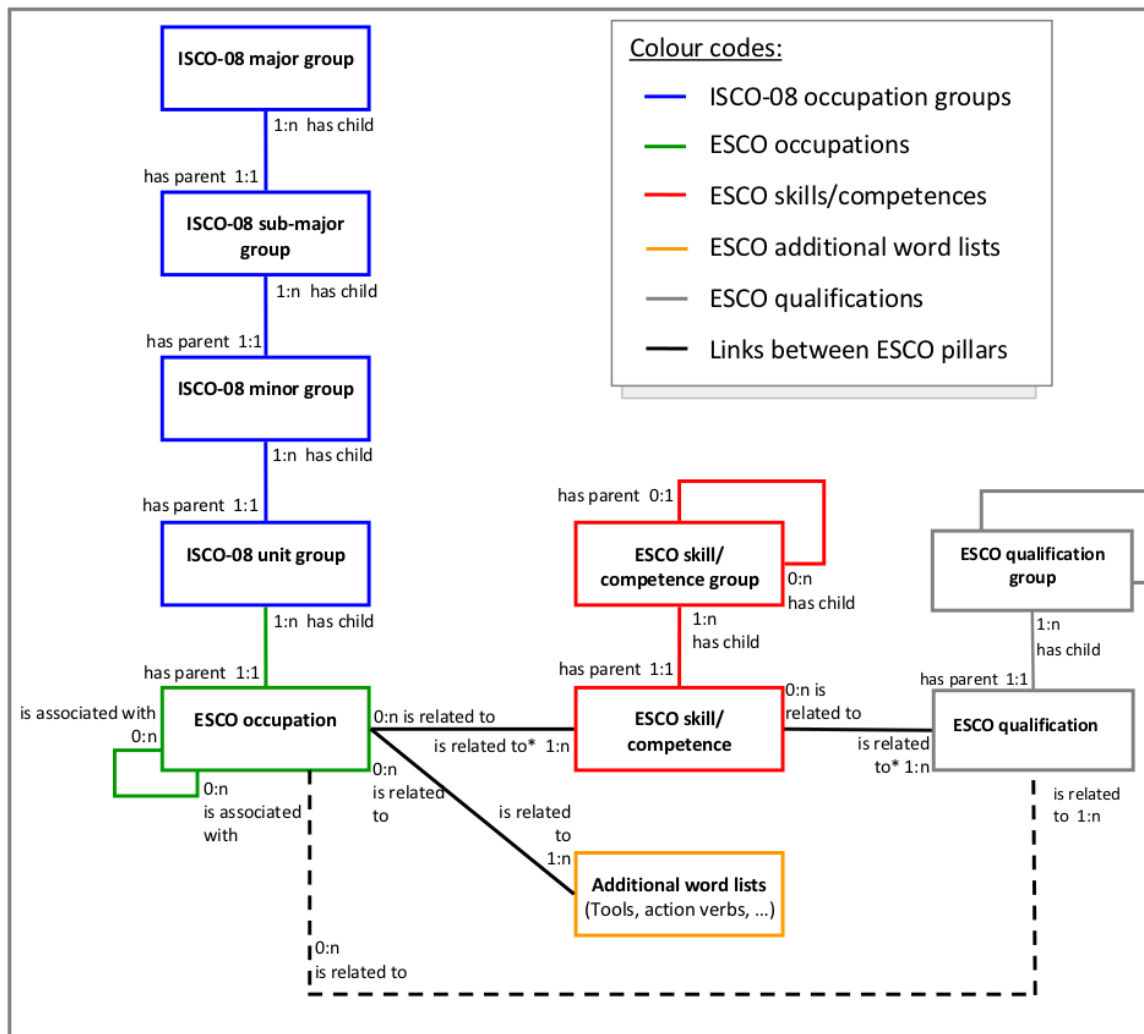

Figure 3. ESCO Data Model¹¹.

An *occupation* according to the ESCO definition is a “grouping of jobs involving similar tasks and which require a similar skills set”¹². Table 2 depicts two examples of ESCO occupations: *Database engineer* and *Business consultant*. For both occupations, a hierarchical structure including the four ISCO layers can be established. In addition to this hierarchical structure, it is possible to define further relations between different occupations and occupation groups, e.g. *Telecommunications Engineer is related to Graduate engineer (electronics/telecommunications)*.

Table 2. Hierarchy of ESCO occupations.

ESCO	Occupation	Database engineer	Business consultant
ISCO	Unit Group	Database designers and administrators	Management and organisation analysts
	Minor Group	Database and network professionals	Administration professionals
	Sub-Major Group	Information and communications technology professionals	Business and administration professionals
	Major Group	Professionals	professionals

As presented in Figure 3, relations between concepts are not limited to the same pillar. Thus, it is also possible to define relevant skills/competencies and qualifications for a specific occupation. For example, the concept *Database engineer* is (amongst others) related to the competencies *Data modelling* and *Data warehouse*. In addition, it is related to the qualification *Cisco Data Centre Application Services Design Specialist*.

ESCO defines *skills* as “the ability to apply knowledge and use know-how to complete tasks and solve problems”¹³. Based on this, a competence is “the proven ability to use knowledge, skills and personal, social and/or methodological

¹¹ https://ec.europa.eu/esco/escopedia/-/escopedia/ESCO_data_model

¹² <https://ec.europa.eu/esco/web/guest/escopedia/-/escopedia/Occupation>

¹³ <https://ec.europa.eu/esco/web/guest/escopedia/-/escopedia/Skill>

abilities, in work or study situations and in professional and personal developments”¹⁴. ESCO contains both skills/competencies for performing a specific occupation as well as cross sectoral skills and competencies. While occupation-specific skills and competencies are structured according to the respective industry domains, the following cross-sectoral skills/competencies groups exist: *Application of knowledge, Attitudes and values at work, Language and communication, Social skills and competencies, Thinking skills and competencies*. Contrary to qualifications (see below), skills and competencies are independent of any formal assessment.

A *qualification* is defined as “the formal outcome of an assessment and validation process which is obtained when a competent body determines that an individual has achieved learning outcomes to given standards”¹⁵. The ESCO qualifications are structured according to different industry domains. Furthermore, ESCO distinguishes between certification bodies on different levels:

- *National qualifications*, for example the German craftsman are referenced via national databases.
- *Qualifications awarded at national level but regulated at European level* are used to describe harmonised requirements for performing EU-wide activities.
- *(International) qualifications, certificates and licenses linked to tasks and technologies* are usually requirements for being allowed to work in a specific domain, e.g. a forklift license.
- *(International) qualifications and certificates linked to occupations and sectors* are usually requirements for working in a specific occupational area, e.g. aeronautics and rail traffic.

It is possible to define relations between concepts of the qualifications pillar and concepts from the other pillars. The relation can be detailed by different qualifiers (*required for, recommended for, useful for* etc.). For example, the qualification *Airline Transport License* is required for the occupation *Commercial pilot*. To depict the learning outcomes of qualifications, they can be related to skills and competencies. For example the qualification *Project Management Professional* is related to skills/competencies like *project administration, project management, crisis management* etc.

4.2.2 Classification

Since skills and competencies are in the focus of this work the corresponding ESCO pillar was extended. Besides the existing sub-classes *job-specific* and *transversal skills/competencies* and *physical attributes*, the classes *training* and *job-related experiences* were added. Both classes are further divided into sub-classes as presented in the following.

The first sub-class mainly consist of transversal skills and competencies. It is further divided into more specific categories, e.g. leaderships & management and planning & work organisation (cf. Table 3). To complement these categories with additional skills and competencies that are necessary in a specific company setting, they can be extended by referencing existing collections of transversal skills/competencies, e.g. DISCO¹⁶. For increased usability, it is possible to extend DISCO with company-specific skills/competencies. Furthermore, it is possible to hide irrelevant skills/competencies.

Regarding the category physical attributes, the underlying data mainly mentioned the readiness according to specific activities. For example, the readiness to travel is an important physical attribute for working as a field technician.

Table 3. Skills and Competencies for services in the field of renewable energies.

Category	Sub-category	Name
Skills & Competencies	Leadership & Management	Ability to Leadership
		Ability to employee motivation
		Ability to conflict management
		Ability to employee training
		Ability to project management
	Planning & work organization	Endurance
		Ability to work under pressure
		To be proactive
		Self motivation
		Self organization
		Personal responsibility
Flexibility

¹⁵ <https://ec.europa.eu/esco/web/guest/escopedia/-/escopedia/Qualification>

¹⁶ http://disco-tools.eu/disco2_portal/

		Conscientiousness
		Motivation
		Neatness
		Planning skills
		Ability to work organization
		Ability to work independently
		Structured way of working
		Systematic way of working

The category *training* is further divided into the sub-classes *formal education*, *vocational training*, and *academic studies*. For renewable energies, vocational training is further divided into training in *technical occupations* and training in *business occupations*. An extract of relevant trainings is depicted in Table 4. As can be seen in Table 4, there are no entries for business occupations training. This is due to the fact that the underlying data did not contain any respective entries.

Though the concepts in the class training might seem very similar to the roles as presented in Table , there is a great difference between the both. Using roles, it is possible to group different activities, e.g. an employee with the role plant designer performs several activities that might require a variety of different competencies. In doing so, a training concept can be used to define a necessary competency for a specific role, e.g. the sales representative might need graduation in renewable energy finance.

Table 4. Trainings for services in the field of renewable energies.

Category	Sub-category	Sub-category	Name	
Training	Formal Education		Graduating from „Hauptschule“	
			Graduating from „Realschule“	
			Graduating from „Gymnasium“	
	Vocational Training	Technical Occupations		Training as a Fitter
				Training as an Electrician
				Training as a Mechanic
				Training as a Foreman
				Training as a Technician
				Training as a Mechanical Engineer
				Training as an Industrial Mechanic
				Training as a Mechatronic
				Training as an Electronics Engineer for energy plants
		Business Occupations	n/a	
	Academic Studies			Graduated in Mechanical Engineering
				Graduated in Electrical Engineering
				Graduated in computer science
			Graduated in Energy Management	
			Graduated in Renewable Energy Finance	

The *job-related experiences* are of particular importance for defining requirements regarding the provision of specific services. This category contains skills and competencies that are required for performing certain activities. Job-related experiences are further divided into sub-categories in *experiences in performing activities*, *experiences regarding legal regulations*, and *experiences in using technologies*. Table 5 presents an overview about several examples for providing renewable energies services.

Table 5. Occupational experiences for services in the field of renewable energies.

Category	Sub-category	Name
Job-related Experiences experiences	Functions	Knowledge of welding
		Experience in maintenance
		Experience in error diagnostics
		Competence for controlling wind energy plants
		Competence for controlling photovoltaic plants
		Competence for controlling biomass power plants
	Legal regulations	Knowledge in the use of the “Erneuerbare Energien Gesetz”
		Knowledge in the field of occupational safety
		Knowledge of regulations for the installation of electrical systems
	Use of technology	Experience with measurement technology
		Experience with MRP Software
		Experience with ERP Software
		Experience with diagnostic systems
		Experience with remote service systems
		Experience with monitoring systems

Besides concepts for the skills/competencies pillar, the data also provided several insights about *qualifications* in renewable energies. The qualifications are as presented above (see Sect. 0) divided in the categories *national qualifications*, *national qualifications with European level*, *international qualifications for tasks and technologies*, and *international qualifications for occupations and sectors*. Examples for these qualifications are the driving licence and the switching authorisation as presented in Table 6. Due to the underlying data, there are also national qualifications. However, by evaluating additional sources other relevant qualifications can be added.

Certifications can be issued for products and services as well as for persons and systems. Regarding service provision, the focus is on certifications for persons. These certificates verify that a person has knowledge in a specific area and is allowed to provide certain services. Due to legal regulations, proven certification is sometimes necessary to participate in tendering. In addition, companies can present the certifications of their employees and, thus, distinct themselves from competitors.

Table 6. Qualifications for services in the field of renewable energies.

Category	Sub-category	Name
Qualifications	National qualifications	Driving licence
		Switching authorisation
		GL-Certification
	National qualifications with European level	n/a
	International qualifications for tasks and technologies	n/a
	International qualifications for activities und sectors	n/a

5 Using the Classification

The classification of competencies can be used to associate service process in the domain of renewable energies with required competencies. Since the competencies identified by means of the data collection presented in Sect. 0 cannot cover all aspects of the domain, it is also necessary to enable an extension of the classification. This is achieved by hierarchical structuring of the competencies according to the ESCO system. Using this classification system, company-specific competencies can be easily integrated.

Following the advices on implementing competency management systems as presented by Lindgren, et al. (2004), different aspects of competency management are supported:

- Specification of competency needs: Using the classification, it is possible to denote skills, competencies, and qualifications that are required for performing specific activities as presented in Sect. 0. In addition to enriching company-specific service processes with competencies, it is also possible to establish reference processes for the domain that can be used by different industries. Based on these reference processes, companies can assess which competencies are required for providing specific services.
- Identification of competency gaps: The skills, competencies, and qualifications of the classification can further be used to provide an overview over competencies of different employees. Using this overview and the specification of company needs for different activities, it is possible to identify suitable employees. If no suitable employee can be found for performing a specific activity, this is clearly an indicator for a competency gap. It is either possible to provide advanced training for employees or to hire new employees to fill this gap.
- Competence sourcing & development, project staffing: A clear definition of required competencies can improve job advertisements to the effect that a better matching between applicants and company needs can be established. In addition, advanced studies are described more precisely when using a unified classification of skills, competencies, and qualifications.

5.1 Mapping of skills, competencies, qualifications and services

This section shows the use of skills, competencies and qualifications to simplify the assignment of employees to service processes by means of a use case from practice. The basis for this is the process “Preparation of Troubleshooting” in the field of wind energy, depicted in Figure 4. Starting point of the process is the message of an incident at a wind power plant. This message is triggered either by a plant manager or by a service employee who is on site. The service employee has the task of carrying out the order and documenting the activities.

At first, a suitable service employee will be selected based on the availability and the required know-how by using MRP Software. Then the required spare parts to the execution of the order are planned, by using ERP Software. The service employee analyses the incident on site based on error lists from the manufacturer. For comprehensibility reasons, the process of troubleshooting is embedded in a sub process and not shown here.

Figure 4. Process Preparation of Troubleshooting with directly assignment of roles.

The allocation of human resources that operate the Activities of the service is currently achieved by direct referencing of roles (sometimes even more explicit persons) (Figure 4). This static assigning impedes a direct reference to the competencies that are necessary to operate the activities. If an employee acquires or loses a skill, competency, or qualification, this information is not linked to the role directly. Therefore the selection of employees is not based on their actual abilities.

To address the mentioned problem, the paper proposes the approach to link activities with necessary skills, competencies, and qualifications. The approach is illustrated in Figure 5. It is shown that the planning of spare parts requires experiences with ERP Software, etc. The classification in this paper can be used as a template to describe skills, competencies, and qualifications in this way. In addition, the selection of competencies can be simplified based on existing classifications such as DISCO. For example in DISCO the competence “Experience with ERP Software” can be referenced by the following levels: interdisciplinary – computer skills – special application software - commercial software – ERP – MRP tool.

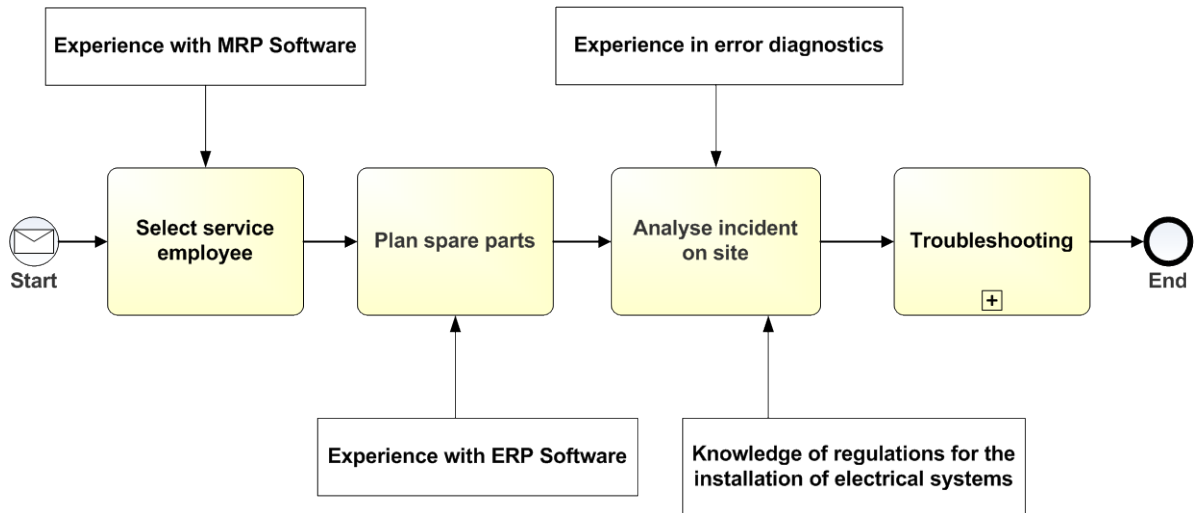

Figure 5. Process with assignment of skills and competencies.

5.2 Mapping of employees and services

The assignment of activities and skills, competencies and qualifications of the process is shown in Table 7 again. The assignment of employees and skills, competencies, and qualifications can be done analogously.

Table 7. Assignment of activities and competencies.

Service	Activity	Experience with/in			Knowledge of
		MRP Software	ERP Software	Error diagnostics	Regulations for the installation of electrical systems
Preparation of troubleshooting	Select service employee	X			
	Plan spare parts		X		
	Analyse incident on site			X	X

Table 8 shows the assignment of employees and skills, competencies, and qualifications, related to the application example. This overview can always be updated with the actual ability of the employee and, thus, it provides an up-to-date basis for taking decisions for assignment to specific service processes.

Table 8. Assignment of employees and competencies.

Employee	Experience with MRP Software	Experience with ERP software	Experience in error diagnostics	Knowledge of regulations for the installation of electrical systems
Employee A	X	X		
Employee B	X			X
Employee C			X	X

Thus, an indirect association between employees and activities can be achieved. The advantage is an improved selection accuracy according to the employee’s actual ability. At this point, a resource scheduling for the provision of the service can be done. Table 9 shows the planning related to the application example in which three different employees are required for provision.

Table 9. Assignment of employees and the service “Preparation of Troubleshooting”.

Service	Activity	Employee
Preparation of Troubleshooting	Select service employee	Employee A or B
	Plan spare parts	Employee A
	Analyse incident on site	Employee C

Through the integration of the approach into existing resource planning systems, optimization of resource scheduling can be achieved. In addition, job advertisements can be create more effectively due to the better definition of the field of activity.

By applying the classification in the ESCO system, the various skills, competencies, and qualifications can be stored in a consistent terminology. The opportunity to define relationships between different terms via synonyms is in particular helpful for doing this. These synonyms make it possible to classify external acquired skills, competencies and qualifications in a structured way.

6 Conclusion and Discussion

In this paper, an approach to structure and unify skills, competencies, and qualifications in the field of renewable energies was presented. For this purpose, various sources were analysed and the results were merged in a classification. The classes were classified using the European standard ESCO pillars skills/competencies, qualifications, and occupations. The proposed classification is an initial proposal for the structuring and standardisation in the field of renewable energies. The plausibility and applicability needs to be confirmed in practical use. The usability of the presented classification has already been approved in the context of the conducted workshops with service providers of the industry. It is hoped that in practice there is a broad acceptance of this first comprehensive approach for classification of skills, competencies, and qualifications and that it will be enhanced gradually over time.

Moreover, an approach for an indirect allocation of human resources and service processes was presented. An application example showed how the approach brings a high degree of practicability in practice. The structuring and standardisation supports the selection process of employees and increases effectivity and reliability.

Les déterminants du succès du mode d'entrée des PME de services industriels "soft" sur les marchés émergents: étude de cas

Victoria Botvina

Aix-Marseille Université

Cette réflexion sur les modes d'entrées de PME de services industriels "soft". La prise en compte des facteurs d'internationalisation et le problème de l'établissement des relations d'affaires à deux niveaux - la constitution du réseau et son activation – constitue un sujet critique au sein des PME. Les connaissances théoriques sur le rôle des immigrés dans ce processus sont encore limitées. A partir d'une analyse qualitative exploratoire longitudinale d'étude de cas unique sur la période 2008 à 2013 - combinant la recherche-action et l'observation participante - le sujet traite du choix du mode d'entrée correspondant le mieux aux besoins des PME et leurs performances sur les marchés émergents.

Introduction

Le développement croissant de petites et moyennes entreprises (PME) du secteur de la haute technologie "Born Global" (BG) et qui sont propices à une internationalisation rapide, attire de plus en plus l'attention des chercheurs en stratégie d'internationalisation (Filatotchev et al., 2009 ; Servantie, 2007 ; Varma, 2009). Ce phénomène a déjà été examiné. Les théories déjà proposées incluent: l'approche par les spécificités de ces firmes (Bell ; McNaughton, 2000; McDougall et al., 2003), la stratégie de niche (Atamer, 2012; Rennie, 1993; Rasmussen ; Madsen, 2002; Almor, 2000; McDougall et al., 2003), la forte valeur ajoutée mondiale de leur produit/service (Bell et al., 2003), le rôle de l'équipe dirigeante, son expérience et engagement vers l'international (Persinger et al., 2007; Oviatt ; McDougall, 1994) ; la disposition préalable d'un réseau international (Bell, 1995; Coviello ; McAuley, 1999). Pourtant notre compréhension sur leur développement reste toujours limitée, surtout lorsqu'il se déroule dans des pays émergents (Ngyuen et al., 2013; Bourcieu, 2005).

Les pays émergents manquent souvent de transparence et leurs institutions sont instables. Dans cet environnement incertain et versatile, il devient difficile pour les PME, d'identifier et d'exploiter les opportunités (Nguyen et al., 2013). L'acquisition de connaissances contribue à une mobilité accrue et à une internationalisation plus rapide, ce processus étant façonné par l'équipe dirigeante et la culture organisationnelle de la société (Zahra, 2005). L'entreprise avec différentes orientations culturelles peut repérer et poursuivre différents types d'opportunités (McDougall ; Oviatt, 1994), en particulier dans le contexte des pays émergents, au travers de son capital humain (Batjargal, 2007 ; Goxe ; Viala, 2009 ; Adler ; Kwon, 2002 ; Zhou et al., 2007).

Le capital humain d'une société contribue considérablement à l'établissement de réseaux sociaux. Les études existantes sur les relations construites entre les différentes communautés ethniques évoquent la valeur du multiculturalisme (Peng ; Luo, 2000; Ellis, 2000; Xin ; Pearce, 1996). Les attitudes et un héritage culturel similaires fortifient le réseau de relations entre les membres d'une communauté ethnique en créant des opportunités pour le développement des affaires : accès aux connaissances du marché local et de son système de distribution, accès aux partenaires et associés potentiels ainsi qu'au financement (Yeung, 2004 ; Nkongolo-Bakenda ; Chrysostome, 2013). Ellis et Pecotich (2001, 129-130) ont trouvé l'importance "of prior social ties", ainsi que "awareness of foreign market opportunities" comme les deux antécédents critiques à l'internationalisation. Les prédispositions d'un réseau social sont importantes pour le développement des entreprises dans le contexte des pays émergents : "Such social networks can provide unique information benefits to those who are connected by exclusive or non-redundant personal ties irrespective of whether the nature of the social relations is strong or weak (Burt, 1992,1997)" (Zhou et al., 2007, 676).

Le rôle des réseaux sociaux, du capital humain, comme des facteurs clés du processus d'internationalisation des PME BGs sur les marchés émergents, a fait l'objet de nombreux travaux. Pourtant la recherche sur l'impact du multiculturalisme du capital humain et des liens sociaux de l'équipe managériale pouvant influencer le processus d'internationalisation de l'entreprise n'est encore qu'émergente. Concrètement, l' "interrelation between informal networks and formal modes of international business activity requires further investigation" (Jones et al., 2009, 3). Au sens large, la revue de littérature met en exergue l'attention modeste portée à la recherche sur les modes d'entrée des PME. La performance des PME BGs sur les marchés de pays émergents mériterait également plus d'attention. Brouthers (2013, 9) remarque que la question centrée sur la corrélation entre le choix du mode de présence de la société et son succès est encore sans réponse. Les résultats des recherches actuelles sont contradictoires (Filatotchev et al., 2009). De nouvelles méthodes d'analyse sont à envisager et il est nécessaire d'approfondir ces recherches par des analyses qualitatives longitudinales pour différencier la requête quantitative la plus fréquente afin d'apporter les résultats plus enrichissants (Brouthers ; Hennart, 2007).

Les recherches sur le mode d'entrée sont souvent spécifiées par activité et secteur. Le mode de contrôle varie selon l'activité de la firme (Ekeledo ; Sivakumar, 1998) et les lois du secteur qui peuvent être différentes et propres à chaque pays, voir définies par chacun des états constituant le pays étudié (Porter, 2004). Plusieurs auteurs mettent en évidence

l'importance de distinguer les types de service. La littérature identifie cinquante types de services, "Different service types require varying modes of behaviour in international operations" (Cicic et al. 1999, 93). Les services soft requièrent un fort degré de contact avec les clients. Ils ne peuvent pas être exportés (Erramilli, 1990). Il est très difficile de résoudre les problèmes de mode d'entrée pour les services soft en raison de l'importance des dimensions relationnelles : "In service industries, and especially so in professional services, sales and production of services cannot be kept separate (Gummeson, 1979)" (Sharma ; Johanson, 1987, 22). Cette inséparabilité "has the strongest impact on internationalisation" et, dans le cas de service soft "major adaptation of existing models" est demandée (Cicic et al., 1999, 85, 83).

Ainsi, la présente communication souhaite apporter un éclairage sur la recherche des modes d'entrée de PME BG sur les marchés des pays émergents. Notre recherche s'est portée sur les PME de service industriel soft qui s'internationalisent sur les marchés émergents, ce qui offre une certaine extension aux études précédemment réalisées sur les modes d'entrée au secteur des services industriels (Erramilli, 1991 ; Erramilli ; Rao, 1990 ; Sharma ; Johanson, 1987 ; Sharma, 1989 ; Cicic et al., 1999). Concrètement, dans cette étude nous mettons l'accent sur le rôle et l'impact du multi-culturalisme du capital humain d'une société pour transférer des connaissances et de l'expérience sur le marché d'internationalisation (et non sur la relation entre l'expérience et le mode de contrôle ou d'investissement). Nous considérons que les immigrants participent à réduire l'incertitude, à franchir certaines barrières d'entrée tout en diminuant le coût de transaction et de fonctionnement. Nous étendons les travaux à l'internationalisation de service en suggérant que le choix du marché d'internationalisation et le développement de la PME de service industriel soft dans les marchés émergents ne dépend pas seulement de l'objectif classique prescrit pour les sociétés de service - "client-following" - mais aussi des facteurs spécifiques du capital humain de l'entreprise, de ses réseaux et de ses connaissances pluriculturelles. Ainsi, notre recherche vise à améliorer la compréhension de l'impact des immigrants dans la stratégie d'internationalisation de PME BG et sur ses résultats. Plus particulièrement, nous étudions les effets des transferts de connaissances des immigrants et de leurs réseaux sur le mode d'entrée d'une PME BG sur les marchés des pays émergents, ce qui n'est pas le cas des études précédentes concentrées quant à elles sur le fonctionnement des entreprises multinationales (Jones et al., 2009 ; Zhou et al., 2007). Nous élargissons la vue traditionnelle sur l'internationalisation de service en tant que phénomène étudié sur le PME, et non limité aux seules multinationales.

La Russie est le premier producteur mondial de pétrole brut. L'économie de la Russie est basée sur ses ressources pétrolières et, de ce fait, elle est fortement dépendante du prix du pétrole sur le marché mondial. Pour gérer au mieux cette menace qui pèse sur l'économie russe, un plan de développement appelé "Stratégie Énergétique 2030", a été signé par le Président. L'idée directrice du plan consiste à transférer des technologies des pays développés vers la Russie, ce qui est d'ailleurs une idée commune aux autres pays BRICS. Notre objectif était d'étudier le cas en profondeur, afin d'en tirer une théorie et de la généraliser à d'autres cas similaires.

Notre principal argument théorique est que le mode d'entrée et les résultats d'activité d'une PME de service industriel soft, sur les marchés émergents, dépendent à la fois d'une bonne adaptation de l'offre au contexte du marché d'internationalisation et du capital humain multiculturel de l'entreprise. Pour la recherche en entrepreneuriat international, l'étude sur la contribution des immigrants est d'autant plus importante que plusieurs revues ont montré que les articles récents (Jones et al., 2011 ; Kiss et al., 2012 ; Peiris et al., 2012) n'ont pas pris en considération cet aspect. De plus, comme le remarquent Peng et al. (2008, 920), le processus d'internationalisation sur les marchés émergents nécessite d'être étudié attentivement pour comprendre : "What determines the success and failure of firms around the world ?".

1 Cadre conceptuel adopté

Pour notre recherche, nous nous intéressons au mode d'entrée de service industriel soft. L'intérêt pour la recherche sur l'internationalisation des services est apparu graduellement tout au long des années 90. Comme le précisent Pauwels et Ruyter (2005), les principaux thèmes recensés dans ce domaine sont focalisés sur la phase de pré-"start-up". La littérature fait comprendre que le mode d'entrée est la suite de l'étape préparatoire de la société de service soft. La réussite du processus dépend de la coopération entre les acteurs des réseaux et de la manière d'exploiter ses savoirs et ses compétences. Les réseaux sociaux peuvent jouer un rôle essentiel dans la collecte et la synthèse des informations (Borch et Huse, 1993). La plupart des décisions économiques sont assez complexes et il est nécessaire de collecter des informations provenant de multiples sources officielles, tel que les consultants, avocats et banquiers. Dans une PME, cela est surtout la prérogative de l'équipe dirigeante (Marchesnay, 1997). Un entrepreneur cherchant à développer son entreprise, doit donc s'enquérir régulièrement de la disponibilité des ressources humaines et des modes de financement, de la présence de concurrents potentiels, etc.

La littérature scientifique, notamment Wiedersheim-Paul et al. (1978), Erramilli (1990), Patterson et Cicic (1995), Ekeledo et Sivakumar (1998), distingue deux types de services: "hard" et "soft". Les services hard ont un faible degré de contact avec les clients (Patterson and Cicic, 1995) comme dans le cas de compagnies aériennes, de banques, d'éditeurs de logiciels et autres supports médiatiques, etc. Les chercheurs (Terpstra et Yu, 1988 ; Weinstein, 1977 ; Ekeledo et Sivakumar, 1998) remarquent que le mode d'entrée du secteur de service hard ne présente pas de différence significative avec celui du secteur manufacturier, tandis que le secteur de service soft présente une problématique à part.

Les services soft (tel que le consulting et autres services professionnels) impliquent un fort degré de contact avec les clients. Il est donc difficile de séparer les consommateurs du processus de production. Les caractéristiques des services

soft sont: l'intangibilité, la périssabilité, l'inséparabilité et l'hétérogénéité (Ekeledo et Sivakumar, 1998, 278). A cause de l'importance de la dimension relationnelle, les problèmes de mode d'entrée pour les services soft sont compliqués à résoudre. Un rapprochement physique, par l'implantation, d'une compagnie réalisant des prestations intellectuelles, est justifié par le degré de participation de ses clients au déroulement des prestations (Philippe et al., 2009, 24). Selon Ekeledo et Sivakumar (1998), les services soft ont quatre modes d'entrée: filiale totalement détenue, co-entreprise en capital, franchise ou accord de collaboration.

1.1 Les modalités d'internationalisation des services soft

L'accompagnement de la clientèle existante à l'international est le facteur prépondérant sur le choix de mode d'entrée des services soft (Erramilli et Rao, 1993). Les auteurs se focalisent sur le choix binomial entre différents modes de contrôle : complet et partiel, les éléments de stratégie globale et de motivation ayant une importance égale. Erramilli (1991) développait le concept « U-shape » de relation entre l'expérience et le mode de contrôle ou d'investissement. Selon lui, l'entreprise de service soft choisit la forme juridique de la filiale dès le début. Avec l'expérience, elle change sa forme de présence en faveur de co-entreprise en capital avec mode de contrôle partagé. Ensuite, une fois l'expérience internationale acquise, elle retourne vers une forme de filiale. Ekeledo et Sivakumar (1998) expliquent cette logique d'action par le facteur « client-following » : au début, en rentrant sous l'ombre du client, l'entreprise prend un positionnement de « niche » sur le marché et crée une filiale. Puis, à force de trouver un meilleur équilibre par rapport aux régulateurs du marché local, elle crée une co-entreprise en capital avec la société locale. Plus tard, maîtrisant la gestion des risques du pays d'accueil, l'entreprise étrangère reprend une forme de filiale, avec mode de contrôle complet.

Majkgård et Sharma (1999), après avoir analysé 362 sociétés internationales de services, arrivent à identifier les facteurs auxquels les services soft sont soumis dans le contexte de leur choix du mode d'entrée sur le marché étranger. Les facteurs à influence faible: le prix de service soft; la concurrence entre les firmes locales sur le marché domestique ; la concurrence entre les firmes étrangères sur le marché international ; le fait d'être établi localement sur le marché étranger. Les facteurs à influence forte : les connaissances et les compétences de l'entreprise; la filiale aide à construire, et à maintenir, un réseau de contacts plus large que dans le cas d'un partenariat de collaboration; la construction d'une base de confiance avec le client; la forme de filiale détenue est préférée par les investisseurs étrangers; les accords de coopération à l'étranger sont perçus comme des facteurs importants pour la compétitivité de l'entreprise.

Monnoyer et Philippe (1991) notent que la stratégie des services aux entreprises, y compris le service soft, repose sur « les compétences, la flexibilité et les relations en face à face (proximité géographique) » (Monnoyer et Philippe, 1991, cité par Nagy, 2006 :306). La technologie est un facteur déterminant dans l'internationalisation des services (Léo et Philippe, 2006). En conséquence, le pays de l'innovation bénéficie d'un monopole jusqu'à ce que les autres pays apprennent à produire ou à imiter cette marchandise. En attendant, ceux-ci doivent importer. C'est ce qu'on appelle la théorie de « technological gap » (Posner, 1961). La différence de progrès technologique entre les pays, surtout la possession des hautes technologies dans divers domaines industriels par des pays développés, a créé le besoin de commercialisation de la technologie au-delà des frontières nationales. Elle exige d'être accompagnée par les activités tertiaires y compris les services soft – tel que le consulting et l'assistance technique.

1.2 Le mode d'entrée de service soft et les réseaux

Les études empiriques de Coviello et McAuley (1999) de l'internationalisation des PME producteurs de logiciels, montrent que les relations à l'intérieur des réseaux influencent le choix de marché ainsi que le mode de présence sur le marché étranger, dans le contexte des relations en réseau en cours.

La recherche d'Axelsson et Johanson (1992) montre que le mode d'entrée doit aussi être perçu comme « position-building process », le processus par lequel la position d'une firme est renforcée par l'effet de réseaux (cité par Johanson et Vahlne, 2009 :1415). Leur étude a révélé la complexité associée à l'apprentissage lorsque l'entreprise rentre sur un marché étranger car les liens entre les acteurs sont souvent invisibles. Ceci ne peut être identifié que dans le processus d'internationalisation et les actions en cours. Cet obstacle d'« outsidership » est un manque d'information sur les barrières à l'entrée (barrières institutionnelles de l'Etat du pays d'accueil, linguistiques, culturelles, coutumes et traditions, etc.). L'impasse pour accéder à ces connaissances indispensables provient de la déficience dans la construction du « trusted middleman run » (Johanson; Vahlne, 2009, 1417). L'entreprise qui reçoit les informations de son réseau peut franchir les barrières d'entrée et, ainsi, assurer sa performance. Yeung (2004) a étudié la collaboration entre les entreprises de Singapour et de Hong Kong : les liaisons interculturelles créent une menace en limitant le développement entre des cultures sociales différentes. D'où l'intérêt d'établir des relations professionnelles avec des représentants possédant une double culture, tel que les étrangers (acheteurs-importateur) du pays d'origine de la société (vendeurs-exportateurs).

L'implication d'immigrés originaires du pays du marché ciblé présente un autre avantage. En effet, le service soft, comme par exemple le service de consulting ou de gestion de projet, exige un niveau évolué d'échanges oraux. Cette particularité de service soft consiste en des connaissances tacites (« Tacit Knowledge ») qui sont similaires à l'intuition (Polanyi, 1966). Elles sont apprises et accumulées à travers les expériences (Munier, 1999). Ces connaissances tacites sont difficilement codifiables pendant le processus d'internationalisation. Cette particularité augmente l'implication des

ressources humaines dans la production des services, malgré les barrières de la langue du pays d'accueil. A cet égard, Cyr (2006, 5) souligne « Dans ce contexte, la connaissance de la langue du pays facilitera grandement le processus d'internationalisation » ainsi que la perception des connaissances par le client car « la quantité et la qualité des informations que le questionneur peut obtenir ne seront manifestement pas les mêmes selon qu'il puisse ou pas communiquer dans la langue du pays. » L'auteur mentionne les responsables de la société dans le processus d'internationalisation des PME et l'interprétation adéquate de leurs expériences. De nombreux chercheurs s'accordent sur le fait que les personnes les mieux placées pour se renseigner et comprendre la situation réelle du marché sont les acteurs du terrain choisis. Ce sont ces agents multiculturels (Ellis et Pecotich, 2001 ; Yeung, 2004), avec leurs réseaux, qui peuvent collecter les informations stratégiques de terrain.

Les canaux d'information formels et informels contiennent beaucoup plus d'actualité du pays que l'information diffusée à l'export. On peut considérer que l'impact langagier est d'autant plus justifié que l'un des objectifs des services soft est le transfert, voir le partage, des connaissances avec les clients. Par ailleurs, cela impacte la qualité et la satisfaction perçues par le client. Dans le contexte du marché émergent, Nagy (2006 :307) souligne l'importance des canaux d'information « informels », car les TIC y sont limitées.

L'analyse du cadre théorique adopté nous fait conclure que, avant toute réflexion concernant la forme de présence sur le marché du pays étranger, l'entreprise est soumise à une étape préparatoire importante de pré-internationalisation. Celle-ci repose sur les décisions des responsables, l'environnement de l'entreprise, son développement dans le marché global et le processus d'acquisition des connaissances et d'information. Ces stimuli influencent la volonté d'exploiter les marchés étrangers. Pendant cette étape, la société accumule les atouts – elle implique notamment ses employés immigrés – et travaille ses réseaux dans le but d'accélérer le processus d'internationalisation.

2 Méthodologie

L'approche qualitative approfondie sur la recherche du mode d'entrée semble très demandée (Brouthers ; Hennart, 2007). Cela résulte du fait que chaque cas est unique et justifie une étude par pays. L'étude de cas a été reconnue comme une approche d'étude sur l'influence du réseau spécifique à l'internationalisation des BG (Sharma ; Blomstermo, 2003 ; Falize ; Coeurderoy, 2012 ; Coviello, 2006). Cette approche est « very suitable for international business/international entrepreneurship research (Sinkovics et al., 2008 ; Welch et al., 2011) » (Vissak ; Zhang, 2009, 250). Elle a aussi été largement utilisée pour les recherches sur le mode d'entrée des services soft, notamment pour le consulting technique (Sharma, 1989 ; Sharma ; Johanson, 1987 ; Cicic et al., 1999) et l'influence des immigrés dans le développement de sociétés à l'international, sur les marchés émergents (Vissak ; Zhang, 2014 ; Aliaga-Is ; Rialp, 2013).

Il n'y a pas de nombre idéal de cas dans cette approche méthodologique (Vissa ; Zhang, 2014 ; Yin, 2009). Notre recherche se cantonne à l'étude d'un seul cas bien défini dans le temps et dans l'espace – un cas unique. Bien que cette méthode - avec une légère capacité de validation externe - soit moins généralisable que la méthode quantitative (Voss et al., 2002), nous l'avons privilégiée grâce à son retour sur les résultats plus enrichissants et profonds (Yin, 2009) demandés dans les recherches de mode d'entrée (Brouthers ; Hennart, 2007). Il s'agit d'un cas unique - un phénomène non rare mais sur lequel on a encore très peu de connaissance (Yin, 2009 ; De Ville 2000), qui se déroule dans un environnement complexe et instable (Wacheux, 1996) – la caractéristique principale des marchés des pays en transition. L'approche quantitative est apparue comme impraticable dans notre contexte: les spécificités du secteur d'activité et la culture du pays n'ont pas permis d'effectuer les démarches d'analyse à l'aide d'interviews. Pour accéder aux acteurs des pays en transition et ainsi assurer la fiabilité des données, l'immersion au sein d'une entreprise et la participation à la stratégie d'internationalisation nous a semblé la solution la plus évidente pour notre recherche: « La qualité des données en bénéficie » (Hlady Rispal, 2002).

Cette étude de cas s'est faite grâce à une Convention Industrielle de Formation par la Recherche (CIFRE) qui a permis un encadrement spécifique. La présente recherche a aussi bénéficié d'un financement et de la collaboration d'un partenaire socio-économique (PSE) – une société d'assistance technique et de consulting en ingénierie. Ainsi, l'auteur a bénéficié d'une relation de proximité avec l'entreprise de septembre 2008 à janvier 2013. A partir d'une analyse qualitative exploratoire longitudinale, nous avons pu examiner le rôle des employés étrangers sur le mode d'entrée des PME des services industriels «soft» et les résultats obtenus sur les marchés émergents.

Deux méthodologies ont été successivement mises en place chez le PSE : recherche-action et recherche-observation. Dans un premier temps, de septembre 2008 à juin 2009, l'information initiale était collectée à partir de revues de: articles de presse, études historiques et documentaires - pour reconstituer une partie de la chronologie -, analyse des rapports officiels concernant la libéralisation du marché oligopolistique du pays émergent - pour bien comprendre les tenants et aboutissants de la législation du secteur pétrolier. Pendant cette période, nous avons procédé à des allers-retours entre théorie et terrain en gardant le statut de « chercheur-ingénieur », tout en étant à la fois animateur et évaluateur. Ce double statut rend possible la création de connaissances scientifiques par la conceptualisation et la construction de l'outil de recherche (Chanal et al., 1997). La méthode des cas est destinée à analyser une situation réelle « in vivo » par l'ordonnateur d'une entreprise afin d'initier une décision managériale (Wacheux, 1996). « La recherche intervention ne peut exister que s'il existe une volonté d'apporter des changements à la situation initiale, en collaboration avec les acteurs de l'entreprise, et accompagnée d'un dispositif permettant de produire de la connaissance scientifique » (Zawadski, 2011, 11). C'est le cas de notre recherche puisque nous avons accompagné la PME de service industriel soft dans sa stratégie d'internationalisation sur un marché émergent afin d'en identifier le mode d'entrée. Pour

l'approche terrain, la recherche évolue au cours de l'immersion dans l'organisation (Hlady-Rispal, 2002 ; Yin, 2009). Dans un second temps, de juin 2009 à décembre 2013, nous avons procédé à l'observation participante afin de mieux comprendre et analyser le mode de fonctionnement du PSE. Lors cette étape, nous avons collecté et analysé des compte-rendus de réunions, de missions, de téléconférences, etc. effectués dans le cadre de l'accompagnement du PSE sur le terrain. Afin de rester neutre durant la phase d'intervention, nous avons préféré l'instrument d'investigation par récits de missions pour avoir l'avis d'un maximum de parties pertinentes et une vision la plus globale possible. L'étude de cas nous a permis d'accumuler les données et de généraliser les résultats de deux visées de recherche: visée transformative de recherche-action et la visée compréhensive et explicative par l'observation participante. Le travail de narration analytique qui a permis de valider nos propositions de recherche résulte de la mise en application de ces démarches.

En choisissant l'étude de cas unique comme approche, le chercheur doit être conscient du risque de mettre "tous ses œufs dans le même panier". Suivant les recommandations de Yin (2009), quatre éléments ont été respectés dans notre recherche afin d'en garantir le caractère scientifique, la qualité, la fiabilité, la validité et la robustesse des résultats: authenticité du cas - nécessité de décrire une situation réelle de la vie professionnelle ; urgence de la situation dans le cas - nécessité de s'assurer de l'actualité ou bien nécessité de diagnostiquer le problème ; orientation pédagogique du cas - nécessité d'effectuer une formation dans le domaine particulier traité par le cas ; finitude du cas - nécessité de présenter une situation globale.

Pour respecter les critères discriminants mentionnés ci-dessus, des séjours prolongés ont été effectués sur le terrain de la recherche (en Russie), au sein de la compagnie du PSE, cela afin de comprendre les particularités de l'activité, de la culture et du langage. Ces démarches ont été exigées par le problème perçu et évoqué au sein du PSE. Nous avons terminé notre recherche en 2013 par la phase "d'arrachement" du terrain qui a permis le recul nécessaire et suffisant sur le sujet pour avancer des idées novatrices puisque "la justification d'une recherche sur un terrain unique n'est en effet pas de valider des concepts déjà connus (un cas de plus n'est pas probant pour "vérifier" une théorie), mais d'en proposer de nouveaux" (Berry, 1999, 5).

3 Etude de cas

Le contexte de la recherche est particulier à double titre : elle se déroule en Russie dont l'économie est en transition du collectivisme étatique au libéralisme et elle concerne une PME du type BG de services industriel soft, opérant dans des secteurs oligopolistiques: les secteurs pétrolier et parapétrolier.

D'après l'évaluation de la COFACE pour l'Union Européenne, les opportunités du marché russe sont grandes. En 2006, l'exportation française vers la Russie a progressé de 42% par rapport à l'année précédente. En 2010, affectée par la crise en 2009, elle a progressé de 30% et en 2011, de 15%. Par contre, le climat des affaires reste préoccupant à cause de la corruption, du système institutionnel faible, des droits de propriété (les institutions régionales et fédérales ne sont pas forcément d'accord sur les règles à appliquer) et de l'efficacité du gouvernement. La Russie manque de technologie et de capitaux pour exploiter ses gisements. Elle a besoin de travailler avec des entreprises occidentales et d'adopter - partiellement - leurs cultures opérationnelles.

La conduite de projets pétroliers à l'international est complexe. Il existe une multitude d'acteurs et de services. Il est nécessaire de comprendre la structure du marché visé ainsi que les interactions entre les acteurs. La communication est complexe. Notre rôle, dans l'organisation, a été de faciliter le développement et la performance du PSE sur le marché russe en servant de support à la communication entre les acteurs du terrain (les partenaires et clients potentiels) afin de bâtir la stratégie d'internationalisation du PSE. Cette place a semblé profitable car elle permettait d'accumuler, de façon légitime, des observations utiles. En effet, cela a facilité l'accès au processus d'élaboration de la tactique et stratégie de l'entreprise par l'équipe dirigeante.

3.1 Présentation du PSE

Le PSE est spécialisé dans l'assistance technique et la formation professionnelle auprès de grandes entreprises industrielles des secteurs pétrolier et parapétrolier. La société a été créée en avril 2000, en France, par cinq ingénieurs issus du secteur et ayant fait partie d'une équipe d'experts d'une des « supermajors » du secteur. Cette équipe avait pour rôle d'évaluer le personnel technique de supervision, de développer et réaliser un plan de formation et d'assistance technique pour la Division Forage d'une compagnie algérienne à Hassi Messaoud. Plus de 350 superviseurs et ingénieurs ont été formés (3 ans de formation par personne). Une fois le projet terminé, les experts se sont associés pour valoriser leurs compétences et savoir-faire et proposer ce type de service à d'autres entreprises du secteur pétrolier. Le DG a contribué majoritairement au développement du PSE en prenant à sa charge l'assurance crédit qui servit à créer la société, les locaux du siège social ainsi que la gestion administrative. Les autres associés, quant à eux, se sont limités à apporter leurs connaissances, leurs expériences ainsi que leurs réseaux de contacts. Le PSE a remporté, en 2009, pour sa stratégie et sa croissance à l'international, le Trophée de l'Export lors du Forum International Class Export co-organisé par la Chambre de Commerce et d'Industrie Marseille Provence (CCIMP). Le PSE a établi des partenariats dans 37 pays. L'activité principale du PSE est l'assistance technique. Ceci implique répondre à des appels d'offres et placer du personnel spécialisé en CDD (de 6 à 24 mois) ou CDI dans les compagnies importantes du secteur. Le PSE gère les contrats et les salaires du personnel placé et facture ses clients mensuellement. A ce jour, le PSE compte 42 employés à

travers le monde, dont 14 employés de bureaux et 28 spécialistes (en poste chez des clients). La formation du personnel est aussi commercialisée. Les formations sont souvent modifiées selon les besoins des clients. Une fois les contrats obtenus, des supports sont préparés par des experts externes (possédant généralement 20 à 30 ans de métier sur le sujet à enseigner ainsi qu'une expérience reconnue en tant qu'instructeur en centres de formation ou chez des compagnies importantes du secteur). Le noyau dur de l'effectif est constitué d'une vingtaine d'experts qui sont systématiquement sollicités par le PSE. Ce sont les « Knowledge Angels » auxquels se réfèrent Muller et al. (2012). Le volume de contrats et de jours de formations vendus varie d'une année sur l'autre.

La majorité des affaires (85%) est amenée par l'équipe dirigeante. Le premier contact se passe directement entre le client et les associés-dirigeants du PSE. Il permet de définir les besoins du client sur le terrain et d'y répondre adéquatement. Le reste des affaires résulte de l'activité de prospection des commerciaux et des réseaux de connaissances personnelles de ces derniers en lien avec le marché ciblé. La société est présente dans de nombreuses régions (Europe, Moyen et Extrême Orient, Afrique du Nord et du Nord, Amérique du Nord, etc.) au travers de représentants, de succursales ou d'unité commerciale complètement intégrée à la maison-mère.

3.2 Immersion

De mai à août 2006, l'auteur a effectué un stage au sein du PSE. Pendant ce stage, l'auteur a analysé ses pratiques d'implantation au Moyen-Orient, en Roumanie, en Italie et au Portugal. Il a été observé que la volonté d'implantation était en partie liée au contexte du marché ciblé et que la difficulté principale consistait à détecter le bon mode d'entrée pour chaque pays et les spécificités de service de l'industrie choisie (investissements, équipements, matériels, etc.) tout en prenant en compte le fait que, dans une PME, le problème d'investissement survient en premier lieu. Pour minimiser le coût de transaction et de fonctionnement à l'international, le dirigeant a toujours choisi une personne en fonction de ses connaissances personnelles, de ses compétences linguistiques et, si possible, ayant la nationalité du pays considéré. Les représentants du PSE à l'international sont ainsi tous imprégnés de la culture locale, et maîtrisent la langue du marché ciblé.

Connaissant l'origine et la maîtrise des langues russe et anglaise de l'auteur, le DG du PSE lui proposa un stage ayant pour mission principale l'identification de possible sponsoring et/ou partenariat avec des sociétés actives dans les secteurs pétrolier et parapétrolier, l'objectif étant la représentation des services du PSE, et de ses partenaires, en Russie et en Europe de l'Est.

A la fin du stage, le DG proposa à l'auteur de représenter la société en Europe de l'Est et en Russie ainsi que d'assurer la prospection dans le secteur pétrolier. Désireux de poursuivre ses études scientifiques, l'auteur déclina l'offre d'embauche.

Fin 2007, plus d'un an après son stage, l'auteur a finalement rejoint le PSE en tant que responsable développement pour la Russie. L'intervention au siège social du PSE débuta en septembre 2008. L'objectif était, dans un premier temps, de trouver un sponsor faisant office de représentant local puis, en fonction du volume d'affaires dégagé, de proposer à ce même représentant d'ouvrir une filiale pour le PSE.

3.3 Déroulement du projet et résultats

En ligne avec les objectifs du PSE, nous avons procédé à l'application de la recherche-action pour analyser ses deux activités principales sur le marché russe et définir les axes stratégiques d'évolution interne et externe. Nous avons ensuite défini les actions à entreprendre pour donner un essor au développement des affaires en Russie à court et moyen termes et le pérenniser sur le long terme. Pour réaliser ce diagnostic, nous avons utilisé différentes sources d'information: (1) des rapports commerciaux en lien avec la démarche d'internationalisation du PSE, les bilans de la société et autres documents permettant de mieux comprendre les avantages concurrentiels du PSE sur d'autres marchés instables, notamment en Afrique du Nord et au Moyen-Orient; (2) des compte-rendus de conversations avec les associés du PSE et autres salariés, représentants commerciaux, associés, collaborateurs et clients de la société, ainsi qu'avec des prospects rencontrés lors d'un salon professionnel à Moscou; (3) des publications analytiques: avis d'experts dans des articles de presse industrielle, des cours théoriques universitaires russes sur l'économie du secteur pétrolier, des articles généralistes sur l'économie russe parus dans la presse russe et étrangère; (4) des études du secteur pétrolier en Russie, y compris sur les besoins en assistance technique et en formation professionnelle: RBK (un groupe de média russe faisant partie de l'indice RTS), Xerfi700, Douglas-Westwood, données de Rosstat (Service fédéral russe de statistiques); (5) une étude de la législation relative aux investissements étrangers dans le domaine des hydrocarbures: actes juridiques du Code Civil de la Fédération de Russie, Code Fiscal de la Fédération de Russie, Code de la Fédération de Russie sur les Délits Administratifs; (6) l'expertise de Mme M. en législation, finance et taxation sur le marché russe; (7) les résultats du benchmarking réalisé pendant la création du site Internet de la société; (8) divers articles correspondant au sujet de recherche, des cahiers industriels, des études de marchés, etc.

L'ensemble de ces informations a été assimilé par le DG qui a conceptualisé la stratégie d'entrée sur ce marché à fort potentiel d'opportunités et de croissance. En effet, la Russie est le deuxième exportateur mondial de pétrole. Mais le PSE n'avait jamais travaillé avec des entreprises russes et n'y était pas connu. De plus, le PSE n'avait jamais employé ou placé de personnes russes. Pour éviter, autant que possible, tout problème d'ordre financier, juridique ou comptable, le DG privilégia d'abord une stratégie de développement à travers une compagnie sponsor, c.à.d. une société active dans

le secteur ciblé et susceptible de présenter les services du PSE (et de ses partenaires) en Europe de l'Est. Idéalement, cette société devait avoir fait ses preuves, être bien implantée au niveau régional, offrir un (ou des) services complémentaires et être de taille équivalente (les compagnies de taille supérieure pouvant, selon le DG, menacer l'individualité et l'image du PSE). Afin de sceller ce partenariat, le PSE proposait une réciprocité de représentation de services dans les régions où il est déjà présent.

Il est important de noter que l'établissement d'un partenariat fiable revêt un caractère particulièrement stratégique pour une société de service « soft ». En effet, ce type de collaboration implique un transfert de connaissances et compétences, fruits d'expériences acquises chèrement sur le terrain. Il faut donc être très vigilant quant au choix du partenaire. Finalement, cette méthode est apparue comme trop risquée et fut, de ce fait, abandonnée par le DG. Une autre stratégie d'implantation considérée par le DG consistait à identifier les clients fidèles du PSE opérant déjà sur le territoire russe. Hors, il est apparu que les gérants et actionnaires locaux conservent une grande autonomie décisionnelle. Il a donc été nécessaire, pour le PSE, d'établir de nouveaux contacts et de maintenir le dialogue avec les « anciens – nouveaux » clients. Aidé des commerciaux du PSE, l'auteur a effectué plusieurs recherches. Les commerciaux ont sollicité leurs nombreux contacts pour connaître les projets en Russie pour lesquels le PSE était susceptible de les accompagner. Un seul projet a été décelé. Celui-ci consistait à accompagner le client dans son développement en fournissant l'assistance technique. Pour faciliter la collaboration et réaliser cette prestation de service, le DG - qui avait déjà été confronté à une telle pratique au cours d'étapes précédentes d'internationalisation de l'entreprise - a décidé de s'implanter sur le marché.

Le temps est un facteur critique du secteur d'activité du PSE. Les projets ont souvent des durées de vie courtes et les délais de réponse requis, par le client, pour les appels d'offres, sont souvent d'une à deux semaines maximum. Une implantation directe sur le marché permet à la fois un allègement du travail administratif et une acceptation plus rapide des réponses aux appels d'offres. Trois formes d'implantation ont été proposées par l'expert mandaté par le PSE: un bureau de représentation, une succursale et une filiale. La solution initialement retenue fut l'ouverture du bureau de représentation. La lenteur administrative (liée aux modalités d'enregistrement des sociétés étrangères auprès d'un organisme spécial situé dans la capitale du pays) puis les restrictions imposées au niveau commercial par ce type de structure ont incité le DG à considérer la "filiale". Celle-ci est plus avantageuse au niveau fiscal et juridique mais elle implique la présence d'une personne physique sur le territoire alors que, à cette période, aucune personne digne de la confiance du DG n'était en mesure d'engager les démarches nécessaires.

Finalement, l'ouverture de la succursale est apparue comme le mode d'entrée le mieux adapté. Il a été décidé que l'auteur s'occuperait de l'ouverture de la succursale dans sa ville natale, Novosibirsk, troisième ville de Russie. Celle-ci est devenue effective en juin 2009. Des prestations d'assistance de direction et de secrétariat ont été intégrées au contrat avec l'agence consulting de Mme M., ce qui a permis au PSE de minimiser les frais. Enfin, la fonction de l'auteur a évolué pour prendre la direction de la succursale russe.

L'enregistrement de la nouvelle structure effectué, tous les supports (site internet, édition du cours, catalogue, brochure, triptyque, etc.) ont été traduits en russe pour satisfaire les exigences des décideurs locaux: « la langue officielle de notre pays est le russe. Nous vous demandons de nous envoyer le descriptif du cours en russe. » insista M. K. – responsable formation d'une grande société pétrolière russe. Ce travail de traduction a été réalisé par l'auteur et Mme E., camarade de promotion, rentrée chez le PSE à mi-temps, en tant qu'assistante pour des travaux de correction de textes techniques. Mme E. est docteur en mathématiques et avait 5 ans d'expérience en tant que commerciale en Russie. En juin 2009, Mme E. devint attachée commerciale, à mi-temps, pour la Russie et les pays de la Communauté des États Indépendants (CEI). Cette collaboration avec Mme E. permis à l'auteur, dès juin 2009, de procéder à l'approche d'observation participante pour la recherche. Les principaux supports d'analyse pour cette étape étaient les comptes-rendus de travail et un journal de recherche - rapports d'opérations commerciales hebdomadaires. Ce dernier a été constitué à partir de rapports détaillés de missions, préparés par les membres de l'équipe mobilisée pour l'analyse du terrain et pilotée par l'auteur.

Dans le même mois, une mission à un salon professionnel en Russie a été effectuée par l'auteur, Mme E. et l'un des associés du PSE. Plusieurs contacts ont été pris et un contrat a été signé pour une prestation de perfectionnement du personnel d'une société pétrolière russe sur un logiciel de forage. Le projet s'est inscrit dans une niche où aucun concurrent était présent. Le PSE était « la seule société capable d'offrir cette formation spécifique » commente le responsable formation de la société pétrolière russe, M. S. Pour effectuer cette formation, le PSE a constitué un groupe de travail franco-russe. A travers ces sessions de formation, l'auteur a appris à aborder et gérer les interactions techniques et culturelles d'un groupe de travail constitué d'italiens, d'algériens, de français et de russes. Ce projet fut une réussite, la collaboration entre experts issus de la zone méditerranéenne et des universitaires russes ayant donné pleine satisfaction au client.

Ce premier client a ensuite délégué, au PSE, l'évaluation de certains de ses collaborateurs. Dans le cadre de ce projet, le PSE a pu pousser plus loin la démarche initialement adoptée en se faisant accompagné par les services de plusieurs universités russes. Ce projet a été accepté par le client comme un projet de la formation obligatoire.

Ces projets-pilotes ont fait ressortir des facteurs non observables, liés en grande partie à la spécificité du client, à celle du PSE ainsi qu'à l'espace et au temps réels. Ces facteurs ont été détectés au gré des conversations et des multiples réunions avec les responsables formation du client. Il s'agit de procédures internes relatives à la prise de décision concernant le profil des prestataires. Ces règles internes au client existent pour protéger ses objectifs à long terme, la formation étant considérée comme un investissement sur du personnel qui sera mobilisés sur des projets clés à venir. La

proposition commerciale du PSE a alors été adaptée aux nuances de fonctionnement du client découvertes par l'équipe de front-office du PSE (l'auteur, l'attachée commerciale russe et les ingénieurs experts russes et européens en forage). Les experts du PSE ont développé et animé les cours, accompagnés par l'auteur et Mme E. Ils ont aussi profité de cette opportunité pour évoquer d'autres problèmes opérationnels et techniques avec le client et l'aider à définir ses besoins. Ainsi, l'équipe du PSE est répartie de chez le client avec deux contrats supplémentaires.

Un second projet de développement a été initié en 2010, dans le cadre de l'année de croisement culturel France – Russie. Un partenariat a été établi avec les cinq universités du Pétrole & Gaz les plus prestigieuses de Russie. Au travers de ce partenariat, le PSE a tenté d'apporter des méthodes et un savoir-faire en terme de formation aux compagnies pétrolières majeures, celles-ci étant déjà clients des universités. La valeur ajoutée du PSE ne se limite pas à l'apport de compétences et de connaissances théoriques. Le PSE a une grande expérience opérationnelle de terrain, à l'international. Hors, c'est précisément cette expérience de terrain qui fait défaut aux universités russes. Le catalogue de prestations du PSE a été intégré aux sites internet des universités. Il attire beaucoup d'attention de la clientèle des universités. Enfin, cet intérêt marqué engendre la nécessité de renforcer les compétences linguistiques du PSE afin d'assurer le bon déroulement des projets de formation, les supports devant obligatoirement être fournis en russe.

Fin 2010, l'auteur présenta au DG une étudiante ukrainienne en commerce international (pour trouver cette candidate, l'auteur avait contacté son ancien responsable de faculté) Celle-ci accepta un CDI un an après, en tant qu'assistante export pour la Russie et CEI.

Les efforts de commercialisation d'assistance technique (2ème activité du PSE) n'ont pas produit les résultats escomptés malgré les adaptations du produit de base en fonction des circonstances du marché ciblé. En effet, les clients potentiels objectaient typiquement que : « Une équipe de forage russe comprend 9 personnes et coûte 4500 roubles par jour (env. 120 euros). C'est deux fois moins cher que le tarif d'un de vos spécialistes de base! ». Les retours étaient du même acabit concernant l'offre du PSE pour la fourniture de matériel de forage innovant car la main d'oeuvre des prospects et ceux-ci sont satisfaits du travail accompli. Par conséquent, l'offre du PSE en terme de consulting technique (conseil, audit, ingénierie, formation et expertise) en forage est la plus adaptée au marché ciblé.

4 Discussion et les implications managériales

La littérature consultée a mis en évidence l'importance du rôle des employés immigrants, de leurs connaissances du marché, leurs liens utiles, leur expérience dans le développement international de PME de type BG (Filatotchev et al., 2009 ; Vissak ; Zhang, 2014 ; Nguyen et al., 2013 ; Zhou et al., 2007). Les auteurs remarquent que, dans le contexte de pays émergents avec des systèmes institutionnels faibles, les relations informelles jouent un rôle significatif sur ces marchés souvent caractérisés par une instabilité, des turbulences, un manque de transparence, etc.

Dans le cas présent, l'implantation d'une PME BG de service industriel soft, les trois immigrants slaves - parmi 14 employés - ont influencé son développement à l'international. Par le moyen d'activation du réseau (McDougall et al., 2003 ; Johanson ; Vahlne, 2009), le directeur de la PME étudiée a pu trouvé des sources d'information fiables devenues stratégiquement importantes lors de la prise de la décision (Hrebiniak ; Joyce, 1985) du mode de présence sur le marché ciblé. Pour ce faire, le directeur a identifié et sélectionné la personne la mieux placée pour se renseigner et comprendre la situation réelle du marché – l'acteur de terrain privilégié est un agent multiculturel (Ellis ; Pecotich, 2001 ; Yeung, 2004). Par conséquent, la distance « psychique » et « physique » se trouve raccourcie grâce à l'expérience et au réseau de l'agent (McDougall et al., 2003 ; Johanson ; Vahlne, 2009 ; Sousa ; Bradley, 2006).

La stratégie initiale d'entrée de cette PME BG était « strategic resource seeking » (Dunning, 1998) : elle consistait à rentrer sur le marché par le biais d'un partenariat avec une société identique en taille et proposant un service supplémentaire ou complémentaire au sien. Cependant, la barrière de la confiance est apparue comme insurmontable. En effet, les relations créées sont souvent basées sur l'honneur, la bonne exécution du travail à accomplir, la coopération dans les zones de conflits (et à risque), etc. Les bonnes références se répandent moins rapidement que les mauvaises. Une mauvaise expérience avec un prestataire peut se répandre dans le milieu via les forums et les réseaux de connaissances, avec pour conséquence la perte d'une partie voir de tout un marché. Ne pouvant contrôler ce risque, le dirigeant s'est ensuite orienté vers un autre concept d'entrée : « client-following » (Erramilli ; Rao 1990). La complexité de la bureaucratie administrative du système d'Etat russe s'est avérée très handicapante pour la PME étudiée. Le projet a pu être abouti grâce au réseau (Johanson ; Vahlne, 2009) de l'employée immigrante. Pour pénétrer un marché convoité dans un pays émergent, l'avis d'un expert juridique et financier du marché ciblé est indispensable. Le décideur, l'employée immigrée et l'expert mandaté se sont concertés à maintes reprises durant la phase de pré-rentrée. Durant cette étape préparatoire, il a été possible de développer et améliorer les ressources et capacités de l'entreprise (internes ou externes) (Wiedersheim-Paul et al., 1978). Des séances de « brainstorming » ont permis d'aboutir à un accord quant à la meilleure forme de présence pour le service industriel soft sur le marché ciblé, s'assurant ainsi que celle-ci se concrétiserait non seulement par rapport aux projets de la PME (Léo ; Philippe, 2001) mais aussi par rapport aux ressources dont l'employée immigrée disposait ainsi que la possibilité d'en assurer le mode de fonctionnement sur le nouveau marché. La forme de présence sur le marché est un choix partagé entre le dirigeant d'une PME BG et l'employée immigrante qui s'engagea à diriger la nouvelle structure locale tout en minimisant son coût de fonctionnement. Dans le cas étudié, le positionnement géographique sur le marché de la PME de service industriel soft a une importance moyenne. L'employée immigrée accède aux clients potentiels sur les salons professionnels - la communication en russe est propice au développement de relations d'affaires favorables et favorise la création d'un

espace de confiance (Yeung, 2004). Le premier contrat obtenu fut le fruit du travail accompli, en grande partie, par les employées immigrées qui, au gré des rencontres avec le client, ont su percevoir les nuances de propos de leurs interlocuteurs et faire en sorte que l'offre soit adaptée pour les satisfaire au mieux. L'impact de ces facteurs non observables sur le succès d'une entreprise est développé dans plusieurs études scientifiques de l'école « autrichienne ». Nous supportons la réflexion de Jacobson (1992) qui débattait des questions telles que : l'innovation continue, la flexibilité, ainsi que les influences non observables de la performance des entreprises.

Dans notre étude, nous avons constaté le rôle important des immigrés dans le développement de la PME BG en service industriel soft mais aussi celui des experts. Lorsque le client est prêt à dialoguer sur les modalités du contrat, le processus de concrétisation de l'offre de service démarre. Il s'agit d'une étape qui implique la participation d'experts ou Knowledge Angels (Miller et al., 2013). Ce sont eux qui sont en contact direct avec les responsables formations du client pour créer l'offre finale. Ces « Knowledge Angels » sont aussi impliqués dans le processus de vente (en étant face aux équipes d'experts du client) et ensuite, en étant face aux stagiaires, dans les salles de cours. Enfin, durant ces prestations de services soft, les experts peuvent mettre en lumière d'autres opportunités de formation qui amèneront l'entreprise à signer d'autres contrats.

Le cadre conceptuel proposé permet de faire plusieurs préconisations pour réussir l'implantation d'une PME de type BG de service industriel soft : (1) être conscient du rôle important du capital humain multiculturel ; (2) adapter l'offre de service au marché ciblé ; (3) impliquer des experts originaires du pays ciblé ; (4) traduire tous les documents et supports dans la langue du pays ciblé ; (5) un avis expert sur la législation fiscale du marché ciblé est obligatoire sur les marchés volatils ; (6) les experts de l'entreprise n'ont pas qu'un rôle technique mais ils sont aussi de véritables agents commerciaux pour la réussite du projet.

5 Conclusion : les limites et les perspectives

Les retombées de nombreuses études montrent la nature fragmentaire des recherches sur le mode d'entrée des entreprises de services, en particulier pour obtenir des données provenant de sources empiriques sur la gestion stratégique du processus d'internationalisation, ainsi que son adaptation et son développement, dans le contexte des pays d'économie en transition (Kennedy, 2005 :119). La discussion de cette section est donc nécessairement généralisée dans le but de fournir des lignes directrices pour les recherches futures. Les limites de la recherche dans le cadre conceptuel sont bien définies par l'encadrement choisi, par le temps et l'espace (une seule industrie, une seule entreprise), dans le cadre méthodologique : l'étude de cas unique.

Les perspectives envisagées consistent à étudier la nature du réseau (personnel ou professionnel) du dirigeant d'une PME de serviceS « soft » et comment il intervient dans sa réussite à l'international. La recherche pourrait être étendue à une autre PME de services « soft » ou à l'implantation dans un autre pays émergent.

Les résultats obtenus montrent que les PME de service « soft » se développent à l'international en s'appuyant sur leur capital humain, précisément des immigrés provenant des pays émergents ciblés pour l'exploitation, sur leurs réseaux en tant qu'outil d'accès à une information fiable dans un environnement volatil, sur la différenciation de l'offre et sur la réactivité pour exploiter une stratégie de niche. La nature des services « soft » n'est pas immédiatement compréhensible, ce qui, pour convaincre les clients, nécessite d'exploiter les capacités rhétoriques du personnel en contact, de faire attention à l'image projetée et de gérer les relations et les interactions avec les clients. De plus, nos résultats font apparaître l'importance de l'étape préparatoire pour la réussite du projet d'implantation dans ce contexte. Le décideur, l'employée immigré, l'expert juridique et financier, tous se réunissent dans l'étape de pré-entrée. Suite à l'activation du réseau, la prospection de la société sur le marché ciblé commence. La société accède aux clients en développant les relations d'affaires et en découvrant les facteurs non-observables.

Societal, Territorial and Welfare dimensions of Economic Intelligence in a Services Based Economy in France

Christian Bourret

University of Paris East Marne-la-Vallée, DICEN IDF / IFIS

In France, the Economic (EI) or Competitive Intelligence (CI) has gradually emerged as an important tool for strategic decision in business with some delay regarding other countries. Appeared in an industrial economy, it has gradually integrated the dimensions of services' economy, and so the digital dimension and that of social networks. Having clarified our methodological positioning, we will discuss the changing context in which EI develops with the transition from an industrial economy to a service-oriented economy in a global competition for business companies, but also for States and local communities. We then will present different approaches to "French" EI before proposing a synthesis approach, with particular emphasis on strategic, territorial and societal dimensions.

En France, l'Intelligence Economique (IE) s'est progressivement affirmée comme un outil important pour la décision stratégique en entreprise, avec un certain retard par rapport à d'autres pays. Apparue dans une économie industrielle, elle a progressivement intégré les dimensions de l'économie des services, ainsi que la dimension numérique et des réseaux sociaux. Après avoir précisé notre positionnement méthodologique, nous évoquerons le contexte en pleine évolution dans lequel elle se développe avec le passage d'une économie industrielle à une économie centrée sur les services, dans une concurrence mondialisée concernant les entreprises, mais aussi les Etats et les collectivités locales. Nous présenterons ensuite les différentes approches de l'IE « à la française » avant d'en proposer une approche de synthèse, insistant sur les dimensions stratégiques, territoriales et sociétales de l'IE.

1 Introduction

With the globalization of the economy and its corollary of generalized competition, not only between companies but also between States and local authorities, the issue of Economic (EI) or Competitive Intelligence (CI) has become essential. It gradually became important to the detriment of inquiry or intelligence (*renseignement*) with always sulphurous connotation linked with military or secret services. These profound changes in the global context of the EI applications have both given it a new legitimacy and a much broader area of action for not only for companies but also for States and Local Authorities.

We now encounter different and complementary approaches to Economic and Competitive Intelligence. Firstly a micro approach regarding Enterprises (EEI) or EI as an aid to strategic decision that corresponds to the first approaches of EI in France as technological watching, close enough to Anglo-Saxon approaches of Business or Competitive Intelligence. There is now a more global approach (macro), more social and territorial (attractiveness) of EI corresponding to a new approach by the government in France (Revel, 2012) after more Business and Companies origins (Martre¹⁷'s report in 1994, Carayon¹⁸'s reports in 2003 and A. Juillet's action¹⁹). These developments represent another aspect of global context of changes in which issues of Economic Intelligence development take place: a shift from focusing on industrial prospect (goods and products driven) to a Services Driven Economy (Du Tertre) economy. If the EEI remains important, other more comprehensive and holistic approaches have emerged: TEI (Territorial Economic Intelligence) and SEI (Strategic Economic Intelligence).

Having clarified our methodological positioning, we will discuss the changing context in which EI develops with the passage of an economy driven by industry to a services driven economy. We then present different approaches to "French" EI prospects: EEI, TEI or SEI, before proposing a synthesis approach, with particular emphasis on Territorial, Societal and Welfare dimensions of EI.

¹⁷ Henri Martre is a French [telecommunications engineer](#). He headed both the French [Délégation Générale pour l'Armement](#) (DGA) the aerospace conglomerate [Aérospatiale](#) and the [French Aerospace Industries Association](#) (GIFAS). He is considered one of the main promoters in France of "[competitive intelligence](#)", being with P. Clerc president of a commission which produced a report important for the beginnings of Economic Intelligence in France.

¹⁸ Lawyer, Member of Parliament (MP) for Tarn's department until 2012, Bernard Carayon has been in the French Parliament particularly invested in issues of Economic Intelligence and Economic Patriotism. He was president of the Commission which produced the 2003 report on Economic Intelligence.

¹⁹ After responsibilities within various companies (Ricard ...), Alain Juillet has been heavily involved in the French intelligence services. He was manager for Top Competitive Intelligence in France depending of the Prime Minister Offices (2003-2009).

2 Methodological aspects

Our analysis is based on participation in seminars, symposia and workshops, interviews with key actors in the EI (Economic Intelligence) or TI (Territorial Intelligence) field, with the integration in networks of experts and researchers.

A literature review is constantly updated (see references). It is articulated in a field dimension acquired by PhDs or masters works. We are in a critical posture focused on information and communication sciences (ICS) in a perspective of research – action. This paper constitutes a more theoretical part of our works.

We try to adopt the position of "committed neutrality" proposed by N. Heinich with a view to build knowledge for action with the complementarity of informational and communicational approaches also in relation with management projects.

The more comprehensive approach to Business, Economic or Competitive Intelligence we offer includes new approaches to Quality and Evaluation as an Organizational and Situational Intelligence, relying on the notion of "sustainable information". Data quality is essential. In the context of an intangible economy, "sustainable information", assuming both "more sharing, fairness, innovation and responsibility", also implies sharing and appropriate conservation strategies (Bourret; Ccaly; Chambaud, 2008).

It is at our level, trying to participate to the project of Edgar Morin, relaying Blaise Pascal to "work to well thinking" ("*travailler à bien penser*") (Morin, 2013, 61) to "think differently" (Morin, 1999) and in particular to think globally complexity and change. In this perspective, EI has both, in every organization, internal dimensions (exchanges and collaborative dynamics) and external dimensions (control of the competitive environment) both with an informational dimension: obtaining and getting the right information to the right person at the right time to make the best decision and also communicational dimension: lobbying, influence externally, but also foster cooperation both internally and also with customers and suppliers.

The dramatic development of ICT, with the addition of new tools and Internet technologies, including Web 2.0 and Social Networking, has also contributed significantly to the evolution of Competitive Intelligence.

The issues of Open and Big Data and that of the development of Social Networks both in their external aspects (new marketing process, visibility on the Web, e-reputation) and in their internal aspects (collaborative organization) is to take into account, the open data primarily concerning public organizations and private companies being concerned by big data

In France, the CNIL (*Commission Nationale Informatique et Libertés*) organized a seminar about the issue of Open Data on July 2013. Participants stressed the idea that the open data is primarily a tool for modernizing public action and of general interest for Democracy which needs the best opacity and privacy for citizens and transparency for the State, when it is often the opposite that happens. Open Data is an essential component of transparency. Personal data is not *a priori* the first concerned by Open Data. Open Data have no personal nature, they concern mainly State (or linked organizations such as Health Insurance Offices) or Local Authorities data (maps, raw data, general indicators).

But we have entered a period of "Revolution of the Data." "Putting the world in data" lead us to redefine the way we act, and to create knowledge infrastructure of a new kind. The boundaries between the different categories of data, personal or public, anonymous or indirectly identifiable are not always clear.

3 From a Product and Industrial Approach to a Services Based Economy Approach

In its beginnings, EI or CI has grown in an industrial approach especially using technology watching tools and industrial property with the strong importance of analyzing the patents taken out by the companies (Dou, 1995).

In France, Economic or Competitive Intelligence is often considered as a relatively new concept appeared in 1994 with the Martre's report and developed after the Carayon's report (2003) and the action of A. Juillet (2003–2009) in the Prime Minister offices.

It also exists another approach: EI or CI was also a main goal for the companies since a long time as "Organizational Intelligence" (Wilensky, 1967). Then CI meets the concepts of Quality and Evaluation. Wilensky stressed the importance of information. He warned that "the competent organization of the intelligence function cannot substitute for political and administrative leadership judgement" (Wilensky 1967, xi). He emphasizes that "the danger of technicism is in direct proportion to the shortage of educated men ... social science is to be incorporated into decision making" (Wilensky, 1967, 190).

The changes have been very significant since thirty years as outlined by G. Gramaccia (2008). Three iconic innovations that have become symbolic of managerial efficiency, have profoundly changed the thinking and practice of cooperation in organizations: the Total Quality Management (importance of recognition), the Project Management (autonomy and subsidiarity) and the Knowledge Management with the pragmatic of digital link with aspects of "cognitive capitalism" in the global context of a "networked society" (Castells, 2001).

Wolton (2014) highlighted the fashion effects of vocabulary ("obsessive words"). "For ten years, we spoke of "information highways" and of "information society", then it was the obsession of the "networked society", now the fashion is about "all digital" and to the "extended man."

EI integrates all these evolutions. While Martre's report (1994) stressed the importance of information and favored Competitive Intelligence applied to enterprises, ten years later (2003), Carayon's report proposed to articulate business competitiveness and social cohesion.

The challenge now is to adapt the concepts and methods of Competitive Intelligence to a service-based economy (Du Tertre) also incorporating societal and welfare approaches or from the so-called "Goods Dominant Logic" (GDL) to a Services Dominant Logic "(SDL). This notion of services has expanded to include customers and suppliers and also within the organization in relation to the logic of value creation at all different levels and the definition of cost centers and profit centers. Everyone now produces data within the company or organization with in relation the difficulty of storing all this data and with a typically problematic of EI, the challenge of analyzing to give the relevant information faster and discovering weak signals.

This production of huge amounts of data is linked with the obsession of quantitative and measurable management, denounced by both V. de Gaulejac (*La société malade de la gestion*, 2005) and H. Mintzberg "*Remarque sur un bien vilain mot : efficience*" (2001, 479–485), and so by E. Morin (2013) speaking of "*barbarie bureaucratique*" or "instrumental reason" has replaced "real rationality" or C. Revel²⁰ (2012), pointing after others drifts in quality approaches and, more specifically, in the evaluation actions.

In a context dominated by the urgency, the issues of meaning and cooperation have become central with those of recognition at work and confidence, particularly in its digital dimension. New approaches to EI in a services, intangible and digital society must take into account all these elements.

4 What Positioning for Economic Intelligence: Entreprise Economic Intelligence (EEI), Territorial Economic Intelligence (TEI) or Strategic Economic Intelligence (SEI)?

4.1 Entreprise Economic Intelligence (EEI)

As we already mentioned, the Martre's report on *Intelligence Economique et stratégie des entreprises* (committee chaired by P. Clerc²¹ involving also P. Baumard and C. Harbulot) established in France twenty years ago (1994) a basic and fundamental reflection and an official recognition of Economic Intelligence, moving away from the intelligence (inquiry), with more military and police backgrounds.

The definition of EI given in this report translates this initial positioning corresponding to Entreprise Economic Intelligence (in French : *Intelligence Economique d'Entreprise*).

"Economic Intelligence can be defined as the set of coordinates research, treatment and distribution, for its operation, useful information for economic actors. These different actions are carried out legally with all the guarantees of protection necessary to preserve the assets of the company in the best conditions of quality, time and cost. Useful information is that is needed by the different levels of decision of the company or the community, to develop and implement consistently the strategy and tactics necessary to achieve the goals set by the company to improve its position in its competitive environment. These actions within the company, are organized around a continuous cycle generator of a shared vision of the goals of the company." ²²

The aspects of decision support and risk analysis are essential.

In the field of EI, Entreprise Economic Intelligence is a specific community. It held its workshop on the campus of the Ecole Polytechnique (Palaiseau) in December 2013 on the theme: "*L'Intelligence Economique d'Entreprise face au défi du numérique*."

In his preface to the book of D. Rouach, R. Salmon²³ extended the EI prospects (1999). He highlighted the "pitfalls of EI" : information overload, technical specialization (already denounced by Wilensky in 1967) which divides the activities, which prevents dialogue and any overall vision, increased uncertainty and instability in the environment.

²⁰ Former student of the *Ecole Nationale d'Administration* (ENA), Claude Revel career's is since 1989 dedicated to Business Intelligence. Associate Professor at Skema Business School (Nice-Lille) responsible for EI in companies and president of a consulting firm in EI, she has become Delegate Interministerial for Economic Intelligence (DIIE) in May 2013.

²¹ Philippe Clerc is since 1997 Director of Economic Intelligence, Innovation and Information Technology in the French Assembly of Chambers of Commerce and Industry. He is also Chairman of the AFDIE (French Association for the Development of Competitive Intelligence).

Particular acknowledgements to him for our very interesting discussion during the Economic Intelligence symposium in Ajaccio in december 2013

²² In French in the Martre's report : « *L'intelligence économique peut être définie comme l'ensemble des actions coordonnées de recherche, de traitement et de distribution, en vue de son exploitation, de l'information utile aux acteurs économiques. Ces diverses actions sont menées légalement avec toutes les garanties de protection nécessaires à la préservation du patrimoine de l'entreprise, dans les meilleures conditions de qualité, de délais et de coûts. L'information utile est celle dont ont besoin les différents niveaux de décision de l'entreprise ou de la collectivité, pour élaborer et mettre en œuvre de façon cohérente la stratégie et les tactiques nécessaires à l'atteinte des objectifs définis par l'entreprise dans le but d'améliorer sa position dans son environnement concurrentiel. Ces actions, au sein de l'entreprise, s'ordonnent autour d'un cycle ininterrompu, générateur d'une vision partagée des objectifs de l'entreprise.* »

²³ Robert Salmon was Vice Chairman of L'Oréal in charge of General Direction of Prospective.

In the first approach, the EEI owed much to Technological Watching and especially on technical exploitation of patents. R. Salmon highlights the risk of a "vision of the industrialist watch" (Rouach, 4). He was one of the first to be attentive to overview new forms of competition such as benchmarking.

But, for him, these two facets of EI are insufficient. "Because they are based only on a rational and formalized methodology, Technological Watch and Competitive Watch *stricto sensu* withdraw by definition a whole field, the social, cultural and moral aspects, that only a finer approach to information allows to penetrate, which is at work in the Societal Watch".²⁴ It will take years to EI to develop these prospects outlined by R. Salmon.

D. Rouach offers a definition of EI with which we agree: "Business Intelligence is a new way of thinking to interpret the information to act, and a mode of action to share information for the benefit of the performance. It finally permits going from adaptation to anticipation and give leaders no longer possible scenarios, but decoding and mental patterns to better manage uncertainty and complexity. It is also a body of principles, often of common sense, that can not underestimate the competitor and adopt some form of intellectual humility "(1999, 16–17)²⁵.

In the extension of Carayon's report (2003), the definition of EI proposed by A. Juillet (2006) reflects the broadening of perspectives and gives the outlines of a "French EI" with a national strategic dimension: "The Economic Intelligence consists of the control and protection of strategic information to any economic actor. Its triple purposes are the competitiveness of the industrial framework, security of the economy and of companies and strengthening the influence of our country."²⁶

This EEI met Social Networks and Web 2.0. If the processes and jobs around Economic Intelligence evolved with the passage from an industry driven economy to a services driven economy with the importance of immaterial stakes, it has also been heavily jostled by the emergence of new ICT tools (data mining ...) and social networks, both externally and internally. These changes correspond to a 2.0 company where the flow of information decompartmentalizes jobs. Externally, organizations develop strategies presence on social networks: visibility, new forms of marketing and customer relations: social network, e-reputation, new ways to innovate and create (open innovation and crowdsourcing) ... (Balagué; Fayon, 2011). Internally, there is the dynamics of social networks as a collaborative process that fundamentally changes the positioning and the practices of Economic Intelligence.

All these changes justify for M. Perrett²⁷ (2013) the importance of "Social Intelligence." In the EEI perspective, for him, "Social Intelligence is the New Frontier for Business Intelligence." This is the "Frontier" with the meaning of the Far West in the United States in the mid-nineteenth century: pioneering spirit, conquest of new territories to develop ... For him, "The ever expanding use of social media and mobile technologies has dramatically changed how we communicate and how we interact with the companies that sell to us. As channels of communication expand to include social media networks, blogs, forums and chat rooms, digital and physical lives are intersecting more than ever. What people do online provides an increasingly accurate picture of their customer profile, including lifestyle choices, buying preferences and brand perception."

This approach opens new fields in EEI, especially with neurosciences but also raises ethical issues on the use of Big Data and the privacy of citizens (personal and sensitive data).

4.2 Economic Intelligence and Territorial Intelligence

EI in its broader approach necessarily met territories that not concerned in an important manner EEI in its first formulation.

Territorial Intelligence is a special field of research with its networks and its positioning. According to JJ Girardot²⁸: "Territorial intelligence is the science having for object the sustainable development of territories and having for subject the territorial community." This approach meets some aspects of Economic Intelligence but is above all dedicated to the "territorial community", with a key role of inhabitants, associations and Local Authorities".

Also Economic Intelligence and Territorial Intelligence have – but in a different vision about the priority given to the actors - a systemic approach in focusing on interactions between actors.

After a strong investment on industrial property and technological watching in its origins, French EI was heavily involved in cooperative networks (clusters or competitiveness poles: in French *pôles de compétitivité*, cf. H. Dou).

²⁴ In French in the text: « *Parce qu'elles reposent uniquement sur une méthodologie rationnelle et formalisée, la veille technologique et la veille concurrentielle stricto sensu évacuent par définition tout un champ, l'ordre social, culturel et moral, que seule une approche plus fine de l'information permet de pénétrer, celle qui est à l'oeuvre dans la veille sociétale.* »

²⁵ In French: « *L'intelligence économique est un nouveau mode de pensée permettant d'interpréter l'information pour agir, et un mode d'action pour partager l'information au profit de la performance. Elle permet enfin de passer de l'adaptation à l'anticipation, et de donner aux dirigeants non plus des scénarios possibles, mais des décodages et des schémas mentaux pour mieux gérer l'incertitude et la complexité. Elle est aussi un corps de principes, souvent de bon sens, qui permettent de ne pas sous-estimer l'adversaire et d'adopter une certaine forme d'humilité intellectuelle.* »

²⁶ In French: « *L'Intelligence Economique consiste en la maîtrise et la protection de l'information stratégique pour tout acteur économique. Elle a pour triple finalité la compétitivité du tissu industriel, la sécurité de l'économie et des entreprises et le renforcement de l'influence de notre pays.* »

²⁷ Mark Perrett is Worldwide Social Intelligence Solution Development Leader for HP Enterprise.

²⁸ JJ Girardot, Ricerca e Sviluppo-Res per the politique socialization, 1-2/2009. ISSN: 1970-9080 <http://www.territorial-intelligence.eu/portail/site/>

The cluster concept has been proposed by M. Porter in 1998. It is often compared with the model of the Italian districts. But while the Italian districts specialized in a particular product (sneakers Montebelluna), the cluster covers a wide area of activities, such as health and is involved in all the steps of the value chain: R & D, training ... Porter (1998) gave the following definition: "A cluster is a geographic concentration of interconnected companies as suppliers of goods and services in closed industrial branches; firms delivering the final product cooperate with universities and with their competitors ". A district is mostly composed of very small family companies, while a cluster hosts small, medium and large companies²⁹.

France has preferred the notion of "competitiveness pole" or in French "*pôles de compétitivité*", defined as "clusters serving business and job growth." They are a partnership between private (enterprises) and public organizations, based around a theme and a specific region often on a technological field (ex electric car in Saclay) or environmental or digital projects (smart city). The "*pôles de compétitivité*" correspond to a specific labellisation by the French State. Another associative projects not subsidized directly by the State take the name of "clusters". So in Ile-de France (Paris Region) it exists a "Cluster Tourism Paris Val d'Europe" located in Marne-la-Vallée area (Disney and University Paris East Marne-la-Vallée).

A "*pôle de compétitivité*" try to bring together large and small firms, Research organizations and Educational establishments, all working together on a specific Region to develop synergies and cooperative efforts around a shared theme.

The goal of "*pôles de compétitivité*" is "to build on synergies and collaborative innovation projects in order to give partner firms the opportunity to become the first in their markets, both in France and abroad"³⁰

The first specificity of the "Cluster Tourisme Paris Val d'Europe" in Ile-de-France Region to point out is that it concerns a very important services sector in France: Tourism. It is based on 3 different levels: enterprises, teaching, and research. It wants to play the role of catalyst and facilitator of projects on the whole Ile-de-France Region and not only on the Marne-la-Vallée area.

The international attractiveness of Val d'Europe sector, its hotels' capacity (the fifth in France after Paris, Lourdes, Nice and Lyon) and its exceptional accessibility (TGV ...) are the major advantages of Marne-la-Vallée for the development of a new cluster of excellence dedicated to leisure, sports and big events.

As a result of agreements signed between the State and the Euro Disney (first in 1987 and recently extended to 2030) this site is going to double its capacity to welcome and hospitality attractions within a high densification of tourism activities (business tourism, green tourism, sustainable tourism such as *Village Nature* project).

This cluster also bets on the development of a sector of higher education and research dedicated to business tourism, hospitality, leisure with strong interactions between private companies and public agencies. In addition to the university sector, with one or two research laboratories, it will include public or private schools and different degrees from the BTS degrees, Professional Licences (Bachelors), Master and PhD with, for example, a school that will train managers and executives of large groups hotel on the model of the Lausanne's school³¹.

4.3 Territorial Economic Intelligence (TEI)

Economic Intelligence gave birth to another particular approach: Territorial Economic Intelligence (in French : *Intelligence Economique Territoriale*), notably proposed by the French prefect Rémy Pautrat to organize a system that makes sense in a coherent policy to promote growth and employment, linking industrial policies, territories development policies and economic development actions, often most separated at both central and local levels, with a clear lack of coherence and coordination.³²

This Territorial Economic Intelligence can be defined as valuation, coordination and protection of economic assets, industrial and technological know-how on territories and their SMEs networks to transform them into decisive comparative advantages in a now globalized competition.

This approach of TEI wants to propose a unified and coordinated system, with the key role of "*pôles de compétitivité*" to promote regional development. It involves the creation of networks of experts and policy makers, inter-companies and inter-administrative organisations and Local Authorities, but also between government, business companies, universities, schools and the different actors of local economic and social development. It also has a "militant" and training role, according to its founders, essential to help building sustainable competitiveness of French companies.

Note that the Chambers of Commerce and Industry practice activities they describe as "Territorial Watching". In fact, it rather corresponds to activities of Economic Intelligence on a specific territorial area.

The role of government and public powers is crucial. So in November 2013, the Prefecture of Region of Ile-de-France, in partnership with the Interministerial Delegation for Economic Intelligence (C. Revel), held its annual conference on the theme of "*L'Intelligence Economique au service de la recherche et de l'innovation*".

4.4 Strategic Economic Intelligence (SEI)

Another comprehensive formulation of French Economic Intelligence is Strategic Economic Intelligence (SEI) or in French: *Intelligence Economique Stratégique* (IES).

The strategic dimension of EI was already present in the title of the Martre's report (1994). In his preface to the book edited by M.-A. Duval (2008), A. Juillet had already pointed out that "the term of Economic Intelligence is too narrow ... it is likely that the current trend will lead us gradually to a Strategic Intelligence concept, corresponding to apply the methods and tools of economic intelligence in every sector of our environment"³³(in Duval, 2008, 15).

The concept of SEI (Strategic Economic Intelligence) is in this logic.

SEI offers its 12th European Forum on September 2014 on the theme "*L'Intelligence Economique dans la société, les entreprises et les organisations. Les stratégies des acteurs dans un monde en mutation*" in Troyes (France). The different workshops offer to think, in addition to tools and uses of SEI, to the management of crisis, the European dimension of SEI, the success stories of French SMEs, research and territories approaches, and, in partnership with ADBS³⁴ a workshop about to collect and develop the uses of Big Data.

Thematics correspond to the overall perspective drawn by C. Revel (Revel, 2012, 86) of "comprehensive and professional management of economic and geo-economic challenges of globalization in France" to "regain the initiative and intellectual influence and the principle of general interest (Revel, 2012, 231–237)"³⁵.

Each community of researchers and stakeholders (companies leaders, Chambers of Commerce and Industry, experts and consultants): EI, TI, EEI, TEI, SEI ... have their own congresses, seminars, forums, days studies, symposia, often in competition.

4.5 A comprehensive and systemic approach as a synthesis: Strategic, Territorial and Societal Economic Intelligence?

We take the risk of trying to propose a comprehensive and systemic approach in synthesis of the different French approach of EI: Strategic, Territorial and Societal Economic Intelligence (in French: *Intelligence Economique Stratégique, Territoriale et Sociétale*) according to the systemic approach proposed by E. Morin where a system is built by the interactions between all its actors.

The actors were listed by M. Rodriguez³⁶ (2005): Government, Universities, Companies, Associations, Support Organizations ... We more explicitly do reference to Chambers of Commerce and Industry and to Local Authorities.

The different types of watches (technological, commercial, strategic, social ...) (Rouach, 1999, 24–26) correspond to different jobs in the various concerned organizations, which also have the tools and practices that can differentiate them.

These different EI jobs and the different skills covered were defined by a document proposed by the A. Juillet's services (*Référentiel dit de Matignon*) (2005).

Their exercise correspond to different EI situations: forecasting and prospective, support to decision, watching in different areas mentioned, analysis of information ... The concept of situation is essential for us: each EI situation in each organization providing a relevant context for the action can be considered in an approach of "semiotic situational and interactional analysis" (Mucchielli, 2010).

We have recently proposed an approach of Situational Analysis in a case of Territorial Intelligence for the sustainable developed of an area in economic difficulty (Bourret; Meyer, 2014).

5 Innovation's Dimensions

EI has always been linked to innovation. The 12th European forum about SEI offers a workshop on 'leveraging the prospective for innovation. "

The innovation dimension is at the heart of developments over the last 30 years highlighted by G. Gramaccia (2008) cited above. According to L. Ferry (2014), who places in the wake of J. Schumpeter (1942), the "destructive innovation" rather than profit, is the essence of capitalism, constantly offering new products and services destroying the old ones, breaking with traditional values to do the individuals lose their references and only become captive consumers, companies constantly creating new needs. It is also another formulation of "change for change" or "*bougisme*" denounced both by N. Alter and H. Mintzberg.

We consider innovation broadly as proposed by G. Garel (2011) who asked the question of the often difficult relations between management and innovation: "Can we manage innovation? ". Management, as it organizes, finalizes and constrains activity, is it opposite to the innovation needs for freedom and autonomy? Does not the organization impede innovation? He proposed a definition of innovation with which we agree: "Innovation is a new way to create

³³ In French : « *l'expression d'intelligence économique est trop restrictive ... on peut penser que l'évolution en cours va nous mener progressivement vers un concept d'intelligence stratégique consistant à appliquer les méthodes et outils de l'intelligence économique dans chacun des secteurs de notre environnement* ».

³⁴ ADBS: French Association of Professionals of Information and Documentation.

³⁵ In French : « *gestion complète et professionnelle des enjeux économiques et géoéconomiques de la France dans la mondialisation pour « retrouver l'initiative et l'influence intellectuelle et le principe de l'intérêt général* ».

³⁶ Available on : http://fr.wikipedia.org/wiki/Intelligence_%C3%A9conomique

value in a broad sense for customers, users, to the entity responsible for innovation or for the individual". For us, innovation is creating value with all the difficulty of moving from the individual to the collective aspects, from the perspective of daily action highlighted by N. Alter (2005).

Innovation has a territorial dimension. We thus find the perspective outlined by Godet - Durance - Mousli (2010) report to "liberate innovation in the territories" and, in particular, innovation in organizational size and / or social size, with the convergence of 3 concepts: "*métis*", "*reliance*" and "*resilience*." The report emphasized the importance of organizational and societal innovations whereas traditionally in France, mainly technical innovation is valued, then it does not create the most jobs. The report presents many examples that can be called TEI, valorizing in particular the case of local companies in the Vendée's department where the number of job seekers is rather low although Vendée is not having major assets.

Club Méditerranée was an organizational innovation in the service sector with a genuine co-production services between GM (nice members) and GO (nice organizers) in the tourism sector and also with a territorial dimension in all places of implementation of its "villages".

"Club Med" was created in 1950 by Belgian Gérard Blitz. The first villages were established in Majorca, Corfu, Djerba ... Gilbert Trigano joined the club in 1954 for the provision of camping equipment. He was going to impose its brand with a model of entertainment around social mixing and shared activities, corresponding to a form of utopia. Success was at the appointment, particularly in the 1980s, with a strong diversification abroad (USA, Japan, China, Thailand ...).

The success was undermined by the start of the Gulf War (1991) which limited the mobility of travelers and serious plane crash in Senegal with the deaths of people going on holiday in the Club's villages. This turning point also corresponded to Gilbert Trigano's departure, in favor of his son Serge. In 1997, the shareholders appointed P. Bourguignon, former CEO of EuroDisney as the new President. It was replaced in 2002 by Henri Giscard d'Estaing. In 2002, the Agnelli's family (Fiat) majority shareholder in the "Club Med" group sold much of its shares to Accor group, which sold them 2008 "Club Med" has very changed. Restructuring, closures of many "villages", and a target shift to a more selected public. Many of its original followers are no concerned by these developments and ask for changing the name of the company.

Although some aspects have been widely criticized, we can consider that the "Club Med" at least in its initial version, corresponded to a specific approach of Territorial Intelligence and Competitive Intelligence in a period of development of a new Services driven Economy with the need to tackle new societal challenges (expatriation, exoticism, looking for relationships ...) around innovation for sustainable growth and welfare in a Welfare and Leisure Society.

Our systemic approach to EI also has a social dimension. In the continuity of G. Garel's proposal, we consider innovation as "value creation", including people becoming committed actors of their own destiny in an interactionist perspective. So we meet the notions of "reliance" and "resilience" (both of individual people and then collective aspects on a specific territory) in a perspective of sustainable development of territories.

6 Societal Intelligence Dimensions

For us EI also has an important societal dimension.

We distinguish clearly the "societal intelligence" from the "social intelligence" envisaged in particular by M. Perrett (2013). For us, the societal dimension of EI is very different from the definition of customer profiles for marketing approach in EEI.

With specific approaches indeed, for us, EI is also concerned by the area of Social and Solidarity Economy (SSE) in the perspective of Keynesian Welfare State

Social protection is not only a cost (symbolized by the debate on the deficit of the Social Insurance in France), but is also an investment, as outlined D. Libault³⁷ (2012) and a factor of competitiveness for the Nation, contributing to the preservation and development of its human capital. It was already the prospect of Carayon's report (2003) that put in relation business competitiveness and social cohesion in Economic or Competitive Intelligence.

In the perspective outlined by P. Clerc and H. Azoulay (in Duval, 2008), the societal dimension of EI may correspond to initiatives to promote the sustainable development on areas in difficulty, particularly for unemployed young people without particular degrees but with some skills and motivations and living in disadvantaged neighborhoods. In this perspective, the Young Creators of Activities Groups (in French GJC : Groupements de Jeunes Créateurs) that developed around DUCAs (Academic Degrees for Creators of Economic Activities)³⁸ and their role as a lever for development: personal reconstruction by creating their own business, are an interesting experience. There are

³⁷ Dominique Libault: is General Director of French EN3S (National School for Social Security) and former Director of Social Security in the Ministry of Social Affairs.

³⁸ Young Creators of Activity Groups (GJC), are now opened to a broader public. They federate partnerships around DUCAs between University (through its IUT : Institutes of Technology), a local mission dedicated to unemployment (*mission locale*) and often shop management (*boutiques de gestion*). The first DUCA was created by the IUT and the local mission of Melun Senart in 2001. Since others were opened especially in Ile-de-France region with the support of the Regional Council (Marne-la-Vallée, Paris, ...). The GJC (15 nowadays) are federated in a national association: the ANGC (National Association of Crators Groups).

some “success stories” in gardening, specific regional food activities, clothes ... Young creators are very proud of their successes for them and for their family, which gives some hope and meaning to their life.

In its social dimension, our overall approach to EI is anchored firmly in the territories. For us, the territory is shaped by local projects (such as territory or context for action of companies) that contribute to its development, particularly in the economic dimension in sensitive areas, such as in the case of Duca.

These projects correspond to the articulation of two key concepts: the "reliance" and "resilience."

The need for reconstruction of the social tie has been repeatedly emphasized especially by S. Paugam (2010). E. Morin and R. Sainsaulieu particularly stressed the need for "reliance" for our entire society, especially outlining the role of “intermediary organizations” and, in the first place, the voluntary sector of associations (Sainsaulieu, 2001).

The concept of "resilience" is also essential. It appeared in the Physical Sciences as the ability of an element to return to its original shape. It then concerned Psychology. Resilience, understood as personal ability of an individual to bounce back in a situation of difficulty or distress, it has gradually shifted to the notion of collective resilience of a group or a community, to get most recently to the notion of resilience of all actors of a territory (Territorial Resilience). This may be illustrated by Creators Groups. In this perspective, Economic Intelligence joins Territorial Intelligence (Bourret-Meyer, 2014).

The synthesis approach of EI we propose is both an essential tool and a way of thinking and acting to support the organization (especially enterprise) or a national or local community in its evolution, it helps including "*savoir affronter l'incertitude*" which, for E. Morin in the "*Sept savoirs nécessaires à l'éducation du futur*" (1999) is a major issue. In his preface to this book, F. Mayor, then Director General of UNESCO, stressed that "one of the most difficult challenges is to change our ways of thinking in order to cope with the growing complexity, to the rapid change and to the unpredictable" ³⁹. We believe that new approaches of Economic Intelligence, focusing on the creation of meaning, cooperation and trust, both internally and externally, based on a global approach of complexity for decision support, can contribute.

In this perspective we have proposed some ways for an approach of Societal (Welfare) and Territorial of Economic Intelligence in a Services driven Economy to tackle societal challenges around new Innovation for Sustainable Growth and Welfare.

7 Conclusion

In this paper we have proposed a synthetic analysis of new approaches of Economic or Competitive Intelligence and especially Societal, Territorial and Welfare and dimensions of Economic Intelligence in a Services driven Economy in France.

We proposed an extension of Economic Intelligence approaches, which, in its beginnings, focused on the industrial sector to new areas explored in territorial, societal as social cohesion, services' innovation on a territory.

EI, very focused in its beginnings on supporting strategic decision in companies in an industrial economy has gradually concerned the services sector with the management aspects of intangible patrimony and all the aspects of digital economy.

Especially we have presented developments and different positions of EI corresponding to its different possible formulations and specific points of views: Entreprise Economic Intelligence (EEI), Territorial Economic Intelligence (TEI), Strategic Economic Intelligence (SEI) ... We propose a formulation of a systemic approach of a global Strategic, Territorial and Societal Economic Intelligence.

For us, EI is "hologrammatic" (in the words of E. Morin and JL Le Moigne) of the issues for any organization (companies, but also regional or local authorities, national States, experts' organizations ...) in a competitive environment: EI as economic intelligence on territories with all the societal dimension as well as information intelligence as organizational intelligence (with dimensions decision support and risk analysis goals but also innovation, cooperation ...)

The elements of thinking are proposed in the perspective outlined by C. Revel already mentioned (Revel, 2012, 86) of a "complete and professional management of economic and geo-economic challenges of globalization in France" to "regain the initiative and intellectual influence and the principle of general interest (Revel, 2012, 231–237). It was already largely that of Carayon's report who hoped to articulate business competitiveness and social cohesion (solidarity) (Carayon, 2003), which is even more justified in times of economic crisis and that of social ties.

We hope that this broad and societal approach of EI can also allow to contribute to "renew the vision of knowledge societies for peace and sustainable development" (Mansell; Tremblay, 2013) in a Services driven Economy to tackle new societal challenges around Innovation for Sustainable Growth and Welfare.

Introduction

Pour nombre d'économistes, l'entrepreneuriat constitue le moteur du développement économique (croissance économique, création d'emplois et innovation) d'une manière générale et plus particulièrement au niveau local. Mais, le développement de l'activité entrepreneuriale s'appuie également sur un cadre institutionnel approprié (Baumol, 1968,1990). Les politiques publiques peuvent ainsi contribuer à créer un climat des affaires dynamique dans un espace territorial donné. Cette question a été à l'origine depuis une vingtaine d'années de l'apparition d'une grande variété de concepts reliant entrepreneuriat et développement territorial, et plus particulièrement dans un cadre urbain ; la ville étant ayant historiquement joué un rôle économique majeur (Braudel, 1979).

Les concepts de « ville entrepreneuriale » et de « ville durable » ont ainsi été élaborés depuis le début des années 2000, d'abord pour montrer que les initiatives entrepreneuriales prennent place dans un espace géographique donné, dans un cadre institutionnel approprié (Levratto, Torres, 2010), et deuxièmement qu'une ville durable repose sur les trois items du développement durable (efficacité économique, éthique sociale et préservation de l'environnement (Jansson, 2013) et qu'elle constitue le modèle approprié pour répondre aux défis à venir sur le plan urbain en alliant étroitement développement économique, initiative individuelle et protection de l'environnement.

Ce focus sur la ville entrepreneuriale et la ville durable montre l'importance, s'il n'était nécessaire, de la localisation géographique des activités économiques : la ville est en effet appréhendée dans le cadre de ces deux concepts comme un cadre approprié pour le développement d'activités économiques. Cependant, sans remettre en question l'importance au cadre territorial, la référence à la ville stricto sensu nous apparaissant trop restrictive (les frontières urbaines étant essentiellement de nature administrative), nous avons donc opté pour le vocable de territoire, plus générique, tout en conservant le principe d'une combinaison entre entrepreneuriat et préservation de l'environnement. Nous définissons dans ces conditions, le territoire entrepreneurial durable de manière à combiner les notions de ville entrepreneuriale et de ville durable dans un même concept. Un territoire est par conséquent un territoire (soit un espace géographiquement défini) dont le développement repose sur un cadre institutionnel propice à la création d'éco-entreprises et au développement d'éco-activités, ces dernières étant appréhendées comme la source d'une croissance économique à venir respectueuses des ressources naturelles, voire à l'origine d'une troisième révolution industrielle (Demailly, Verley, 2013 ; Rifkin, 2012), combinant à la fois croissance économique, amélioration du bien-être et protection de l'environnement. La création d'éco-entreprises est, dans ce cadre, perçue comme étant le moyen de générer des activités nouvelles respectueuses de l'environnement (York, Venkataraman, 2010), outre le fait que la réglementation environnementale (Porter, Van der Linde, 1995) oblige les entreprises existantes à adopter des modes de fonctionnement plus respectueux de l'environnement. L'initiative individuelle et la régulation publique sont dans notre propos complémentaires, non substituables.

Notre objectif est d'appliquer cette grille de lecture à l'étude d'un territoire particulier, celui de l'agglomération urbaine de Dunkerque (CUD)⁴⁰ située dans le département du Nord de la France, sur le littoral de la Mer du Nord. Ce territoire présente la particularité de s'être développé à partir des années 1960 (et pour une large part à l'heure actuelle également) sur une trajectoire techno-industrielle reposant sur des actifs spécifiques (industrie sidérurgique et métallurgique, puis pétrochimique) qui a imprimé sur plusieurs décennies un développement économique et social local, reposant notamment le salariat ouvrier. La crise de la sidérurgie et des chantiers navals des années 1970, puis le ralentissement de la croissance économique des années 1990, ont conduit les responsables publics à chercher à définir une nouvelle stratégie de développement reposant d'une part sur la diversification des activités industrielles et de l'entrepreneuriat d'autre part, alors que la CUD a développé depuis les années 1990 une politique publique visant à réduire la pollution industrielle, très importante dans l'agglomération.

Dans un contexte économique marqué par une croissance faible, un taux de chômage élevé et des problèmes environnementaux importants, nous nous sommes interrogés sur la possibilité de ce territoire de changer de trajectoire techno-industrielle, de l'industrie lourde et le travail ouvrier salarié, vers un développement économique plus respectueux de l'environnement reposant sur la création d'éco-entreprises. Pour ce faire, nous avons cherché à identifier les ressources entrepreneuriales de ce territoire et les modalités de leur mobilisation. Nous procéderons donc en deux

⁴⁰ La Communauté urbaine de Dunkerque regroupe 18 communes, totalisant environ 200 000 habitants : Dunkerque, Armbouts-Cappel, Bourbourg, Bray-Dunes, Capelle-la-Grande, Coudekerque-Branche, Coudekerque-Village, Craywick, Ghyvelde, Grand-Fort-Philippe, Grande-Synthe, Gravelines, Leffrinckoucke, Loon-Plage, Saint-Georges-sur-l'Aa, Spycker, Tétéghem, Zuydcoote.

temps. Nous présenterons dans un premier notre cadre théorique pour définir le territoire entrepreneurial durable et les indicateurs qui s'y rattachent, pour confronter dans un second temps cadre théorique avec la réalité économique du territoire dunkerquois.

1 Le territoire entrepreneurial innovant : vers la construction d'un cadre théorique

1.1 Cadre d'analyse et concepts

1.1.1 De l'économie territoriale à l'économie des proximités

L'activité économique ne se développe pas de façon homogène au niveau d'un territoire donné. Les raisons de ce développement inégal sont complexes, et ne résident pas uniquement dans la présence ou l'absence de ressources (humaines, naturelles, ou autres). La question du développement économique des territoires, mais également de leur capacité à innover, est explorée par les économistes depuis la fin du 19^{ème} siècle, avec l'accélération de l'industrialisation (Verley, 1997), depuis les travaux fondateurs de von Thunen (2009), Weber et surtout Marshall (1890) dont les économistes ont largement repris et développé les concepts (effets d'agglomération, externalités, etc.) depuis les années 1970. Les théories sur les milieux innovateurs du GREMI pendant les années 1980 ont en effet clairement mis en évidence l'étroit lien entre la dynamique des entreprises présentes sur un territoire et le territoire dans lequel elles sont insérées (Claval, 2008).

Ces considérations nous conduisent à mettre l'accent sur la proximité qui se décline sur différents modes : la proximité est à la fois géographique et organisée par les acteurs économiques insérés dans ledit territoire (Torre, Rallet, 2005 ; Uzunidis, 2010). La proximité géographique désigne en règle générale la distance qui sépare deux agents économiques ou deux entreprises. La proximité organisée se réfère aux réseaux de relations sociales entre différentes entités. Citons à titre d'exemple une entreprise organisant le territoire géographique dans lequel elle est insérée en développant des relations marchandes avec d'autres entités ou des relations sous-traitance industrielle. De la proximité géographique et organisationnelle découle la proximité cognitive entre les agents économiques, sur laquelle nous reviendrons ultérieurement.

L'ensemble de ces notions et concepts forme un corpus, l'économie territoriale, qui se définit aux niveaux géographique et économique. Son objectif est précisément de répondre à trois questionnements : a) comment est organisée la production (quelle est par exemple la part respective de grandes et de petites entreprises ?), b) comment les agents économiques présents sur un territoire innoveront ? Et c) quel est le degré d'attractivité du territoire en matière d'investissements, mais également pour la création d'entreprises nouvelles ? En d'autres termes : comment les ressources et les relations de proximité contribuent-elles à la création d'entreprises d'une part et à améliorer les performances des entreprises existantes d'autre part ? Mais, également comment les entreprises utilisent cette proximité pour exister et croître ?

L'économie territoriale est une discipline scientifique complémentaire de la géographie économique. Celle-ci a développé trois types de proximité auxquelles nous nous référerons dans le cadre de notre analyse : a) géographique (distance), b) économique (relations) et c) organisationnelle (normes et comportements des acteurs économiques – entrepreneurs et entreprises), d'où écoulent deux concepts majeurs : a) les effets externes produits par le territoire par les relations entre les entreprises, ainsi que par d'autres acteurs (relations verticales et/ou horizontales – *supply chain* – formant ensemble une niche de compétitivité grâce à la présence de ressources spécialisées, d'informations, etc. b) Les effets d'agglomération produits par le regroupement spatial d'entreprises (Isnar, 1956), lesquels ont un impact majeur sur la croissance démographique, le développement d'infrastructures, de services aux entreprises, etc., car ils sont porteurs d'externalité positives (réduction de coûts unitaires pour les firmes quelle que soit leur taille).

Ces questions nous conduisent à nous interroger à la fois sur la réalité de l'entreprise (en tant qu'organisation) et de l'entrepreneur (en tant que fonction économique et d'innovation) ? Nous définissons l'entrepreneur comme l'agent économique qui crée un réseau de relations socio-économiques duquel il extrait les ressources en connaissances et financières dont il a besoin pour créer de nouvelles idées et de nouveaux marchés. L'entrepreneur contribue au rayonnement économique d'un territoire, dont il extrait par ailleurs les ressources dont il a besoin.

Partant de ces considérations, nous définissons le modèle du territoire entrepreneurial durable (TED), comme une combinaison des trois types de proximité évoqués ci-dessus : spatiale, organisationnelle et cognitive, l'ensemble de ces proximités participe ainsi à la création d'externalités positives, sources de productivité et d'innovations (produit, procédé, organisationnelle). La proximité spatiale se caractérise par la réduction des distances (et du temps) qui séparent physiquement les acteurs économiques ; condition permissive au développement de relations de reconnaissance et d'inter-reconnaissance entre ceux-ci. La proximité organisationnelle est définie par l'appartenance à une même organisation (entreprise, laboratoire de R&D, université, service à l'intérieur d'une même organisation ou administration, etc.), à un même réseau (intra-organisationnel et/ou inter-organisationnel) ou, plus largement à une même « communauté de destin » (Uzunidis, 2010). La proximité cognitive renvoie à l'adhésion des acteurs à une même conception de l'innovation, au même paradigme (technologique et/ou organisationnel), aux mêmes routines, heuristiques, algorithmes de pensée, conventions, traditions, croyances, codes internes, langages et/ou procédures d'apprentissage, de délibération, de prise de décision et de gouvernance (Depret, Hamdouch, 2004). Elle se situe donc au sein même des organisations, des réseaux et des communautés.

Les relations de proximité contribuent à la coordination du processus d'innovation (Madeuf et al., 2005). Celui-ci, à la fois flexible et évolutif, impose à l'entreprise ou à l'entrepreneur le besoin impératif de disposer des différents types de moyens technologiques et intellectuels, d'acquérir et de combiner en permanence des ressources matérielles et immatérielles. D'un autre côté, la théorie de la connaissance appliquée à l'entreprise nous enseigne que la capacité d'adaptation et l'efficacité de l'entreprise dépendent de ses capacités cognitives, de ses codes d'interprétation de l'information elle-même, de ses compétences et de ses procédures mises en œuvre pour la résolution des problèmes qu'elle rencontre (Dosi et al., 1999). L'information scientifique, technique et industrielle constitue un système de connaissances (capital savoir) qui sont articulées, formalisées et susceptible d'être communiquée ou transférée. Ce système est un moyen de production identifiable en tant que tel (Laperche, 2001, 2007). Son utilisation est source d'innovation dans le déroulement normal du processus de production. La tâche du dirigeant ou de l'entrepreneur consiste donc à trouver l'équilibre entre la gestion des partenariats et le développement des instruments internes de l'organisation (Laperche, et al., 2006). Pour survivre et se développer une entreprise doit acquérir de nouvelles connaissances, grâce auxquelles elle pourra créer de nouvelles compétences.

Largement fondé sur la thèse de Marshall, Piore et Sabel (1984) avaient construit un modèle de la production flexible où la proximité reposait sur des relations multidirectionnelles et horizontales. La dynamique de l'évolution des structures et de l'organisation du système local de production met en évidence l'importance des petites entreprises. Plus flexibles et plus adaptables, elles sont plus aptes que les grandes à renouveler le système local et productif et à créer de nouveaux emplois. En outre, la proximité entre les grandes et les petites entreprises sont aussi encadrées dans le système social et politique local. Les institutions sociales locales (Etat, collectivités territoriales, entreprises) tiennent un rôle significatif dans l'organisation et l'évolution de l'activité économique au niveau d'un territoire géographique donné. Cet espace a en effet été façonné au cours du temps par des rapports de pouvoir, des rivalités, des relations de concurrence et de coopération entre les acteurs (Benko, Lipietz, 2000) qui ont contribué à façonner son image, sa bonne ou sa mauvaise réputation. Ainsi, la région du Nord-Pas de Calais dans laquelle se situe la CUD a été façonnée depuis le 19^{ème} siècle (et même bien avant, dès la Renaissance) par une activité industrielle intense (textile, sidérurgie, extraction houillère, etc.), qui en a fait l'une des régions pionnières de l'industrialisation française. A l'heure actuelle, ce passé industriel est encore bien présent, pas seulement dans les friches industrielles (dont nombre sont depuis devenues des hauts lieux du patrimoine industriel et culturel de la région), mais dans le poids relativement important des grandes entreprises industrielles (par rapport à la moyenne nationale) et par son corollaire, le poids relativement important de la population salariée ouvrière.

1.1.2 La proximité spatiale

La prise en considération de la proximité spatiale consiste à mettre l'accent sur le raccourcissement des distances géographiques entre les acteurs économiques (entre les entreprises elles-mêmes, entre les entreprises et les institutions publiques). Ce rapprochement géographique, voir l'« atmosphère industrielle » qui en est le produit (Marshall, 1890, 1958), a clairement été identifié par nombre de chercheurs en économie et en géographie comme étant propices à l'innovation et à la créativité. Les théories des milieux innovateurs (Maillat, Perrin, 1992) et les clusters (Porter, 1998, 2003), s'appuyant sur cette observation, mettent en évidence dans leurs travaux la capacité d'un territoire à innover en prenant en considération l'émergence de nouvelles entreprises en tant que telles et la création d'entreprises nouvelles par des firmes existantes et/ou des institutions publiques de recherche par exemple, résultant précisément de cette proximité géographique.

Le territoire se présente alors comme un système territorialisé de valorisation de capitaux, de production et d'échanges (marchandises, d'informations, de capitaux, de connaissances, etc.). Sa caractéristique principale est la formation et la mise en valeur des ressources spécifiques et la réalisation des combinaisons particulières de ces ressources spécifiques. Cette approche intègre à la fois les relations inter-entreprises et l'intervention des acteurs institutionnels que nous avons évoquée plus haut.

1.1.3 La proximité organisationnelle

La proximité spatiale façonne les comportements entrepreneuriaux et institutionnels, contribuant à créer des relations synergiques entre les acteurs. L'environnement de l'entreprise est alors considéré comme un ensemble de ressources qui relie les différentes composantes de la firme, séparées verticalement ou horizontalement par la division du travail.

La théorie des réseaux consiste à replacer l'entreprise dans son environnement. Cet environnement est riche et ne se réduit pas à des relations marchandes. Camagni (1991) appréhende ainsi l'environnement de l'entreprise comme un ensemble de ressources qui relie les différentes composantes de la firme organisée verticalement ou horizontalement par la division du travail. L'environnement de la firme (quelle que soit sa taille) n'est pas alors considéré comme une donnée naturelle, voire neutre, mais il est perçu comme le produit de décisions prises par les acteurs économiques. Les firmes contribuent ainsi à façonner par leurs décisions l'environnement économique et social dans lequel elles sont encadrées.

Selon le contexte économique (caractérisé par un taux de croissance économique donné), les entreprises vont soit opter pour une organisation concentrée ou au contraire déconcentrée. Toute firme peut être amenée par exemple à déconcentrer son activité en fonction des effets d'agglomération du territoire dans lequel elle est insérée. Ces effets

d'agglomération vont générer des externalités en matière de communication et d'information. Ils vont aussi contribuer à la diversification de l'offre (via une stratégie plus fine en matière de division du travail), élargir le marché du travail (besoin de nouvelles qualifications et/ou compétences). On observe un double phénomène, d'une part un phénomène de la localisation de nature centripète, d'autre part de nature centrifuge. Le premier contribue au regroupement des activités pour exploiter les économies d'échelle, ainsi générées, le second contribue à la dispersion dans un espace géographique donné de l'activité économique, pour tirer profit des effets de spécialisation et des économies d'échelle qui en découlent.

Cependant, la proximité organisationnelle ne se limite pas aux seules firmes et aux stratégies qu'elles développent pour capter des nouvelles ressources, elle émane également des institutions (publiques pour une large part) qui interviennent pour stimuler et/ou accompagner la création d'entreprises. Les collectivités territoriales (au niveau local, régional ou autres) se livrent à des opérations de surenchères pour attirer des entreprises et/ou des entrepreneurs, pour générer des activités nouvelles. Le concept très connu de la classe créative (Florida, 2003) participe cet état de faits, la réussite économique des villes en particulier (de territoires en général) serait en effet liée à leur capacité d'attirer des acteurs économiques créatifs (par exemple des diplômés de haut niveau), porteurs de nouveauté et de créativité en ce début de siècle, période où l'activité économique reposerait en priorité sur des savoirs de haut niveau (tableau 1).

Tableau 1. La classe créative de R. Florida.

<p>Eléments de définition de la « classe créative »</p> <p>Corrélation positive entre la croissance économique des villes et l'existence en son sein d'une classe créative. Une classe créative est composée d'individus créatifs hautement diplômés, des individus engagés dans la résolution de problèmes inédits, s'appuyant sur des connaissances complexes et des individus impliqués dans les professions des arts, de la mode, du design, etc. La classe créative contribue à créer un « people climate ». Pour se développer une ville doit être en capacité d'attirer des talents. Les « 3T » : Talent, Technologie, et Tolérance.</p>

Source : Florida, 2002.

1.1.4 La proximité cognitive

La proximité cognitive renvoie au partage plus ou moins formalisé d'expériences, de représentations, codes, langages, modèles qui résultent de, et facilitent dans le même temps la communication de toute information au sein des organisations. La proximité cognitive s'appuie sur un réseau dense de relations sociales que nous avons évoqué plus haut (proximité organisationnelle). Par ailleurs, les firmes produisent des flux d'information en leur sein (entre les différents services constituant une entreprise), une partie de celles-ci est aussi diffusées vers l'extérieur (vers d'autres entreprises ou des institutions publiques, mais aussi les consommateurs). La proximité cognitive est facilitée par les proximités spatiale et organisationnelle et contribue notamment à la création de communautés de pratiques, via l'atmosphère industrielle évoquée plus haut.

1.2 Le territoire entrepreneurial durable, cadre théorique et définitions

1.2.1 Une définition générique

Partant de ces considérations préalables, le territoire entrepreneurial durable (TED) repose sur l'interaction de quatre items qui découlent des trois types de proximité que nous avons énoncés : a) politique publique et réglementation (fiscalité, conseil, financement, etc.), b) entrepreneuriat et le potentiel de ressources de l'entrepreneur (création d'entreprises, développement des entreprises existantes, opportunités entrepreneuriales, etc.), c) innovation et ressources technologiques (programme de recherche & développement (R&D), relations de coopération entre les entreprises et/ou les universités et/ou les centres de recherche) et d) le climat économique propre au territoire (taux de croissance économique, part des petites et moyennes entreprises par rapport au nombre total d'entreprises, etc.). Ces quatre items interagissent de manière synergique au niveau d'un espace spatial donné, soit d'un territoire donné (figure 1).

Figure 1. Le territoire entrepreneurial durable (TED).

Le concept du territoire entrepreneurial durable réunit les trois formes de proximité (spatiale, organisationnelle et cognitive) précédemment décrites. L'activité économique se déroule dans un cadre géographique donné (le territoire). Les acteurs privés et publics organisent ce territoire, pour les premiers en développant des activités ou en en créant de nouvelles. Les seconds définissent des politiques de développement dont l'objectif est de favoriser le développement d'activité. La proximité organisationnelle s'appuie et contribue à nourrir la proximité cognitive entre les acteurs économiques et institutionnels, favorisant l'innovation et la création d'activités. S'agissant d'un territoire entrepreneurial durable, l'objectif n'est pas seulement de créer des activités nouvelles en général, mais des éco-activités en particulier.

1.2.2 Le Territoire entrepreneurial durable : quels indicateurs ?

A partir de cette définition générique du territoire entrepreneurial durable, nous avons retenu (via la figure 1) un ensemble d'indicateurs pour l'évaluer (tableau 4). Dans le tableau ci-dessous, nous avons distingué quatre items : 1) le contexte entrepreneurial et le climat des affaires, 2) le contexte institutionnel en faveur de l'entrepreneuriat, 3) le contexte environnemental et 4) le contexte technique et scientifique.

- 1) L'item « contexte entrepreneurial et le climat des affaires » regroupe des informations relatives à la fois sur la densité du tissu économique local (concentré ou décentralisé via la part des PME par rapport au nombre total d'entreprises), le dynamisme entrepreneurial (taux de création d'entreprises), enfin il faut aussi prendre en compte la durée de vie des entreprises et la part de la population activité salariée par rapport à l'emploi total. Même s'il est possible d'exercer une activité entrepreneuriale en tant que salarié (e), la part des travailleurs indépendants est un bon indicateur de l'activité entrepreneuriale dans un territoire, quelle que soit la taille de celui-ci.
- 2) L'item « contexte institutionnel en faveur de l'entrepreneuriat » permet d'évaluer la capacité d'un territoire donné à créer un contexte favorable à la création d'entreprises et à leur développement. Nombre de travaux de recherche ont montré l'importance du contexte institutionnel pour soutenir et encourager l'entrepreneuriat depuis les travaux fondateurs de Baumol (1990, 1993). Par le biais de mesures de politique publique et par la mise en œuvre d'une réglementation appropriée, les comportements individuels sont orientés de manière par exemple à soutenir les initiatives individuelles. Les institutions formelles et informelles doivent être distinguées. Les premières sont celles qui sont précisément créées par le biais de mesures de politique publique comme énoncé plus haut. Les secondes découlent de la proximité cognitive et sont façonnées par les coutumes, les traditions, les valeurs, etc. et forment l'encastrement socio-économique dans lequel sont insérés les acteurs économiques : les autorités locales ont-elles mis en place des mesures de sensibilisation à la création d'entreprises vis-à-vis de publics divers comme par exemple les jeunes, les personnes âgées, etc. Pour les personnes ayant un projet plus ou moins arrêté, des agences de conseil et de suivi à la création ont-elles été prévues ? Quel est leur rôle par exemple en matière de financement, pour monter le business plan ? La période de suivi s'arrête-elle dès la création de l'entreprise ou se poursuit-elle pendant plusieurs années ? Nous sommes en ce sens proche de la définition de la ville entrepreneuriale adoptée par Levratto et Torres (2010). Mais, d'autres éléments peuvent également être pris en considération, comme la taille de la ville (les grandes villes

sont-elles plus dynamiques en matière d'entrepreneuriat ?), l'initiative individuelle et l'enseignement supérieur (Barreneche Garcia, 2014). Cette conception de la ville entrepreneuriale met implicitement en évidence une très vieille idée que les utilitaristes, comme C. Beccaria ou P. Verri, avaient développé dès le 18^{ème} siècle selon laquelle en substance le marché n'est jamais saturé, mais que la dynamique entrepreneuriale est cumulative. On retrouve cette idée dans la définition de la Fédération canadienne de l'entreprise indépendante (FCEI) (Mallett, Gaudreault, 2013) selon laquelle les villes qui sont aujourd'hui des villes entrepreneuriales le sont parce qu'elles étaient déjà dans le passé, les premiers habitants ayant cherché à exploiter avec efficacité les ressources dont ils pouvaient disposer dans le territoire qui est devenu la ville entrepreneuriale dynamique actuelle. La FCEI classe les villes canadiennes à partir de 14 indicateurs répartis en trois groupes définis comme suit : a) présence, c'est-à-dire une représentation de l'importance et de la croissance de l'entrepreneuriat et de la diversité industrielle, b) perspective, soit des indicateurs associés à l'optimisme et aux plans de croissance et c) politiques, soit les indicateurs associés aux mesures prises par les administrations municipales en matière d'imposition et de réglementation des entreprises (tableau 2). La particularité de l'étude canadienne est de combiner à la fois des données statistiques, des faits et sondages d'opinion. Contrairement à la conception de Levratto et Torres (2010) (tableau 2) et de Barreneche (2014), la FCEI ne mentionne pas la présence d'institutions d'enseignement supérieur et/ou d'universités, elle est davantage orientée vers sur le dynamisme entrepreneurial existant et sur les modalités de l'action publique au niveau du territoire urbain.

Tableau 2. La ville entrepreneuriale : éléments de définition.

<i>Critères de définition de la ville entrepreneuriale selon le classement de la fondation ECER (European Cities Entrepreneurship Ranking)</i>
Promotion : événements, université, guides, NTIC, etc. Anté-crédation : viabilité du projet prévisionnel d'activité, services juridiques, formations, etc. Post-crédation : services, gestion opérationnelle, accès études, durée d'accompagnement, etc. Financement : soutien des organismes publics, investissements privés, fonds de garanties, aides publiques, etc. Environnement économique : transport, énergie et développement durable, amélioration urbaine, cadre de vie, capital connaissance, disponibilité compétences, réseaux, immobilier d'entreprise, etc.
<i>Les trois déterminants d'une ville entrepreneuriale d'Andrés Barreneche Garcia</i>
Taille de la ville Initiative individuelle Institution d'enseignement supérieur

<i>Présence</i> Augmentation des établissements commerciaux Etablissements commerciaux par habitant Taux d'emploi indépendant en pourcentage de l'emploi total Entreprise du secteur de l'information et de la culture <i>Perspective</i> Prévision du rendement des entreprises Attentes relatives à l'embauche de salariés à plein temps Etat général de l'entreprise Permis de construction d'établissements commerciaux, industriels et institutionnels Satisfaction à l'égard de la vie <i>Politiques</i> Equilibre fiscal de l'administration municipale Coût de l'administration municipale Sensibilisation de l'administration municipale aux petites entreprises locales Rendements municipaux Présence d'outils d'information en ligne pour les permis et les licences Evolution par rapport à 2012

Source : Levratto, Torres, 2010.

Le principe du concept de la ville entrepreneuriale vise en définitive à expliquer comment l'entrepreneuriat se développe dans un cadre urbain déterminé en particulier en mettant l'accent sur les moyens d'accompagnement à la création d'entreprise, mais également à l'environnement économique dans lequel se développe l'activité entrepreneuriale, y compris en soulignant l'importance des institutions d'enseignement supérieur (Levratto, Torres, 2010 ; Barreneche, 2014).

Le concept récemment développé par Acs et al. (2014) du système national de l'entrepreneuriat, qui part d'une réflexion critique sur le concept très connu du système national d'innovation est riche d'enseignement. Les auteurs partent de l'observation selon laquelle le concept du système national d'innovation ignore l'entrepreneur, qui est pourtant un acteur fondamental de l'innovation, en référence aux écrits de Schumpeter, de Kirzner et Von Mises sur lesquels s'appuient principalement Acs et al. (2014, p. 479). Ces derniers définissent le système national de l'entrepreneuriat comme suit : la dynamique, institutionnellement intégrée d'interactions entre des attitudes entrepreneuriales, la capacité et les aspirations par des individus, en qui entraîne l'affectation de ressources vers la création d'entreprises et de nouvelles activités entrepreneuriales. Le système national de l'entrepreneuriat se définit par conséquent comme un ensemble d'interactions systémiques dans un cadre institutionnel préalable défini pour soutenir l'activité entrepreneuriale précisément. Les auteurs ont réuni pour ce faire 18 indicateurs (tableau 3). Ces indicateurs sont placés dans un contexte institutionnel qui prend en compte 17 autres indicateurs⁴¹.

L'objectif d'Acs et al. (2014) est de réunir les données nécessaires pour construire un modèle économétrique (ce qui n'est pas notre intention à ce stade de notre recherche). Pour notre part, nous en avons tiré quelques éléments pour construire le modèle du territoire entrepreneurial durable.

Tableau 3. Les indicateurs du système national d'entrepreneuriat.

Indicateur	Description
Reconnaissance des opportunités	Pourcentage de la population âgée entre 18 et 64 ans indiquant qu'elle pense qu'il y aura de bonnes opportunités entrepreneuriales dans leur région et qu'elle les réalisera au cours des six mois à venir
Qualification	Part de la population âgée entre 18 et 64 ans déclarant avoir les connaissances et les qualifications pour créer une entreprise
Attitude face au risque	Part de la population âgée entre 18 et 64 ans indiquant que la peur de la faillite ne doit pas les empêcher de créer une entreprise
Situation des entrepreneurs existants	Part de la population âgée entre 18 et 64 ans qui connaissent personnellement une personne qui a créé une entreprise au cours des deux dernières années
Carrière	Part de la population âgée entre 18 et 64 ans qui pensent que créer une entreprise est un bon choix de carrière
Statuts	Part de la population âgée entre 18 et 64 ans qui accordent aux entrepreneurs qui réussissent un haut statut social
Statuts et carrière	Moyenne entre les deux indicateurs précédents
Motivation	Taux de création d'entreprises créées par une opportunité d'affaire
Entreprises créées par des femmes	Part des femmes créatrices par rapport au nombre total d'entreprises
Niveau technologique	Part des entreprises créées dans des secteurs de moyenne ou de haute technologie
Niveau d'éducation	Taux de création d'entreprises créées par des dirigeants ayant suivi des études secondaires
Concurrents	Taux d'entreprises créées dans des marchés où beaucoup d'entreprises n'offrent pas le même produit
Nouveaux produits	Taux d'entreprises créées qui offrent des produits nouveaux pour au moins quelques consommateurs
Nouvelles technologies	Taux d'entreprises créées utilisant des technologies de moins de cinq ans
Présence de gazelles	Taux d'entreprises créées ayant un taux élevé en matière d'emploi (qui attendent d'avoir plus de 10 salariés en cinq ans)
Exportation	Taux d'entreprises créées exportant une partie de leur production
Investissement informel	Montant moyen de l'investissement informel par personne au cours de trois dernières années
Présence de Business angels	Part de la population âgée entre 18 et 64 ans réunissant des fonds pour soutenir la création d'entreprises par d'autres entrepreneurs

⁴¹ Marché intérieur, urbanisation, marché de l'agglomération, éducation supérieure, risque d'affaire, usage d'Internet, corruption, libéralisme économique, égalité des sexes, capacité d'absorption de nouvelles technologies, formation du personnel, dominance du marché, dépenses nationales de RD, stratégie des entreprises, globalisation et taille du marché des capitaux.

Mais dans notre cas, s'agissant d'un territoire entrepreneurial durable, nous serons attentifs au fait que les autorités locales privilégient par une politique de soutien adéquate la création d'éco-entreprises, ceci en liaison à la fois avec l'item du contexte environnemental, mais également du tissu économique local (industriel, tertiaire, concentré, etc.). La politique d'accompagnement des entreprises peut être prolongée par la création de zones d'activité (éco-zone, parcs scientifiques ou autres), combinant à la fois proximité spatiale et organisationnelle.

- 3) L'item « contexte environnemental » apporte des informations sur la capacité d'un territoire en faveur de l'environnement : quelle est sa politique en matière de développement durable et pour protéger la biodiversité ? Des moyens financiers sont-ils alloués en ce sens de manière également à sensibiliser la population à cette question. Enfin, un ensemble d'autres questions doivent être étudiées, telles que l'existence d'une politique au niveau locale particulière active en matière d'énergies renouvelables, ou encore pour privilégier l'éco-construction (au-delà de la réglementation en la matière), le tri sélectif et le traitement des déchets ménagers ou encore la mise en œuvre d'une politique en faveur de l'écologie industrielle, en coopération avec les acteurs privés présents sur le territoire. La définition de la ville durable est assez complexe, sauf à appliquer les trois piliers du développement durable : efficacité économique, intégration sociale et protection de l'environnement.

Le concept de la ville durable suscite de nombreuses controverses et fait l'objet de définitions très variées (tableau 4). Il est bien antérieur au concept de développement durable lequel remonte au rapport Brundtland à la fin des années 1980. Le concept de la ville durable tire ses racines d'une réflexion beaucoup plus ancienne qui remonte aux années 1960-1970 voire au début du 20^e siècle avec les travaux de l'urbaniste Patrick Geddes (1915). Celui-ci considérait que les processus sociaux et la formes qu'ils prennent dans l'espace sont liés et qu'en modifiant la forme il était possible de modifier la structure sociale. Ces premières approches de la ville durable sont très intéressantes car elles mettent l'accent sur deux points qui sont largement plébiscités à l'heure actuelle : d'une part l'autosuffisance, on parlerait aujourd'hui de circuits courts, d'autre part sur la qualité de l'environnement physique et par conséquent de la qualité de vie des habitants, éléments que nous retrouvons dans le concept actuelle de la ville durable, en sachant et comme le souligne la Charte d'Aalborg : « chaque ville étant différente, c'est à chacune qu'il appartient de trouver sa propre chemin pour parvenir à la durabilité » (cit  par Emelianoff, 2007, p.52).

Les définitions de la ville durable par les chartes européennes ont largement mis l'accent sur les aspects sociaux, c'est notamment le cas de la Charte d'Aalborg (1994). La Charte de Leipzig (2007) met notamment l'accent sur la lutte contre les inégalités par exemple en créant et/ou préservant des espaces publics de qualité, en développant un système de transport urbain et en renforçant l'économie locale. Le ministère de l'écologie en France par la circulaire du 23 mars 2009 relative à la Territorialisation de la mise en œuvre du Grenelle de l'environnement a créé les éco-cités qui repose sur les trois piliers du développement durable : économique, social et écologique. Tout comme les éco-quartiers, mais à une échelle moins importante sur le plan territorial.

Tableau 4. La ville durable : une large gamme de définitions.

<i>Les trois piliers de la ville durable (à partir de Attour, Depret, 2014)</i>
Dynamisme économique : créativité, innovation, entrepreneuriat et attractivité Intégration des communautés : emploi local, mieux vivre ensemble, démocratie participative, préservation du patrimoine Protection de l'environnement et amélioration du cadre de vie des habitants
<i>Définition de la ville durable par David Morris (1982) (Emelianoff, 2007)</i>
Le développement autosuffisant est un développement qui stimule la capacité à satisfaire localement les besoins fondamentaux. Une ville qui réussit sur le plan du développement durable est une ville dont les nombreux et divers objectifs des habitants et des entreprises sont atteints sans que le coût en soit supporté par d'autres personnes ou d'autres régions
<i>Définition de la ville durable par G. Haughton et C. Hunter (1994) (Emelianoff, 2007)</i>
Une ville durable est une ville dans laquelle les habitants et les activités économiques s'efforcent continuellement d'améliorer leur environnement naturel, bâti et culturel, au niveau du voisinage et au niveau régional, tout en travaillant de manière à défendre toujours l'objectif d'un développement durable global.
<i>Définition de la ville durable par Cyria Emelianoff (2007)</i>
Une ville capable de se maintenir dans le temps, de garder une identité, un sens collectif, un dynamisme à long terme Une ville offrant une qualité de vie en tous lieux et des différentiels moins forts dans les cadres de vie, exigeant une forte mixité sociale et fonctionnelle Une ville d'où émerge un projet politique et collectif, dans la ligne de l'Agenda 21 de Rio (article 28). La ville durable ne doit pas exporter les coûts d'urbanisation et son développement sur les autres populations, les générations futures ou sur les écosystèmes. La ville durable doit combiner qualité de vie, réduction des inégalités sociales et réductions des inégalités écologiques. Pour cela un projet global est nécessaire.

A partir de ces définitions assez globales de la ville durable, des chercheurs ont entrepris de définir une grille de lecture pour classer des villes en fonction de leur degré de durabilité. Tanguay et al (2010) ont regroupé les indicateurs suivants sous les trois piliers du développement durable (tableau 5). A partir des grandes catégories qui sont ci-dessous identifiées, des informations plus précises sont recensées, comme par exemple la densité de la population urbaine, la qualité des déchets, le taux de criminalité, la participation de la population à l'administration des affaires publiques, le nombre de ménages ayant un faible revenu, la qualité des déchets recyclés, le taux de diplômés dans la population âgée de plus de 18 ans, etc. La multiplication du nombre de variables présente l'avantage d'un modèle plus précis permettant de cerner tous les aspects d'une ville durable. Mais, la multiplication du nombre de variables peut également conduire à complexifier inutilement le modèle.

Tableau 5. Définir la ville durable par des indicateurs économiques, sociaux, institutionnels et environnementaux.

<i>Dimension du développement durable</i>	<i>Indicateurs</i>
Economique	Revenus et dépenses des ménages Emploi et chômage Activités économiques
Social et institutionnel	Démographie Habitat Education Sécurité Santé Bien-être Services sociaux Gouvernance Budget des administrations publiques
Environnemental	Energie Transport Qualité de l'air Bruit Eau potable Espaces verts, écosystème et patrimoine Déchets

Source : Tanguay et al.,2010, p. 411.

- 4) Le « contexte technique et scientifique » permet de réunir des informations sur la capacité scientifique et technique du territoire, sur ses ressources scientifiques et techniques. Existe-il sur le territoire une université, des centres de recherche, publics ou privés, des écoles d'ingénieurs ? Quel est le taux de diplômés ? Ce point est rarement abordé en tant que tel, sauf à mettre explicitement l'accent sur les structures de l'enseignement supérieur comme nous l'avons vu ci-dessus.

Dans le tableau 6 nous avons réuni l'ensemble des indicateurs définissant le territoire entrepreneurial durable en vertu des quatre items que nous avons distingué et des diverses définitions (ville entrepreneuriale, ville durable, etc.) que nous avons présentées ci-dessus.

Tableau 6. Le TED, la construction d'un indicateur synthétique.

Items	Caractéristiques majeures
Contexte entrepreneurial et climat des affaires	Part des PME/nombre total d'entreprises, globalement et par secteur Taux de création d'entreprises Taux de pérennité des entreprises à 1 an et à 5 ans Taux de la population salariée Répartition de la population active par CSP Niveau de qualifications et compétences Présence sur le territoire de complexes industriels (voire de sites à risques)
Contexte institutionnel en faveur de l'entrepreneuriat	Politique de sensibilisation vis-à-vis des jeunes (et d'autres publics sensibles par exemple les personnes âgées, les chômeurs de longue durée, etc.) en faveur de l'entrepreneuriat Politique d'accompagnement à la création d'entreprise Présence d'agences à l'accompagnement à la création d'entreprise Présence d'incubateurs, de parcs technologiques, de ruches d'entreprises, etc. Fiscalité en faveur de l'entreprise

Items	Caractéristiques majeures
Contexte environnemental	Politique publique en faveur du développement durable et de la biodiversité Programme de recherche en faveur des éco-technologies Programme pour faciliter l'utilisation des énergies renouvelables Soutien spécifique en faveur des éco-entreprises Développement d'une stratégie d'économie industrielle Mise en place d'une politique de collecte, tri et traitement des déchets ménagers
Contexte technique et scientifique	Présence d'un centre universitaire Présence de laboratoires de recherche publics ou privés Taux de diplômés

Notre objectif est dans la seconde partie, d'appliquer cette grille de lecture au cas particulier de l'agglomération dunkerquoise.

2 Dunkerque, vers un territoire entrepreneurial durable ?

2.1 La construction d'une agglomération sur le temps long

2.1.1 Points de repères historiques

L'étude d'un territoire donné ne se réduit pas à la description de son état présent, sauf à considérer cette situation comme l'aboutissement d'une évolution sur le long terme. Par cette description sur le long terme, nous avons donc cherché à identifier la trajectoire techno-industrielle de ce territoire, avant de chercher à identifier les indicateurs qui pourraient un territoire entrepreneurial durable.⁴²

Le territoire de la CUD présente la caractéristique principale d'être un site industrialo-portuaire dont l'origine remonte au début des années 1960 pendant la période de la reconstruction (Laperche et al., 2011). L'économie locale se trouve ainsi encadrée dans une trajectoire techno-industrielle particulière : la construction du site sidérurgique a généré une importante population ouvrière employée dans de grandes entreprises. L'objectif des autorités publiques est alors de réduire la concentration des activités économiques dans la métropole parisienne (Gravier, 1947) en créant les « pôles de croissance », capables de réorienter les flux économiques (Perroux, 1955). Il s'agissait également de restructurer l'industrie pour faire face à la concurrence internationale de plus en plus forte et de mieux insérer l'industrie française dans la division internationale du travail. C'est dans cet esprit que furent également construites les zones industrialo-portuaires de Dunkerque, Fos-sur-mer (près de Marseille) et Le Havre (Vigarié, 1979). Les restructurations industrielles qui ont marqué depuis ces territoires n'ont pourtant jamais effacé leur spécialisation industrielle.

Nous distinguons trois périodes (plus une) dans l'évolution du territoire dunkerquois : 1) la phase d'industrialisation, 2) la crise économique et 3) la reconversion fondée sur la diversification des investissements et 4) le développement de l'entrepreneuriat.

2.1.2 La phase d'industrialisation

L'industrialisation lourde débute à Dunkerque dans les années 1960 (Boutillier, Uzunidis, 1998 ; Coppin et al., 2000). Il ne s'agit pas du produit de relations de proximité organisationnelle entre des acteurs économiques vivant sur un même territoire (proximité spatiale), mais d'une industrialisation forcée, décidée de façon unilatérale et construite de toutes pièces par l'Etat, notamment dans le cadre des cinquième et sixième plans (respectivement 1966-1970 et 1971-1975). Le choix des sites industriels qui recevront d'importants investissements publics est réalisé par la DATAR, créée en 1963 en privilégiant les zones 1) en crise dans le but de ré-équilibrer les niveaux de développement, 2) situées en bord de mer afin de pouvoir jouer un rôle d'interface entre les courants commerciaux internationaux et nationaux. A la différence de Fos-sur-mer, Dunkerque est d'emblée isolée dans son hinterland. Lille (actuellement le troisième port fluvial français) est historiquement reliée par le biais de canaux et de voies terrestres aux ports belges et hollandais (tels Rotterdam et Anvers). Dunkerque n'a donc pas pu créer de synergies économiques entre entreprises et institutions pour créer des « effets d'agglomération endogènes » (Fujita, Mori, 1996) conséquents dans la région du Nord/Pas de Calais.

L'industrialisation de Dunkerque s'inscrit ainsi dans la stratégie de restructuration de l'industrie (lourde) qui repose sur l'installation d'industries sidérurgiques au bord de l'eau. Dunkerque peut ainsi importer des matières premières d'outremer, moins onéreuses que l'utilisation du charbon et du fer extraits des mines du Nord/Pas de Calais et de Lorraine. Ces grandes unités sidérurgiques, « unités motrices », doivent ensuite créer des effets d'entraînement conséquents en aval et en amont de la filière et ainsi constituer un « pôle de développement ».

Le complexe industriel dunkerquois se construit autour d'Usinor. La décision d'implantation est prise en 1956, la production débute en 1962. A partir d'Usinor se constitue un pôle sidérurgique et métallurgique en liaison avec les

⁴² L'afflux de ces ouvriers généra au début des années 1960 un problème de logement important. Les ouvriers furent d'abord logés dans des caravanes, en attendant la construction de logements HLM.

chantiers navals implantés à Dunkerque depuis 1898⁴³ : Usinor (devenu Arcelor, puis Arcelor-Mittal), Vallourec (devenu Europipe), Creusot Loire (Vadunes et Ascométal), viennent d'adoindre aux chantiers navals de France. Les sociétés de raffinage British Petroleum-Elf et Total-Compagnie française de raffinage partagent un certain nombre d'équipements productifs et utilisent le même réseau d'oléoducs. Elles fournissent l'énergie nécessaire (via EDF) et les hydrocarbures dont ont besoin les entreprises du premier groupe. Elles font pression pour susciter la formation d'une filière pétrochimique à Dunkerque pour diversifier et développer leur clientèle locale. La construction d'un vapocraqueur, mis en service en 1978, a pour but de répondre à cette demande et a pour conséquence de nouvelles implantations d'entreprises en aval de la filière. Enfin, de grandes entreprises « périphériques » peu intégrées à la filière métallurgique sont également présentes. Leur installation a essentiellement été motivée par la situation géographique de Dunkerque : dans l'agro-alimentaire, c'est le cas de Lesieur implantée depuis le début du 20^{ème} siècle et dans le secteur de la cimenterie, de Lafarge. A cela s'ajoute un ensemble de petites et moyennes entreprises (PME) spécialisées dans les activités portuaires qui se répartissent en deux groupes : celles qui entrent dans le réseau de sous-traitance des grandes entreprises industrielles et du bâtiment d'une part, et celles qui poursuivent leur propres objectifs de production d'autre part.

L'implantation de ce complexe industriel repose sur une forte intervention de l'Etat par le biais de mesures directes (subventions, réduction d'impôts) qui sont destinées à financer la plus grande partie des travaux d'infrastructures (en matière portuaire notamment). Les apports des commandes publiques sont considérables. Par l'intermédiaire des grandes entreprises publiques, l'Etat est allé au-devant de tous les besoins d'Usinor : énergie (implantation de la centrale nucléaire de Gravelines⁴⁴), moyens logistiques (construction d'une gare de triage, construction de voies navigables), en approvisionnement en matières premières au prix le plus bas possible.

2.1.3 La reconversion fondée sur la diversification des investissements

Dans les années 1980, la politique industrielle et d'aménagement du territoire change de cap. En 1984 les pôles de reconversion sont lancés. Dunkerque est l'un d'entre eux sur les 15 créés. Ce sont des zones géographiques où la restructuration de certains secteurs industriels engendre d'importantes difficultés économiques et sociales. C'est dorénavant l'attractivité des investissements (notamment étrangers) qui doit permettre de relancer l'activité économique. Par ailleurs, les investissements privés doivent prendre le pas sur les investissements publics comme outils principaux de la reconversion et du développement des territoires (Ziel, 1998).

De 1970 à la fin des années 1980, le nombre d'implantations étrangères est modeste (4 en 1970 et 17 en 1988). Leur nombre augmente pendant les années 1990 (70 établissements étrangers à Dunkerque en 1997 (dont 49 unités dans l'industrie et 21 dans le tertiaire. En 2009/2010, les établissements étrangers implantés à Dunkerque regroupaient 13 000 emplois, positionnant Dunkerque comme le deuxième site de la région du Nord/Pas de Calais en capitaux étrangers après Lille (Laperche et al., 2011). Depuis cette période, la situation s'est cependant fortement dégradée, nombre d'investisseurs étrangers se sont retirés ou sont en passe de l'être. Mais, la stratégie de diversification n'a pas abouti. L'économie dunkerquoise reste concentrée sur l'industrie lourde. A l'heure actuelle, Dunkerque regroupe 13 sites classés SEVESO, soit le plus important site français. Avec l'implantation du terminal méthanier, un quatorzième site sera implanté prochainement. La date de son entrée en service ayant été retardée à plusieurs reprises, il n'est pas possible pour l'heure d'en donner la date exacte.

A la fin des années 1990, les investissements étrangers ont contribué à développer le complexe industrialo-portuaire de Dunkerque. C'est aussi au début des années 1990 que l'Université du Littoral Côte d'Opale (ULCO) ouvre ses portes pour participer au renouvellement des qualifications et des compétences répondant au besoin d'une économie du 21^{ème} siècle. Cependant le territoire industriel dunkerquois reste très fragile et très concentré. Les six filières regroupent la plus grande partie de l'emploi industriel, certaines d'entre elles sont extrêmement concentrées comme l'énergie, la sidérurgie (tableau 7).

⁴³ La fin du 19^{ème} siècle est marquée en France par un effort important d'industrialisation qui se concrétise notamment par la construction de voies ferrées et l'aménagement des sites portuaires (le Plan Freycinet du nom du ministre des travaux publics de l'époque, lancé en 1878). A Dunkerque, ces travaux de modernisation ont eu un impact important sur l'activité économique avec la création de grandes entreprises, comme Lesieur créée en 1908 pour bénéficier des avantages logistiques du port (importations d'arachides des colonies africaines françaises).

⁴⁴ Il s'agit de la plus grande centrale nucléaire d'Europe de l'ouest, soit la deuxième d'Europe, après la centrale ukrainienne de Zaprija.

Tableau 7. Les six principales filières industrielles dunkerquoises.

Filières	Nombre d'entreprises	Nombre global de salariés	Nombre moyen de salariés
Energie	9	2545	282
Sidérurgie	9	7143	797
Métallurgie	261	7248	28
BTP	388	5524	14
Chimie-parachimie	31	1747	56
Agro-alimentaire	47	1704	36

Source : Chiffres Ville Dunkerque, Chambre de commerce et d'industrie de la côte d'Opale, consulté le 29/05/2014.

Dunkerque est le premier pôle énergétique européen composé de la centrale nucléaire, le terminal gazier qui voit transiter depuis la Norvège l'équivalent du tiers de la consommation française en gaz naturel, la plus importante unité de production de gaz industriels, une activité de raffinerie, la réception du Port de Dunkerque de plus de 6 millions de tonnes de charbon par an. Mais, certains secteurs qui perdent le plus d'emplois en France sont surreprésentés sur le territoire dunkerquois. Il s'agit en particulier de la sidérurgie/métallurgie, activité où Dunkerque détient une position de leader en particulier avec Arcelor-Mittal, mais également avec d'autres grosses entreprises : Ascométal, Valdunes, Aluminium Dunkerque et Ajinomoto.

Arcelor-Mittal Dunkerque est considéré à l'heure actuelle comme une des unités les plus performantes d'Europe en dépit des réductions d'effectifs qui se justifient par les gains de productivité et l'externalisation de fonctions. D'autres grandes entreprises dunkerquoises affichent aussi une santé fragile. L'entreprise de métallurgie, Ascométal, ancienne filiale d'Usinor, appartient désormais au fonds d'investissement Apollo qui est son principal actionnaire. L'entreprise emploie 1900 salariés en France répartis sur 10 sites dont les trois principaux sont Dunkerque (avec 550 salariés), Hagondange (Moselle) et Fos sur mer (Bouches du Rhône). Actuellement, le groupe doit faire face à une dette de 360 millions d'euros contractée lors de son rachat par Apollo en 2011, et a été placé en redressement judiciaire en mars 2014. Un accord a été recherché entre le fonds d'investissement et les banques créancières : Morgan Staley et Bank of America. Plusieurs repreneurs se sont faits connaître : deux fonds américains (Apollo et Anchorage), une offre du groupe brésilien Gerdau et une émanant d'investisseurs français (portés par la Holding Sparking Industrie). C'est cette dernière offre qui a été retenue par le Tribunal de commerce de Nanterre⁴⁵. Le problème principal de l'entreprise ne serait pas tant celui du marché⁴⁶, que du management que l'entreprise doit améliorer sur quatre points majeurs : qualité des produits, rapidité de livraison, prix et innovation⁴⁷.

Valdunes, leader européen des roulements ferroviaires, a également été placé en redressement judiciaire en mars 2014. Elle emploie 500 salariés dans le Nord-Pas de Calais, dont 479 dans l'agglomération dunkerquoise. Plusieurs de ses marchés se sont en effet effondrés (fret ou transport de personnes), la société ayant été écartée de plusieurs appels d'offre de la SNCF en particulier. En un an, son chiffre d'affaires a baissé de 25%. Quatre offres de reprises ont été annoncées⁴⁸. L'offre retenue est celle du groupe chinois M. A. Steel, leader chinois de la sidérurgie, est l'une des cinq entreprises cotées en Bourse en Chine. L'entreprise est essentiellement présente sur le marché chinois pour des trains. M. G. Valdunes va ainsi entrer sur le marché des TGV chinois. Pour sa part, le groupe chinois va profiter du réseau commercial de sa nouvelle filiale française. Le groupe chinois a l'intention d'investir dans un centre de recherche mondial sur les produits ferroviaires dans sa filiale française qui devrait ainsi participer aux programmes de recherche du pôle de compétitivité I-Trans. Les usines seront modernisées et les emplois maintenus⁴⁹.

Aluminium Dunkerque appartient au groupe anglo-australien depuis 2007. Implanté à Dunkerque depuis 1991, le site assure les deux-tiers de la production française d'aluminium. Elle est aussi la plus grosse unité de production d'aluminium de l'Union européenne. Elle emploie 615 salariés à Dunkerque et en fait vivre environ 3000 autres dans la région du Nord-Pas de Calais. Le groupe est accusé de vouloir délocaliser ses usines dans les pays émergents où l'énergie est bon marché. 82 millions d'euros ont cependant été investis en 2012-2013 pour la construction d'un nouveau four et une nouvelle station électrique. D'autres projets d'investissements sont aussi à l'étude, mais 65 salariés vont perdre leur emploi d'ici 2015, et un plan d'économie a été mis en place. Pour des raisons de compétitivité. Par

⁴⁵ Cette offre a été choisie car elle sauvegarde le plus d'emplois. Elle prévoit la levée de 230 millions d'euros de financement et bénéficie de 35 millions d'euros de prêt de l'Etat, via le fonds d'investissements économique et social. Le gouvernement envisage aussi de faire entrer la banque publique d'investissement BPI France dans le capital du groupe. L'objectif de l'offre française est de faire redevenir Ascométal le leader européen des aciers spéciaux, pour ensuite envisager une consolidation européenne (*Le Monde*, 22/5/2014, *Les échos*, 22/5/2014). Les quatre actionnaires individuels (Franck Supplisson, Jacques Schaffnit –actuel président d'Ascométal - Guy Dollé et Noël Forgeard) n'apportent que 10% des fonds, 80% des apports proviennent de groupes financiers majoritairement étrangers.

⁴⁶ Le groupe est spécialisé dans des aciers spéciaux pour les secteurs de l'automobile, du pétrole et de l'industrie mécanique.

⁴⁷ Source : AFP, 5 mars 2014, *Nord Littoral*, 12 mars 2014.

ailleurs, le contrat signé avec EDF signé en 1991 pour alimenter l'entreprise à un prix très bas se termine fin 2016. Or EDF ne sera plus en mesure d'assurer le même tarif, en particulier en raison de la réglementation européenne⁵⁰.

Enfin, Ajinomoto est un groupe japonais spécialisé dans la production d'aspartame, il emploie à Gravelines (sa seule usine européenne) 103 salariés, auxquels s'ajoutent 30 emplois induits. Cependant, en raison de la surproduction mondiale d'aspartame, le groupe japonais a décidé de recentrer son activité sur le Japon et a mis en vente l'unité de production de Gravelines. Le site est installé depuis 1991 à proximité de l'usine Coca-Cola⁵¹, l'un de ses principaux clients. Il a été initialement créé en partenariat entre Ajinomoto et l'américain Monsanto, sous le nom d'Euro-aspartame. En 2000, suite au désengagement de Monsanto des édulcorants, Ajinomoto a repris l'intégralité des actifs via sa filiale Sweeteners Europe. En 2006, Ajinomoto avait annoncé sa volonté d'accroître ses capacités de production essentiellement au Japon et dans une moindre mesure au Gravelines. Mais, depuis les prévisions concernant l'augmentation de la demande mondiale d'aspartame ont fondamentalement changé. Par ailleurs, le coût de production de l'unité française est 30 à 40% supérieur aux unités chinoises concurrentes. Mais, la chute des ventes est également due à l'arrivée sur le marché d'un nouveau produit, une alternative naturelle aux édulcorants de synthèse, la Stevia⁵².

De plus, d'après le tribunal de commerce de Dunkerque, en 2013, plus d'un millier de salariés dunkerquois (contre 712 en 2012) ont été concernés par des procédures, soit de sauvegarde, de redressement ou de liquidation judiciaire, soit une augmentation de 45% par rapport à 2012. Le nombre de procédures cependant n'a augmenté que de 6%, mais celles-ci ont concerné davantage de salariés. Ce sont donc des entreprises de taille importantes en termes d'effectifs, mais aussi des entreprises plus anciennes. Même constat inquiétant pour le nombre d'ordonnances d'injonction à payer, qui est passé de 620 à 682 entre 2012 et 2013. Ce qui montre que les entreprises ont de plus en plus de difficultés à payer leurs charges et ont par conséquent des problèmes de trésorerie⁵³.

Les groupes multinationaux ont une stratégie globale où les territoires sont des réservoirs de ressources, qu'elles soient humaines, énergétiques, financières ou infrastructurelles. En conséquence, les entreprises localisent et délocalisent leurs activités en fonction des ressources offertes sur un territoire donné (cf. craintes d'Aluminium Dunkerque pour le renouvellement du contrat avec EDF. De nombreuses entreprises se sont localisées à Dunkerque pour bénéficier des infrastructures (port, prix des terrains⁵⁴). Une réglementation tatillonne, l'évolution négative du marché (voir par exemple la baisse de la demande d'aspartame), le prix d'une ressource qui augmente brutalement peuvent faire évoluer les choses très rapidement. Par ailleurs, la pression financière sur ces grandes entreprises est de plus en plus forte, compte tenu de la composition de leur capital. Les fonds d'investissement recherchent la création d'une valeur pour l'actionnaire, « Shareholder value », souvent au détriment des résultats économiques. La nécessité de faire face à la concurrence des pays à bas coûts de production (Chine, pays émergents) impose une croissance à l'efficacité et de l'innovation, mais qui nécessite du même coup des investissements conséquents, qui se heurtent précisément à la pression de la finance. Les groupes industriels mondialisés appréhendent le marché mondial comme un immense terrain de jeu sur lequel il place leurs pions.

D'un autre côté, suite à la fermeture des chantiers navals et problèmes économiques multiples, les institutions locales (Ville, Communauté urbaine, Port autonome) ont misé dans les années 1980 sur le renforcement de l'attractivité de la ville grâce au développement d'un nouveau cadre urbain et d'amélioration de l'offre de services aux particuliers. Ce grand projet, « Opération Neptune », financé pour partie par des fonds européens, repose sur la valorisation des friches industrielles pour reconstruire le centre-ville et pour que la ville s'ouvre sur la mer. Le projet Neptune a été fortement critiqué car les habitants ne se seraient pas approprié ce nouveau lieu. A partir de 2001, l'agence d'urbanisme de dunkerque et souligne la nécessité de construire une « ville à vivre » (Boissonnade, 2011), point de départ d'une réflexion qui donnera naissance à l'éco-quartier. En 2011, un éco-quartier situé sur les friches des chantiers a vu le jour. L'éco-quartier doit répondre à une nécessité de mixité sociale. Mais, quel que soit le type d'habitation (HLM, pavillon ou appartement de standing), les bâtiments sont chauffés par le réseau de chauffage urbain qui fonctionne en récupérant une partie de la chaleur d'Arcelor-Mittal. Cependant, si le quartier est desservi par une ligne de bus, aucun commerce (y compris alimentaire) n'a encore été implanté. Une vie sociale semble avoir du mal à se développer, les habitants ayant des difficultés pour s'approprier les lieux, y compris ce que suppose un éco-quartier en termes d'usage limité de l'automobile et du tri des déchets.

⁵⁰ Sources : *Le Monde*, 12/06/2014, *L'usine nouvelle*, 18/04/2014, *La voix du nord*, 10/04/2014, 24/04/2014, 17/05/2014.

⁵¹ Coca-Cola possède cinq unités de production en France. Coca-Cola Dunkerque produit 90% de la production du groupe en France. Le site est même l'un des premiers producteurs d'Europe occidentale, avec 360 000 canettes de coca-Cola à l'heure. Il est implanté à Socx, près Dunkerque, depuis 1989. La moitié de la production de Socx est exportée. Son activité est très importante. Un emploi Coca-Cola en induit 12 autres. L'usine de Socx se distingue par des efforts particuliers pour réduire sa consommation d'énergie (-20% depuis 2008) et d'eau (-15% depuis 2008). Des techniques ont été développées de manière à recycler l'énergie d'une machine à une autre. Pour réduire la consommation d'eau des compteurs affichent la consommation en temps réel et ligne de production par ligne de production. Grâce à l'ensemble de ces efforts, l'usine consomme 1,19 litre d'eau pour produire un litre de boisson, contre 1,65 en 2004.

⁵² Sources : *La Voix du Nord*, 30/04/2014, *L'usine nouvelle*, 2/05/2014.

⁵³ Source : *La Voix du Nord*, 15/01/2014.

⁵⁴ Si des entreprises, y compris des entreprises à risques, classées SEVESO, bénéficient de bonnes conditions d'accueil en matière du prix des terrains et peuvent développer ainsi leur activité. D'un autre côté, cette facilité a un impact sur le prix des terrains des habitations de particuliers qui se trouvent à proximité (Grislain-Létrémy, Katossky, 2013).

Mais, l'agglomération dunkerquoise cherche également à privilégier le développement de la culture. Ce fut notamment le cas dans le cadre des manifestations qui ont eu lieu en 2013 « Dunkerque, capitale régionale de la culture », le Fonds régional d'art contemporain (FRAC), situé dans un des anciens ateliers de construction navale, a également ouvert ses portes. Mais, au-delà des manifestations d'inauguration, le site peine à se développer et cherche encore son public.

En dehors du FRAC, d'autres bâtiments industriels anciens – dont la construction remonte pour la plupart à la fin du 19^e siècle – ont été réhabilités principalement situés dans le quartier de la Citadelle, haut lieu de l'activité économique et maritime jusqu'aux années 1960 (date de la construction du port industriel) : des entrepôts de matières premières (tabac, sucres, par exemple), immeubles de sociétés commerciales et maritimes, bâtiments industriels (minoterie, filature) (voir tableau 8). Le recensement (qui n'est pas exhaustif) donne une idée de l'évolution de l'organisation économique sur le territoire de l'agglomération dunkerquoise, des activités économiques qui se sont succédées. L'activité de ces bâtiments industriels historiques, dont un grand nombre a été réhabilité, se concentrée autour du port : sociétés de transport maritime, stockage de marchandises, fabrication de biscuits alimentaires pour les marins, de toiles de jute (sacs, bâches, etc.).

Tableau 8. Le patrimoine industriel dunkerquois réhabilité (sélection).

Nom du bâtiment	Année de construction	Utilisation originelle	Date de réhabilitation	Utilisation actuelle
Entrepôt des tabacs 1	1868	Construit par un entrepreneur dunkerquois est vendu à l'Etat pour conserver le tabac venant des colonies	Fermé en 1972 Racheté par la CUD en 1974	Musée portuaire depuis 1992
Entrepôt des tabacs 2	1881	Stockage de tabac		Université du littoral depuis 1991
Immeuble de la société Worms et Cie	1835	Société d'armement de navires de commerce	Transformé au début des années 1920 restauré après la seconde guerre mondiale	Société Sagatrans (entreprise de transport maritime)
Entrepôt réel des sucres (ou Halle aux sucres)	1897 (début des travaux) 1899 (fin des travaux)	Lieu de stockage de denrées alimentaires	Remis en état après la guerre (propriété du Port Autonome) puis transféré à la CUD	Remis en état après la guerre A partir de 2014/2015 accueillera : Centre de mémoire de l'agglomération Agence d'urbanisme de Dunkerque Ecole nationale des cadres territoriaux
Entrepôt réel des sucres (ou Halle aux sucres) Construction d'un deuxième bâtiment	Entre 1900 et 1902	Lieu de stockage de denrées alimentaires	2014 Ouverture d'un earning center Implantation de services administratifs et transfert du centre de formation des cadres territoriaux	Bombardé en 1940 rasé en 1946
Maison Coquelle-Gourdin	1908	Résidence privée d'un entrepreneur, Félix Coquelle qui fut aussi député et maire de Rosendaël	La maison a été cédée à la ville par la famille en 1941	Propriété de la CUD Depuis 1992 siège de la MJC de Rosendaël
La « cathédrale » des Chantiers de France	1949	Construction de navires	Rénovée pendant les années 1990	Chantiers navals fermés en 1987 FRAC depuis 2013

Nom du bâtiment	Année de construction	Utilisation originelle	Date de réhabilitation	Utilisation actuelle
Les entrepôts frigorifiques de l'Union	1955	Mise en service d'un nouveau magasin frigorifique pour remplacer l'ancien construit pendant la première guerre mondiale Stockage de denrées alimentaires	?	Propriété du Port autonome Loué depuis 1987 par le Centre d'archives du Nord SAS
La minoterie Fichaux	1856	Transformation du blé en farine Fabrication de pain ou biscuits de mer pour la marine	Entièrement détruit pendant la seconde guerre mondiale à l'exception du magasin industriel transformé pendant les années 1950 en usine à textile	En cours de rénovation
Filature Rigot-Stalars	1865	Fabrication de produits textiles en coton puis se spécialise dans le jute et la confection de toiles, sacs, bâches et ficelles Rachetée par la société Rigot-Stalars à la fin de la première guerre mondiale	Fermée en 1972	Diverses occupations : concessionnaire automobile puis magasin de meubles jusque la fin des années 1990. Racheté par la ville depuis et restaurée

2.1.4 Construire un cadre propice au développement de l'entrepreneuriat

Pour faire face au déclin de l'emploi (en grande partie ouvrier) salarié et à la montée du chômage, les responsables politiques (au niveau national et local) ont cherché à favoriser la création d'entreprises. Les mesures prises au niveau local, en l'occurrence de la CUD, sont le produit des mesures définies au niveau national qui se mettent en place progressivement à partir de la fin des années 1970. Après plusieurs décennies pendant lesquelles l'emploi se conjugait forcément avec salarié, la transition vers l'entrepreneuriat est une opération difficile.

A partir de la fin des années 1990⁵⁵, trois grands textes de lois ont été promulgués pour promouvoir l'entrepreneuriat en France. Le premier, par ordre chronologique, est spécifique à l'entrepreneuriat scientifique (loi de 1999 sur l'innovation et la recherche), le deuxième a pour objectif majeur de faciliter la création d'entreprise (loi pour l'initiative économique de 2003) et la troisième est notamment à l'origine du statut de l'auto-entrepreneur (loi de modernisation de l'économie de 2008). Il ne s'agit pas de détailler chacun de ces textes de lois, mais de mettre l'accent sur un processus qui a débuté depuis la fin des années 1990 et qui vise à assouplir le cadre administratif de la création d'entreprise en France. Toutes les catégories de la population peuvent être concernées : les salariés, les hommes et les femmes, les jeunes et les personnes âgées, les diplômés ou non diplômés, les chômeurs ou les salariés. Un ensemble de dispositions a été prévu. La loi de 2003 d'initiative économique constitue une étape importante dans ce processus puisque d'une part elle vise à alléger la procédure administrative de création, mais aussi et surtout en supprimant le principe d'un montant de capital minimum pour créer une SARL. La loi de 2008 de modernisation économique va dans le même sens en créant le statut de l'auto-entrepreneur. La création d'une auto-entreprise est ouverte à tous, que l'on soit salarié ou demandeur d'emploi, étudiant ou même fonctionnaire⁵⁶, qu'il s'agisse d'une activité principale ou complémentaire. Le chiffre d'affaires ne doit pas être supérieur à 80 000 euros HT pour une activité d'achat/revente, de vente à consommer sur place et de prestation d'hébergement ou de 32 000 euros HT pour les prestations de services. La procédure de création est très simple. Elle se fait par voie électronique. L'auto-entrepreneur reçoit un numéro SIREN.

Mais, au-delà du cadre institutionnel visant à faciliter sur le plan administratif la création d'entreprises, il est également nécessaire d'accompagner et de conseiller le futur entrepreneur. C'est le rôle des boutiques de gestion, qui ont vu le jour pendant la décennie 1980. La création des boutiques de gestion relève d'une initiative individuelle, même si elles entretiennent des partenariats avec des institutions publiques, telles que les chambres de commerce et

⁵⁵ La volonté visant à promouvoir l'entrepreneuriat ou tout au moins à protéger les petites entreprises est bien antérieure à cette période : loi Royer en 1973, suppression de la patente en 1977 remplacée par la taxe professionnelle.

⁵⁶ Les fonctionnaires sont nombreux à devenir auto-entrepreneurs selon la Commission de déontologie de la fonction publique. Les secteurs privilégiés sont : le commerce, l'hôtellerie, la restauration, métiers liés au bien-être et au conseil, les services à la personne, les travaux de BTP chez les particuliers. Les fonctionnaires qui optent pour ce statut ne réduisent pas leur activité professionnelle principale, mais profitent de leurs jours de congé pour exercer une activité complémentaire.
<http://www.initiatives.tv/1149-le-statut-de-l-auto-entrepreneur-profite-aux-fonctionnaires.html>

d'industrie, la Caisse de dépôts et Consignations, etc. A l'heure actuelle, dans l'agglomération dunkerquoise, la création d'entreprise est bien encadrée. L'ensemble de ces institutions se partagent des candidats à la création d'entreprise, relativement peu nombreux.

Lanterne rouge pendant de longues années en matière de dynamisme entrepreneurial, la région du Nord-Pas de Calais a construit depuis le début des années 2000 un cadre institutionnel visant à promouvoir la création d'entreprise (Cour des comptes, 2012). Le programme de soutien à la création d'entreprise dans le Nord-Pas de Calais est lancé en 2001 grâce à l'action combinée de l'Etat, du conseil régional, des conseils généraux du Nord et du Pas de Calais, la Caisse des dépôts avec l'appui de l'APCE⁵⁷, qui créent le PRCTE⁵⁸ 1 (2000-2009). L'objectif affiché est de passer de 10 000 à 15 000 créations d'entreprises par an. Le PRCTE repose sur sept objectifs⁵⁹. Ces objectifs ont été élargis dans le cadre du PRCTE 2 (2010-2013)⁶⁰. D'autres programmes ont été lancés dans ce cadre, comme par exemple : le développement de l'économie sociale et solidaire, de l'artisanat ou des entreprises commerciales et de services. Un effort particulier a également été réalisé pour soutenir l'innovation dans des secteurs ciblés. Citons à titre d'illustration : l'éco-construction, les matériaux avancés (biosourcés, textiles composites), le traitement des déchets (Cour des comptes, 2012, tome 3, p. 230).

Au niveau de la CUD proprement dite un ensemble de mesures a été prises pour faciliter la création d'entreprises d'une part, et attirer de nouveaux investisseurs d'autre part.

L'aide à la création d'entreprise repose sur deux principes le financement des structures d'aide à la création d'entreprise d'une part, et le développement de l'entrepreneuriat d'autre part. La CUD consacre, selon ses propres sources, un budget de 520 000 euros par an pour soutenir l'activité économique locale. Depuis 2001, environ 1500 entreprises auraient ainsi été créées, soit près de 4000 emplois. La CUD finance des professionnels d'aide à la création (exemple : Flandre initiative, Flandre création, etc.), qui apportent gratuitement leur aide aux porteurs de projets. Mais, sont également présents sur le territoire dunkerquois des réseaux nationaux (exemple : Entreprendre ensemble) et les relais institutionnels classiques (CCI, chambre de métiers et de l'artisanat, etc.), l'université et les ruches d'entreprises (tableau 9). A cet ensemble s'ajoute Dunkerque Promotion, dont le rôle n'est pas, contrairement aux structures précédentes n'a pas pour mission de soutenir les porteurs de projets, mais pour améliorer l'attractivité du territoire dunkerquois, pour en particulier attirer de grandes entreprises, créatrices d'emplois salariés.

Tableau 9. Les institutions d'aide à la création d'entreprises dans l'agglomération dunkerquoise et le type d'aide apportée.

Institutions	Types d'aide apportée
<i>Graines d'affaires</i> Coopérative d'activité et d'emploi pour aider pour les personnes désirant tester leur projet grandeur nature	Liquidation judiciaire
<i>Graines de bâtisseurs</i> Coopérative d'activité et d'emploi dans le bâtiment	Liquidation judiciaire
<i>Flandre création</i> Boutique de gestion soutenue par la CUD Association loi 1901	Accompagnement des créateurs et de repreneurs d'entreprise de la naissance du projet à l'autonomie complète Formation à la création et à la gestion d'entreprise Aide au montage de projets financiers et administratifs et vérification de la cohérence du projet Aide à la recherche de financement

⁵⁷ APCE : Agence pour la création d'entreprise.

⁵⁸ PRCTE : programme régional de création et de transmission des entreprises.

⁵⁹ Les sept objectifs du PRCTE 1 sont les suivants : 1/ amener le NPC au niveau national de la création et reprise d'entreprise, 2/ faciliter l'égal accès de tous les publics à l'initiative, 3/ mobiliser l'ensemble des acteurs pour susciter en région l'esprit d'initiative et l'envie d'entreprendre, 4/ sensibiliser les chefs d'entreprise susceptibles de céder leur entreprise et préparer les transmissions, 5/ organiser un dispositif de proximité lisible et performant destiné à accueillir, accompagner et former les porteurs de projets et suivre les entreprises nouvelles, 6/ permettre la création d'un dispositif de financement et de garantie adapté aux besoins de toutes les entreprises, et 7/ encourager la mise en œuvre des acteurs, renforcer les coopérations territoriales et fonctionnelles, faciliter les échanges d'informations et d'expérience (Cour des comptes, 2012, tome 3, p. 228).

⁶⁰ Les objectifs du PRCTE 2 sont les suivants : 1/ développer des politiques en faveur de publics spécifiques (femmes, jeunes, auto-entrepreneurs), 2/ territorialiser le PRCTE en s'appuyant notamment sur les communautés d'agglomération, 3/ développer des dispositifs de formation à la création et la reprise d'entreprise et le volet ressources humaines, et 4/ articuler le PRCTE aux autres thèmes du Schéma régional de développement économique (SRDE) (Cour des comptes, 2012, tome 3, p. 228).

Institutions	Types d'aide apportée
<i>Initiative Flandre</i> Boutique de gestion Association loi 1901 soutenue par la ville de Dunkerque	Complète l'offre de services de <i>Flandre création</i> Prêts d'honneur (prêts sans garantie ni intérêts) Subventions A aidé en 2013 près de 230 entreprises, soit 580 emplois générés ou consolidés
<i>Chambre de commerce et d'industrie de la Côte d'Opale</i>	Accompagnement à la création d'entreprise pendant trois ans
<i>Chambre de métiers et de l'artisanat</i>	Accompagnement pour la création d'entreprises artisanales
<i>Université du Littoral Côte d'Opale</i>	Licence professionnelle et master professionnel pour la création d'entreprise
<i>Entreprendre ensemble</i> Association loi 1901 Appartient au réseau <i>Entreprendre ensemble</i>	Accompagnement des créateurs et repreneurs Financement sous forme de prêts d'honneur Action spécifique en faveur des public en difficulté
<i>Centre Entrepreneuriat du littoral (CEL)</i> Université du Littoral Côte d'Opale	Public étudiant uniquement Sensibilisation à l'entrepreneuriat Formation à l'entrepreneuriat Accompagnement hébergement
<i>Couveuse d'entreprise Dunkerque Littoral</i>	Créée par <i>Flandre création</i> Tester son projet en grandeur réelle avant de démarrer pendant une durée de 6 à 12 mois
<i>Comité Local d'Aide aux Projets (CLAP)</i>	Aider et accompagner les 16-30 ans qui ont un projet culturel, sportif, humanitaire ou économique Soutien logistique, technique et financier éventuel
<i>Ruche d'entreprises de Saint-Pol-sur-Mer</i>	Accompagner et héberger pendant la phase de démarrage (maximum 48 mois) les porteurs de projets dans les technologies de pointe
<i>Dunkerque Promotion</i> Association loi 1901 Regroupe six partenaires : CUD, CCI, Port autonome, Ville de Dunkerque, Conseil général du Nord, Communauté de communes des Hauts de Flandre	Prospection de porteurs de projets Gestion des projets d'implantation, de développement et d'investissement d'entreprise Promotion économique du territoire de Dunkerque et de sa région Améliorer l'attractivité du territoire dunkerquois

2.2 L'agglomération urbaine de Dunkerque : un territoire entrepreneurial durable ?

L'agglomération dunkerquoise est-elle un territoire entrepreneurial durable ? L'enquête sur le terrain étant en cours de finalisation, nous avons réuni dans le tableau ci-dessous (tableau 10), les indicateurs effectifs permettant que qualifier (ou non) cette agglomération comme un territoire entrepreneurial durable.

Tableau 10. L'agglomération urbaine de Dunkerque : un territoire entrepreneurial durable ?

Items	Caractéristiques appliquées à l'agglomération dunkerquoise
Contexte entrepreneurial	Taux de chômage supérieur à la moyenne nationale (13,4%) – contre 11 pour la moyenne nationale 92% de la population active est salariée (contre 90% au niveau national) Taux de création d'entreprise 15,4% en 2012 (comparable à la moyenne nationale) Economie dominée par un noyau de grandes entreprises industrielles (Arcelor-Mittal, EDF, etc.) et la fonction publique territoriale (la CUD est le 2 ^{ème} employeur de l'agglomération) Pôle d'excellence de l'énergie Importance de l'entrepreneuriat parapublic et associatif 13 sites classés SEVESO Centrale nucléaire

Contexte institutionnel en faveur de l'entrepreneuriat	Réseau dense d'agences d'accompagnement à la création d'entreprise : chambre de commerce et de l'artisanat, Flandre initiative, Flandre création, Entreprendre ensemble, consultants, etc. Un pôle universitaire : l'Université du Littoral-Côte d'Opale Centre d'apprentissage Ruche d'entreprises de Saint-Pol et de nombreuses zones d'activité
Contexte environnemental	Développement de l'écologie industrielle Coopération avec l'ULCO pour mesurer la qualité de l'air Programme de protection de la biodiversité Première ville française pour avoir mis en œuvre le tri sélectif des déchets 2010 : organisation de la 6 ^{ème} conférence européenne des villes durables et ratifie la charte d'Aalborg Construction d'un éco-quartiers sur la friche des chantiers de France Réseau dense de transport urbain (bus circulant au gaz naturel, mais usage de la voiture dominant) Plan d'action de la Maison du Développement Economique entre 2012 et 2014 pour favoriser l'adaptation des emplois et des compétences aux évolutions induites par les mesures du Grenelle de l'environnement pour renforcer l'information dans ce domaine, sensibiliser les professionnels du bâtiment, etc.

Eléments de conclusion (provisoire)

En dépit des efforts entrepris pour déconcentrer l'activité économique et promouvoir l'entrepreneuriat (taux de création d'entreprise en nette hausse depuis 2010, en particulier grâce au statut de l'auto-entrepreneur), la CUD reste dominée par l'emploi salarié (public et privé) et les grandes unités de production dans l'industrie lourde (sidérurgie) et l'administration territoriale. Le contexte social difficile (fort taux de chômage) ne contribue pas à créer une demande sur laquelle des entreprises pourraient être créées et se développer. La présence de grandes entreprises, mobilisant des actifs spécifiques importants, contribue à rigidifier ce territoire qui a énormément de difficultés à se transformer pour devenir un territoire entrepreneurial durable.

Purchasing business solution services: A review

Saara A. Brax, Mervi Vuori, Laura Wirtavuori

Aalto University, School of Science

The purpose of this paper is to provide an overview of the literature currently available on purchasing integrated business-to-business services and solutions based on the method of systematic review. By thorough retrieval methods, an exhaustive sample of 34 relevant papers was compiled. The key research themes identified in the data set are buyer-supplier relationships, organizational buying behavior, the changing of business models, sustainability, and governance and contracts. The study concludes that a major gap exists in this field of research. Due to its high practical relevance, this domain provides ample research opportunities for both servitization and purchasing scholars.

1 Introduction

Reflecting the increasing importance of services in all industries, the past two decades have been characterized by a proliferation in service research. Initially, scholars have focused on consumer services, professional services, business-to-business (B2B) services and industrial services; however recently, increasing attention has been paid to integrated solutions, product-service-systems (PSS) and servitization of manufacturing businesses. This attention has provided in-depth knowhow for service provider companies in order to effectively develop, market and deliver their services. Whilst the customer perspective has been central especially in the service marketing literature, the main focus has been on customer satisfaction, perceptions of the provider firm as well as service offering. Actual purchasing practices required to successfully source B2B services have received less attention. This article addresses the knowledge gap in service purchasing by focusing on solution service offerings in B2B and industrial contexts.

The purpose of this paper is to provide an overview of the literature currently available on purchasing integrated business-to-business services and solutions based on the method of systematic review. The aim is to provide theoretical and conceptual grounds as well as suggest topics for future research in this important yet neglected area. In particular, this review will focus on purchasing of contract-based, integrated full-service offerings that are often called 'solution services'. Whilst solution services can go by various names, they share common characteristics: they are complex, represent a critical aspect of the client firms' operations and often cover an extended period of time.

This review systematically identifies scholarly papers published in the crossing of service solutions research and purchasing research. By thorough retrieval methods, an exhaustive sample of 34 relevant papers was compiled. The articles were systematically analyzed with a content analysis method using a combination of a structured coding framework and further emergent codes. In the following section this study briefly presents the B2B solution offerings and industrial services as the main context of research interest. Next, the systematic review methodology is described in two subsections that explain the retrieval process of the article set and the analysis procedures implemented in the review. The findings section begins with an overview and summary of the research and continues with an analysis of the solutions offering aspects. Then, the main research themes identified in the data set; i.e., buyer-supplier relationships, organizational buying behavior, the changing of business models, sustainability, and governance and contracts, are discussed.

The paper concludes with a discussion. Whereas interesting research themes are developing already, the study indicates that a research gap exists in this field of research. Whereas issues of buying and purchasing are often mentioned in producer-focused articles, the number of studies focusing on purchasing as the core topic and using empirical data from the customer side is scant. Finally, the article closes by listing the most critical areas in which new research contributions about solutions purchasing are needed.

2 Background: B2B Solution offerings

Business models based on full-service value propositions (Stremersch et al. 2001) and integrated solutions (Brax and Jonsson 2009, Nordin and Kowalkowski 2010) delivery have spread as a way of doing business in many capital-intensive industries like manufacturing of production systems and vehicles (c.f. Lay et al. 2010). While many companies began developing and providing such business in the 1990's, since the year 2000 this business approach has taken on fast growth and become the dominant business model in many industries, such as in corporate ICT services.

Research on the phenomenon has also grown rapidly (Turunen and Toivonen 2011). This research has mostly focused on the provider side and their perspective, studying the challenges of marketing and providing solution-like product-service hybrids and ser-vices. Several reviews of this literature have been published already (Baines et al. 2009, Nordin and Kowalkowski 2010, Beuren et al. 2013, Lightfoot et al. 2013). Research has also investigated the interface and relational bonds between the provider and the client firm (Tuli et al. 2007, Holmlund 2008, Holmström et al. 2010,

Hakanen and Jaakkola 2012). Also, some studies focusing on the customer side have appeared as well (Ulaga and Chacour 2001).

At the same time researchers and practitioners have recognized the challenges in professional purchasing of increasingly large and technically complex services (e.g. Stremersch et al. 2001, Lindberg and Nordin 2008, Heikkilä et al. 2013) and knowledge-intensive business services (Pardos et al. 2007). While the literature on service purchasing is still scant, more contributions have started to appear recently (Fitzsimmons et al. 1998, Kotabe and Murray 2004, van der Valk 2008). Still, observations on practical cases have indicated that the costs of purchasing and negotiating solution service deals are considerable for both parties (Heikkilä et al. 2013). Purchasing of solutions is demanding because solutions require tailoring and integration of the service to customer's processes (Brax 2005, Brax and Jonsson 2009).

3 Methodology: systematic literature review

The study is based on a systematic literature search (cf. Tranfield et al. 2003) combined with a focused conceptual content analysis approach (see also Eisenhardt 1989, Krippendorff 2004). First, all major databases were searched to build a pool of research articles that focus on solution offerings (based on abstract data).

3.1 Search protocols

The databases searched were EBSCO, Emerald, JSTOR, ProQuest, Sage, ScienceDirect, Scopus, Web of Science and Taylor & Francis. Because the search engines of the databases differ, small technical adjustment was needed in some cases. Generally, the following search rule was implemented to identify literature associated with the solution offerings context:

- "solution offering*" OR "industrial service*" OR "product-service system*" OR "integrated solution*" OR "business solution*" in abstract

Next, within this data pool of identified articles, a second search was performed to identify research that focuses on purchasing such offerings. To begin, articles that contained the word 'purchasing', 'procurement' or 'buying' in the article title or abstract were included:

- buy* OR purchas* OR procur* OR sourc* in abstract

Additional limitations were used where available:

- only Full Text
- Language: English
- Scholarly (peer reviewed) journals only
- Publication type: Academic Journal / Search in journals
- Document Type: Article

The literature searches identified 171 articles; 57 articles had the purchasing related search term in the article title. These 171 articles were inspected based on the abstract by the researchers to ensure the search terms were included, as well as that articles represented a relevant academic discipline (for instance, the term 'integrated solution' is used in chemistry). This resulted in a core sample of 39 articles that fulfilled the search criteria. During the retrieval processes the authors identified six other potentially relevant articles that did not fulfil the formal search criteria of search terms in the abstract fields, and these were added to the sample. For instance, one such article referred to 'sustainable solutions' but was clearly focusing on solution offerings with environment-friendly goals. Thus the content analysis started with a sample of 45 articles. Out of these, 11 articles were excluded for the following reasons: the full-text analysis revealed they did not focus on purchasing or industrial services and solutions; the articles were non-academic; or the role of purchasing in the research design was assessed as marginal during the coding process. Therefore, the size of the final sample was 34 articles.

3.2 Content analysis

The analysis was conducted by two individual researchers working as a team. The analysis was based on alternating periods of collective and delegated analysis tasks. The articles were first read through to get an overview. The full texts were uploaded to Atlas.ti software package to enable computer-assisted shared coding practices. Each researcher conducted their own coding to a separate version of the hermeneutic unit, and these were synced and compared daily.

An initial coding scheme was planned prior to coding and supplemented with further relevant codes as findings emerged and developed during the coding. The initial coding scheme included:

- *Descriptive basic codes* to tag academic discipline, methods, data, research questions, hypotheses, conclusions, comparisons, etc.

- Codes to identify the *relevance of the study from the perspective of purchasing* (purchasing as main focus, adjacent topic, marginal note; studied focal problem, as explaining or causing another problem, not a relevant part of research design).
- *Codes indicating the solution offering context*, namely the specific solution type that was studied (e.g. integrated solution; PSS), and the complexity of the offering being bought (complex, moderate, simple).
- The *perspective* (buyer, seller, combined) and the *purchasing domain* (public, private, PPP) were also marked up.
- Remaining codes focused on the *purchasing related content* and know-how more specifically, identifying various purchasing related sub-themes, steps and stages of the purchasing process, structural aspects of the purchasing function, relational setting (transactional or relational), success factors, and whether frameworks or models were used or produced.

After the first round of coding the expanded coding scheme was assessed and analyses were continued with more detailed research and cross-data comparisons. These analyses were conducted side-by-side with writing the research report, aiming at a presentation that both provides structure to the area, identifies dominance and lack of themes, as well as provides a brief commentary of the research contribution in the key themes.

4 Findings

4.1 Overview of research

The identified 34 papers represented marketing (16 articles), production and operations management (11) or general business and management (7) and their publishing years ranged from 1981 to date. The earlier years were dominated by marketing research whereas general business and management perspectives emerged in 2000's. Despite some early papers in 1990's, the interest on the subject in production and operations management discipline activated in 2010's. Nevertheless, the topic has remained marginal over the years.

Research was published in the following journals:

- Industrial Marketing Management (8 articles)
- International Journal of Operations & Production Management (3)
- International Journal of Production Economics (2)
- Journal of Cleaner Production (2)
- Procedia CIRP (2)
- The following journals were represented by one contribution: Construction Management and Economics; Engineering, Construction and Architectural Management; Industrial & Corporate Change; Information & Management; International Journal Of Computer Integrated Manufacturing; International Journal of Service Industry Management; Journal of Business & Industrial Marketing; Journal of Business Logistics; Journal of Business Research; Journal of Business-to-Business Marketing; Journal of Construction Engineering & Management; Journal of Global Marketing; Journal of Marketing; Journal of World Business; Production Planning & Control; The Asian Journal of Shipping and Logistics; Transportation Journal.

Figure 1a. Use of research designs in the articles. 1b. Breakdown of method choices in the sub-disciplines.

Over half of the studies were based on quantitative survey approaches (see Figure 1). While some studies administered mail surveys, gathering quantitative data through structured interviews was common. Nine papers were based on a case approach, one in a qualitative survey approach, and six studies were either conceptual or based on a literature review. In this limited data set, marketing has a strong emphasis on the survey approach.

4.2 Solution offerings

The most researched category in the identified set of articles is industrial services with 15 studies. The early studies mostly focus on industrial services, and until year 2011, all marketing articles focused on industrial services. The concept of product-service-systems emerges in 2003 (Stoughton and Votta 2003), relatively quickly after the PSS concept appeared in published articles (e.g. Roy 2000). Altogether nine papers focus on PSS.

Clearly, in the early papers the use of terminology differs between the academic disciplines. The offerings discussed under terminology such as industrial services, solutions and systems in marketing tend to be less complex than those discussed on POM studies. The term industrial in early marketing papers does not refer to manufacturing but includes all kinds of business services. Also, outside this set of articles a similar term to product-service-system, written as the product/service system, has been used in marketing in a more limited meaning:

“The main approach is to create a total product/service system. Whatever the customers purchased initially, the company can then present them with related benefits provided by other items in the product line. In this way, they come to realize the existence and value of a total consumption system. McDonald’s no longer sells hamburgers but complete meals...” (Rosenberg and Czepiel 1992, 47–48)

This clearly has influences the validity of the data set; whereas earlier papers on industrial services analyze common business-to-business services, recent studies under this term focus on solution offerings (Lukassen and Wallenburg 2010, Altuntaş and Tuna 2013). Furthermore, the recent studies in marketing use the terms PSS (Everhartz et al. 2014, Gesing et al. 2014) and solutions (Töllner et al. 2011, Oruezabala and Rico 2012). Also, in the more recent studies the concepts are used somewhat similarly across the disciplines. To summarize, in the purchasing studies of the marketing stream, it looks like the focus has shifted from business services characterized by moderate complexity towards complex integrated solutions and PSS. In the field of POM, the interest has stayed on integrated solutions and PSS, but this field has activated in purchasing research relatively recently.

4.3 Domain of purchasing

The analysis distinguished whether the studies focused on sourcing in the private sector or the public sector. As can be seen in Table 1, the majority of 22 articles have the private sector as the sourcing context. This was the case especially in the early marketing studies. The public sector based perspective of public-private partnerships (PPP) is strongly represented in the more recent research (Davies 2004, Chan et al. 2009, Cheung et al. 2010, Datta and Roy 2011, Bankole et al. 2012, Oruezabala and Rico 2012, Roehrich and Caldwell 2012, Datta and Roy 2013, van der Valk and Wynstra 2014). In these studies, a public entity sources a complex or moderately complex solution from a private sector entity. The contract periods can be years or decades, making the private company a partner rather than a supplier. These studies on PPP make a valuable contribution in the study of purchasing solutions, because majority of them are based on in-depth case analysis, and thus provide detailed information about actual sourcing projects with their pros and cons.

4.4 Perspective

As can be expected, majority of the studies take the buyer’s perspective and use data gathered from organizational buyers and decision-makers on the buying side (25 articles). In three papers the dominant perspective is seller’s. Six studies took a combined perspective and obtained data from both the provider and the client. Interestingly, most marketing studies represented the buyer (14 papers out of 16), whereas POM studies often took a combined perspective (4 out of 11). Given the small size of the sample of articles, further statistical analysis is not purposeful. Nevertheless, it seems that in this set of articles the combined perspective increases over time as the interest shifts towards more complex solutions; case research designs are more common in this context because due to their uniqueness, gathering large statistical data sets from complex solutions is difficult.

4.5 Research themes

Based on our analysis regarding the research themes in the articles, five main categories can be formed, including changing business models, buyer-supplier relations, organizational buying behavior, governance and contracting and sustainability. The majority of articles fall under the organizational buying behavior –category, with marketing as the dominant academic discipline. Articles in this category address the buying center structure, involvement of buyers and other organizational members in purchasing decision making, use of referrals in different cultural contexts; in addition differences between goods and services are examined.

Figure 2. Overview of the distribution of topics in the data set.

Changing business models includes articles focusing on drivers and barriers in purchasing and implementing product-service systems. Additionally, micro- and macro-level studies on PPP adoption are included in this category. Implementation of the through-life perspective can be regarded as an emerging topic. Studies addressing buyer-supplier relations comprise articles focusing on the impact of servitization on buyer-supplier relationships, differentiation of buyer-supplier interaction patterns and service quality aspects linked to relationship characteristics. Studies in the governance and contracting –category address performance based contracting and pricing models. Sustainability has risen as a recent topic including contributions concerning the environmental, as well as economic and social aspects.

4.5.1 Organizational buying behavior

The majority of articles in our sample can be categorized into the “organizational buying behavior” –theme. This stream of research dominates the early contributions in the data set and has become less central in the recent contributions.

Johnson and Bonoma (1981a) study how different buying center dimensions are affected by organizational characteristics and purchasing situation when purchasing capital goods and services. The studied dimensions include: hierarchy levels involved in communications with the buying center; departments and functions involved in decision making; individuals in the buying network; connections between buying group members; and purchasing manager’s communications. Taking a communications view on buying center structure and relations, the authors explore the dynamics of the network behind purchase decision-making in a buyer company. These buying center dimensions are further defined in another Johnson and Bonoma (1981b) study, which examines the purchasing process for industrial services and capital goods in terms of functional involvement and tasks performed by these functions.

In the area of accounting services, Lynn (1987) analyses how firm characteristics including size and the existence of an audit committee, as examples, influence the structure of the buying center and the involvement of participants in purchasing decision-making. Lynn (1987) finds that in small firms the decisions on purchases are made more independently and the CEO is likely to play a substantial role, whereas in larger firms more people are involved in purchasing decision-making.

Also in the context of purchasing financial, informational and promotional services, a study on decision-making processes and the involvement of buyers in different buying situations by Webster (1993) discovers that buyers are showing either medium –or high involvement across all professional service categories. The study finds that buyers are more involved in the decision making process when the company has been using the service for long.

Griese and Kurpitz (1985) analyze the decision-making behavior of firms that are purchasing ICT-systems. Companies they labeled as ‘intensive decision-makers’ were found to be particularly thorough during the various stages of the purchasing process. As part of the decision making process these firms carefully prepared the documentation of requirements, collected information from several sources and consulted various external parties. These firms were found the most active also in further developments of the purchased systems after the actual buy-decision.

Taking the seller’s perspective into service purchasing Lichtental and Shani (2000) include environmental, organizational, group and individual factors to their framework of organizational buying behavior to study client-agency relationships in the advertising industry. They find that sales executives’ knowledge corresponds with majority of the factors included in the OBB framework and suggest that service providers should use this knowledge to tailor their offering.

Money et al. (1998) study the impact of national culture into using word-of-mouth referrals in industrial service purchasing in Japan and US. Roth et al (2004) further analyse the extent to which national culture (based on the firms’

national origin and its location of operation) and network relationships (organization buying experience, types of referral sources used) are related to the use of direct versus indirect purchasing processes for various types of industrial services.

The study by Jackson et al. (Jackson et al. 1995) resonates with the OBB theme, as it surveys differences and similarities between goods and services from organizational buyer perspective in various industries. Goods and services are found to differ across a range of dimensions; as main differences, the authors find that evaluation of quality is more difficult for services than it is for goods, services require more collaboration between the buyer and the seller and that different people are involved in the purchasing process for goods and services.

The most recent study in the OBB theme takes place in the context of capital goods, as Töllner et al. (2011) conceptualize the criteria for a customer solution from buyer perspective. They analyze whether the relevance of solution criteria differs across different buying center members (users, buyers and deciders). Töllner et al. (2011) find that criteria for a customer solution consist of requirements definition, customization and integration, deployment and post-deployment support; in addition, signaling (i.e. seller showing commitment and preparing an initial concept suggestion already during the early stages of the process), co-ordination and time management are included. The results confirm the suggested differences in criteria relevance across different buying group members, for example users are more interested in the customization of solutions, whereas buyers are strongly interested in the requirements definition and signaling activities.

4.5.2 Buyer-supplier relations

The theme of buyer-supplier relations soon followed the OBB theme and contributions in this theme still appear regularly. Buyer-supplier relations and their characteristics in a servitized environment are studied by Bastl et al. (2012) and Saccani et al. (2014), who focus on the impact of servitization in buyer-supplier relationships in terms of information exchange, operational linkages, legal bonds and adaptations. Further, Saccani et al. (2014) associate different service types with buyer-supplier relationship characteristics, using a framework similar to the one used by Bastl et al. (2012). Also Wynstra and van der Valk (2006, van der Valk and Wynstra 2014) raise the issue of linking service categories with different buyer-supplier interaction patterns. They emphasize differentiated interactions as the foundation for successful service exchange and design. Interaction patterns reflect the underlying usage situations; therefore differentiated approaches are needed for purchasing different services as well as managing service suppliers.

Relationship quality is discussed in three papers. Panigyrakis and Veloutsou (Panigyrakis and Veloutsou 1999) study the multiple internal and external relationship interfaces employed by a brand manager in a buyer company in terms of time allocation as well as importance and quality of the relationship. Focusing on buyer-supplier relationship building, Barry and Doneu (2011) study relationship quality in cross-cultural setting. Their main finding is that buyers tend to emphasize trust, commitment and satisfaction: when these factors are present in the relationship, the buyer is more likely willing to continue the relationship with the service provider in question. Buyers in collectivist cultures emphasize relational factors more than buyers in individualistic cultures, who are more inclined towards economic factors. In any case, relational investments on the part of the service provider are called for the establishment and retention of long-term buyer-supplier relationships. The three relationship characteristics of trust, commitment and satisfaction are also in focus in the study by Homburg and Garbe (1991). These authors conclude that relationship trust, commitment and satisfaction are driven by service quality, in particular the process-related quality.

4.5.3 Changing business models

Articles focusing on changing business models highlight drivers and barriers in purchasing and implementing product-service systems. An early article in this stream by Menon et al. (1998) looks at supplier selection criteria in the context of third-party logistics business models. The article by Davies (2004) is a classic article that addresses the migration of manufacturers towards 'down-stream' towards the end-user as they provide complete solutions. Stoughton and Votta (2003) discuss opportunities and barriers related to implementing a chemical management system as PSS, noting in particular that successful implementation requires aligning incentives between the service provider and the buyer. In addition, buyer's capability to assess total costs related PSS implementation is raised. Gesing et al. (2014) find that over-dependence on a supplier, loss of know-how and increased risk may constitute barriers towards PSS implementation in a buyer company; on the other hand, buyer company capabilities, resources, management style as well as underlying processes constitute main drivers for make-or-buy decisions in PSS context (Everhart et al. 2014).

In the context of changing business models, there are a number of articles discussing public-private partnerships. On macro level, Cheung et al. (2010) 2010 study negative and positive factors related to adopting PPP in procuring large public works and make a comparison between Hongkong, Australia and UK, finding that the attractiveness of PPP related to both efficiency and economic-driven factors, however emphasis of these factors varies between the countries studied. Another comparison study (Chan et al. 2009) discusses PPP drivers in China and Hongkong, noting that economic drivers are rated higher in China whereas in Hongkong, efficiency related drivers dominate. The capability of PPP to provide an integrated solution for public/infrastructure services was however deemed as the most important driver in both countries. On micro level, Roehrich and Caldwell (2012) investigate the implications of PPP provision from supplier perspective, emphasizing the need to unbundle the service offering for the sake of better risk management

and contract fulfillment. However, the effect of this unbundling may seem more expensive for the buyer, who is left with the challenging task of evaluating costs related to different service bundling/unbundling solutions and related contracting options. Through-life incentives are suggested as one alternative for driving mutually beneficial PPP arrangements. The importance of taking the through-life perspective into evaluating the feasibility of a PSS business model is also emphasized by Bankole et al. (2012) who conceptualize PSS through affordability in a multi-party setting.

4.5.4 Governance and contracting

Governance and contract issues are important aspects of complex solutions and addressed in most of the studies to some extent, whereas four articles specifically focus on this topic. Relationship governance aspects concerning complex product-service-systems are discussed by Roehrich and Lewis (2011), whose model describes the interrelationships between relational and contractual governance in an inter-organizational setting. In the domain of contracting, Datta and Roy (2011) conceptualize performance based-contracting in operations strategy in a framework comprising customer and service provider operations, contract definition and service delivery. Establishing a customer-solution team, understanding customer processes and inventory ordering pattern are found to be essential factors in enabling successful delivery of performance-based contracts. In a later study, the authors set up three alternative risk sharing scenarios for a performance based contract in outsourcing complex service solutions in the defense industry (Datta and Roy, 2013). Lukassen and Wallenburg (2010) focus on pricing and contracting in third-party logistics services by making an article review on industrial and logistics services in this context: based on literature, service pricing is found to have an effect on the relational outcomes in the respective relationships between buyers and service providers.

4.5.5. Sustainability

Sustainability is the most recent addition to the themes in the set of articles, featured in four studies. In the healthcare sector, Oruezabala et al. (2012) approach sustainability in public-private partnerships by studying sustainable procurement expectations that purchasing managers have for service providers. Sustainable procurement is linked to evaluating the supplier offering, optimizing the supply base, increased expectation on supplier innovations and increased need to evaluate total costs related to the purchased solution.

Bratt et al. (2013) look into green purchasing and criteria development in public procurement context. The authors evaluate the process for criteria development in terms of strengths, including the transparency of the process and documentation as well as weaknesses, including short-sightedness of the applied perspective and lack of clear definitions of objectives related to sustainability.

Altuntaş and Tuna (2013) focus on sustainability from environmental perspective by examining supplier evaluation criteria in logistics services; based on literature, the authors conceptualize environmental performance criteria for evaluation of on one hand, green real estate and green logistics services and on the other hand, green supplier evaluation and improvement of logistics services.

Discussion

Despite the number of articles was much smaller than what was anticipated in the beginning of the study, the review points towards several important insights.

The first conclusion from the study is that the extent to which purchasing of solutions has been studied does not correspond to the scale of solutions business in practice. Furthermore, the studies that exist so far remain highly fragmented. Therefore this study has identified a promising field for researchers to explore.

The second conclusion is that the leading purchasing and supply chain management journals have not reacted to the increasing activity in the context of solution offerings and product-service systems. A large part of the studies in the sample identified by this study represent the perspective of marketers and the marketing discipline. What is clearly missing in this area so far are the implications for the purchasing function, for example in terms of evaluating solution alternatives based on through-life costing, creating new supplier evaluation criteria, conducting the sourcing process including requirements definition and managing service providers capability during extensive contract periods. Thus, there are ample opportunities for purchasing scholars to enter this area of research.

One peculiarity is that none of the widely-cited 'classic' articles in the solutions literature made its way to the data set. For instance, 'Managing the transition from products to services' by Oliva and Kallenberg (2003) has over 1100 citations; this article does not even contain the word 'buy'. 'State-of-the-art in product-service systems' by Baines et al. (2007) has over 700 citations and mentions buyer-seller relationship in one sentence. All widely-cited articles focus on the development of integrated solutions (Brady et al. 2005, Davies et al. 2006, Windahl and Lakemond 2006, Brax and Jonsson 2009) and product-service-systems (Mont 2002, Tukker 2004, Aurich et al. 2006, Mont and Tukker 2006, Neely 2008). In other words, the searched streams of literature are thoroughly dominated by the provider's perspective.

As the third conclusion, this study suggests that servitization scholars with access to solution provider companies investigate the buyer's perspective. In order to produce novel contributions of highest possible relevance, purchasing and servitization scholars should collaborate by developing joint research projects.

Revisited in the perspective of Hill's views on services, with some insights on EU and France

Damien Broussolle⁶¹

First draft / preliminary results

Abstract:

A new definition of service has been proposed by Hill (1999) and endorsed by SNA and BOP last updates. The paper studies its consequences for industrial classifications, such as ISIC, and the respective shares of goods and services producing sectors. The first section reminds the main characteristics of the new definition. The second section scrutinises the list of sectors of ISIC Rev. 4 and 3.1 in order to show within which category (goods or services producing) the headings falls. The major changes concerns what may be called manufacturing services and information goods producing sectors, the former being previously included in goods and the latter in services-producing. The third section proposes a measure of the share of each broad category for EU 27 (2008–2011) and France (1995–2011). The tertiarisation trend, is preserved, even if several significant differences appear with standard presentations. Manufacturing services, at present added to services-producing by far supersede Information goods, added to goods-producing.

JEL codes: L8; E01;

Keywords: tertiarisation; industrial structures; services

Since many decades in almost all countries, there has been a steady trend toward tertiarisation (services-producing), whether measured through the share of employment or value added (Gadrey 2003, Memedovic Lapadre 2009). Obviously this trend is fairly depending upon the definition of the service, which induces in turn that of services producing activities (Daniels Bryson 2002). For instance there has been a debate on whether public utilities, such as power generation should be considered as services industries or not. Nonetheless, even if public utilities were not entirely included in services industries, the aforementioned trend would not be altered, but it could be so with a more radical change in the service definition. Yet, it happens that an innovative interpretation of what a service is, was popularised by Hill 1999 and was endorsed by SNA and BOP last update (Broussolle 2014, SNA 2009, IMF 2009). This new approach considers that since services cannot be isolated from the producer or the consumer, they are mainly characterised by the impossibility of establishing ownership rights over them.

This move has two main consequences for the tertiarisation trend: on the one hand several activities formerly included in goods producing industries, could be viewed as services, when they operate on goods that they don't own, i.e. processing goods for third parties that remain their owners. These circumstances may lead to a new category of "manufacturing services" (IMF 2009).

On the other hand several activities, which were formerly viewed as services industries, could be re-categorised in goods producing. It is the case for all traditional services activities which output may be subject to ownership rights, such as film production, software and several Knowledge Intensive Business Services (KIBS). Those industries are producing what SNA 2008 designates as knowledge-capturing products.

The accurate consequences of the new perspective, either on the classification of services activities or on the tertiarisation trend, have yet to be drawn. They might prove to be significant. The purpose of the paper is to suggest a first assessment of those potential changes, which may influence several aspects of economic policies related with the deindustrialisation issue.

It is at least a major subject of concern in the euro area, for instance the European Commission Europe 2020 strategy aims at increasing to a 20% the share of industry in EU GDP, if not in all developed countries. One aspect is the extent of deindustrialisation, since quite a few services producing activities may be seen as goods producing. What is customarily called deindustrialisation could rather be a shift in goods-producing sectors, when new ones are included. Another aspect concerns international trade, whether on a strategic level or on an academic one. On the strategic level, the issue deals with what economic sectors do increase exports within the current transactions account? Activities which output is prone to ownership rights may be great contributors; consequently they should be supported, even if they are not included in the long-established manufacturing group. On the academic level, when the services activities are better delineated, their poor cross border trade capacities is strengthened, since several traditional viewed services industries

⁶¹ Maître de Conférences en Economie Habilité, Institut d'Etudes Politiques 47 avenue de la Forêt Noire F-67082 Strasbourg CEDEX, damien.broussolle@unistra.fr

that were actually major exporters, shift to goods producing. Hence, the already dominant share of goods-producing sectors in exports anew increases.

The paper is structured as follows. First it will briefly remind the main aspects of the new perspective on services. Second, it will draw its consequences on the categorisation within goods-producing and services-producing industries in the perspective of the International Standard Industrial Classification (ISIC, Rev. 3 and 4). The actual purpose of this study will be to suggest evolutions, consistent with the new approach on services. That process will show which broad sector would expand or shorten. The last section will use detailed data to measure the effects of the new reorganisation on the tertiarisation of employment and value added.

1 The new service definition and its issues

The new definition of service departs to a certain extent from familiar views, which are mostly grounded on intangibility (materiality) and non-storability, whereas goods are material or physical entities⁶²:

It is especially centred on the fact that services are flows (Hill 1977), which induces that they are not separate entities from the provider or the recipient, thus they cannot be traded separately from their production. Consequently no ownership rights may be established over services. This innovative view owes much to Hill's works (1999), it is endorsed by the manuals of the National Accounts (SNA 2009) and of the Balance of Payments (IMF 2009) (see box n°1).

The new view have several significant upshots, the major one is that some industries, commonly regarded as services-producing are mainly providing goods (Hill 1999), a fact which may appear fairly disturbing. Conversely several manufacturing classified industries are producing services. As mentioned, the very effects of those elements have yet to be drawn, both on industrial taxonomies and on the measurement of the industrial sectors.

Box n°1: Services enhanced definition, original in SNA (2009) manual

Services § 6.17

“Services are the result of a production activity that changes the conditions of the consuming units, or facilitate the exchange of products or financial assets. (...) services are not separate entities over which ownership rights can be established. They cannot be traded separately from their production. By the time their production is completed, they must have been provided to the consumers.”

Originals 6.208

“The production of books, recordings, films, software, tapes, disks, etc. is a two-stage process of which the first stage is the production of the original and the second stage the production and use of copies of the original. The output of the first stage is the original itself over which legal or de facto ownership can be established by copyright, patent or secrecy. (...)”

Knowledge capturing products

6.13 – *“(...) some service-producing industries may produce products that have many of the characteristics of goods. For convenience, the products of these industries are described in the SNA as **knowledge-capturing products**”.*

6.22 – (...) *“The outputs of these industries, over which ownership rights may be established, are often stored on physical objects (whether on paper or on electronic media) that can be traded like ordinary goods. They have many of the characteristics of goods in that ownership rights over these products can be established and they can be used repeatedly. (...)”*

The new perspective carries two main consequences for the categorisation of activities: firstly it provides a substance to the concept of manufacturing services and secondly it raises doubts on the categorisation of the output of traditionally viewed service-producing activities. Altogether thus, it prompts for a reorganisation of the customary services vs. goods producing separation in industrial taxonomies.

1.1 Manufacturing services

Manufacturing like industries may provide services in several circumstances, even as their main output. This possible occurrence is well-recognised for repair services, but the new perspective on goods and services goes further on. Every time an economic unit, even customarily ranked within goods-producing, performs an activity for third parties, on goods which it does not own, it is providing a service. Indeed in these circumstances its output may not be isolated from the producer or the recipient and, as such, it is not prone to ownership rights. This derives from the fact that the manufacturing operation is performed on materials not belonging to the economic unit, which is thus an essential

⁶² Selon la définition qu'en donne l'INSEE, « relèvent de l'industrie les activités économiques qui combinent des facteurs de production (...) pour produire des biens matériels destinés au marché ». Les biens sont des « objets physiques pour lesquels il existe une demande, sur lesquels des droits de propriété peuvent être établis (...) ».

feature. As it may be understood, it is an extension of the repair case. This approach is already applied in the BOP with the treatment of goods sent or received from abroad for processing (IMF 2009). Prior to 2008, that activity was regarded as exports of goods and when coming back, as imports. According to the new treatment, when there is no ownership change between the principal and the agent, these movements shift to services transactions. Similar views have somehow been also applied in ISIC rev. 4. Consequently when a manufacturing like unit provides that kind of service as its main activity, it should be included within the services sector, for instance in a manufacturing services heading.

An analogous reasoning also applies to construction activities, among which several are usually performed as sub-contractors, on third parties owned materials (see next section).

1.2 Information goods: knowledge capturing products, original and copies

The new information economy significantly relies on dematerialisation and delivery through New Information and Communication Technologies (NICT).

Because the output of several commonly viewed services-producing industries may be digitalised, it can be delivered separately from their producer and stored. Furthermore it becomes possible to apply over it ownership rights. In order to take into account that evolution, since 1993 the SNAs have acknowledged for a category of products bearing both characteristics of goods and services (box n°1), which the 2008 update calls *Knowledge-Capturing Products*. Subsequently several traditionally viewed services-producing industries are deemed to produce goods-like products. In fact they are true goods as Hill's (1999) paper convincingly demonstrates by referring to the concept of *original*:

An *original* is the result of a creative process that produces an intangible entity. It may be copied as many times as necessary, without being altered. Enduring originals, such as a patent or an architect's plan, may be viewed as some kind of new assets. Therefore, if used over a long period it is considered as an intangible asset by SNA. An original is definitely a good (Hill 1999 p. 440), "An original is the archetypal immaterial good. It is a good because it is an entity over which ownership rights can be established and which is of economic value to its owner". SNA acknowledges for this fact since SNA 2008 (§ 6.208, see also 10.99 sq.). It is worth underlining that the original is not the physical matrix of CD, film... the original is the very intellectual production that can be stored on some device (Hill 2003). Copies are undoubtedly goods as well, but as every goods they can be sold outright or made available under a license. When sold outright, a copy is a good, to be considered a [fixed] asset if used in production for more than one year. A copy purchased with a license may still be regarded as a commodity ([fixed] asset) if according to SNA "the licensee assumes all the risks and rewards of ownership copies (SNA 2009, § 10.100)". The manual suggests that the only situation when a license does not fall within the asset/ commodity case is when it does not involve a long-term contract. In these circumstances, the transaction relates to a flow of services.

Several services-producing viewed industries can produce originals, thus goods. Those originals, as well as their copies, can be sold outright as goods (for instance database sale), or through subscription as services (for instance database instant access). When economic units are customarily producing originals or assets as primary output, they should be categorised within goods-producing units, even if they are commonly viewed as services-producing. For example, since most software is commonly sold outright or through long-term access contracts, where ownership may be viewed as transferred, they are not services. Hence, the software programming industry should no more be included in the services sector.

Finally let us underline that although any manufacturing activity maybe turned into a services one, depending on the contractual relations between the producer and the customer, true services-producing may not be turned into goods-producing.

Next section will study what are the consequences of those innovations on industrial classifications.

2 A new interpretation of industrial taxonomies

This section points out the main consequences of the new definition of the service for the categorisation of goods and services producing sectors. The analysis covers both ISIC rev. 3 and 4 since a major revision has taken place in 2008, which has led to a break in their presentation. It gives an occasion to pinpoint the changes that shed a better light on services activities, even if the partition between goods and services producing is not their main purpose (Rev. 3.1 p. 10, Rev. 4 p. 9).

2.1 General principles of the reorganisation

In accordance with the views presented in the previous section, any goods-producing activity, which output is, on a main and usual basis, neither separable from the provider, nor from the recipient, maybe classified within the services-producing sector. This especially concerns manufacturing like activities, which are carried out as subcontractors for third parties on not owned, or more commonly described as not self-produced, materials. Conversely, any activity over which output, on a main and usual basis, ownership rights maybe established, i.e. which output is separable either from the producer or the consumer, is classified within the goods-producing sector, whether services like or not. This especially concerns information activities, usually classified within services producing.

As stated in ISIC manuals (Rev. 3 and 4): “Manufacturing units may process materials or may contract with other units to process their materials for them. Both types of units are included in manufacturing.” (UNO 2002 p.69, UNO 2008 p. 85). Thus unfortunately manufacturing entries are hardly ever established according to the criteria whether the activity is carried out on products belonging to third parties or not. Moreover, in the accompanying commentaries that characteristic is not systematically mentioned, even when industries may be concerned, for instance with textile or wearing apparels, still some hints are provided. Be that as it may, Rev. 4 introduces improvements to distinguish proper manufacturing activities, from manufacturing services, or else services related and incidental. Those improvements partly take into consideration the new advocated service perspective. For instance, as a major step towards the recognition of a broad manufacturing services heading, all specialised repair activities are now separately classifiable⁶³. Following the same orientation, contrary to the Rev. 3.1 presentation, that was customarily incorporating services related activities --or installation when carried out as a special activity⁶⁴, with their goods-producing group, in the Rev. 4 they are now quite often detached in a dedicated sub-heading. For instance: *support activities to agriculture and post-harvest crop activities*, as well as *forestry* (#024), or *Remediation activities and other waste management services* (#3900) are separately gathered. In the division 09, *Mining support service activities* are also better delineated and enhanced, than in the previous Rev 3.1 sub-division.

Finally, even if ISIC utterly states that it is not interested in the goods-services producing categorisation, the last revision render visible the services that were earlier incorporated within goods producing sectors.

Still it is worth noticing that whereas ISIC delineation, between an activity and its maintenance and repair corresponding one, depends on the results of the output being a new product or not⁶⁵, the rationale of this paper relies on the fact that the former produces commodities and the latter services. What is at stake thus is the possibility or not to establish ownership rights on the output, or alternately stated if the operated materials are or not self owned. This principle may need some explanations particularly with installation activities, they will be provided, in the appropriate section.

2.2 A look at the main headings of ISIC that deserve discussion

Before scrutinising the main sections, let us begin with three general considerations:

First, a usual grouping of goods-producing and services-producing sectors, agglomerates agriculture, mining, manufacturing, and construction, in the first class; and all other industries, including government, in the other one (Kutscher & Personick 1986, Memedovic & Lapadre 2009). Let us notice that this way of doing allocates utilities to services-producing, whereas many continental studies include them in goods-producing (Schettkat & Yocarini 2006, Demmou 2010, Shreiber & Vicard 2011). Other studies of deindustrialisation do not use a goods vs. services presentation (Montresor Vittuci-Marzetti 2011). This debate will be settled below when tackling with utilities.

Second, albeit Agriculture, forestry and fishing may include services activities, whether concerning service activities incidental to agriculture as mentioned in the ISIC manual, or services activities according to the new service approach, due to available data, the analysis focuses on industry and services sectors.

Third, even if the main discussion is based on ISIC Rev. 4 ordering and presentation, the text also addresses ISIC Rev. 3.1, when it is useful and illuminating. Two tables summarises how headings may be categorised, thus gathered and reorganised.

B Section: Mining and quarrying

This section is definitely belonging to goods-producing; nevertheless some of the technical operations, particularly related to the extraction of hydrocarbons, may be carried out for third parties by specialised units as a manufacturing service. They are mainly grouped in division 09 (*Mining support service activities*).

C Section: Manufacturing

The bulk of the section obviously rests with goods-producing, with the exception of some divisions. They concern manufacturing or repair and maintenance services, as for instance *metal working service activities* (#259) or *Repair and installation of machinery and equipment* (#33, see table n°). *Installation of industrial machinery and equipment* (#332), is a service when the installer is not the manufacturer of the equipment, or when being a subsidiary/ affiliate of the manufacturer, installation is its main activity. It is the case of the specialised installation heading.

Printing and reproduction of recorded media (#18) and Printing and service activities related to printing (#181) included in Manufacturing are evoked with section J Information and communication.

⁶³ In ISIC. Rev.3.1 « Activities of units primarily engaged in maintenance and repair of industrial, commercial and similar machinery and equipment are, in general, classified in the same class of manufacturing as those specializing in manufacturing the goods » (UN 2002 p.).

⁶⁴ “Assembly and installation of machinery and equipment in mining, manufacturing, commercial or other units, when carried out as a specialized activity, is classified in the same class of manufacturing as manufacture of the item installed.” (UN 2002 p.)

⁶⁵ “As a general rule, the activities in the manufacturing section involve the transformation of materials into new products” (UNO 2008 p. 86)

D & E sections: Utilities

The traditional view of utilities covers power and water supply and related activities, which quite often are included in services-producing.

However, the production of electricity, gas, steam and air conditioning is not to be considered as a service provision. It is not because electricity... could be regarded as a material entity, contrasting with “immaterial” services, but because electricity... are separable from their producer or recipient and thus prone to ownership rights. It is also worth noticing that their production and consumption are distinctive operations, whereas, for instance, it is not so in the case of telecommunications services. In fact, only their delivery or long-distance transport is a service activity. However this dimension of the activity is seldom purposely identified. As the ISIC manual puts it, “the network [*permanent infrastructure*] dimension of those activities is not decisive” (UN 2008 p. 165). Yet long distance transport of fluids through pipelines is captured in division *pipeline transport activities* (#4930). Since European directives concerning network industries, such as railways, postal services or power generation, command to isolate the transportation from the production activities, it should become more and more easy to capture the services share of the output. As a matter of fact, the European classification, NACE Rev.2, retains four sub headings to transport and delivery of gas and power (Table n°3).

For similar reasons *water supply; sewerage, waste management and remediation activities* (Table n°1) are not to be regarded globally as service activities. Obviously, water supply may incorporate several sub processes that belong to services, such as water transportation or sanitation. Nevertheless, usually, what is sold is the water itself, not those services per se. The final product is processed water, which can be stored and isolated from its provider or user. The whole operation is akin to that of producing standard goods using intermediary inputs and services. Actually, selling water services only, for instance sewerage would require that the customer remain the owner of the water, on which the services would be applied.

An adapted line of reasoning is to be applied to recycling and waste disposal. Recycling (#383 *Materials recovery*), where the operator becomes the owner of the waste, which he may sell after transformation as input for further processes, is not a service activity. Contrary to waste disposal, its main dimension does not rely in getting rid of refuse (i.e. essentially a collect, transport and storage activity). It is important to make a proper distinction between the common language, which may see recycling activities as bringing a service to customers, as every economic activity do, and the essence of those activities which is acquiring waste to transform it into new raw materials. In this perspective, Rev. 3.1 that included *Recycling* in manufacturing industries was accurate, even if its motive almost certainly was not that of this paper.

As stated above, waste collection, disposal or sewerage are mainly services activities. Nevertheless, it is worth mentioning that the activities grouped in the sub heading *Waste treatment and disposal* (#382), may in the near future become goods-producing, when derived power generation and similar productive operations have reached a dominant share of their turnover. When this is achieved the recycling dimension will supersede the disposal dimension.

The ensuing, *Remediation activities and other waste management services* (#39) heading, which gathers decontamination and cleaning of soils and groundwater activities complies with the service definition.

Table 1. *Water supply, sewerage, recycling.*

Rev. 3.1 presentation

D (Manuf.)	37	Recycling	<i>goods</i>	See main text
O (Personal serv.)	90	Sewage and refuse disposal, sanitation and similar activities	Mainly <i>services</i>	collection & treatment of household and industrial waste, not for a further use

F section: Construction

The Construction section is traditionally categorised with goods producing, but several sub-activities are services producing, not considering allocating workers for construction, which belongs to the business services sector.

The *Specialised construction activities* (#43, see table n°3) concerns: “the construction of parts of buildings and civil engineering works, without responsibility for the entire project” (UN 2008 p. 175). Those activities are mostly carried out under subcontract, and may be directly done for the owner of the property, especially in repair construction. For instance they encompass *Demolition and site preparation* or *Building completion* services (including repair services), which are carried out on non self-produced parts. Thus overall they are services producing activities.

Construction installation activities grouped in *Electrical, plumbing and other construction installation activities* (#432), consistently with *Installation of industrial machinery* (# 332), are providing services, because most often the installed part is not self-produced by the company, or when adapted, not fundamentally transformed and the value of the installed parts is rather low as compared to the service dimension of the whole activity. Besides, as exposed before, those activities are carried out as specific activities.

G section: Trade

No doubt that almost all activities gathered in the trade section provide services. However considering the deindustrialisation debate, it is worth mentioning that trade includes what Bernard & Fort (2013) name factoryless goods producer (FGP), i.e. plants and firms that are primarily involved in activities related to the overseas production of manufactured goods, but are incorporated by statistics within wholesale. Those economic units organise manufacturing abroad, for instance they design and market their own goods. They are at the head of an international manufacturing process, and thus they could be grouped in the manufacturing section. In USA according to Bernard & Fort (2013) FGP establishments, amounted to a 6.5 percent of total wholesale in 2002 (10.5 in 2007) and account for 10.2 percent of employment and 5.2 percent of output. If shifted to the manufacturing sector it would displace to manufacturing at least 431,000 workers to as many as 1,934,000 workers from wholesale in 2007.

Those views apply on “wholesale establishment that performs design/ engineering/R&D activity at the establishment and either conducts manufacturing operations at the establishment itself or purchases manufacturing services from a domestic or foreign company” (Bernard & Fort 2013 p. 12). It is worth noticing that the new definition of services also tends to shift those economic units to goods-producing, for two reasons. On the one hand they are involved in the production of information goods (design; engineering and R&D). On the second hand, as principals, i.e. buyers of foreign manufacturing services, they are the owners of the transformed goods, which production they have initiated. Therefore the new service definition supports the interpretation of Bernard & Fort. Yet, it will not be implemented in this paper because the special information required was not available.

J Section: Information and Communication

The section has been created with ISIC Rev. 4, its forewords stresses that it includes: “the production and distribution of information and cultural products” (UNO 2008 p. 205). Quite many of those cultural products, over which ownership rights maybe established are actually information goods, or in SNA’s terms Knowledge-capturing products, only their delivery is a service activity. It is hence the chief section which interpretation is impacted by the new service definition.

The case of *Printing and reproduction of recorded media* (#18) and *Publishing* (#58) is especially interesting. Although the former activity is traditionally viewed as belonging to the manufacturing industries, with a few exceptions⁶⁶, and the latter to services, the new perspective tends to revisit this disconnection. Truly indeed Printing result in an isolable entity thus belongs to goods-producing, but Publishing may also be so attributed. As the manual states: “Publishing includes the acquisition of copyrights to content (information products) and making this content available to the general public by engaging in (or arranging for) the reproduction and distribution of this content in various forms” (UN 2008 p. 206). While the distributive part of the activity definitely belongs to services, but is most frequently carried out independently by various stores and retailers (included in Trade section), the other components of the activity are concerned by production and reproduction. In these last circumstances, the product (asset if an original) under exchange is prone to ownership rights, and thus the activity falls within the goods-producing sector. Let us emphasise that this rationale is applicable to all sub-sectors which deal with information goods production, such as software, directory or mailing lists, newspapers, motion pictures (see Table n°2).

For the two divisions: Motion picture, video and television programme production, sound recording and music publishing activities and Programming and broadcasting activities (#59 & # 60), the main principles drive to separate programming or production (i.e. the activity of making a motion picture, a video or a TV programs, or else making a matrix through recording⁶⁷) and the broadcasting or distribution. The former falls within the goods-producing category, since it results in an information good, whereas the latter within services. However, those two activities are not always distinguished. Although mixed, the sub-headings may generally be counted with goods-producing because the main

⁶⁶ Division #18 Printing and reproduction of recorded media, is included in Manufacturing in ISIC rev. 4, of which #1812 is Service activities related to printing.

⁶⁷ Music and sound recording may either result in a service or in an information good depending on the commercial contract. However since it is mixed with Publishing it is categorised in goods producing.

share of their value added is external to the sole broadcasting activity. However there are three exceptions, sub-headings #5912, #5913 and #5914 (see Table n°2).

Table 2. Information and Communication (#58-63).

Division	Group	Class	Description	Category
Division 58			Publishing activities	goods
	581		Publishing of books, periodicals and other publishing activities	
	582		Software publishing	
Division 59			Motion picture, video and television programme production, sound recording and music publishing activities

		6201	Computer programming activities	goods
		6202	Computer consultancy and computer facilities management activities	services
		6209	Other information technology and computer service activities	services
Division 63			Information service activities	
	631		Data processing, hosting and related activities; web portals	Mainly Serv., because 6311> 6312
		6311	Data processing, hosting and related activities	Services: not owned or self-produced data
		6312	Web portals	goods
	639		Other information service activities	goods
		6391	News agency activities	see text
		6399	Other information service activities n.e.c.	see text

Computer programming, consultancy and related activities sub-section (#62) includes programming activities that result in information goods, such as software.

Information service activities (#63), includes data processing and web portals activities, of which several headings may be included in goods-producing, when then produce and sell information. Most frequently data processing operates on third parties data (see Rev. 3.1 accompanying comments), whereas web portals activities provide data or information they have mostly produced (gathered). Since the provision of information is also organised through a long term access license, it is useful to remind how SNA deals with such transactions. A copy purchased with a license is regarded as a commodity (or fixed asset) if “the licensee assumes all the risks and rewards of ownership copies (SNA 2009, § 10.100)”. The only situation when a license does not fall within the asset/ commodity case, is when it does not involve a long-term contract. In these circumstances the transaction relates to a flow of services. Consequently, a long-term license of use, which is quite frequent, is almost analogous to full ownership and outright sale.

Other information service activities class (#639) is quite mistakenly labelled. This class includes, activities such as news agencies, which main object is to sell information, which is obviously separable from its provider or receiver, thus an information good.

Section M: *Professional, scientific and technical activities* (#69–75), gathers mainly services producing activities, but the purpose of several maybe producing authorised documents, design charts or reports, over which ownership rights may be established. When it becomes their main output they have to be categorised in information goods producing. It is especially the case of *Advertising and market research activity* (#73), which object is the creation of advertising campaigns and placement of such advertising in periodicals... those output take a separable form, or result in advisory document or reports (marketing and poll research).

Finally, altogether as compared to common practice, which tends to agglomerate broad sections to measure the tertiarisation and deindustrialization trends, this analysis shows that there are at least height headings or sub headings that are related to services in broad sections A-B-C-F, that are usually viewed as purely goods-producing. Conversely there are nearly a dozen headings, or sub headings, that relates to goods in broad sections D-E-J-M that are usually viewed purely connected to services-producing. The result of the preceding survey is summarised in table n°3.

Table 3. ISIC Rev. 4 Main list of industries (excerpts).

	96	Undifferentiated goods-producing activities of private households for own use	goods	
	97	Undifferentiated service-producing activities of private households for own use	services	
Q	99	Extra-territorial organizations and bodies	services	

The next step of the study consist in measuring how much the new reading affects the share of goods producing and services producing.

3 What changes for goods and services producing shares?

To be implemented, the reorganisation requires at least detailed data at the four digit level, but they are not available on the OECD STAN database dedicated to industrial data and ordered accordingly to ISIC principles. However, Eurostat provides annual detailed enterprise statistics for various industries arranged following NACE classification, which is inspired by and very close to ISIC, but which does not cover the entire economy (see below).

The analysis of the evolution of industrial shares requires a rather long period of comparison. Unfortunately the new ISIC Rev. 4 classification has introduced in 2008 a major divide in statistics series. This gap cannot be bridged, because the changes between Rev. 3.1 and Rev. 4 are too numerous and too deep, for instance a great number of manufacturing headings have been split into three, even four new divisions, also the number of headings have been significantly extended. Another difficulty comes from the creation of new broad sections like Information and Communication (J).

The same phenomenon occurred for NACE. Thus series of data following ISIC Rev. 3.1 (resp. NACE 1.1), may range up to 2007; new series following ISIC Rev. 4 principles (resp. NACE 2) begin in 2008. As a consequence recent tables are based on NACE 2 and the old ones on NACE 1 or NACE 1.1⁶⁹.

Two series of tables are proposed. The first series is based on NACE 2 (ISIC Rev. 4) and concerns the share of employment and value Added (at factor costs) in goods and services producing sectors for the UE 27 as a whole and for France. They range from 2008 to 2011. The second series of tables concerns France only and use a particular national source (see appendix for the characteristics of the source). It is based on a special extraction of enterprise data at the finest unrestricted level (five digits) of NACE 1 (1995 to 2002) & 1.1 (2003 to 2007). This level is not available in Eurostat database, yet it is especially valuable to classify as much as possible the results in headings approximately close to those of Rev. 4.

It must be reminded that in the two series of tables the depicted economy is not entire; several major broad sections are not included in both the databases, such as Agriculture-fishery, Finance-Insurance and Government. In addition, because Structural business statistics (SBS) from Eurostat covers only business economy, in this database Education, Health and social works activities are missing. These deficiencies significantly lessen the tertiarisation trend and the proposed figures may not be comparable with other similar studies. However that phenomenon does not impede this analysis, since its main goal is to scrutinise what are the consequences of the new service definition on the share of employment and VA as compared to the standard views.

3.1 The tertiarisation preserved

Let us warn the reader that due to a shortage of time, the subsequent sub-sections are only sketchy.

The new presentation does not change our broad views on the hierarchy among major sectors, it even magnifies it, nor does it impede the long standing evolution towards services.

Table 5. UE 27 employees (NACE 2 / ISIC 4).

%	Standard presentation					New arrangement			
	2008	2009	2010	2011		2008	2009	2010	2011

Real estate activities	1,43	1,49	1,47	1,48		1,43	1,49	1,47	1,48

⁶⁹ As a matter of fact there has been a slight change in the European classification in 2003 (NACE 1.1), which included few aspects that were eventually confirmed with NACE 2/ ISIC Rev. 4. This update has only little consequences for this study. It essentially affects wholesale and, marginally, 722 A-Z Software publishing.

Source: Eurostat Structural Business Statistics (SBS)

Whether measured, by employment or Value Added, the share of services sectors raises with the new arrangement (Tables n°5 to 8), by 4 to almost 10 points of percentage, depending of the reference and the country under scrutiny.

This result most of all derives from two conflicting changes; the first one concerns the better delineation of Manufacturing and Construction services, which in turn increases the share of services producing, by approximately at least 7% for UE 27. It is worth underlining that the influence of Construction services is well above that of Manufacturing services. As a matter of fact Construction services at least amount to a 50% of the Construction section. The second one is the creation of Information goods, which indeed tends to increase the share of Goods-producing activities, but by a mere 2 or 3 percentage points. This study thus shows that the weight of Manufacturing services, by far supersedes that of Information goods. Nevertheless that first learning does not exhaust the subject.

Indeed the comparison between employment and value added tables gives rise to another interesting finding. The share of the goods producing sectors measured in VA is larger than when done in employment (respectively that of services producing is smaller), both with the standard and the new arrangement. However this imbalance tends to increase when the shares are measured through the new method. It is especially noticeable for France, which level of goods-producing is lower than EU 27. Similarly, the fall of goods-producing nearly vanishes when using the new definition when measured in VA for EU 27. These facts illustrates that the VA per employee produced by the newly measured manufacturing services --hence subtracted to goods producing, is smaller than that of the information goods sectors --which are added. In other terms, Information goods sectors are more productive than Manufacturing services. This finding is to be combined with that of the next sub-section.

3.2 Tertiariation in the two last decades in France at a glance

Let us now turn to findings concerning especially the French economy, for which it has been possible to gather data ranging from 1995 to 2011 (Tables n°10 to 7). However, due to the change in the classification, they are split in two series of tables. The two series use consistent sources and data, but are built on two versions of the NACE / ISIC classification. In order to facilitate the reading, the table following NACE 1 has been rendered, as much as possible, close to the NACE 2 ordering. For instance Recycling and Water supply have been removed from Manufacturing and similarly several services-producing headings are depicted out of their formally intended broad sections. Nevertheless, as previously noticed the changes introduced in 2008 are so deep and numerous, than an adequate matching for all headings is out of reach. Nevertheless, broad figures and several divisions are consistent and the evolution of the share of goods and services producing sectors may be read on the whole period.

As explained above the new definition confirms and even increases the tertiarisation phenomenon (Graph n°1a & b)⁷⁰. Moreover the study corroborates the usual profile of the deindustrialisation tendency (Kutscher Personick 1986), as stressed for instance by Montresor Vittucci Marzetti (2011): « For a long time, the global process of tertiarisation was accompanied by rising industrial shares in total value added, but from 1970, tertiarisation coincided with relative downsizing of the manufacturing sector » (Memedovic Lapadre 2009 p. 49).

Nevertheless, the new definition tends to lessen the tertiarisation trend by approximately 2 points of % (Tables n°9 & 10). This remark may seem at odds with the year 2010, for which data arranged consistently with the new definition, depict a stronger increase in tertiarisation, than those according to the standard method. This occurrence, even more obvious for the value added figures, actually illustrates that the data ordered according NACE 2 principles, better measure Manufacturing services, which reach almost a 3% in 2010, as compared to a mere 1.1% in 2005, when assessed accordingly with NACE 1.1.

That circumstance somehow hides the fact that, in the last decades, the discrepancy between the standard and new modes of presentation tends to shrink (Tables n°9 & 10). Two reasons may be proposed to explain this phenomenon: due to the reducing pace of the reorganisation of production process, Manufacturing services expands more slowly than before. In addition, the long established weakening of the goods producing sectors also affects the magnitude of manufacturing services. In other words, outsourced activities (agent activities) are affected by the size of their principals. From 1995 to 2007, in France the weight of Manufacture services in employment, has decreased from a 1.2% to a 1%. Conversely, Information goods sectors are in an exact opposite situation: they experience a growth trend. It is thus possible to envision that, in the future, those two tendencies will cross each other, with as an impending consequence a potential rise in goods-producing.

⁷⁰ The data presented don't reallocate temporary workers in the users sectors, as for instance Bernard, Smeets and Warzynski (2014) or Shreiber and Vicard (2011) do. If done so, it would have approximately add a 10% employee in Manufacturing, and reduce Real estate, renting and business activities employment by an 18%, thus slightly lessening the deindustrialisation. Let us however notice that, while this correction is relevant for the measurement of employment shares, it is not for Value Added.

4 Conclusion

The paper suggests a way to reorganise industrial classifications, such as ISIC Rev. 3.1 and 4, to take into account the new definition of services proposed by Hill (1999) and implemented by both SNA and BOP last updates. The changes essentially regard three headings: Manufacturing services, Construction services and Information goods. The former designates manufacturing like services that are operated for third parties on materials that are not self produced or not self owned. A similar rationale applies to Construction services that mostly cover site preparation, installation and specialised construction. Information goods relates to the output of activities, on which ownership rights may be established and which may be sold like goods, for instance software or data. The two former headings add to services-producing, whereas the latter, formerly regarded as services activities, adds to goods-producing.

The reorganisation of the classification lists is tested on Eurostat and INSEE data. Altogether the tertiarisation, as understood as a bigger services-producing sector, is preserved. This proves that the shift of Manufacturing and Construction services has a bigger effect, than that of Information goods. As a matter of fact it is essentially due to Construction services that amount to at least a 50% of the of ISIC Construction division. However the tertiarisation/deindustrialisation trend is affected, since the share of services-producing is growing slower when measured with the

new definition. Implementing the new definition would hence facilitate increasing the share of industry value added as the EC requested. Nevertheless, the last result, which is mostly based on the French case, has to be checked on other countries.

On the whole, it must be underlined that the findings of this first work need to be confirmed and sharpened for several reasons. Firstly they mix up better measurement of services as of ISIC updates and Hill's new definition. Secondly, since the long run trends derive from data mostly ordered under the old classification (Rev. 3.1), it is necessary to make sure that they hold under the recent update. Thirdly the results also need to be tested against more countries to become more relevant. It will be the task of a future work.

Finally the study arouses a comment regarding exports. The current account of the BOP mainly gathers cross-border trade, or in GATS terms mode 1 exports. Many studies have shown that services activities are poor cross-border traders; the new definition strengthens those views, because it reallocates to goods account, information related exports on which ownership rights may be established. This concerns a large share of property rights flows that are grouped in the Charges for the use of intellectual property heading (services account). Moreover exchanges of motion pictures, TV shows and software that were viewed as flows of services become classified within goods. Altogether hence the exports of services shrink, while that of goods increase.

French special data

Source : Ficus 1995–2007

Le fichier Ficus est une extraction de la source statistique SUSE : Système Unifié de Statistique d'Entreprises. Ensemble cohérent de données individuelles et statistiques sur les entreprises, la source statistique SUSE provient de l'exploitation conjointe de deux sources : l'une fiscale, qui regroupe les bénéficiaires industriels et commerciaux (BIC) et les bénéficiaires non commerciaux (BNC) et l'autre statistique, l'enquête annuelle d'entreprises (EAE).

Zone : France

Secteur d'activités :

Les activités suivantes :

- L'agriculture, sylviculture, pêche
- Les Activités financières et d'assurance
- l'administration
- les activités associatives et extra-territoriales ne figurent pas dans les tableaux car :
- le fichier Ficus couvre partiellement ces secteurs.
- le plan comptable des activités financières est particulier.

De même, les données sur les entreprises ayant un code activité « défense » sont interdites de diffusion.

Sélections effectuées sur le fichier :

Les observations ayant des numéros siren non renseignés ont été éliminées.

Les observations en double ont été éliminées. On retient les observations dont le montant de la valeur ajoutée est le plus élevé.

Les croisements :

Activités Niveau 700 X (Nombre d'entreprises, Effectif salarié moyen, Valeur ajoutée brute aux coûts des facteurs)

Les tableaux :

13 tableaux, un par année de 1995 à 2007

fichiers en format sas, du type taaa.sas7bdat (*aaaa*) représentant l'année

Le secret statistique en quelques chiffres :

Un certain nombre de cases peuvent être à blanc en raison du secret statistique et fiscal.

Les règles du secret statistique, avalisées par la CNIL dans un avis du 27 mai 1997, concernent le nombre d'unités agrégées d'une part, le poids de chaque unité dans le montant agrégé d'autre part.

Les seuils à appliquer sont les suivants :

- Règles du nombre d'unités
 - Cas général : une donnée agrégée ne sera pas communiquée lorsqu'elle concerne moins de trois unités
 - Cas particulier : En matière de fiscalité des personnes physiques ce seuil est porté à 11 unités

Règle du poids des unités

Une donnée agrégée ne sera pas communiquée lorsqu'elle comprend un élément dominant qui représente plus de 85% du montant agrégé.

Précaution d'emploi :

Les mouvements sur les durées et dates d'exercice, les changements d'activité, les modifications de structure (fusion ou scission d'entreprises) ne rendent pas les évolutions annuelles cohérentes

Service Innovation Research: Looking for Definition and Boundaries

Angela Caridà¹, Marco Galvagno², Maria Colurcio³

¹University Magna Græcia of Catanzaro, ²University of Catania

The paper outlines the intellectual structure of Service Innovation research to provide a comprehensive review of the literature. Authors adopted a rigorous statistical approach and three different multivariate statistical techniques (e.g. non-metric multidimensional scaling, cluster analysis and factor analysis) to identify contributions playing a pivotal role in this domain, and the relationships between different research fronts. Results show three research perspectives, and five common themes, which have been largely debated by scholars. Finally, the study traces emerging trends and gaps to provide a basis for continuous expansion of the service innovation research field.

1 Introduction

In the late 1990s, service innovation started to get attention in all western countries in correspondence with the extension of the process of servitization (Vandermerwe; Rada, 1988) and the overcoming of the conceptual distinction between goods and services (Gummesson, 2005). In a context increasingly becoming service-centric both the service industry and the traditional manufacturing firms become dependent on services (Edvardsson et al., 2013): “*the service is the foundational concept of the exchange and consists of the application of specialized competencies (knowledge and skills), through deeds, processes, and performance for the benefit of another entity or the entity itself*” (Vargo; Lusch, 2004, 283).

In the last few years the interest of scholars in the service innovation has led to an intense scientific debate which has been reflected in the increasing number and type of official research meeting (workshop, roundtable, conferences, special group of interest, special session, theme of annual conferences), as well as, in the increasing number of publication on the subject (Kindström; Kowalkowski, 2014). Specifically, Carlborg et al., (2014) in their recent contribution on Service Industries Journal highlighted that more than the 82% of papers on Service Innovation have been published over the past 10 years (e.g. 106 out of 128 papers published between the 1986 and 2010).

Contributions on Service Innovation are heterogeneous and show different perspectives. Some researches stressed the different degree of novelty between service innovation and product innovation: the former are incremental and less radical than product innovations (Johnes and Storey, 1998), and are less technology-based (De Brentani, 2001). Other studies (Edvardsson et al., 2010) stressed that Service Innovation processes are more difficult to be managed through a stage gate model, as they are less formal than product innovation processes. De Brentani (2001) pointed out the collaborative nature of Service Innovation stressing the role of human resources. The contributions that mainly emphasize the reach of Service Innovation come from scholars who framed the theory of innovation in a service context (Galloway; Weinstein, 1997; Drejer, 2004; Michel et al., 2008) encompassing all types of innovation and challenging a view of innovation built on technology as the engine of renewal in society. According to the Service Science perspective, Service Innovation enables the value creation for all the actors involved in the business relationship (customers, employees, communities and all the stakeholders) (Moller et al., 2008; Bitner et al., 2008; Bettencourt, 2010).

Despite the top position in the research agenda, Service Innovation is poorly understood (Maglio et al., 2007). Studies are sparse (Ettlie and Rosenthal, 2011), and the terminology and labels are heterogeneous. A clear definition and a shared perspective of this research domain lack so far.

On the point some scholars claimed that we have no really systematic knowledge of what Service Innovation is and how it occurs (Sundbo, 1997) and called for further research (Ostrom et al., 2010).

This paper aims to contribute to the scientific debate bridging such a literature gap throughout the review and analysis of the literature on Service Innovation (Bitner et al., 2008). The paper seeks to summarize and classify extant research and to explain the main topics, and the relevance and the significance of various approaches used.

Particularly, its main objectives are: a) delineating the intellectual structure of research about Service Innovation as represented in the academic literature; b) identifying the different theoretical perspectives and common themes that characterize and define the Service Innovation literature and to highlight the connections between them; c) looking for emerging trends and gaps in the literature by comparing the most recent papers (published in 2014) to those representing the field's core.

The remainder of the paper is organized as follows. In the next section we present our literature review methodology. Subsequently, we outline the analysis, and the results. Finally, we present the conclusions of the paper with regard to research contribution and suggestions for future research.

2 Data and Methods

Our analysis follows mainstream methodologies of bibliometric technique: co-citation analysis (e.g., Acedo et al., 2006; Nerur et al., 2008). Co-citation analysis is used in information science to map the structure and the evolution of a research field. This technique is based on the idea that science has a structure that can be empirically defined by a measure based on the intellectual link between documents – the co-citation strength – that is equal to the number of documents that have cited a given pair of documents (Garfield, 1979; Small; Griffith, 1974). Co-citation strength is therefore interpreted as a measure of similarity of the ideas contained in the two documents. The study of its distribution and the analysis of the relationships between citing and cited publications allow scholars to describe the intellectual structure of a research area (McCain, 1990). The methodology we adopted is based on Garfield (1979) and Small (1987) technical descriptions of deriving co-citation maps. It involves two stage-process: the data collection and data analysis. The former relates to both the identification of a set of articles, which represent the intellectual core of the field, and the construction of the co-citation matrix containing a co-citation frequency for each pairs of article as a measure of their similarity. The latter relates to the application of three different multivariate statistical techniques: multidimensional scaling, cluster analysis and factor analysis (McCain, 1990). Over the past two decades the co-citation method has been applied across various research fields, such as, strategic management (Nerur *et al.*, 2008), consumer behavior (Hoffman; Holbrook, 1993; Galvagno, 2011), and organizational behavior (Culnan et al., 1990).

2.1 Data collection

The present study applies an *ad hoc* heuristic method to delimit the Service Innovation literature that includes both the pertinence and the relevance criterion. Data were selected from ISI Thomson Web of Knowledge by searching published articles (excluding proceedings, or working papers) in the fields of Business, Management and Operation Research with the words “service innovation*” or “nsd” or “new service development” or “innovation in service*” within title, abstract or keywords (*pertinence criterion*). The search generated a preliminary set of 399 articles published between January 1986 and June 2014.

Bibliometric methods ask for the selection of the articles representing the intellectual core of the field (*relevance criterion*). It is a critical step in the analysis. Indeed, the selection process has to ensure the full-compliance with two criteria: i) the core has to be as large as possible and ii) documents forming the core have to be truly important to the field. Previous studies have used a conventional measure to find the core, such as, the 100 most highly cited articles or those with at least 50 citations (Distefano, *et al.*, 2012; Ramos-Rodríguez; Ruíz-Navarro, 2004). Consistent with this approach only articles with at least 50 citations were selected. This threshold led us to identify a core set of 31 most influential contributions, which account for the 51% of the total number of citations collected by the original set of 399 articles (see Table 1).

Table 1. The set of articles.

#	Article	Citations	#	Article	Citations
1	Gallouj and Weinstein (1997)	295	17	Gadrey et al. (1995)	86
2	Barras (1986)	206	18	Neu and Brown (2005)	83
3	Atuahene-Gima (1996a)	193	19	Matthing et al. (2004)	81
4	Drejer (2004)	149	20	De Brentani (1995)	80
5	Edvardsson and Olsson (1996)	146	21	Alam (2006)	77
6	Menor et al. (2002)	143	22	Spohrer and Maglio (2008)	77
7	Sundbo (1997)	142	23	Bitner et al. (2008)	76
8	Ostrom et al. (2010)	136	24	Bullinger et al. (2003)	76
9	Hipp and Grupp (2005)	135	25	Berry et al. (2006)	75
10	Goldstein et al. (2002)	126	26	Menor and Roth (2007)	67
11	Maglio and Spohrer (2008)	120	27	Meyer and DeTore (2001)	59
12	Avlonitis et al. (2001)	116	28	Nijssen et al. (2006)	56
13	Alam (2002)	113	29	Oke (2007)	53
14	De Brentani (2001)	113	30	Kelly and Storey (2000)	52
15	Sirilli and Evangelista (1998)	97	31	Francis and Bessant (2005)	51
16	Atuahene-Gima (1996b)	87			

Each of the 31 articles was paired with every other article and the co-citation frequency of each pair computed from the total references received in ISI. The outcome of this process was a 31 by 31 matrix of co-citation counts. The next step

involved converting the co-citation matrix into a proximity matrix, using Pearson’s correlation coefficients. This allows us to standardize co-citation data and to avoid possible scale effects.

2.2 Data analysis

First of all, we employed non-metric multidimensional scaling (MDS) in order to map relationships between the articles. Second, we applied a cluster analysis in order to identify a limited number of groups of papers which present characteristics that are highly coherent and significantly related to one another within each group, whilst notably different to the works belonging to the other groups. Finally, factor analysis was used to identify which papers make up each factor and their degree of contribution or loading as an approximation of the relative influence that each of them has within the research field.

The MDS allows us to project the papers on a two-dimensional map. Data from the correlation matrix have been processed through the ALSCAL routines of the SPSS statistical program. The values for goodness of fit (STRESS=0.19) and the explained variance (RSQ=90.0%) allow us to deem this representation as a good approximation of reality⁷¹. The purpose of this representation is twofold. On the one hand, the MDS shows co-citation links among articles: points (papers) positioned at the center of the map are linked to many different research themes and present, thus, an heterogeneous citation profiles. On the other hand, the MDS reduces data space. It places the articles on a bi-dimensional space, allowing the easier interpretation of the relative positioning of the clusters of contributions.

Next to MDS, a hierarchical cluster analysis with Ward’s method was applied to data. This technique allows obtaining a series of groups of significantly related documents. Hierarchical clustering determines the belonging to a group by analyzing distance between pairs of documents in the multidimensional co-citation space. Dendrogram analysis and agglomeration schedule were used to choose how many clusters to keep. In order to better visualize and frame them in a conceptual space, the clusters were superimposed on the MDS graph.

Along with the two previous techniques, we also employed a principal component analysis of the co-citation matrix, with a varimax rotation, in order to reveal the ‘hidden’ subject matter. Yet, factor analysis can give us another piece of information regarding the structure of the field. If a structure is present in the data it will show by being decomposed in its constituent factors (i.e. common themes or research fronts). The relevance of factor analysis in this context is based on the notion that papers which are related to one another will, in general, be repeatedly cited together in subsequent publications, while works which are rarely or never cited together will not.

If this assumption is true, then factor analysis can use the co-citation entries to determine which contributions are grouped together and therefore share a common element. It does so by producing a number of ‘factors’, each of which captures a common element of the documents that are grouped together.

3 Results

3.1 Descriptive analysis

The most productive journals on Service Innovation (from 1986 to 2014) are Research Policy (5 articles), Journal of Product Innovation Management (4 articles), Journal of Operations Management (3 articles), International Journal of Service Industry Management (3 articles), Journal of Business Research (2 articles), Journal of Service Research (2 articles), Journal of The Academy Of Marketing Science (2 articles), Service Industries Journal (2 articles), and others with 1 article each (Table 2). At evidence, the debate has developed in the innovation and the service science literature, for the most part.

Table 2. Publishing Journals.

Journal	Number of articles	%
<i>Innovation Management Journals</i>	16	51.6%
Research Policy	5	16.1%
Journal of Product Innovation Management	4	12.9%
Journal of Operations Management	3	9.7%
International Journal of Operations & Production Management	1	3.2%
International Journal of Production Economics	1	3.2%
Production and Operations Management	1	3.2%

⁷¹ McCain (1990) suggests that if the STRESS value is less than 0.2 and the RSQ is higher than 85%, a two dimensional solution is a parsimonious one, which provides sufficient explanatory power.

Journal	Number of articles	%
Technovation	1	3.2%
<i>Service Journals</i>	7	22.6%
International Journal of Service Industry Management	3	9.7%
Journal of Service Research	2	6.5%
Service Industries Journal	2	6.5%
<i>Marketing Journals</i>	4	12.9%
Journal of the Academy of Marketing Science	2	6.5%
International Journal of Research in Marketing	1	3.2%
Industrial Marketing Management	1	3.2%
<i>Miscellaneous</i>	4	12.9%
Journal of Business Research	2	6.5%
California Management Review	1	3.2%
Mit Sloan Management Review	1	3.2%
Total	31	100.00%

With a publication rate of 51.6%, Innovation Management Journals are the most influential journals in the Service Innovation literature.

Results indicate a small prevalence of empirical articles using quantitative methods. Only two articles were published in practitioner-oriented journals.

3.2 Bibliometric analysis

The figure 1 shows the MDS map and the three clusters of papers obtained through the Ward’s hierarchical method.

The map outlines: 1) positions of papers according to the map’s axes; 2) identifiable paper groups which represent specific research perspectives or approaches; 3) location of these groups with respect to each other; 4) proximities of papers within groups and across group boundaries (‘border papers’). Commentary on each point follows.

Although the construction of the axes is arbitrary, the position of the papers on the map suggests a meaning for them. Accordingly, we named “theoretical approach” the horizontal axis and “level of analysis” the vertical axis. Specifically, papers located on the left-hand side of the map (quadrant I) have a marketing approach (e.g. Matthing et al., 2004, Edvardsson; Olsson, 1996), while those located on the right-hand side of the map (quadrant III and IV) have a more service science approach (e.g. Maglio; Spohrer, 2008; Spohrer; Maglio, 2008; Bitner et al., 2008).

With respect to the vertical axis, papers on the top side of the map (quadrant III) focus on the definition and conceptualization of service innovation even if with different perspectives (e.g. Francis and Bessant, 2005; Drejer, 2004; Ostrom et al., 2010). Articles on the bottom side of the map (quadrants I and IV) focus on the different models of development of new services (e.g. Menor et al., 2002; Goldstein et al., 2002).

3.2.1 Cluster analysis

The hierarchical clustering method was employed to group papers together on the basis of their correlation relationships; thus, generally, papers within each group share the same perspective or research approach. Starting from the top right area and proceeding clockwise, the groupings derived from mapping are: (1) ***Service science***; (2) ***Innovation and technology management***; (3) ***New Service Development***.

Figure 1. MDS map and Cluster.

Cluster #1: Service Science. It comprises five articles trying to set a research agenda for service science and including service innovation among the research priorities. Although articles in this cluster are frequently cited, their positioning on the map indicates that they cannot be identified as being central to the service innovation literature. Specifically, from the service science perspective, service innovation is seen at the core of the theoretical development of a science of service systems.

Cluster #2: Innovation and technology management. The seven articles within the cluster two are deeply influenced by the innovation studies. Articles in this group cover a variety of topics in the domain of economics and management of innovation. Most of them are indeed published in journals as *Research Policy* and *Technovation* with a management perspective on the construction of a theory of innovation in services. Cluster number two contains generally old articles, that represent what Carlborg et al. (2013) call “the formation phase”, trying to establish service innovation as a distinct research area. This cluster is weighted towards the papers with the greatest number of citations, containing 5 of the 10 most cited papers and encompassing almost the 40% of the citation total for the panel. This indicates that these are quite important papers within the body of service innovation research. Papers within this cluster are concerned largely with defining the research domain, giving theoretical frameworks and models that guide service innovation scholars.

Cluster #3: New Service Development. This group appears to be the structural center of the service innovation research domain. It contains the greatest number of articles in our panel (19 out of 31), and includes those papers adopting an ‘assimilation’ perspective (Coombs; Miles, 2000), trying to applying concepts related to the traditional product-centric orientation to services.

With respect to the position of each group, a not-surprising finding is the centrality of cluster #3. The reason, of course, is that almost all articles within these two groups pertain expressly to service innovation literature. Graphically, the proximity between group boundaries suggests the relatedness of their intellectual appeal to other research streams. For example, both the cluster #1 (Service Science) and cluster #2 (Innovation in Services) are concentrated in a small portion of space, their proximities reflect researchers’ strong tendencies to cite articles belonging to each cluster together. Differently, the position of articles belonging to the cluster #3 (New Service Development), are scattered over the space; it suggests that this cluster contain scholarly contributions from less related research streams. The centrality of a cluster – how closely it is positioned to the axes origin – suggests that the cluster’s articles are perceived to be of interest to many surrounding groups. Articles having positive correlation with other articles across cluster boundaries deserve further study. They generally create a bridge between two research perspectives and frequently borrow new ideas from other clusters to improve or extend the research of the cluster they belong to. The Ward clustering, for example, puts Gadrey et al. (1995) and Nijssen et al. (2006) in cluster #3 (New Service Development), but they are also high correlated with some articles in cluster #2 (Innovation in Services). The main reason being that, although they focus on New Service Development, both try to conceptualize innovation in services.

3.2.2 Factor analysis

The hierarchical cluster analysis placed the co-cited articles into mutually-exclusive clusters (Figure 1). It has been complemented by factor analysis to obtain additional information about the common themes researched within the service innovation domain. The co-citation entries are used in factor analysis to determine which articles share common elements, with each factor capturing a common element of the documents that are grouped together. Although using both cluster analysis and factor analysis may seem redundant, each technique offers some specificity that provides additional insights concerning relationships between the articles.

Table 3. Factor Analysis.

	F1 20.3%	F2 17.0%	F3 14.0%	F4 13.2%	F5 10.5%
Gallouj & Weinstein (1997)	.957				
Drejer (2004)	.938				
Barras (1986)	.925				
Sirilli & Evangelista (1998)	.908				
Hipp & Grupp (2005)	.847				
Sundbo (1997)	.795				
Francis & Bessant (2005)	.600				
Nijssen et al. (2006)	.555				
Avlonitis et al. (2001)		.923			
DeBrentani (2001)		.896			
AtuaheneGima (1996b)		.836			
Oke (2007)		.823			
Gadrey et al. (1995)	.521	.597			
Berry et al. (2006)		.587			
Kelly & Storey (2000)		.583		.412	
Goldstein et al. (2002)			.937		
Edvardsson & Olsson (1996)			.841		
Bullinger et al. (2003)			.838		
Menor et al. (2002)			.807		
Menor & Roth (2007)			.720		
Meyer & DeTore (2001)			.611		
Alam (2002)				.951	
Matthing et al. (2004)				.910	
Alam (2006)				.824	
AtuaheneGima (1996a)		.407		.603	
DeBrentani (1995)		.499		.573	
Maglio & Spohrer (2008)					.875
Ostrom et al. (2010)					.867
Spohree & Maglio (2008)					.764
Bitner et al. (2008)					.747
Neu & Brown (2005)					.593

* Extraction method: Principal component analysis. Rotation method: Varimax with Kaiser normalization. Rotation converged in 6 iterations.

The strength of factor analysis relates to its ability to detect common, underlying dimensions on which variables or objects may be located, while the strength of cluster analysis method lies in its ability to indicate group membership. In this study, we use cluster analysis to identify different research approaches or perspectives featured the service innovation literature, whereas we use factor analysis to highlight the common themes on which scholars speculate and discuss. Articles dealing with the same topic or theme will tend to contribute more frequently to a specific factor (McCain, 1990) and factor loadings indicate the degree to which an article belongs to or loads on that factor.

Interestingly, factor analysis presents several “cross-boundary” groupings, not captured by the cluster analysis or shown on the map. To include a contribution in a trend, its loading has to be equal to or greater than 0.4. Papers have a great relevance to the corresponding approach if the loading is greater than 0.7. The resulting model produced five factors (see Table 3), explaining more than 75.0% of the total variance. All 31 papers loaded on at least one factor. Significantly, almost the 70.0% of the contributions are loaded with a weight greater than 0.7. This data corroborate the relevance of these works within their respective approaches. Likewise, it can be observed that a small number of works exhibit considerable loading in more than one factor (Atuahene-Gima, 1996a; DeBrentani, 1995; Gadrey et al., 1995; Kelly and Storey, 2000). These works are of even greater interest, as they bridge two or more researched themes, and allow us to observe a broader spectrum of influences among different topics, thus helping us to understand their evolution and the ties.

The factor analysis results allow us to define the relevance of the articles in terms of scholarly contribution and intellectual associations.

Cluster analysis produced three different perspectives that characterized research on Service Innovation; factor analysis interprets the intellectual connections among these articles. After analyzing the loadings on each factor, we named the five factors: (1) *innovation in services*; (2) *new service development critical success factors*; (3) *new service development process and models*; (4) *customer interaction and involvement*; (5) *Service Logic: conceptualization and setting*.

Factor 1: Innovation in Services. This factor groups eight articles of our sample and explains the 20.3% of the variance. It encloses studies aiming to provide a general theoretical approach for the conceptualization (Drejer, 2004;

Gallouj and Weinstein, 1997; Barras, 1986) of innovation in services from an economics, management and policy point of view. Along these lines, a first group of papers takes a closer look at the technological innovation in the service sector (e.g., Gallouj and Weinstein, 1997; Barras, 1986) and its effects on the economics system as a whole. Another group of papers try to extend measures and concept developed for the manufacturing sector to the service sector (Sirilli and Evangelista, 1998; Hipp and Grupp, 2005; Njssen et al., 2006). Other topics covered by contributions loading on this factor include issues of management of innovation in services (Sundbo, 1997) and the application of the Schumpeterian perspective to innovation in services (Drejer, 2004). These studies address the need of the academia for theories applicable to services, and are complemented by empirical based contributions that provide a taxonomy of both innovation in service (Sirilli, Evangelista, 1998; Hipp, Grupp, 2005; Francis and Bessant) and of service companies (Sundbo, 1997). Innovation in services encompasses both the technological and non-technological (Drejer, 2004; Sirilli, Evangelista, 1998; Hipp, Grupp; Barras, 1986) perspective and reveal the prevalence of an integrative approach to innovation (synthesis) able to account for an enlarged view of innovation (Gallouj 1994, Coombs and Miles, 2000, Carlborg et al. 2013).

Factor 2: New service development critical success factors. This factor groups seven articles and explains the 17% of the variance. It encloses studies built on the traditional product-centric orientation and on the idea of product as the primary economic driver. Studies loading on this factor relate to the traditional and well-established New Product Development research stream; they try to extend this perspective to the service sector and to service firms, by reflecting the transition phase from the new product development to the new service development. Papers within this factor embrace a narrow set of NSD topics, such as the critical success factors, which were mainly investigated through large-scale surveys within the financial services industry (Avlonitis et al., 2001; De Brentani, 2001; Atuahene-Gima, 1996a; Oke, 2007). Specifically, a first group of papers emphasize the relationship between the degree of innovativeness and the service business performance (Avlonitis et al., 2001; De Brentani, 2001; Atuahene-Gima, 1996a; Oke, 2007). Other studies outline the key role of ICTs in transforming service activities (Gadrey, et al., 1995), as well as, the positive relationship between the presence of a formal NSD process and the NSD performance (Kelly; Storey, 2000) or the development of an organizational culture to support the human performance and the service innovation (Berry et al., 2006). These contributions, although with a more or less intensity, reveal the prevalence of a demarcation approach to innovation, and thus that new services should be developed differently than new tangible products (Coombs and Miles, 2000, Carlborg et al. 2013). This stream of research is essentially characterised by the attempt to study the relation between the NPD and NSD in order to identify critical success and failure, as well as, their effects on the NSD performance from an operation management perspective, as revealed by the analysis of the journals.

Factor 3: New service development process and models. This factor includes six articles and explains the 14.05% of the variance. Articles embrace a recurring and well-established pattern of research in NSD, addressing the need of both academic and practitioner to systematize the NSD process. Studies loading on this factor focus on the conceptualization and definition of models for the NSD both from a technical-methodological approach (service engineering) (Bullinger et al., 2003) and from a marketing oriented perspective (Edvardsson, Olsson 1996; Menor, Roth, 2007; Meyer, De Tore, 2001). Some authors strongly focused on rules and procedures to guide the NSD process (Meyer; De Tore, 2001), whereas other provided a diagnostic tool to assess the organizations' innovative capability (Menor; Roth, 2007). Four on six contributions (Bullinger et al., 2003; Goldstein et al., 2002; Menor et al., 2002; Edvardsson, Olsson 1996) refer to the new challenging and promising research area of service design (Menor et al., 2002) and acknowledge the service concept like the common feature of both the service design (Goldstein et al., 2002; Menor et al., 2002; Edvardsson, Olsson 1996) and the service quality (Edvardsson, Olsson 1996). This stream of research is essentially characterised by the attempt to define procedures, methods and tools to systematise both the design and the development of services. Similarly to the factor 2, an operation management perspective marks out papers loading on factor 3.

Factor 4: Customer interaction and involvement. This factor includes five articles and explains the 13.01% of the variance. It shows an extension of the research toward the most recent topic of the customers involvement in the innovation process. Studies loading on this factor acknowledge, however, in a more or less explicit manner, the consumers' input as innovative and the interaction as both the focal point of services and the essence of customer involvement (Matthing, et al., 2004; Alam, 2002, 2006; Atuahene-Gima, 1996b; De Brentani, 1995). Most studies are characterized by a normative approach strictly focused on the customer interaction and involvement (e.g. definition of a set of activities and procedure for involving users in a new service development program) (Matthing, et al., 2004; Alam, 2002, 2006; De Brentani, 1995), whereas the contribution from Atuahene-Gima (1996b) investigates, in a more general manner, the effects of a market orientation on innovation in manufacturers and service firms. Most studies of our sample relate the B2B service context (e.g. financial, high-tech transportation and communication) and a qualitative research design. Different from the latest studies on the customer engagement (Verhoef et al., 2010; Brodie, et al., 2011) contributions we focused on outline a company centric perspective. This research theme is essentially characterised by the attempt to operationalize and implement the market orientation approach to satisfy the customers' needs. Both an organization and operational management focus feature contributions loading on factor 4.

Factor 5: Service Logic conceptualization and setting. This factor includes five articles and explains the 10.06% of the variance. It outlines diversified patterns of research pivot on the latest perspective of service science. Studies loading on this factor claim for service as broad, interdisciplinary, and cross-functional service research discipline in its own right (Spohrer; Maglio, 2008); they conceptualise service as the application of competences for the benefit of

another (Vargo; Lusch, 2004) and call for its scientific understanding (service science) to advance the ability to design, improve, and scale service systems (Ostrom, 2010; Maglio; Spohrer, 2008; Spohrer; Maglio, 2008). Studies range from the conceptualization of a service science theory (Maglio; Spohrer, 2008) and the definition of a model for the systematic development of service innovation in practice (Bitner et al., 2008) to the setting of a research agenda (Ostrom, 2010). This factor provides both a conceptual and a practical perspective on the service science, by addressing all the patterns of the research on service innovation we previously identified. It accounts not only for new and emerging topics, such as, service system, service dominant logic (SDL) and value co-creation, but for a new multidisciplinary approach to service and service innovation. Accordingly, service innovation seems to be an established area of research with a specific and different focus from studies on the innovation in service context and NSD-related topics.

The analysis of the interaction between the factors (common themes) and the clusters (research approaches), shows the dominant position of the new service development approach within the Service Innovation research (#2, #3, #4). Innovation and technology management theory is at the base of the innovation in services theme (#1), and service science approach is related to the #5.

Table 4. Distribution of articles by common themes and research approaches.

Common Themes (Factors)	Research Approaches (Cluster)			Total
	Innovation & Technology Management	New Service Development	Service Science	
#1 Innovation in services	7	1	--	8
#2 new service development critical success factors	--	7	--	7
#3 New Service Development processes and models	--	6	--	6
#4 Customer interaction and involvement	--	5	--	5
#5 Service Logic conceptualization and setting	--	--	5	5
TOTAL	7	19	5	31

3.2.3 Emerging trends

To identify emerging trends and gaps in the literature, we compared the most recent papers (published in the first semester of 2014) with those representing the core of the literature, and assigned them to the common themes that the factor analysis identified. Following Acedo and Casillas (2005), an article was assigned to a common theme if it cited at least two of the core papers in that topic. If a paper cited two or more papers from more than one topic, it was assigned to the most-cited one. In line with Boyack and Klavans (2010), we also employed a partial assignment method: a paper was proportionally assigned to various topics according to the number of papers cited from each of them. The Table 5 shows the articles published on Service Innovation in 2014. 21 of the 29 articles (72.0%) were assigned to one or more topics, 23 articles (79.3%) cited at least one paper from the core, while 6 (20.7%) did not cite any papers from the core.

Most of recent research on Service Innovation belongs to the foundational theme of *innovation in services* (#1)(around 27.6% of the assignments). Further, one of every five papers deal with the customer interaction and involvement topic (#4), which also underlines the significant expansion of the marketing perspective within the service innovation studies. Therefore, among Service Innovation scholars, Gallouj and Weinstein (1997) and Alam (2002) articles are definitely more popular than Maglio and Spohrer (2008) or Spohrer and Maglio (2008). The topic related to the *service logic* represents only a very small share of the assignments (around 7%). This limited allocation emphasizes the role of innovation management and New Service Development approaches (on the left and centre of the map) in the Service Innovation literature in comparison to the service science one (on the top-right corner of the map).

Table 5. Articles Published on Service Innovation in 2014.

Common themes and topics of Service Innovation research	Assigned papers*		Partially assigned papers**		Total
#1 Innovation in services	4	13.8%	4	13.8%	27.6%
#2 Critical success factors of new services	1	3.4%	2	6.8%	10.2%
#3 New Service Development processes and models	-	-	2	6.8%	6.8%
#4 Customer interaction and involvement	5	17.2%	1	3.4%	20.6%
#5 Service Logic Conceptualization and setting	-	-	2	6.8%	6.8%
Not assigned, but cites papers from the core	8	27.6%			
No citations to any core papers	6	20.7%			

* A paper is assigned to the cluster from which the highest number of references is derived (at least two or more).
 ** A paper is assigned to various clusters in proportion to the references derived from each cluster.

4 Concluding remarks and suggestions for further studies

Studies of services and especially the study of Service Innovation are moving to center stage (Spohrer; Maglio, 2008) in an attempt to become a research discipline in its own right (Tronvoll, et al., 2011). Despite that, and the great effort of leading scholars in clarifying and classifying Service Innovation, it seems to be poorly understood (Gadrey; Savona 2009). Much researches on Service Innovation literature has taken a considerable number of distinct research fields, deep-rooted in a good dominant logic perspective: “the constructs service development and service innovation have been used interchangeably in past research” (Menor, et al., 2002).

This study addresses the call of the academia for a comprehensive understanding of Service Innovation (Barras, 1986). It provides a systematic review by delineating the intellectual structure of the Service Innovation research within the academic literature.

According to Menor et al. (2002) and to previous studies (Morrar, 2014; Carlborg et al., 2013; Papastathopoulou; Hultink, 2012; Droege et al., 2009; Gallouj; Savona, 2009), data were selected by searching publications with title, abstract, and keywords containing the keyword “innovation in service*”, “service innovation*”, “new service development*” and “NSD” in “ISI Web of Knowledge”.

However, differently from the reviews cited above, both a quantitative and a qualitative approach addressed our study.

The former relates to a bibliometric method, and specifically, the co-citation analysis to the most influential articles regarding service innovation. Furthermore, a rigorous statistical approach and three different multivariate statistical techniques (e.g. non-metric multidimensional scaling, cluster analysis and factor analysis) have been adopted to map relationships among articles, to group the articles in terms of topic’s similarities and to associate single articles with a given approach. Finally, the qualitative evaluation of the full papers has been conducted through the content analysis, in order to systematically categorize each article according to the content of its main topic.

Previous contributions outline the evolution of thinking about the topic according to temporal framework and from the prevailing perspectives of assimilation, demarcation, and synthesis (Morrar, 2014; Carlborg et al., 2013; Droege, et al., 2009; Coombs; Miles, 2000; Gallouj, 1994). Although, the above cited perspective provide an helpful guidance for understanding the Service Innovation, they cannot serve as determinant parameters to divide the different phases of the research on the topic (Carlborg et al., 2013).

The quantitative and qualitative analysis we conducted, allow us to identify three research perspectives/approaches (clusters) – Service Science, Innovation and Technology Management and New Service Development – and five common researched themes (factors) – Innovation in Services, Critical Success Factors of NSD, NSD Process and Models, Customer Interaction and Involvement and Service Logic Conceptualization and Setting.

Not surprisingly, the MDS technique places the Service Science cluster on the edge of the map, proving that, it cannot be considered as a central perspective to the Service Innovation literature. Because of the most recent diffusion of the topic, this result might seem obvious. However, this same trend will mark out the further studies on the topic, as the analysis of the emerging trends in the Service Innovation literature confirmed (p. 14). The Innovation and Technology Management cluster groups quite important papers within the body of Service Innovation research. It represents “the formation phase” (Carlborg et al., 2013), by embracing less recent articles trying to establish Service Innovation as a distinct research area. The MDS map reveals the researchers’ strong tendencies to cite articles belonging to these clusters together (cluster proximity). By including the 61% of the articles in our panel (19 out of 31), the New Service Development cluster represents the structural center of the Service Innovation research domain. It embraces scholarly contributions from less related research streams (articles are scattered over the map), representing a research discipline in its own right.

Studies loading on factor 1 (Innovation in Services) provide a general theoretical approach for the conceptualization of innovation in services addressing the need of the academia for theories applicable to services. With the exception of the contribution from Nijssen et al., (2006), all the articles loading on this factor belong to the cluster Innovation and Technology Management. Studies loading on factors 2, 3 and 4 (Critical Success Factors, NSD Process and Model and

Customer Interaction and Involvement) are essentially characterised by the attempt to identify conditions, procedures and methods to systematise both the design and the development of services, according to a market orientation approach. All the articles loading on these factors belong to the New Service Development cluster. They outline different phases within the NSD research moving from “a transition stage from NPD to NSD” (factor 2), to “an entrenchment stage of NSD” (factors 3) with a significant expansion of the marketing perspective within the service innovation studies (factor 4). This latter trend is confirmed by the analysis of the emerging topics and the related increasing interest of scholars toward the customer interaction and involvement.

Studies loading the factor 5 (Service Logic Conceptualization and Setting) account for a new multidisciplinary approach to service and Service Innovation. All the articles loading on this factor belong to the Service Science cluster. They provide both a conceptual and a practical point of view of Service Science, covering its evolutionary process from a broad range of topics and phases.

Overall, besides the elements considered above, the analysis leaves us with the following issues regarding some research gaps and indicating possible directions for the development of a Service Innovation theory:

- The empty area in quadrant II on the map suggests that studies conceptualising Service Innovation in a marketing perspective are missing.
- Most of the empirical and theoretical research on Service Innovation concentrates on business-to-business settings, while a business-to-customer context should also be considered.
- The Service Science perspective is rarely acknowledged.

Path dependencies between centralized and decentralized innovation processes: A systems thinking approach

Thomas R. Casey, Sampsa Ruutu
VTT Technical Research Centre of Finland

Abstract – In this paper we compare centralized and decentralized innovation approaches and industry structures. We elaborate this comparison first by drawing basis from related innovation, marketing, service and platform literature. We use qualitative level system dynamics to showcase the potential path dependency on both approaches. Furthermore, we hypothesize that, on an overall level, Finnish export industry is currently locked in a self-reinforcing cycle of a centralized approach and discuss different trends that could reverse this cycle and shift the industry towards a more decentralized path.

1 Introduction

Centralized and decentralized organizational structures have been with us for ages and we can witness them in all walks of life. The classical example of these is the comparison between a pyramid which is constructed with a centralized mechanism and an ant heap that emerges on its own in a decentralized manner. Similarly, innovation approaches and market structures can follow more centralized and decentralized processes. Centralized processes have typically been used by corporations with large R&D departments that produce incremental innovations in a cyclical manner through so called stage-gate processes. On the other hand, especially the wide scale diffusion of the Internet has increasingly promoted more decentralized and agile innovation processes driven by smaller actors, and large crowds and communities. There innovations emerge spontaneously in a bottom-up manner which in turn is an especially good environment for growth seeking entrepreneurs.

A similar polarization can also be seen in different literatures. This kind of a division can be observed e.g. between different types of innovation, i.e. between incremental and radical innovation (Anderson; Tushman, 1990) and between the so called predictive and effectual approach for building a business (Read et al., 2009; Brettel et al., 2012). This polarization can also be seen as reflecting the seminal work of Vargo and Lusch (2004) and their original distinction between a Goods-Dominant logic (GDL) and Service-Dominant logic (SDL) where in the former customers are seen as passive entities and in the latter as active participants in value creation.

This distinction can also be a useful way to examine the structure of industries. For example, the Finnish national economy has a large dependency on export (MEE, 2014), but the export industry has been and is currently dominated by large corporations and thus reflects rather centralized processes. For example it has been recently estimated that ten of the largest companies make up for one third and one hundred of the largest companies two thirds of Finnish exports (EVA, 2014). At the same time it has been recognized that in the future greater potential for growth in exports will come from more decentralized structures, i.e. small and medium enterprises (SMEs) seeking global level business (MEE, 2013). While promising trends such as an increasing number of innovative start-ups is observable, overall the Finnish export industry still seems to be locked in a rather centralized structure.

The objective of this paper is to compare centralized and decentralized innovation approaches and industry structures and examine how a shift towards more decentralized and agile innovation processes could occur. The goal is to elaborate this comparison by drawing basis from related literature and by taking a systems thinking approach. Using system dynamics (Sterman, 2000), a high level feedback structure is constructed, which describes how an industry and the corresponding innovation processes can become locked either

1. to a path following a centralized top-down design model corresponding to a predictive approach or
2. to a more decentralized bottom-up agile path corresponding to an effectual approach.

Furthermore, based on this, our aim is to form a hypothesis that, on an overall level, Finnish export industry is currently locked in a self-reinforcing cycle of a centralized approach. Our goal is also to discuss different trends that could reverse this cycle and shift the industry towards a more decentralized path.

The rest of this paper is structured as follows. In section 2 we conduct a brief review of centralized and decentralized innovation approaches and market structures in relevant literature. In section 3 we give a short introduction to system dynamics and construct a qualitative feedback model to showcase the potential path dependency either on a centralized or decentralized process. In section 4 we apply this model to the Finnish export industry, discuss how it seems to be locked on a centralized path and discuss different trends that could reverse this path. Finally in section 5 we draw conclusions.

2 Centralized and decentralized innovation processes and market structures

Centralized and decentralized innovation processes and the revolving cycle between these can be seen in a large body of scholarly work. Foundations for such examinations are often traced back to the work of Schumpeter (1942) who describes the concept of creative destruction where innovative entry of entrepreneurs is the force that destroys monopoly power derived from previous technological and economic paradigms, and sustains long-term economic growth. Especially industries, that are dominated by increasing returns (i.e. where economies of scale and network externalities are strong), can become locked into one dominant design (Arthur, 1990) after which the cost of switching become prohibitive, and a lock-in persists until an architectural shift or large external shock renders the dominant design obsolete (Sberman, 2000).

The cyclical nature has been characterized as a cycle of technological change (Anderson; Tushman, 1990) where technological breakthrough, or discontinuity, initiates an era of decentralized technical variation and selection that in turn proceeds to the selection of a single dominant design followed by a period of more centralized incremental technical progress. This model has also been extended to describe how systems and products evolve in the form of a layered hierarchy of technology cycles where some parts follow more centralized and some more decentralized processes (Murrmann; Frenken, 2006). More broadly, similar considerations have been made on a socio-technical level by Geels and Schot (2007) who describe how such transitions and system changes could occur.

The distinction between centralized and decentralized structures can also be observed in innovation literature where a division is typically made between incremental and radical innovation. Henderson and Clark (1990) broaden the categorization to four types of technological change: incremental innovation, architectural innovation, modular innovation, and radical innovation. The more radical, disruptive innovation has been further categorized into high-end and low-end disruption by Christensen (1997) who describes how companies can become locked to making incremental improvements to their products whose value can in turn be difficult for consumers to adopt and which can thus be disrupted e.g. by more affordable low-end products and technologies.

This polarization between centralized and decentralized structures can also be observed in marketing and service literature. It can be seen as reflecting the seminal work of Vargo and Lusch (2004, 2008) and their original distinction between a Goods-Dominant logic and Service-Dominant logic. They for example characterize that from the point of view of GDL the goods should be standardized and produced away from the market whereas SDL focuses more on cultivating relationships that involve the customers in developing customized, competitively compelling value propositions to meet specific needs. In GDL customers are seen as passive entities and in SDL as active participants in value creation (Vargo and Lusch, 2004)

As it relates to different approaches to building a business a similar distinction has been pointed out by Read et al. (2009) who found that people without entrepreneurial expertise rely primarily on predictive techniques, whereas expert entrepreneurs tend to invert these and use an effectual or non-predictive logic to tackle uncertain market elements and co-construct novel markets with committed stakeholders. This distinction between a predictive and effectual approach has been further characterized in the context of corporate R&D by Brettel et al. (2012) who concluded that the predictive approach is beneficial in projects with low levels of innovativeness whereas effectuation is positively related to success in highly innovative contexts.

Furthermore this division is observable in platform literature (Iansiti; Levien, 2004; Eisenmann et al., 2006; Gawer; Cusumano, 2008) where platforms are typically described as centralized elements (e.g. Microsoft Windows or Google Android operating system) that serve as a mediator for more decentralized innovation by the users of the platform (e.g. software developers, hardware vendors and end-users etc.). Centralized structures often relate to capital intensive industries with long investment and development cycles whereas decentralized structures to industries where the development cycle is much shorter such as consumer goods and services. For example as it relates to wireless communications, mobile cellular network infrastructure corresponds to large scale infrastructure with long investment cycles whereas Wi-Fi access points to more emergent bottom-up way of building wireless connections (Casey, 2013). Another concrete example is different software development processes where the so called waterfall model corresponds to a more centralized structure whereas agile methods, such as scrum, correspond to more decentralized structures.

The centralized and decentralized nature of innovation processes and industry structures can also be modeled with dynamical systems theory (Ali-Vehmas; Casey, 2012). Centralized top-down design value creation mechanisms can be seen as following so called fixed point and limit cycle attractors (Strogatz, 2001) corresponding to systems that have fixed or tightly coupled elements and rather static or cyclical behavior.

Decentralized innovation processes on the other hand can be characterized with a so called strange attractor and correspond more to complex adaptive systems that consist of loosely coupled elements. Complex adaptive systems have a large number of interacting and learning agents, are quick to adapt to new circumstances, and are constantly evolving and unfolding over time (Arthur, 1999). Such systems are commonly described to be exhibiting spontaneous order and working on the edge of chaos. Examples of such decentralized systems are stock markets, ant colonies and the Internet and their structure typically reflects a scale-free structure that follows a power-law (long tail) distribution (Barabási; Bonabeau, 2003). An illustration of this phenomena has been described by Anderson (2006) who characterizes how a long tail distribution of content, products and services is observable in the Internet because the tools of service production and distribution are democratized and supply and demand are connected. This in turn enables mass tailoring and in principle a so called segment of one.

Furthermore, it can be seen that the S-D logic reflects, at least partly, these kinds of decentralized loosely coupled structures as pointed out by Vargo and Lusch (2011) in their consideration of service ecosystems:

However, S-D logic, with its focus away from optimization to learning in a dynamic, changing environment, points toward a need to think about value creation taking place in and central to the emergence and evolution of service ecosystems. A service ecosystem is a spontaneously sensing and responding spatial and temporal structure of largely loosely coupled, value-proposing social and economic actors interacting through institutions, technology, and language to (1) co-produce service offerings, (2) engage in mutual service provision, and (3) co-create value.

3 Feedback model of path dependency on centralized and decentralized innovation approaches

Following these observations, we now move on to constructing a high level qualitative system dynamics model and try to depict a potential system level path dependency on:

1. a centralized approach where value is created and needs are met mostly by centrally planned efficient incremental processes and by leveraging economies of scale or,
2. a decentralized approach where value is created and needs are met by tailoring services for individual needs and by enabling increased end-user value co-creation and choice.

Next, we will first give a short introduction to system dynamics and then present the model.

3.1 Introduction to system dynamics

System dynamics seeks to explain phenomena by modeling the feedback structure of a system. Overall, system dynamics takes an endogenous approach to modeling (the word endogenous means arising from within), where endogenous structure generates the dynamics of a system through the interaction of variables and actors (and their mental models) represented in the model. This modeling approach differs from methods relying on exogenous variables (variables arising from without) which explain dynamics in terms of other variables whose behavior is assumed (Sterman, 2000).

System dynamic diagrams depict the feedback structure of a system with positive and negative causal links and with stocks, flows and delays. The causal links form reinforcing and balancing loops which are the most basic feedback structures. These can be furthermore combined to generic structures known as system archetypes (Senge, 1990; Wolstenholme, 2004), one of which we will apply in our modeling.

In system dynamic models a positive causal link (+) indicates that two variables change in the same direction whereas a negative causal link (-) indicates that two variables change in opposite direction. Reinforcing loops (R) have an even number of negative links and balancing loops (B) an uneven number of negative links.

3.2 System dynamics model

The system dynamics model presented here is based on the shifting the burden archetype (Senge, 1990) and depicts on an overall level the opposite paths of a centralized and decentralized innovation approach an industry can take. In the model in Figure , the need for value creation (i.e. the need to put resources such as workforce or capital to use) can be addressed by creating value through centralized planning and economies of scale (i.e. capital intensive long term investments) which subsequently leads to meeting basic consumer needs (e.g. utility services). This in turn reduces the need for value creation and results in a balancing loop 'B-predictive approach'.

On the other hand, value creation through centralized planning and scale means that the system overall will become more centralized and the market will be concentrated to few larger corporations, and resources and workforce will be aggregated. This in turn means that less value creation will occur through decentralized co-creation which subsequently leads to a lower possibility for meeting individual end-user needs. The inability of the system to meet individual needs subsequently leads to a reinforcing loop ('R-Centralization of the system') that can lock the system on a path of creating value through centralized planning and scale. Overall, such a system is characterized by incremental innovation, extensive use of the predictive approach, GDL mentality, long term investments, capital intensive way of working and a small number of large (tightly coupled) actors. End-users remain here as passive entities that consume the basic good or service provided.

Figure 1. Qualitative system dynamics model depicting a path dependency on either a centralized predictive approach or a decentralized approach (adapted from Senge (1990)).

An opposite path can be observed if a more decentralized effectual approach is chosen where the need for value creation is fulfilled through decentralized co-creation. This subsequently leads to more tailored services and meeting individual end-user needs and in turn to less of a need for value creation and a balancing loop 'B effectual approach'. When value is created by serving individual consumer needs it leaves a smaller space for value creation through centralized planning and economies of scale. This subsequently leads to a less centralized system where smaller players (e.g. SMEs and individual software developers) have a larger role, resources and tools of service production and distribution are democratized, more decentralized forms of funding (such as venture capital) exists and in general workforce is more decentralized. This subsequently leads to more value creation through decentralized co-creation and meeting individual end-user needs. This in turn leads to a reinforcing loop ('R Centralization of the system') that works in the opposite direction when compared to the predictive approach and can lock the system on a path of creating value through a more decentralized and effectual approach.

Such a system is characterized by radical innovation, dominance of the effectual approach, SDL mentality, low cost of technology and tools of service production (e.g. the Internet), short development cycles for products and services and in general by loosely coupled adaptive actors and innovative entrepreneurs. End-users are active participants and plenty of two-way interaction exists.

4 Case: Finnish export industry

Next, utilizing the model above we hypothesize that, on an overall level, Finnish export industry is currently locked in a self-reinforcing cycle of a centralized approach. Figure 2 represents a visualization of the self-reinforcing positive feedback loop 'R Centralized system' depicted in the system dynamics model above in Figure 1. The ball sliding down the hill symbolizes the self-reinforcing mechanism of the path taken and the top of the hill a tipping point which needs to be reached in order for the self-reinforcing mechanisms to start working in the other direction.

Figure 2. Visualization of the self-reinforcing dynamics between a centralized and decentralized approach.

Our hypothesis is that the Finnish export industry is currently locked on a path of a centralized predictive approach where large corporations focus on building and exporting large scale investment goods with long investment and development cycles. We also discuss different trends that could reverse this cycle, so that a tipping point could be reached and a shift towards a more decentralized path could occur.

4.1 Current locking to a centralized path

Overall, the Finnish national economy has a large dependency on export. Roughly stated it can be argued that the Finnish export industry has been and is currently dominated by large corporations. For example it has been recently estimated that ten of the largest companies make up for one third and one hundred of the largest companies two thirds of Finnish exports (EVA, 2014). Furthermore, while small and medium enterprises also exist in the export industry, majority of these are mainly serving larger corporations producing investment goods (MEE, 2014).

The three core pillars for export in Finland have traditionally been the forest industry, the mechanical engineering industry and the electronics industry. The forest industry is dominated by three companies: UPM, Stora Enso and Metsä Group. The mechanical engineering industry in turn is largely driven by seven companies: KONE, Cargotec, Konecranes, Wärtsilä, Outotec, Sandvik and Metso. These seven companies represent 70% of all revenue in the industry (MEE, 2014). A large number of SMEs also exist in the mechanical engineering industry (which has a total of 9000 companies altogether) but the SMEs typically work as subcontractors for the leading companies with only 300-400 having their own products (MEE, 2014).

The electronics industry on the other hand has been dominated by Nokia but has lost a significant part of its revenue due to Nokia's recent difficulties. Overall significant structural changes are ongoing especially in the forest and electronic industry where both have been driven by flagship companies which have had little desire or ability to seize small-scale economic potential (MEE, 2013).

Finland has also rather centralized job markets. After the Second World War, the influence of the government on labor market activities has been significant. Since the end of the 1960's, labor market relations have been shaped towards a tripartite cooperation, i.e. centralized economic corporatism based on tripartite contracts of business, labor, and state. Subsequently, during the last decades the labor market system has become an important national institution and an important basis for the welfare state policy (MOL, 2006). Overall, private sector jobs are heavily biased towards employment by large corporations (EVA, 2014).

At the same time, largely because of this centralized nature of the system, it has been rather difficult and unpopular to establish growth seeking small businesses. For example during the recent years just a few companies have been enlisted to Helsinki stock exchange which is an indication that there have not been many companies seeking growth (Talouselämä, 2011). Also, traditionally, funding for growth seeking SMEs has been challenging and bank centric funding to large corporations has been the norm (EVA, 2014).

Thus it can be argued that, overall, the Finnish export industry has traditionally and is still reflecting a more centralized, predictive, goods dominant logic. Roughly put, one could argue, that the self-reinforcing mechanism 'R-Centralization of the system' depicted in Figure 1 has locked the system on a path of creating value through centralized planning and scale. Therefore, the traditional Finnish export industry can in many ways be characterized by incremental innovation, extensive use of the predictive approach, GDL mentality, long term investments, capital intensive way of working and a small number of large (tightly coupled) actors in the lead.

4.2 Possible shift to a decentralized path

While traditionally Finnish export industry has been dominated by a more centralized approach there are many ongoing trends that could reverse this path. For example, recently, there has been a significant increase in the number of growth seeking SMEs in Finland. This has been driven especially by an emerging vibrant start-up scene where Finland is becoming one of the start-up hubs of northern Europe (Wired, 2013; Techrepublic, 2014). This recent development has been fueled particularly by entrepreneur communities such as Aalto Entrepreneurship society, start-up sauna and large scale events such as Slush⁷².

Furthermore, what is observable now, is that becoming an entrepreneur is increasingly becoming an attractive option for young graduates (Kauppalehti, 2014). Also plenty of skillful engineering force has been released from Nokia due to its difficulties and many have founded their own company.

Venture capital funding is also becoming all the time more available and Finland is among top European countries especially when comparing venture capital investments to the gross domestic product (EVA, 2014). Recently, Finland came in at third place – behind the UK and France – for equity financing in Europe with a 12 per cent share of all investment into European venture capital-backed companies (Venture village, 2013).

The startups are typically driven by Information and Communications Technology (ICT) and in many cases work with mobile technologies. Overall, a major underlying driver is affordable ICT technology and the Internet which offers direct access to global markets. The growth of the gaming industry (companies such as Supercell and Rovio) has been the flagship of this trend but it is also observable in the context of more traditional industries.

In fact, it can be seen that large companies are gradually reorganizing themselves and becoming platforms for growth seeking SMEs and their own workers to innovate. The traditional product business is gradually shifting towards a more service and customer oriented direction driven especially by ICT and the ability to maintain real time connections to the products sold⁷³.

Furthermore, large companies are trying to make their organizations more adaptive by using more agile processes e.g. in software development and project management and by using “Intrapreneurs”, that is, workers who act like entrepreneurs within their organization. Large companies are also gradually embracing the so called approach of creating shared value (Porter; Kramer, 2011) and want to become platforms for society at large (Alahuhta; Kosonen, 2011).

The goal of shifting towards a more decentralized structure is also increasingly endorsed by the Finnish government that is encouraging entrepreneurship and SMEs to seek growth. It has been stated that public authorities and industrial competitiveness policy must focus on supporting the birth of such success stories. Industrial competitiveness policy must also promote the development of the capital markets and also ensure that Finland is a welcoming investment market for businesses. Overall, it is seen that global challenges offer traditional industries an opportunity for growth and renewal (MEE, 2013).

This is already partly observable in some statistics, e.g. as shown in Figure 3 where the proportional number of SMEs and micro enterprises has been showing promising growth (the economic recession is also observable in the statistics). At the same time the proportional number of large corporations has declined more drastically and the trend of job creation by smaller companies is likely to continue.

⁷² aaltoes.com, startupsauna.com and www.slush.org (accessed 10th of June, 2014).

⁷³ This is enabled by technology concepts such as the Internet of things, Industrial Internet, and Machine-to-machine communications.

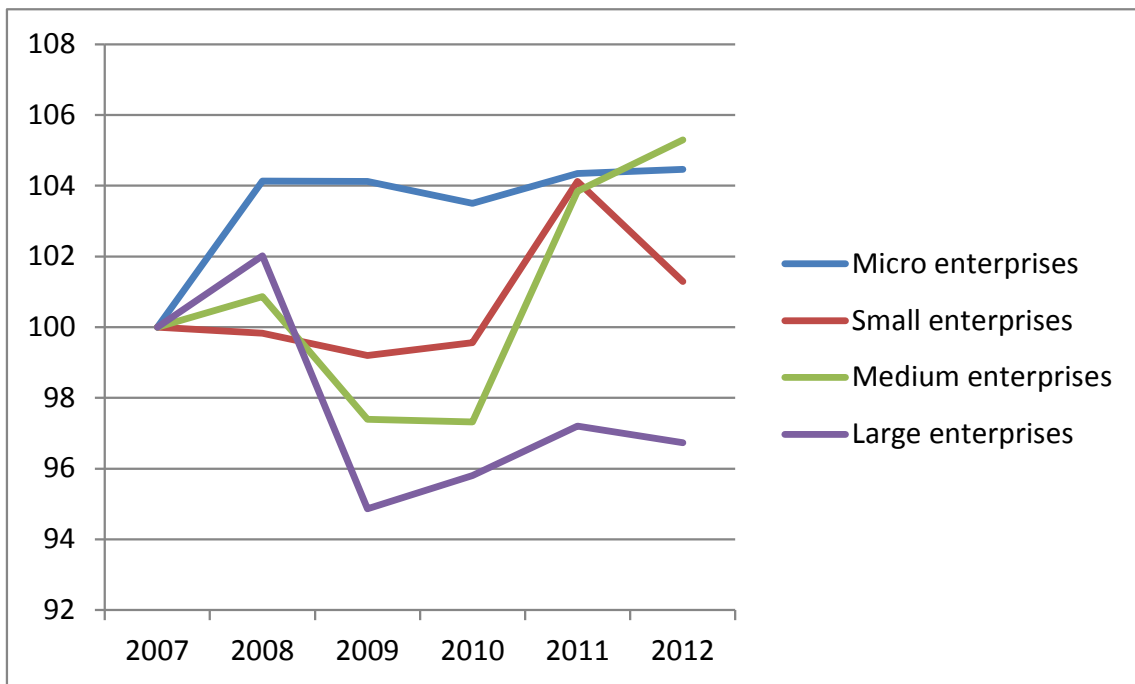

Figure 3. Number of micro, small, medium and large enterprises in Finland (2007 = 100)(source: Statistics Finland, Business Register 2012).

Thus, overall, there are many trends that could shift the Finnish export industry towards a more decentralized, effectual approach with a stronger focus on SD-logic. This would mean that the reinforcing loop ‘R Centralization of the system’ in Figure 1 would be reversed and the ball depicted in Figure 2 would reach a tipping point and, on an overall level, a path of creating value through a more decentralized and effectual approach would be taken. Therefore, in the future the Finnish export industry could be increasingly characterized by radical innovation, dominance of the effectual approach, SDL mentality, short development cycles for products and services and by innovative growth seeking entrepreneurs.

5 Discussion

Overall, we recognize that the presented hypothesis and the system dynamics model depicted above are simplifications that need further discussion and empirical analysis. However, the distinction between centralized and decentralized innovation approaches and industry structures can serve as useful basis for discussion and can be seen as reflecting, at least on an overall level, system structures e.g. in the Finnish export industry.

While the distinction between the centralized or the decentralized approaches can be a useful one, it is important to note that neither one of these approaches should be regarded as being better than the other but their usefulness depends on the context. Although recently, especially with the large scale diffusion of the Internet, the trend is towards more decentralized structures, the centralized approach and leveraging economies of scale is still important especially for large corporations in infrastructure industries that need centralized expert based planning and hierarchical structures to organize large workforces. However, we would also like to point out that decentralized innovation processes can be beneficial and complementary for capital intensive industries as well because of the transformative role of ICT in every industry. For example, in the future so called “smart city” solutions require that many traditional industries such as construction and energy are integrated with ICT and more decentralized processes. More complexity in the operating environment and within industries also calls for new approaches.

While we also recognize that the proposition brought forth here, that GDL corresponds more to centralized and SDL more to decentralized structures, needs more discussion, this same principle could apply to the GDL versus SDL distinction. It can be argued that the Goods-Dominant logic is still a useful point of view especially for infrastructure driven companies. Still, it is often the case that GDL dominates where a more decentralized SDL oriented approach would be much more useful.

Furthermore, the model presented here could be expanded to having multiple layers in a similar manner as Murmann and Frenken (2006) have expanded the cycle of technological change (Anderson; Tushman, 1990) to a layered hierarchy of technology cycles. Some parts of the overall system are likely to follow a more centralized approach and can serve as platforms for smaller actors to innovate as suggested in platform literature (Iansiti; Levien, 2004; Eisenmann et al., 2006; Gawer; Cusumano, 2008).

In addition to expanding the analysis to multiple layers, future work could also be focused on empirical analysis. Comparisons could also be made to other countries such as the U.S. whose market structure can be seen as being more decentralized (e.g. in terms of job markets and entrepreneur culture) or Germany where the large number of so called

Mittelstand companies (i.e. companies that are in the upper ranges of the SME category) played an important role in economic growth.

6 Summary

In this paper we compared centralized and decentralized innovation approaches and industry structures. We elaborated this comparison by drawing basis from related literature and used qualitative level system dynamics to showcase the potential path dependency on both approaches.

Furthermore, we hypothesized that, on an overall level, Finnish export industry is currently locked in a self-reinforcing cycle of a centralized approach where large corporations focus on building and exporting large investment goods with long investment and development cycles. In addition to this the paper discussed different trends that could reverse this cycle and shift the industry towards a more decentralized path. Such trends are e.g. the increasing number of growth seeking SMEs in Finland, an emerging vibrant start-up scene and the trend of large companies reorganizing themselves and increasingly becoming platforms.

Managerial Innovations in Healthcare

Laura Castrén, Arto Karila

Aalto University, Finland

Due to the current economical recession and the aging population, public healthcare is in a financial crisis. So far, there has been little competition or customer orientation in public health services and it has not even been possible to measure its productivity. Nevertheless, there are growing pressures to increase competition, customer orientation and productivity in healthcare. We are studying the role of managerial and service innovations, assisted by the use of Internet and social media, in implementing this change. We have conducted a series of interviews at a specialized healthcare clinic, where significant increases in productivity and quality have been achieved through managerial innovations.

1 Introduction

Substantial literature indicates that service industries, and especially governmental services, lack the capability to perform as efficiently as manufacturing industries. Manufacturing companies are squeezed by market-driven performance and quality comparison that reallocates resources from inefficient to more efficient and innovative firms (Dunleavy and Carrera, 2013) while governmental services usually lack this mechanism. Combined with the immortality of public organizations, this leads into stagnation. Performance measurements in the public sector are still at their early stages, although some academics have already measured the productivity of governmental services (Jones and Thompson, 2007).

However, the ongoing recession urges the implementation of efficient methods that can provide information about performance and quality, fueling innovation in public organizations without research and development departments of their own. We need more knowledge of how performance indicators and managerial innovations affect the healthcare system and its performance.

1.1 Paradigm Shift in Healthcare

Healthcare has traditionally been very hierarchical and provider-centric with minimal customer orientation or right for the customer to choose. The recent EU directive (2011/24/EU) on the application of patients' rights in cross-border healthcare, effective as of late 2013, is targeted to advance structural changes and resource reallocation. Increasing competition in Europe will give local healthcare organizations incentives to pay attention to performance, ratings, quality, and customer needs. The emerging market-orientation can promote withdrawal from the path-dependency that sets invisible limitations to organizations' choices. This path-dependency is grounded not only in artifacts, such as operational models, routines, and processes, but also in a socially constructed conception of an organization's limitations and possibilities.

National interpretations of the implementation of the directive vary: the implementation can either spark dynamics and innovations or help protect the old national model of healthcare service production which can be detrimental to the development of quality and performance. The new market-oriented situation challenges healthcare service providers' renewal capacity forcing organizations to seek for innovative ways to reallocate the limited resources in order to maximize their health-related outcomes in the national framework.

We argue that healthcare providers' efficiency and innovative capacity correlates with the shift in the legitimacy base demanding operational transparency and information systems' capability to capitalize on decentralized information and embed it in the customer processes (Teece, 2009).

This study points out some policy and managerial implications of the enlargement of the resource-based view on and customer co-creation in the innovative process within healthcare and addresses managerial innovations in healthcare in the theoretical framework of Resource-Based View and Service-Dominant Logic (Vargo and Lusch, 2004). We highlight the issue by both viewing the process and implications of managerial innovations and utilizing the implantation of social media in the healthcare context.

1.2 Managerial Practices and Organization's Performance

Throughout the 19th and 20th centuries, the productivity of manufacturing has on the average increased by over three per cent (3%) per annum while the productivity of service production has increased by only one per cent (1%) per annum (Kauhanen et al. 2014). In manufacturing competition and structural changes have been significant sources of growth of productivity whereas even in private services structural change (paradoxically) can result in the exit of the more efficient organizations.

One explanation to this paradox can be that personnel resources shift from the exiting companies to new but less effective ones (Kauhanen, 2014). In the public sector, organizations reach after a couple of operational years almost immortality. Originally Kaufman (1976) used the term to refer to the extraordinary nature of the public sector. This

static nature emerges when a conflict between an organization's *modus operandi* and the wider environment's normative, regulative or cognitive legitimacy breaks, forcing political powers to dictate a new order (Dunleavy and Carrera, 2013).

In an extensive study on management practices, Bloom et al. (2011) compare management practices in 20 countries indicating how well the fast implementation of new managerial practices correlates with increases in efficiency and performance. The fast innovation implementation generates competitive advantage. Bloom et al. (2011) indicate that companies adopting critical management practices concerning "monitoring, targets and incentives" not only are the performers in terms of profitability and growth but they also survive longer. In general, governmental and founder-owned companies appear to be poorly managed. Authors relate market competition with management practices, thus, the tougher competition the better the management practices. Research on U.S. hospitals indicates good management practices whereas in schools the managerial practices are poor (Bloom et al. 2011).

1.3 Customer in Healthcare

The term *patient* originates from Latin and old French, positioning a sick person's role to "*enduring without complaint*" (<http://www.etymonline.com>) whereas the role of a user or customer emphasizes activity. In order for the customers to play an active role in Patient-Centric Medicine (PCM) they need access to information enabling them to compare the quality of various health services.

This calls for more transparency and easy public access to both objective and subjective information. Objective information includes things such as success and mortality rates of various operations and cures while subjective information is based on the feedback collected from prior customers. This will give the customers a factual basis on which they can make enlightened choices about their healthcare providers.

Existing literature views low productivity, non-existent or minor inclination on customers' needs, and poor management practices in the absence of competition as attributes of governmental services (Bloom et al. 2011; Dunleavy and Carrera, 2013).

1.4 Social Media in Healthcare

Research on U.S hospitals show activity and interest in the deployment of social media tools in healthcare processes, following the implementation pattern of other managerial innovations (Belt et al. 2012). A study on U.S. healthcare providers' social media use points out how organizations link their social media utilization to their strategic goals, such as marketing unique quality (Revere, et al. 2010), which is nonetheless challenged on social media rating sites.

Research on social media suggests that online rating sites on social media can improve healthcare quality. Verhoef et al. (2014) reviewed 21 articles concerning healthcare ratings on social media. The authors suggest that online ratings have a positive impact on quality but also a bias arising from the small samples and the anonymous nature of sites which cannot be eliminated (Verhoef et al. 2014).

However, according to Kaplan and Haenlein, the credibility of information can be improved. The authors claim that the effective exploitation of the knowledge of the crowd needs to fulfill three criteria: firstly, the audience interested in a topic has to be large enough, secondly, it has to represent divergent stakeholders, and thirdly, actors have to produce the substance autonomously (Kaplan and Haenlein, 2014).

Several studies suggest that the introduction of social media can provide efficient means for collecting and sharing comparative information concerning service producers' quality and performance that may power organizational development (Verhoef et al. 2014, Greaves and Millet, 2012; Emmert et al. 2013). Social media is one step forward towards ubiquitous healthcare which will provide individuals with health-related applications that e.g. generate information on the user's acute state in chronic illness situations and give alerts of pandemics.

Academic discussion on social media in the healthcare context is scanty. However, e.g. Van de Belt et al. (2012) show that although social media is in use in almost every West European hospital, the ability to capitalize its full potential still is scarce. The authors mention two exceptions: the Netherlands and the United Kingdom which are able to follow the U.S. example (Van de Belt et al. 2012). The gap between trustworthy information offerings and user demand creates a need for more academic understanding of how healthcare service providers perceive the utilization of social media tools in co-creation.

However, the majority of academic literature concerning healthcare-related innovations ignores social media's capacity to empower stakeholders although healthcare service users show increasing activity in the Internet seeking for health-related information

1.5 Service Innovation

The era of Patient-Centric Medicine (PCM) calls for the adaptation of market-oriented techniques in order to understand customers' needs and generate new service offerings. The perception of service innovations is more challenging than in manufacturing but Gallouj and Weinstein (1997) provide a useful basis for viewing service innovation as modification of present service offerings. The modification can include any change that adds, associates, dissociates or subtracts something to, with or from the original service (Gallouj and Savona, 2011). Michel et al. (2008) offer a more customer-

oriented definition viewing service innovation as a change in customer involvement and the way they operate in the value-creation process.

Including customers in the innovation process may generate benefits to all potential stakeholder groups. Sundbo and Toivonen base on Service-Dominant Logic (SDL) which emphasizes the intertwined nature of the service provider and the object actor in service value creation (Vargo and Lusch, 2004a, 2008, 2011).

The recent model of user-based service innovation advocates the active role of customers in the service innovation process, bringing forward the potential of social media in the innovation process (Sundbo and Toivonen, 2011). The authors elaborate on the academic marketing management approach introduced by Vargo and Lusch (2004a, 2008, 2009, 2011) who argue for the primary nature of services. In new offerings generation process comes up *co-creation* (Lusch et al., 2007), the term refers to co-operative action with customers and enlarging resource-base over organizational borders.

Value is always focal and inseparable from both the user and the context (Vargo and Lusch, 2004a). Value will be materialized only if a customer unifies the service providers' offerings with their other resources in the certain context (Vargo et al. 2009).

In order to improve quality and speed up the development, traditional techniques, such as surveys, panels and focus groups, are insufficient, especially if service providers are looking for a competitive edge. Organizations pursuing competitive advantages and radical (as opposed to incremental) development need to map out service users' latent needs and capitalize on the wisdom of the crowd (Kaplan and Haenlein, 2014).

Latent needs refer here to wishes and needs that the majority of customers or service users are unable to voice or even to imagine. However, involving lead users (von Hippel, 2005) in the service or product innovation process can benefit all the users, potential users and other stakeholders.

The Internet provides a faster and more cost-effective means to collect feedback, interact, and to co-operate with customers than more traditional tools, such as panels, focus groups and surveys. Social media, such as Facebook, Twitter, You Tube and blogs, has its limitations but nonetheless offers an interactive, participatory and dynamic arena for organizations compares with traditional more static and one-way communication methods. Also the potential of the traditional methods to generate new ideas that can lead into innovations is very restricted. Healthcare providers have still quite limited capability to utilize the power of social media although their customers are already there. As many as 80% of the Internet users seek for health-related information on the Internet (Emmert et al. 2013; Lin and Umoh, 2002; Ardito, 2013).

Fast moving market-oriented companies have already started to utilize the scattered knowledge of decentralized interest groups attempting to address common interests. Kaplan and Haenlein (2014) compare the use of Internet-based social media tools (Wikipedia) to the proliferation of the printing press that democratized the world of knowledge starting in 1439.

Social media driven co-operative projects, underpinned by social media applications, have altered the power positions between product or service producers and consumers. Authors define the co-operative projects as "a special form of social media application that enables the joint and simultaneous creation of knowledge-related content by many end-users" (Kaplan and Haenlein, 2014).

Some pioneering companies, such as iStockphoto and Threadless.com, have expanded their resource-base over company borders to utilize the wisdom of the unlimited audience by adopting the co-creation approach and *crowdsourcing*. An open call to co-create involves customers, potential customers, partners and other interest-groups willing to put effort into it. The term crowdsourcing reflects an attempt to harness the know-how and innovativeness of a large group, consisting of an unlimited number of ordinary people, to carry out a specialized task (Howe, 2006).

The concept of crowdsourcing materializes the theoretical approach of Service-Dominant Logic (S-D L), offered by Vargo and Lusch (2004a, 2008, 2009, 2011), and the Resource-Based View (Penrose, 1959, Barney, 1986). According to Penrose's original definition "it is never resources themselves that are inputs to the production but only the services they can render" (1959), whereas Barney (1986) emphasis the goal-oriented aspect of an organization, pointing out that resources "must enable a firm to do things and behave in ways that lead to high sales, low costs, high margins, or in other ways add financial value to the firm".

A more recent view on resources emphasizes dynamic capabilities that refer to organization's velocity, innovativeness, flexibility, knowing, and quality (Teece, 2009). Teece et al. define dynamic capabilities as "the firm's ability to integrate, build, and reconfigure internal and external competences to address rapidly changing environments. Dynamic capabilities thus reflect an organization's ability to achieve new and innovative forms of competitive advantage given path dependencies and market position." However, the Internet-based vehicles provide an opportunity to elaborate the basic assumption of firm resources, viewing resources as immobile and company-specific.

This study addresses the issue of managerial innovations in the theoretical framework of Resource-Based View and Service-Dominant Logic in the healthcare context.

2 The Theoretical Framework

In this chapter we shall view the performance gap between service industries and a manufacturing. Then we discuss what crucial factors in service industries in general, and especially in public healthcare context, can explain the differences.

2.1 Study Design

This exploratory study aims to deepen the understanding on service innovation in a public value network by viewing managerial practices in public healthcare sector (Sutton and Staw, 1995). In the public healthcare sector services are generated in a systemic way in an ecosystem comprising various actors. This study aims to shed light on value generation process in the value network.

This multiple mixed methods case study utilizes multiple data and includes archive materials, other documents, observations and interviews of public sector staff. The data was collected during a period of six months in 2014.

Data collection has been carried out in a unit of specialized healthcare. The focal unit consists of five clinics with specialized emphasis. The focal clinic co-operates locally with other municipal service providers. Our data comprises interviews with actors embodying different angles and expertise in service process both from professional point of view and local position.

Nine out of ten of the interviewees represented employees with managerial status. The running time of the interviews varied from 1.5 to 4 hours, two interviewees were interviewed twice, and one interviewee was interviewed three times. On the average, an interview lasted for 2 hours. The study questions were based on standardized questionnaires. Moreover, the data includes statistics, such as key performance indicators concerning referrals, queuing times and costs.

We used purposive sampling along data collection process in order to gain an inclusive understanding of the resource-base, co-creation and customer-orientation among the healthcare personnel and especially the managers' means to carry out changes. We have analyzed the interviews using the Atlas.ti software trying to identify themes, patterns, connections and underlying properties (MacInnis, 2011).

2.2 Efficacy Gains by Managerial Innovations

The evidence shows a phenomenal improvement in the focal clinic's efficacy and effectiveness after mobilization of managerial innovations, such as performance indicators and Lean. However, the impetus for the deployment of new managerial practices came from the outside. The organization were confronted a public critique due to the long queuing times.

This forced the management to review the treatment processes, practices and costs. A change program was launched in 2008. Managerial innovations brought the most remarkable productivity improvement by a) the reorganization of a queuing management, b) the introduction of a new appointment system, and c) distillation of the care process. The customers' commitment to the treatment enhanced the performance by reducing "no show" bookings. A considerable change that improved customer commitment included three items: a) the introduction of a treatment plan that enabled customers to preview the whole treatment process, b) fast seizing on symptoms instead of an examination-centric operation model, and c) restricting the treatment to 3 or 4 appointments in comparison to a continuous therapeutic relationship usually lasting several years. Several respondents in managerial position reported that the majority of customers actually benefit more from these shorter interventions that come in time.

The clinic was able to achieve significant time gains by standardization of reporting. Time consuming reporting style induced a remarkable performance gap and individual styles varied. The standardization enabled staff to receive more customers than previously.

To conclude, the most remarkable result of the changes was that in 2007, a clear minority of customers (18%) got into ward care in less than three months, compared with the vast majority of 98% in 2010.

The process innovations improved operational transparency and collegial surveillance. The transparency improvement was achieved through the implementation of an electronic calendar.

The other actors in the value network were just entering into the phase of experimentation of managerial innovations. Due to the experimentation phase, the respondents were unable to report any numeric changes. However, they did report a frustration caused by the reluctance of the staff to adapt themselves to unfamiliar concepts in this context, such as leadership, an electronic calendar application, and performance indicators.

2.3 Internet-Based Tools

The data suggests that the deployment of Internet-based tools and social media is restricted. The majority of informants expressed uncertainty about the organization's presence in social media and company policy concerning the use of social media and poor or non-existent personal knowledge of the use of social media. However, the informants brought forward customers' explicit expectations for both Internet-based media and easier and more flexible interaction, for instance the possibility to make and cancel appointments electronically. According to the respondents, the defective privacy protection of e-mail precludes its use.

3 Conclusions

The studied organization indicates that also public healthcare can break out from the path-dependent way of the inspection of *modus operandi* and improve performance by managerial innovations. Public healthcare can reach significant performance gains but this requires utilization of users' knowledge and user-engagement in order to

guarantee the involvement of all the relevant views. The limited utilization of the information and communication technology in communication with customers refers more to Weberian type of bureaucracy than the value co-creator.

The recent EU directive is one indicator of the rapid changes in the operational environment that force healthcare organizations to innovate. However, this calls for refraining from national protectionism and allowing resources to gravitate from poorly performing units to better performing organizations, even across national borders. The organizations have to focus on performance indicators, transparency, and production of comparative information that enables customers to make enlightened choices.

The immortal nature of public organizations prohibits the natural exit of unproductive service units and emergence of more efficient and effective ones. Administrative structures should not be a goal in themselves, but an enabler of services where they are needed, thus the mobilization of comparative information, and transparency should be advocated. The recent EU directive provides a good base for this-

We have just seen the first phase of the ICT-driven revolution in the healthcare context. Mobile solutions, based on smartphones and such, can provide assistance and information concerning health issues, fitness, and lifestyle coaching and management. New applications can also be used to assist in chronic disease management. Ubiquitous healthcare refers to the emerging area of health-related technology. It utilizes e.g. a large number of patient sensors and actuators to monitor customer's both physical and mental state.

Culture and Entrepreneurial Attitude and the Innovation Dimension in Brazilian Companies.

Cristina Castro-Lucas¹, Eda Lucas CastroSouza², Fernanda Nogueira³

¹University of Brasília, ²UNB, ³University of Lisbon

This paper describes the relationship between cultural variables, the individualism/collectivism and verticalism/horizontalism dimensions, and with entrepreneurial approach, through the innovation dimension, in 33 small, medium and large Brazilian companies. The sample consisted of 450 owner-managers and employees of the 33 companies, divided into 29 activity areas. An instrument of Cultural Values was adopted; the relationship between Culture Entrepreneurial Attitude was tested within the Innovation dimension; analysing models taken from mediation and moderation tests did standard and hierarchical regressions. The Horizontal Collectivism cultural manifestation strength was significant to directly predict the entrepreneurial attitude; the individuals perceive the group as the source of their identity, and develop little confidence in their authority.

Keywords: Culture, Entrepreneurial Attitude, Innovation.

Introduction

The adoption of “national culture” as the subject that resulted in and led this study has allowed a more clear analysis of certain characteristics of the entrepreneurial profile. Or has it? This paper is a result of studies that sought to identify the perception of classical and contemporary authors, as well as and the outcomes of researches on entrepreneurship.

The answer to the question above seems simple; however, culture is not the only explanation of entrepreneurial attitude, which is affected by several factors, including social, psychological and economic ones. The point here is not to decide which of these factors prevails, but to identify, from a sample of entrepreneurs in the city of Brasilia, DF, the relationship between the tendency to certain cultural patterns and entrepreneurial attitude.

Therefore, this article aims to study the entrepreneurial attitude variable through culture, or, based on Hofstede's model, by introducing the results of a research conducted by Souza-Depieri (2005).

This article does not intend to introduce original information, but aims to provide a different perspective on culture and entrepreneurial attitude.

Culture

The idea of culture in ancient Rome was associated to Nature. For the religious men, it concerned the care with the gods; and the Greeks interpreted it as the formation of the body and spirit of a society. In essence, culture represented the relationship among human beings within an organized society. The term culture in its different approaches is considered a produced capital in a given field. Such concept was defined by Bourdieu (1989) as a network or configuration of relationships that depend on the position of the social agents in the social space. From an anthropological approach, culture is normally introduced as a way of doing, feeling and thinking inherent to a given human collectivity. In common sense, culture is one's scientific, artistic and literary knowledge; from a society point of view, culture refers to the capital of intellectual and artistic works (Bonnewitz, 1988). In this case, to distinguish culture as understood by the intellectual elite, mass culture is defined as a group of knowledge and values conveyed by the media and other cultural organizations. From a sociological view, culture is a set of values, norms and practices acquired and distributed by a group of people, encompassing different conceptions (Bonnewitz, 1988). The cultural field consists of symbolic codes, organized in different cultural systems. Thus, according to Bourdieu (1988), culture is a set of perception schemes developed or made by groups of people with legitimate authority.

Souza-Depieri and Souza (2005) have introduced a conceptual overview of culture. They understand it, from a philosophical view, as a system of ideas, techniques and artifacts, behavioral patterns and attitudes that characterize a society; and, from an anthropological view, as concept that depend on learning, as behaviors tend to project the learning perceptions. The anthropological perspective also sees culture as a style, a way of doing things (Da Matta, 1984, 17). Da Matta (1984, 17) states that people acknowledge as important the laws for "family, marriage, sexuality, money, political power, religion, morality, art, food and pleasure in general". Such choices follow an order, which reinforces the idea that the relevance system and limit of a given culture can only be assessed if compared to other cultures.

Studies on culture have shown that human groupings think, feel and act differently. As a result, any analysis on human behavior must consider certain cultural differences. These differences are expressed in different ways, such as by values that Tamayo (1996, 178) defines as "principles and goals that guide one's behavior", or "shared beliefs, symbols and rituals that constitute the cultural elements of a society or enterprise, which, in most cases, are unconsciously incorporated". By applying this definition to organizations, it is convenient to conclude that the values have a direct relationship with the way people perceive their environment. Such values then becomes a mental model

and can be perceived in the everyday speech of the company's employees, not necessarily equally, but depending on factors such as their job position, gender, company sector and the length of service.

Weber (1982) suggests that the main aspect of contemporary culture establishes a kind of influential society, with a rational way of life design. Moreover, one's participation in a group involves patterns of behavior, ideas and ideals. As a result, the culture of a people might be viewed as the result of the power of a group, and of the conflicts in their historical evolution.

Culture, therefore, according to Weber (2000, 246), is an evaluative concept; and values "are not exhausted in valuations, or in the objects with which they are connected". Schwartz's thought (1987) on social values as based on one's basic needs to understand a society and its dynamics must be highlighted here as a necessary tool to understand the relationships between the values of a society and its prevailing ideas.

The study of culture shows that human groups think, feel and act differently. Such cultural differences express themselves in different ways, and represent different expression levels of a culture. These levels are: symbols, which, although visible, convey specific meanings to those who share a given culture - words, outfit, gestures, pictures, flags - their heroes - alive, and deceased, real or imaginary people who represent role models, since they have characteristics there are quite esteemed in a given culture - rituals - collective activities that, although superficial, are considered essential to achieve certain purposes, from simple greetings to ceremonies; and values, the deepest level of all - the tendency to prefer a certain state of affairs from another, or a guided feeling, with a positive and a negative side (Hofstede 1997, 23). The first three levels were grouped by the author of this study and labeled as practices, as they are visible to an outside observer.

Hofstede (1997) shows that culture comes from the social environment; therefore, it is acquired, not inherited. This explains three levels: human nature, or what all human beings have in common - genetically determined, perceived through the human ability to feel fear, anger, love, joy, sorrow, the need to connect with others, to play, to exercise; and the ability to observe the environment and talk about it with other human beings; culture, which establishes how the human nature is expressed; and personality, a unique mental programming that cannot be shared with any other individual, as it encompasses a person's genetic heritage, personal experiences and cultural influences (Figure 1).

Figure 1. Mental programming levels.
Source: Hofstede (1997, 20).

Hofstede (1991, 210) defines culture as "the collective programming of the mind that distinguishes members of one organization from another". It starts in the environment "in which the child grows up" and follows the individual throughout his or her life. In this scenario, working environment is an extension of "school and family life". Thus, since their birth, men have their behavior and experiences defined by customs, language, their behavior at work, and actions as products of their culture.

In this article, the concept adopted is culture because of a mental programming resulting from a continuous learning process "acquired during childhood, when we are most susceptible to learning and assimilating". In this context, the word programming indicates "the most likely, comprehensive responses to each person's past" (Hofstede, 1997). Thus, culture includes all unique actions, activities and interests of a society, conditioned to historical moments, with specific rules and unique reasoning, all which shaping human beings for their purposes.

The organizational environment, in turn, shows several ways of thinking culture, a collective phenomenon shared by people of the same group, and of analyzing it culture within its very context, as the managers' behavior, a result of their relationships established throughout life, "reinforces the prevailing patterns of thought, feeling and actions in all spheres" (Hofstede 1997, 272). The involvement of workplace collective behavior in this analysis is important to understand the relationships among the workers within an environment, and the relationships between them and the internal and external context of the organizations - social systems -, making clear that culture is part of that system and might be considered as organizational culture.

Organizational culture is a dynamic, socially created concept, associated to the space and time dimensions. It involves the relationship between an organization with its environment, its organizational actors, and the benefits that are implemented from the outside and within. From this perspective, culture is considered by Schein (1989, 86) as:

A set of basic assumptions that a group has invented, discovered or developed by learning how to deal with external adaptation and internal integration issues, and that worked well enough to be validated, and taught to new members as the appropriate way to perceive, think and feel regarding these concepts.

On the other hand, the organizational phenomena cannot be analyzed independently, but rather in interaction with values, habits and social ideologies. Thus, it is convenient to associate this study to the local culture - the Brazilian culture, in this case - as a means to determine the cultural trends in which organizations look for their identity, par excellence, and eventually align their inherited characteristics and culture with the changes and transformations in the world today.

Following this line of thought, due to the rules in the productivity game developed in the dynamics of contemporary capitalism, which result to the management foundations and criteria, the organizations ask:

the administrator to turn into a hero, a creator of myths and values, a catalyst for the outbreak of symbols around which crowds of enthusiastic workers are gathered to achieve sustainable productivity and performance (Aktouf 1996, 216).

This leads to some questions, such as: how does the entrepreneur, the manager or the employee, in general, face the organizational culture and its demands? What are the dimensions of the actors' profile, who need to face the organizational culture mixed with management elements such as quality, ethics, ecology, social responsibility and, above all, "propositions for management methods towards cohesion, complicity, the spirit of initiative and creativity at all levels" (Aktouf 1996, 216)?

Then, seeing as crucial the understanding of cultural dimensions expressions, adopted by many authors of the organizational culture, help understand the context experienced by individuals and lead to an increase in researches on culture. The next subsection introduces some significant models that represent an individual or a group within the culture of an organization.

The model developed by Hofstede is now explained for a better understanding of organizational environment and the roles of its actors.

Geert Hofstede's Theoretical Model:

Some studies by Hofstede (1984) that explain culture from the perspective of a person's social environment - whose groups' cultural differences are expressed in different representations - contribute to understand the concept of organizational culture. They help us find the cultural dimensions that identify the relationships among the groups within an organization and show the importance of a national culture as a reflection of the different attitudes and values of the groups' behavior. According to Torres (1999), from then on, culture could be adopted as a causal (necessary and sufficient) predictor variable (necessary but not sufficient), in the extent that a person's intentions and behaviors could be directly related to the cultural group which he or she belongs.

The four dimensions introduced by Hofstede were the basis for characterizing and differentiating culture in the countries that he studied: power distance; individualism or collectivism; masculinity, and uncertainty avoidance. These dimensions are related to the deepest level of cultural expression (values), and respond in accordance with the group's mindset. In Porto's point of view (2004), they define a certain behavior that, when socially accepted, is supported by the group.

The Power Distance dimension is the degree of acceptance from those who have less power within an institution or organization of a country, an unequal distribution of power. It is the measure of a hierarchical distance based on the value systems of those who have less power. The individualism and collectivism dimension is associated to the different ways of self-perception, and one's relationship with the group. It is the reason why individualistic and collectivist societies deal with the role of the individual in different ways. Masculinity and Femininity is the dimension related to the influence of gender differences in determining the social roles, which are culturally determined. The males' behavior is typically associated with strength, firmness, ambition, assertiveness, self-confidence, competitiveness and the pursuit of success and the material progress. The females' role, in turn, focuses on taking care of the household, children and the others in general. The author explains that, in this context, the terms male and female were adopted to refer to gender, that is, men and women have a greater or lesser degree of cultural values associated with both genders. The Uncertainty Avoidance dimension is associated with the degree of anxiety of individuals of a certain group in any unknown or uncertain situation, expressed by stress and a need for predictability, among other aspects, which calls for written or unwritten rules.

A field research was conducted with small, medium and large Brazilian companies, and the results were presented in this article. it aimed to identify differences in cultural patterns and subsequently determine the possible entrepreneurial attitude-oriented relationships among the owners, managers and employees of a company in its different levels. In order to build a context for this study, some cultural traits of the Brazilian culture are described below.

The Brazilian Culture

The uniqueness and originality of every civilization is "performed by the individuals who constituted it". In this line of thought on this, Weber (2000, 246) tries to explain modernity based on the ascetic Protestant values that forged the attitudes towards labor, leading to the accumulation of capital, which, according to Weber, boosted contemporary capitalism and the modern life. Although Weber considers the more complex sociocultural phenomena, he believed that rationality triggered other life values as the following dimensions: economic, social, political, aesthetic and cultural (Weber, 2000, 246).

Human beings, individually or collectively speaking, use their experience, among other things, to build their social identity. Certain geographic and climatic features of Brazil - as well as other characteristics that, added to experiences and economic, political and social factors, are developed in the Brazilians' social life process - build an identity that characterize the Brazilian people. Quoting Da Matta says (1984, 16), Brazil "was discovered by the Portuguese, not the Chinese," and "we speak Portuguese, not French".

By analyzing the spirit that guided the colonization of Brazil, Holanda (1995, 243) identified a characteristic inherited from the Portuguese colonization: a great tendency for adventure, in which the employee "would have a very small role, unlike the adventurer"; and the quest for prosperity without cost, as easy wealth would be boldly chased. It is appropriate to remember that this same tendency inspired the Brazilian slavery system as a mechanism to bring opportunities and wealth to the colony. Furthermore, Holanda (1995 243) refers to a "primitive patriarchal family model" that, since ancient times, has caused a "social imbalance, the effects of which remain today". Such model was adopted in the Brazilian organizations, leading to imbalanced institutional dimensions.

Freyre (1981), referring to the size of the master's house as "great house" (casa grande), considered the core of Brazil's agrarian system, implemented by the Portuguese colonization - the patriarchal family, in which the patriarch has absolute power and controls the network of favors and interests, establishing an aristocratic power -, the representative of a social minority. Freyre (1981) analyzes this master-slave relationship, as well as a patriarchal style that values the personal and friendship ties, which still exist within the Brazilian families and organizations. Although today this influence is outdated and has been modified by technology changes, from the capitalist view, the relationships within national and global markets call for a new social and economic order.

Freyre (1981) states that the master's house shares a connection with the slave quarters; Da Matta (1997) links the house to the outdoors, often treating society as a big family, which is also extended to the organizations. People's behavior differs in these spaces, outdoors and, consequently, in public spaces. A house "filled with values and multiple realities" is a moral and social place, filled with relationships defined in the social dimensions, with a predominantly conservative speech and a space marked by personal recognition.

The outdoors, according to Da Matta (1997), is a locus of battle, of disorganized groups, with no commitment to respect or friendship; it is a dangerous, insecure place. Da Matta (1997) also states that home is not considered a workplace, as the household is not seen as such. Indeed, hard work is meant to the streets, which, as the author says, in "the Roman Catholic tradition", is punishment.

The confusion between these spaces has been transferred to the organizations today, which hold family relationships that confuse "intimate and kind moral relationships with a purely economic relationship. That often results a group of dramatic situations associated with this type of work relationship, in which the economic dimension is subject to, embedded in, the political and moral dimensions" (Da Matta, 1984, 32).

In such dynamics, public and private are mixed; the State is often a fragile factor in such diffuse presence of the institutions and social relations between social classes and groups. The results are irregular, erratic social, economic, political and administrative lives. Industrialization and urbanization have not affected the great significance that family life has always had in Brazil. Indeed, they have increased the significance of individual achievement along with the importance of the family in the core of the companies/organizations.

In patrimonial societies, personal relationships and influence networks are typically used to get a job, to have a project approved, to close a deal with the government. Such characteristic of the Brazilian culture might be praised as a creative feature; on the other hand, it might be negative, since it means bending rules, being favored - the infamous "Brazilian way", a mechanism adopted to establish, maintain and regulate personal or organizational relations. The Brazilian way, according to Da Matta (1984, 98), is a way to harmonize certain "legal rules" that often does not correspond to the demands and relationships of the Brazilian society. The application of such laws, par excellence, is subjected to influence affairs for personal purposes.

Rationality lies "in a clear, sane distinction between desires, personal interests and the actual world", and is expressed in "a demystification of what is real, in refusing simplistic representations of what the world means, which needs to be understood through the institutionalization of organizations on a rational basis" (Coelho, Bandeira, Menezes, 2000, 29).

All considered, it is understood that organizations are organized according to the culture of their members; to identify the dynamic relationships between their groups, which affect directly their members' attitudes, is to understand a company's dynamics and demands that ensure its sustainability or economic survival. Thus, the next section analyzes a conceptual survey on entrepreneurial attitude that aims to identify the relationship between the actions of the group members and the experienced culture.

Entrepreneurial Attitude

To understand the entrepreneurship phenomenon is to research one's relationship with an action. In order to explain the difference between that phenomenon and attitude, it is crucial to explain the various confusing concepts cited by some authors. The entrepreneur is seen as "innovation-oriented, who focuses on the production of changes" (Cruz, 2005, 38). Several authors, according to Cruz' conceptual survey (2005), label such entrepreneur as a "booster" of the social economic development, because "they are the ones who apply new patterns of behavior, and who change values and behaviors based on their creative attitude - the entrepreneurial vision". The entrepreneur, therefore, is an agent of change.

To better understand the line of research adopted in this study, it is necessary to introduce two concepts that often lead to misunderstandings and misinterpretations in the literature. The first concept is behavior, which may be internal to the individual (dispositional) - humor, skills or desire; or external (situational) - the characteristics of a task, social status or physical environment. The second concept is attitude. For Torres and Nebra (2005), attitudes are "relatively stable evaluative responses to a certain entity or situation". The attitudes are perceived according to three components: affective (or evaluative) component, which reflects whether a person likes or dislikes the entity or situation; the cognitive component, which consists of beliefs that person has towards the entity or situation; and the behavioral component, which are the behavioral tendencies towards the entity or situation. According to the authors, "although these components are intertwined, some inconsistencies among them might occur". The affective component is highlighted by Ajzen and Fishbein (2000, 3), as they show how one's mood and emotions affect their attitudes. They note state that "the fear of flying may well predict a negative attitude towards an aircraft, regardless of any other factors that might influence such attitude".

Attitudes, in Rodrigues' view (1972), are the foundation of social situations, such as friendship and conflicts as, by learning the attitudes of certain actors, one could make assumptions of their behavior. For Ajzen and Fishbein (2000, 3), the classical view suggests that social attitudes are assumed as residues of past experiences that would work guide future behaviors. However, after empirical research, these authors recognized that attitudes are considered a measurement tool for positive or negative personal evaluation towards an attitudinal object. They might be adopted to assess an object, concept or behavior in a range of dimensions, such as for or against, good or bad, and like or dislike.

On the other hand, the concept of attitude includes two major components: assessment and belief (Allen, 2000, 6). Assessment is predisposition to respond, favorably or not, to an attitudinal object. These predispositions are acquired through experience, direct or indirect, in which the object would incorporate or reject certain meanings. A few beliefs influence the attitude at a given moment; they are a significant part of one's personal attitude, and shaped by a range of cognitive and motivational processes, which may be based on selective or invalid information, and sometimes do not fit reality.

Much of the scholars' attention towards attitude comes from the attempts to predict social behavior from the study of attitudes. Attitudes, as defined as a disposition to respond, negatively or positively, to a psychological object, are expected to predict and explain human behavior. Positive attitudes should trigger approximation; negative attitudes, in turn, should trigger avoidance.

Rodrigues (1972, 402) shows a clear difference between behavior and attitude when he states that attitudes "involve what people think, feel, and how they would behave towards an attitudinal object". Behavior, in turn, is not only determined by what people desire, but also "by what they think they should do (social norms), by what they usually do (habit) and by the expected consequences of their behavior". Ajzen (1991, 180) concludes that behavior is affected by several other unique factors in a particular scenario, situation and action.

Rodrigues (1972, 401) highlights the ambience factor, as "social attitudes cause a state of predisposition to action that, when combined with a specific triggering situation, results in behavior".

It is worth noting that this research aims to contribute to a conceptual framework on entrepreneurial attitude and its relationship to culture, focusing on the entrepreneur in the Brazilian organizations. Therefore, entrepreneurship shall be explained according to the concept of national culture.

Entrepreneurship and National Culture

The most common scientific approaches on entrepreneurship, according to Filion (1991), are the economic approach, represented by thinkers such as Schumpeter (1998); and the behavioral approach, supported by thinkers such as McClelland (1972). In general, the economists tend to associate entrepreneurs to the company's innovation, profit and the business plan, while the behaviorists focus on creative factor, attitude and motivational factors.

However, the entrepreneurial attitude must be contextualized in the actions, activities and interests of a society, inherent to a cultural system of values and social norms based on their historical moment. Therefore, a conceptual survey on entrepreneurship and the entrepreneur will be introduced, focusing on the social and cultural approaches.

It is worth noting that the entrepreneurs that participated in this study belong to a hierarchical universe - the Brazilian system. They look for alternatives for survival in order to create new social spaces. Da Matta (1997) labels them "malandros" - spivs or rogues -, ranging from a witty, smart, creative, socially acknowledged person, to small-time crooks who risk their lives pulling cons, eventually becoming a criminal.

Cultural traits, added to experiences and economic, political and social factors developed throughout one's social life, build the identity that characterizes an entrepreneur - more specifically, the Brazilian entrepreneur. In the Brazilian society, technology changes, as well as the capitalist rationale and the relations within national and global markets, a new social and economic order, "did not change the role of personal relationships and influence networks to get a job, have a project approved, close a deal with the government". This reminds us of the so-called "Brazilian way", a mechanism to establish, maintain and regulate personal or organizational relationships (Souza-Depieri and Souza, 2005). This characteristic lies in the core of the Brazilian society, and might be understood by the gap between the laws, facts and practices in this society (Ramos, 1966). Barbosa (2006, 41) states that the "Brazilian way" is "a social procedure that, without any doubt, currently defines and distinguishes us". She also says that it is adopted by "all Brazilian society," is a "special manner to solve a problem or handle a difficult or forbidden situation". It is a "creative solution for all emergencies", no matter whether the solution "is final or not, optimal or temporary, legal or illegal". It is worth mentioning here Barbosa's opinion (2006, 19) that the Brazilian way is a social choice, a category "to define the style of a particular population to deal with certain problems".

According to Souza-Depieri and Souza (2005), the Brazilian way, plus the impact of public the country's economic policies - planned "within a individualistic network in the political system", connected to a bureaucracy prone to patronizing practices "found in the Brazilian families, economy, race and culture", plays a significant role in shaping the profile of the Brazilian entrepreneurs. In addition, entrepreneurship is seen as an integrated part of values, habits and social ideologies. It is developed according to the contemporary capitalism dynamics, which creates new foundations and criteria for management towards cohesion, spirit of initiative, creativity and, par excellence, innovation.

Souza (2005) assumes that some entrepreneur-related factors, though not necessarily inherent to them, may "be found in other professionals whose jobs involve creativity and high performance". Souza suggests that entrepreneurship is "dynamic, defined by time and space dimensions", and subject "to context, culture, government policies, among other social, political and economic conditions".

However, Brazil does not have a prolific culture of innovation. This condition reflects the nature of business strategies (not only new businesses!) that simply reproduce previous stories, regarding the traditional management functions such as HR, marketing, IT, finance or the infamous "Brazilian way".

From a sociological view, the Weberian conception considers entrepreneurship as a socially constructed phenomenon within a particular society; in this case, a modern capitalist society. The usual society back in the late 19th Century (in Brazil, it could be defined as a bureaucratic rationality over a rational-legal society), in which private affairs and free enterprise were crushed by a self-ruled State over the civil society; and also interpreted the opposite way, as a deceitfully protective State that disguised its State nature but was actually an instrument of the elite. It was the so-called heritage of the Iberian patrimonialism, reinforced, according to Vianna (1999, p.175), "in the early 19th Century, with the Portuguese State being transferred to the American soil". As mentioned above, Souza (2005) sees entrepreneurship as "dynamic, defined by the time and space dimensions", affected by the "context, culture, government policies, among other social, political and economic conditions", which reinforces the perception that, in Brazil, entrepreneurship acquires unique characteristics, based on the Brazilian society and capitalist model.

The Weberian concept, which tries to explain the development of capitalism in different countries, from the economic ethics spread by the Protestantism and Catholicism (Weber, 2004), sees the entrepreneur as an ideal type, mentally constructed from an economic rationality with modern values.

Schumpeter (1961) defined entrepreneur as someone who seeks new combinations of elements to introduce production, process or product methods in the market, by identifying new export markets or supply sources and by establishing new organization types. From a classical analysis, this author also tried to show the role of the entrepreneurs to explain economic development, by distinguishing the economic entrepreneur of his time and the economic agent during the early years of capitalism, when both capitalist and entrepreneur were from the same category.

Methodology

The research population in this study consisted of owner-managers and employees of small, medium and large companies -retailers, services and factories - in the Federal District, Brazil. 33 companies, from 29 different business activities, were selected. This convenience sample consisted mostly of women (51.3%) whose age ranged between 16-67 (MODE = 19 years of age). 3.8% of the respondents had not completed primary school; 3.3% had completed primary school; 4.9% had not completed high school; 32.9% had completed high school; 20.0% were undergraduates; 22.4% had obtained a college degree; and the others held a master's, Ph. D or a specialization degree). 44.8% of the research participants are in charge of operational tasks, and 21.2% perform technical tasks. The majority, 61.6%, perform trading activities, and 33.3% are in charge of services. 42.4% of the companies in the sample are small enterprises; 30.3% are medium-sized, and 25.6% are large.

The data was collected from 450 respondents, and two instruments were adopted: the first one assessed culture from a range of values, and the second one assessed the entrepreneurial attitude, based on the Achievement, Power, Innovation and Planning dimensions.

The participants' responses to the questionnaire - owner-managers and employees from different levels of 33 different enterprises - were recorded without typos in an electronic database through the SPSS (Statistical Package for

Social Science) software, version 12.0. Descriptive and exploratory analyses were conducted to verify the data input, the distribution of missing data, sample size, extreme cases and the distribution of variables.

To identify the unvaried extreme cases, all variables were turned into Z scores. Those considered as extreme cases showed standard scores higher than or equal to 3.29, $p < 0.001$, two-tailed; multivariate extreme values were identified through the Mahalanobis distance ($= 0.001$) (Tabachnick and Fidell, 2000). 129 unvaried extreme cases and 24 multivariate extreme cases were found. The outliers were removed from the analysis due to their high occurrence. The best methodology would require parallel analyzes (clean data X outliers) but, in this study, the number of outliers is not enough for a regression analysis (Tabachnick and Fidell, 2000). The rejection of extreme cases was based on Tabachnick and Fidell (2000, p. 13), who stated that they have "little impact on the regression equation, so excluding, recovering or changing the variable is recommended".

Regarding response normality, the variables were not changed in asymmetry indices and flattening cases. According to Zerbini (2003) and Carvalho (2003), previous experiments did not show any difference in their analyzes due to a transformation of variables. Moreover, the transformations are not recommended for this type of study, as it is the results are likely to be difficult to assess (Tabachnick and Fidell, 2000).

The regressions were done in three stages: the first consisted of standard regressions; the second analyzed the mediation effects on the relationship between culture and entrepreneurial attitude; the third stage analyzed the mediation effects with the same variables. All univariate and multivariate outliers were removed from these regression analyzes. It is worth noting that all analyzes were done according to the cultural patterns found in the research on which this article is based, as a predictor of the Brazilian cultural pattern - horizontal collectivism.

Results and Conclusions

This article aimed to identify the relationship between the Brazilian culture and its entrepreneurial attitude. The results shown here were found through standard and hierarchical regression analyzes, from which mediation and moderation tests were done with specific variables - type of activity, owner-manager, and company size. A convenience sample 450 people were analyzed, including owner-managers and employees from different departments in the company.

In this context, the culture variable was significant in the Horizontal Collectivism cultural manifestation. The surveyed subjects perceived their group as the source of their identity, and that their relationships were dependent-oriented. This result reinforces such perception, as it verifies a cultural trait identified by Freitas (1997, 44), who called it Personalism, in a "society based on personal relationships", or a "search for close, affective relationships, and Paternalism", i.e., moral and economic dominance. Such characteristic found in this study may be explained by Da Matta (1997), who he says that Brazilians build their relationships via social networks, represented by groups of friends or interests, clans, relatives. Furthermore, this research reinforces what Hofstede (1997, 52) found in his studies: Brazil as a collectivist society, characterized by "deep social networks" in which people differentiate their group, usually consisted of "relatives, clans and organizations."

This result assumes that, in a society with a cultural pattern such as the Brazilian, in which the State apparatus adopts a bureaucratic management system tending to patrimonial practices, the structure of most organizations subject their employees to a group and their power holders. Nunes (1997, 29) states that the entrepreneur is highly motivated to maintain the ties with relatives and friends, relying on their emotional support in times of stress, of need, or for a job search and career promotion. Ultimately, they are the ones who will show approval, confirming their success.

On the other hand, the horizontalism factor, identified in this study as the standard cultural indicator of the sample population, showed unexpected outcomes. Indeed, according to the studies of Hofstede (1997, 38), Brazil is seen as high distance power country, where class differences are noticeable.

The relationship between horizontal collectivism and the Power dimension showed moderation because the company owner is also a manager. It might be explained, according to Schwartz (1987), by the fact that the power holder aim to control personnel and resources. It explains why the business owner also works as a moderator, according to the perception of the sample population.

The tests did not show significant mediation and moderation results among the study variables. It is assumed, therefore, that only the culture factor, an expression of the Horizontal Collectivism pattern, showed significant results in the relationship, through a standard regression with the four dimensions of the entrepreneurial attitude dependent variable - Achievement, Planning, Power and Innovation. The fact that mediation was not detected in this relationship, and Culture was a direct predictor of entrepreneurial attitude, were explained by Da Matta (1984, 17), who sees culture as "a style, a manner and a way of doing things".

It should be highlighted here that this research was based on a sample of owner-managers and employees of small, medium and large companies in the Federal District from into 29 different business segments, with a total of only 33 companies. Therefore, it is convenient to mention here how difficult it is to research culture in such a huge country like Brazil, with clear regional differences and diverse ethnic background.

However, the relevant aspect of this study lies in its attempt to find explanations for a social phenomenon that has been included in the global agenda, especially in Brazil. Moreover, the demands included in this agenda and their intended solutions are characterized by a conflict between archaic and modern social, economic and institutional dynamics. As well as the cultural traits pertaining to the Brazilians' identity, which are found throughout this huge country.

Business models and social innovation: the case of employee welfare services

Dario Cavenago, Elisabetta Marafioti, Mattia Martini

University of Milan Bicocca

The paper explores how business model innovation can generate social innovation. It is commonly agreed in literature that the main engine of social innovation are innovative public policies involving, depending on the situation, both public and private actors or either of the two. The paper adopts a rather different perspective by focussing attention on how companies can generate social innovation and social spillovers investing on business model innovation. In particular, the paper explores organisational business model innovation focussing attention on the adoption of corporate welfare tools. Through a comparative case based empirical analysis, the paper measures the social impact of business model innovation through social return of investment (SROI) analysis therefore contributing to the scientific debate on the topic.

1 Introduction

The goal of the study is to explore how business model innovation can generate social innovation. In particular, the paper analyses the impact of employee welfare services introduction on the transition towards "social business models" or social strategies in private corporations.

Business model innovation can be activated by companies by evolving their value proposition, their set of activities and product/services offer, by redefining the set of actors that are contributing to their activity and, consequently the value creation and sharing systems that are adopted by companies (Amit et al., 2012). The introduction of a social perspective in management can contribute to the innovation in all the four areas listed above and, possibly allows companies to evolve their strategy towards what is commonly defined as social strategy that leads to social innovation.

It is commonly agreed in literature that the main engine of social innovation are innovative public policies involving, depending on the situation, both public and private actors or either of the two. The paper adopts a rather different perspective by focusing attention on how companies can generate social innovation and social spillovers investing on business model innovation. In particular, the paper explores organizational business model innovation focusing attention on the adoption of employee welfare services.

The adoption of this type of services generate an immediate social impact that can be measured in terms of social return of investment (SROI). SROI is a really relevant indicator, since it adopts typically a financial perspective to estimate the economic contribution of a social innovation like the introduction of employee welfare services on the company and, consequently, on the society as a whole. For this reason SROI can be considered as an indicator of social value.

The paper moves from a systematic analysis of literature on social entrepreneurship and business model innovation to identify an interpretative model that, by linking the above mentioned dimensions, explains how the introduction of welfare services can promote innovation at three levels: operations, strategy and society. Employee welfare services introduction, according to the model presented in this paper are an effective way to create a win-win strategy for workers, companies and the society as a whole.

2 Business model and business model innovation

Literature on management has dedicated a wide range of studies to the conceptualization of business models with specific reference to the dynamics of technological change and IT systems introductions. In particular, this approach was oriented toward the improvement of the understanding of the mechanisms that are contributing to economic value creation (Chesbrough and Rosenbloom, 2002). Only recently many scholars dedicated their seminal works to improving the definition of business models contents and identifying their main components. Business model has been defined by Zott and Amit (2010) as composed by content, structure and governance models that allow value creation through the exploitation of business opportunities. Also Casadesus-Mansell and Ricart (2011) identify as components of business models policy choices, asset choices and governance choices. Adopting a wider perspective, Osterwalder and Pigneur (2010) introduces a wider perspective focussing attention, not only on business models components but also on the rationale of how an organization "creates, delivers and captures value" (Osterwalder and Pigneur, 2010, p.14). The elements included in its model are wider, including value proposition, target customers, distribution channels, relationship, value configuration, core competency, partner network, cost structure and revenue model.

According to these authors models, business model innovation arises from an innovation activated in any of the components of business model or in its general concepts and philosophy. Traditionally the main engine of business model innovation is technology, even if also products, processes and value proposition can determine business model innovation. In the following sections of the paper, we explore the role and contribution to social innovation of an engine of business model innovation.

3 Social innovation and corporate welfare

The concept of social innovation is at the core of the debate within the European Commission. With the term “social innovation” literature refers to “a new solution (products, services, models, markets, processes, etc.) that simultaneously meets a social need (more efficiently and effectively than existing solutions) and leads to new or improved capabilities, assets and/or relationships” (Caulier-Grice et al., 2012). Accordingly, the process underlying social innovation implies change in the “product” (the nature of the services offered) and in the ‘process’ (who provides the service and with what resources), which are distinguished from the rest of the initiatives in the social sphere due to the fact that they would be able to improve the quality of life of individuals in the long term. Among the actors of social innovation an important role can be played by the private firms, which have the potential, in terms of economic and organizational resources, to implement those business policies in favour of sustainability - social and environmental - that fall today in the wide concept of Corporate Social Responsibility (European Commission 2001).

The employees welfare, or “second welfare”, is an example of “laboratory for social innovation, that consists of the initiatives of a diverse set of actors - from the third sector to local authorities, from for-profit enterprises to trade unions, from private insurance enterprises to social funds - that are intended to define new processes, models and services to respond to the needs of society. Moreover, research has shown that an escalating number of employers now recognize human capital as a valuable resource and consequently there is an increasing realization that employee personal wellbeing is an important determinant of organizational prosperity (Appelbaum and Shapiro, 1989).

The employees’ welfare is generally understood as the set of benefits and services provided by the company to its employees in order to improve their work and private life (Titmuss, 1958, Greve, 2007). Growing space within companies, but also in public administration, is occupied by the sphere of work-life balance (Burnett et al., 2013). From the point of view of the firm, employees’ welfare is within the compensation & benefit systems, but differs from traditional fringe benefits for the purposes for which they are supplied by the employers. In the first case, these are services offered to specific groups of employees and their aim is the improvement of employee’ working conditions. In the case of corporate welfare the same services are part of variable remuneration policy instruments that the employers usually offer to a wide audience of employees to improve their purchasing power and living conditions more in general.

The employees’ welfare services, or Employee Assistance Programms - EAPs (Davis, 1996 and Gammie, 1997), can be grouped into several categories. The first, is that of sustainable mobility, including facilities for parking, company car, and / or rental of cars at subsidized prices, without forgetting the reimbursements or fuel, but also conventions for the equipment to their employees smartphones, personal computers, etc.. The second group of services is that of health care assistance and pensions. A third area of intervention is related to purchasing, financing and loans, including mortgages and/or low-interest loans, incentives for opening bank accounts and the ability to make purchases in participating stores. The last area, including professional services, wellness and leisure, family and utility services, are all the programs, which are aimed at improving the work-life-balance of the labour force. The employees’ welfare plan and the weight of each area of services depend on many external and internal factors, such as developed cultural norms apparent in the benefits offered by government and private entities in a local market, as well as managers own cultural predilections (Cravens and Oliver, 2001)..

Welfare plans are often the results of a virtuous interaction of different actors, and in particular between the firm, regulatory authorities, employees, labour unions and even society as a whole (Oliver e Cravens, 2001). Empirical literature has highlights that the development of employee’s welfare plan within companies can follow two main different paths, implying different level of engagement of both employers and employees: the first, is a process mainly shared between the firm and the labour unions while the second is carried out unilaterally by the firm (Mallona, 2012). A part from the path chosen, the development of an employee welfare plan is an usually an iterative process composed by four main phases (1) needs’ assessment, (2) program design and model selection, (3) implementation and (4) evaluation. What emerges, is that the first and the latter phases are both crucial for both organizations and employees to achieve positive results with a corporate welfare plan (Davis and Gibson, 1994)..

Considering the outcomes of employees’ welfare plans, they represent a win-win-win strategy for the community, firms and workers. Indeed, the employees’ welfare plans respond to a subsidiary integration function to the public, by solving the needs of various types of workers and their families through the grant of companies’ private resources, while the benefits for employees are mainly linked to improvements in work-life-balance and quality of life, reduction of stress factors, increasing of job satisfaction (Carniol, Cesarini, Fatali, 2012). Corporate welfare plans also represent a strategy for the firm to attract, motivate and retain human resources. The literature leads the employees’ welfare services to the High Performance Work Systems (HPWS), which are a group of work organization and human resource practices which can simultaneously improve the wellbeing of workers and the firms’ performance (e.g. Appelbaum et al. 2000; Arthur, 1994; Becker e Gerhart, 1996; Delery e Doty, 1996; Huselid, 1995; Koch e McGrath, 1996; Lawler ed altri, 1995; MacDuffie, 1995; Pfeffer, 1998; Youndt, Snell, Dean e Lepak, 1996). Accordingly, the provision of employees’ welfare services would allow the organization to improve the committment of its employees and reach positive effects on workers turnover, absenteeism and productivity (Wood e de Menezes, 1998).

4 Social innovation and employee's welfare services as a driver of business model innovation

Some authors have explored the relationship between social innovation and business model innovation. In particular, they have used business model methodology to analysis new forms of business generated by social and socially responsible businesses. In particular, many of these contributions have focussed their attention on social entrepreneurship. According to Mair and Schoen (2005) successful social entrepreneurship is determined by common features and patterns around core strategy, strategic resources, customer interface and value network. Similarly Marquez et al. (2010) developed a concept of inclusive business model on the base of the business model canvass elaborated by Osterwalder and Pigneur (2010). In their elaboration value proposition, the distribution channel, the relationship with the customers, the partner network and the revenue model are the key elements involved. Also in the approach proposed by Yunus et al (2010), social business model is described in terms of value proposition, the social profit equation, the value constellation and the economic profit equation. There are other authors that have focussed their attention on assessing the difference between social and socially inclusive business models.

Regardless of the different approach adopted by various scholars, what emerges is the role of social orientation, social inclusion and social responsibility as a relevant engine of business model innovation that is producing the growth and development of a plurality of new ventures. In fact, the adoption of social orientation as an approach in doing business impacts on the various components of business models forcing companies to introduce new elements that in certain case can lead to the growth of totally new businesses, as in the case of social enterprise. If social innovation is conceived as one of the engine of business model innovation, there must be a continuum between business models, socially responsible business models and social businesses (Figure 1 and 2).

If social innovation is conceived as one of the main engine of business model innovation this must have an impact on business performance measurement models, also including social performance value creation.

The debate around the measurement of social value and social performance is very articulated and the methods proposed in literature are really wide and varied. In Table 1 is proposed a map of the most commonly used methods. This variety witnesses the inadequacy of the different methods that are used. In particular it must be observed that in reality many measurement systems are not used in reality by companies and even SROI (Social Return on Investment), that is often indicated as the most commonly used method, is not so diffused. Therefore improving the understanding of the diffusion of these methods of performance measurement is relevant and will be explored in the empirical section of this paper.

Within the context of this paper we will focus our attention on a specific type of social innovation represented by the introduction of employees welfare services into companies. The scope of this type of innovation is usually more limited in scope then social innovation conceived in a broader sense and as presented in the previous paragraphs. However it is important to stress how employees welfare services innovation can have a positive impact on people's motivation as well as on corporate reputation. As illustrated in Figure 3, corporate welfare services can have an impact on the organisation level of the business model, where a business model is described in terms of operating level, including product, process and activity innovation, organization level, including organization planning and management and people management and, finally, the strategic level, including content/value proposition of the activity, structure and governance models.

Figure 1. The relationship between business innovation and social business innovation.

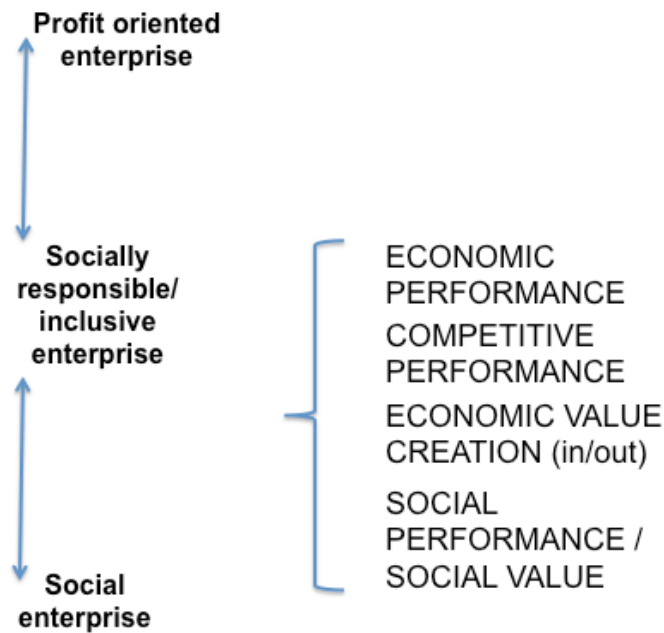

Figure 2. Business performance measurement models.

Table 1. Methods for social value measurement.

METHOD	DESCRIPTION	EXAMPLE	PROBLEMS
Cost-Benefit Analysis/ Cost-Effectiveness Analysis	The most widely used family of tools; counts up costs and benefits (usually using some of the methods described below), and then applies discount rates. Often used for large public programs.	A recent study in the United Kingdom found that using a mix of drug treatment, surveillance, and behavioral interventions instead of prison saved taxpayers up to \$130,000 per offender (and up to \$300,000 if savings to victims were included). ¹	Disagreements about the actual numbers and weightings in the calculation, as well as the conclusions of the analysis.
Stated Preferences	Asks people what they would pay for a service or outcome.	A typical example would ask people what they might pay to preserve an endangered species or to build a park.	Stated preferences often do not correlate with actual behaviors.
Revealed Preferences	Examines the choices that people have actually made to infer the relative worth of different options.	A researcher analyzes house-buying patterns and real estate prices to infer how much people value public parks.	Few fields have enough usable data.
Social Impact Assessment/Social Return on Investment Assessment	Estimates the direct costs of an action, the probability of it working, and the likely change in future outcomes, sometimes with discount rates.	There are literally hundreds of tools of this kind, including Acumen Fund's Best Available Charitable Option Ratio methodology, Jed Emerson's blended value methods; and various Center for High Impact Philanthropy methods.	Disagreements about numbers, weightings, and conclusions; values; how to handle time and discount rates; and intended audience of the calculation.
Public Value Assessment²	Judges how much the public values a service.	The British Broadcasting Corporation assessed its public value.	Not rigorous enough.
Value-Added Assessment	In education, assesses how much a school adds to the quality of its pupils.	Recent uses often show that apparently successful schools are actually good at attracting clever pupils.	Sometimes too complex for parents or the media to understand.
Quality-Adjusted Life Years/Disability-Adjusted Life Years Assessment	In health care policy and research, accounts for patients' objective health and patients' subjective experiences.	Widely used set of measures. Provides a common way to judge the relative effectiveness of clinical treatments and public health measures.	Can be controversial when a particular treatment is not cost-effective.
Life Satisfaction Assessment	Judges social projects and programs by how much extra income people would need to achieve an equivalent gain in life satisfaction.	An imaginative study in Wales showed that modest investments in home safety, which cost about 3 percent as much as home repairs, generated four times more life satisfaction. ³	New approach that remains unproven; highly sensitive to input assumptions.
Government Accounting Measures	In government, accounts for government spending and its effects.	France's <i>bilan sociétal</i> is a set of 100 indicators showing how enterprises affect society. Italy has a similar <i>bilancio sociale</i> .	Much variability across regions; disagreements about which indicators to include.
Other field-specific assessments	Every field has its own cluster of metrics.	A recent Young Foundation study identified nearly 30 measures of value in the built environment, including artificial neural networks, hedonic price models, fuzzy logic, autoregressive integrated moving averages methods, and triple bottom line property appraisals. ⁴	Diversity of these measures means that they are little used for public decision making.

Figure 3. Employees welfare services as engines of innovation.

Figure 4 illustrates how employees welfare services can have an impact on corporate performance and specifically on corporate social performance. Employees welfare services increase employee satisfaction, therefore positively impacting on employees motivation and involvement. An increasing motivation and involvement than has a positive impact on productivity and product/service quality. This activated positive note that is so increasing customer satisfaction and loyalty and therefore reputation that contributes to increasing revenues and enlarging customer base.

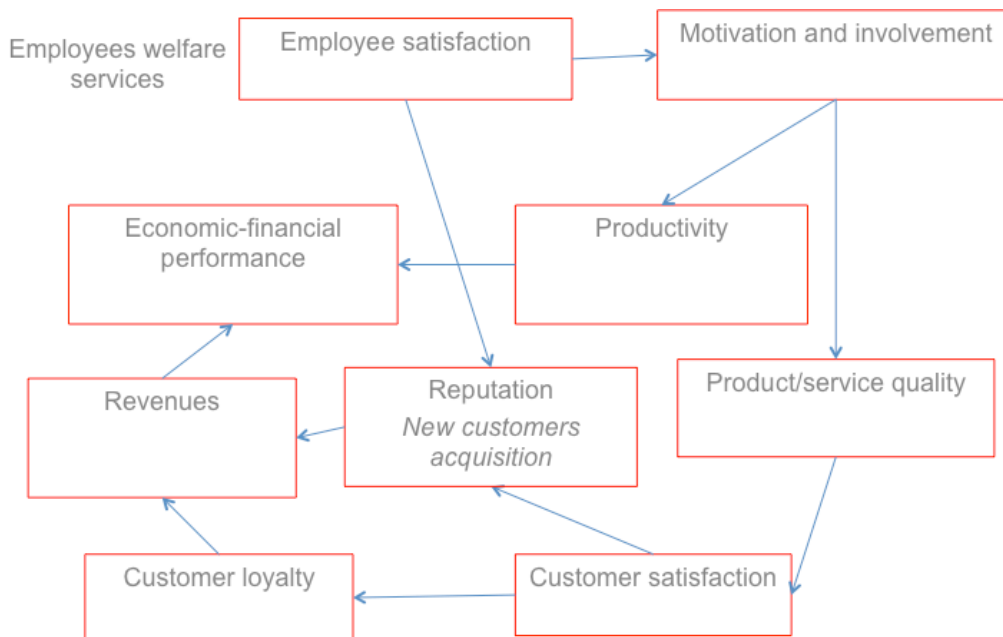

Figure 4. Employees welfare services and corporate performance.

As far as business model innovation is concerned an increased motivation and involvement contribute then to a higher productivity of employees determined by their involvement in processes innovation but also to product and services Improvement obtained by introducing bottom up innovations. Because of this mechanisms employee welfare services can be considered as one of the engines of business models innovation and on of the main drivers of social and socially responsible business models innovations.

5 Methodology

The empirical analysis is conducted on a sample of 67 Italian companies listed in the STAR segment in Milano Stock exchange. STAR is the market segment of Borsa Italiana’s equity market (MTA) dedicated to midsize companies with a capitalization of less than 1 billion euros, which voluntarily adhere to and comply with the following strict requirements:

- High transparency and high disclosure requirements
- High liquidity (free float of minimum 35%)
- Corporate Governance in line with international standards (i.e. a set of rules that determine the company's management)

The companies listed on STAR are leaders in their industry and they represent Italy's economic diversity and strong competitiveness. On April 30, 2013, the 67 companies listed on the STAR segment represent 26% of Borsa Italiana's MTA listed companies. The choice of the sample allowed us to work on a sample of companies that have a smaller size than those that has been analysed in other studies on social innovation and at the same time they represent an interesting observatory because of the excellence in management.

The data collected using secondary data (company reports and presentations, social reports and articles published on the main Italian economic magazines in the last three years on the companies) on the sample are aimed at mapping systematically:

- the degree of diffusion of employee welfare services within companies;
- the type and the pervasiveness of the welfare services adopted (i.e. Type of services, variety, coverage, etc.);
- the relationship among employee welfare services offer and the development of socially oriented business model innovation (therefore exploring the link between corporate welfare and social strategy).

The analysis is completed by the comparative analysis of 5 cases of best practices of socially oriented business model innovation and social performance and impact. The cases have been selected on the base of their reputation as being regarded as examples of excellent introduction in their company of innovations that had a relevant social impact.

6 The diffusion of employee welfare services: the case of Italy

Over the past 40 years, the need for welfare in Italy has changed dramatically as a result of irreversible trends (Mallone, 2012), such as increased life expectancy and the aging of the population, reducing the number of women at work, but also to "elderly "at work, due to the rise up of the retirement age and the disappearance of the large and enlarged family model, which served as a natural and essential support for descending and ascending. Over the past two decades in Italy there is a policy of containment of the "public welfare" undertaken to achieve the objectives of reducing the deficit, which has generated an increasing need for supplementary benefits, not only in the field of supplementary pensions and health care assistance, but also and especially in the services in favour of workers and their families. In light of these trends, in Italy, and in particular at local levels, over the past years substantial public funds has been allocated to finance private companies wishing to adopt supplementary welfare plans, or even the creation of networks of partnerships between small and medium enterprises who wish to cooperate in the development of welfare services targeted to their employees.

The employees welfare services in Italy are not a new phenomenon but were born in the 50s' as an expression of "paternalism" of some large multinational companies (Amatori, 1980; Benenati (1993, 1999). In recent years, however, the corporate welfare has changed, becoming a tool for strategic human resource management with a value of both economic and social nature, designed to meet the needs of workers, reduce costs and improve the organizational performance. Indeed, under the pressure of a growing demand for welfare services by workers and the containment of public expenditures, and in light of the significant tax benefits recognized by law, an increasing number of companies in Italy is enriching the corporate welfare system available to its employees, adopting a policy of total-reward, in which tools of monetary type (salary and variable remuneration) are complemented by non-monetary instruments (benefit and perquisite) to pursue the objectives of fiscal optimization, human resources loyalty, motivation and attraction and building a solid and lasting corporate identity.

A recent survey of more than 300 Italian companies showed that, even excluding supplementary social security, the phenomenon of employees' welfare affects more than 80% of companies with more than 500 employees (Ascoli, Mirabile e Pavolini 2012). About 37% of large companies also offers at least four different types of performance, while 43% include two or three welfare services. The supplementary pension is present in the vast majority of the companies, while among the benefits to medium-low and low diffusion are the interventions for the reconciliation of family and work, those in the field of nursing and long-term care as well as access to housing.

Assolombarda, an association of entrepreneurs, in 2010 undertook a research which relates to the spread of corporate welfare between firms in Lombardy Region. From the reference sample, consisting of about 400 companies, emerges that the welfare initiatives are more frequently present in large companies (88%), while they drops drastically up to 12% of the total, when considering the small and medium enterprises (with less than 250 employees). It has been also highlight that there are different paths and behaviours between large and SMEs in the way employees welfare is introduced: in the firsts, it prevails an agreed decision, through enterprise bargaining agreement or single/multiple agreement; in the seconds, it is more often the result of an unilateral decision of the company.

According to the study conducted in 2013 by McKinsey, the welfare system is very much appreciated by the workers, who "evaluate" it up to 70% more compared to the cost incurred by the company. Accordingly, the "employee engagement index" of workers increased by 30 per cent when the welfare plan is introduced, and by 15% when an existing service is improved (ValoreD, 2013). Research also shows, that both men and women appreciate the corporate

welfare schemes. In particular, more and more persons would like paid parental leave, and that the needs vary considerably depending on the 'positioning' along the life cycle: if within people between thirty and forty years the needs connected to the care of children are the most cited, from fifty onwards workers feel higher the need to help elderly family members.

7 The diffusion of employee welfare services: the empirical analysis

The data collected on the sample of companies included in the star segment show that only a limited number of them (about 30%) publish a social report on a regular base but only 50% of them publish a certified social report. The majority of the companies have a section of their corporate website that is dedicated to social responsibility in terms of activities involved, environmental and green management. The data that is really surprising is the limited space that is dedicated to employee's welfare services both in official reports and corporate websites. Data Have been collected also on social performance measures adopted by sample companies. Also here a surprising data is represented by the fact that only 10% of them use any type of performance measure while the remaining do not declare to use any.

In the second phase of the analysis we focussed our attention on a subsample of 5 companies also including companies that were not listed in STAR segment but were commonly renowned by media as social innovators in their respective fields, with specific reference to employees' welfare services. The cases are presented below.

7.1 Luxottica

Luxottica Group is a leader in the eyewear sector of high-end, luxury and sports eyewear, with over 7,000 stores operating in both the optical and sun in North America, Asia-Pacific, China, South Africa, Latin America and Europe. The company is based in Italy and counts 1,039 employees.

The "welfare package" for employees of Luxottica includes the "shopping card", the health insurance policy, reimbursement of textbooks and several scholarships for the children's of the employees. The decision to set up an employees' welfare system in Luxottica is the result of two parallel forces: on the one hand, the willingness of the entrepreneur to provide support to workers at a time of economic crisis; secondly, to create a "virtuous circle of quality" that can generate resources for employees through a general improvement of labour productivity

The project was launched in 2009 and has been developed within a Governance Committee, which is a bilateral body company's and unions' representation, which has established an indicator related to the increase in the production of quality according to which the resources for welfare are periodically allocated. Since the introduction of the employee's welfare system in 2009, the quality of production has improved continuously through waste reduction, lower absenteeism rates and greater attention of workers to the processes' efficiency.

Luxottica shows a strong attention to sustainability and then to the social and environmental impact of the business. It emerges clearly from the mission which states that the aim of the company is that to concentrate on eye protection and enhancement of the faces of women and men in the world, producing and selling sunglasses and eyeglasses high technical and of stylistic quality, in order to maximize the well-being and satisfaction of consumers, by respecting the environment. In light of the declared values, the company has been active in recent years on a number of social responsibility projects. In particular, Luxottica has founded One Sight, an independent non-profit organization which is committed fight the global crisis of eye care. Then, the plan for the welfare of Luxottica is part of a human resource management system which includes many initiatives promoting quality of work and the personal and professional development of its employees.

7.2 Nestlé Italia

Nestlé, the world leader in the food industry, employs 280,000 persons in more than 100 different nationalities. Over a third of the workforce is located in Europe (33.9 per cent), 38 per cent in the Americas and 28.1% in Asia, Oceania and Africa. The group has been active in Italy since 1875, where he is now the first company in the industry.

The "jewel in the crown" of welfare in Nestlé is made by the project "90 days", for which the company has won the award in 2011 ("Family and Work") in the Region of Lombardy. It includes dedicated areas for the children of employees during the holiday periods and the schools' closing periods, two nurseries, the union agreement for the flexibility of-time and telecommuting, as well as the signing of the Charter for voluntary equal Opportunities promoted by the Ministry of Labour, Ministry of Gender and the non-profit organization – Sodalitas.

Creating Shared Value (CSV) is the principle behind the activities of the Nestlé Group, according to which, to be successful in the long run, a company must create value both for itself and for its shareholders and for society in which it operates, bringing tangible benefits to the people, economy and territory. The Nestlé in Society Board, chaired by the CEO, oversees the strategic implementation of Creating Shared Value across the businesses and it leads the development and evolution of the CSV, environmental sustainability, and all societal objectives and strategies. To feed the corporate culture and create shared value, Nestlé promotes the sustainable development throughout the overall production process and invests from many times in the welfare of its employees. Crucial in the sustainability strategy are the priorities that the Nestlé Group establishes for Europe in the field of human resources, and in particular the all gender balance, employee branding and social compliance. In this regard, the corporate welfare is a practical tool that

the company uses to achieve objectives such as the improvement of working conditions of female employees, the image of the brand and, last but not least, the company attractiveness for workers.

7.3 SEA Aeroporti Milano

The SEA Group is the company that plays the role of manager of the airports of Milan Linate and Milan Malpensa from 1948. The group consists of 14 subsidiaries that operate in four different business areas: aviation, non-aviation, handling and power, with a total number of employees that is 4,854.

The employees' welfare plan of SEA, entitled "SEA for you," is aimed at all employees and consists of 16 initiatives related to 5 macro areas: work-life balance, health, protection and prevention, social services, recreation and Education. The project was developed in 2011 as part of a broader process of reorganization and provides for the active participation of trade unions in all phases of design and implementation. The aim of the welfare project was to support the purchasing power, improving the relationship between working time and free time, contribute to the welfare of those who work in the company, as tools to support the development of the company. The main feature of welfare in SEA is to the governance model which is based on the relationship between three entities, two of which are managed through a bilateral body with equal representation of the company and the employees.

The SEA Group's strategic vision is based on the criteria of sustainable generation of value, considered in its multidimensionality (economic, environmental, and social) and a view based on the mutual reinforcement of the three components. To this end the company has entrusted the governance planning and decision-making on sustainable development at the Group Sustainability Committee, chaired by the President and Chief Executive Officer and convened semi-annually with the participation of the Chief Corporate Officer, Chief Operating Officer and Deputy CEO, Chief Financial Officer and Directors of many organizational functions. In accordance with the company's sustainability vision, SEA is engaged from many years in the development of sustainable innovations, which the company has divided into 3 main areas: sustainability and economic competitiveness, environmental sustainability, social and economic sustainability. Moreover, in its annual sustainability reports SEA report on the evaluation of the projects developed, using a set of indicators, which allow monitoring each of the three areas.

7.4 Tetra Pak Packaging Solutions

Tetra Pak, founded in 1951 by Swedish director Ruben Rausing, now operates in more than 190 markets and has over 20,000 employees worldwide. The Modena headquarters of Tetra Pak Packaging Solutions in Italy is the engineering company of the group that is engaged in research, development and manufacture of machinery for the packaging of liquid food products and employees more than 800 persons.

The starting point for the development of the employees' welfare system in Tetra Pak is the Nordic culture and tradition of "family" that has produced a consistent basis over time to "focus on people," found at the corporate level. The management of the office in Modena has launched in 2009 a plan of corporate welfare in collaboration with the unions, after a careful analysis of all possible innovations to be introduced in relation to the budget allocated by the company. The welfare plan of Tetra Pak include many employees' welfare services, such as the integration of maternity treatment, a flexibility plan, conventions and services in-house, a nursery, a package of insurance for accidents at work and outside, large interventions and hospital admissions, reimbursement of expenses for visits, eyeglasses and medication, for the employee and his family, complementary pensions, reimbursement for study, training, sports and travel expenses.

Tetra Pak defines its-self as a "responsible society" for the attention that it addresses to the environment and the welfare of its employees. The governance of Sustainability has been entrusted to the Global Leadership Team, which is supported by the Corporate Governance Office and a network of local governance, risk and compliance officers. In addition to the employees welfare services, the company is also active in the field of social and economic sustainability, through partnerships with non-government organizations and government organizations, developing projects and initiative which have transformed the overall value-chain: for example, in the recent years, the company has developed more renewable packaging and leaner food processing and filling solutions, increased efficiency and reduce operational impacts as well as helped customers reduce theirs, and created benefits for labour force by supporting the wider development goals of its employees.

7.5 Unipol Assicurazioni

Unipol is an Italian company providing insurance services which was founded in 1961 by the automaker Lancia and then purchased in 1963 by a group of cooperatives located in Emilia Romagna Region.

The project of Unipol for employee's welfare services was started in 2013 and jointly developed by the organizational functions "Sustainability" and "Internal Communication". The welfare services are provided to all the employees and it can be divided into two levels. The first relates to all the initiatives related to income support and support for persons, such as health care and the pension fund. The second relates to the core business including insurance coverage and services that the company offers to employees of the Group on concessional terms.

For the Unipol Group, sustainability is firmly integrated into the way it does business, thanks to a management that combines economic value creation, strengthening governance, environmental protection and social responsibility. Indeed, the Unipol Group has formalized its commitment to sustainable and long-term growth in reference documents for operating procedures in various business areas consolidating coherence with its values and principles.

With reference to sustainability, Unipol has introduced new products to better meet the needs of industry and it has innovated the existing products, adapting them to market changes and the needs of individuals and businesses. Moreover, the company has developed new services and improved the services that already exist, by including the stakeholders' point of view and it has managed the relation with the employees in a sustainable way for individuals and for the company, with a particular attention to the enhancement of diversity and protection of the individual. Furthermore, it has supported the community where operates, by supporting the development, social cohesion, the production and dissemination of culture. Finally, the company each year makes public the company's sustainability results, which are measured by specific indicators identifying the economic, social and environmental performance.

8 Discussion

Table 2 and 3 presented below provides for a synthesis of the comparative analysis of the selected best practices.

Table 2. Employees welfare services offered.

	SECURITY	FINANCING/ LOANS	PROFESSIONAL SERVICES	WELFARE/ FREE TIME	FAMILY	RESTAURANTS	PUBLIC UTILITY SERVICES
Luxottica	Contribution to health care costs			relax areas, bank hours	contribution to medical costs, social assistance, support and contribution to school and kindergartens, scholarships for deserving students, support for summer camps, babysitting service on demand; job sharing		shopping card to purchase grocery products for daily use
Nestlè Italia					teleworking and agile work (on demand), maternity and paternity kit	nurseries	
SEA Aereoporti Milano	Cash assistance , extra professional accident insurance , prophylaxis, medical check-up, prevention campaigns, Spa Treatments		Voucher for study expenses	Summer camps for children and adolescents, summer camp at the beach or in the mountains for children and adolescents, cash for toy, cultural and leisure travel organization	Permits for specialist visits; Part-time "mother"; Flexible hours, Mobility home-work		Listening and help, help desk for seniors

	SECURITY	FINANCING/ LOANS	PROFESSIONAL SERVICES	WELFARE/ FREE TIME	FAMILY	RESTAURANTS	PUBLIC UTILITY SERVICES
Tetra Pak Italiana Spa	shuttle bus	healthcare plans, supplementary pension			company gym	Cover of medical expenses for specialist visits, summer programs, refunds for sports and training, support for enrolment in kindergartens or nursery business	Company's restaurant
Unipol Assicurazioni	Pension fund and health care found			agreements with beauty salons and hairdressers	care services and home care agreements with centres of hospitality and nurturing, educational services and entertainment for children during the summer		Laundry and tailoring of minor repairs , shoe repair service, pick up and return the car in the company by mechanics and tire shops, pharmacy

Table 3. Employees welfare services offered.

	VALUE PROPOSITION INNOVATION	NEW ACTIVITIES INTRODUCED	ORGANIZATION MODEL	STAKEHOLDERS INVOLVEMENT USED	SOCIAL IMPACT MEASURES
Luxottica	Luxottica Group's mission is to dedicate eye protection and enhancement of the faces of women and men in the world, producing and selling sunglasses and eyeglasses high technical and stylistic quality in order to maximize the well-being and satisfaction of consumers, in an environmentally	Managing employees with attention to personal and professional growth needs; sustainable innovation projects through OneSight	One Sight (non-profit organization), Governance Committee (a body corporate and union representation bilateral)	Not available	Quality of production (waste reduction, absenteeism, process efficiency)
Nestlé Italia	The principle behind the activities of the group is "Creating Shared Value"	Sustainable development throughout the production process; investments in the well-being of its employees	Nestlé in Society Board	Annual Stakeholder convening	Environmental impact indicators, indicators of organizational performance, subjective well-being of employees
SEA Aereoporti Milano	The Group's strategic vision is based on the criteria of sustainable generation of value, considered in its 3 components: economic, environmental and social.	Development of projects for economic, environmental and social sustainability	Corporate Social Responsibility Unit, Group Sustainability Committee	Customer satisfaction, Stakeholders' annual survey; multi-stakeholder workshop	Indicators of economic-competitiveness, environmental sustainability indicators, indicators of socio-economic sustainability

	VALUE PROPOSITION INNOVATION	NEW ACTIVITIES INTRODUCED	ORGANIZATION MODEL	STAKEHOLDERS INVOLVEMENT USED	SOCIAL IMPACT MEASURES
Tetra Pak Italiana Spa	The company believes in a responsible industry leadership, creating profitable growth achieved in harmony with environmental sustainability and with our sense of social responsibility.	Innovation along the overall value chain: more renewable packaging and leaner food processing and filling solutions, increase efficiency and reduce operational impacts as well as help customers reduce theirs, and create benefits for labour force by supporting the wider development goals of its employees	Global Leadership Team is responsible for the framework, supported by a Corporate Governance Office and a network of local governance, risk and compliance officers.	Partnerships with non-government organisations (WWF, Thai Red Cross Society, GAIN) and government organisations (United Nations Global Compact)	Not available
Unipol Assicurazioni	The aim of the company is to ensure sustainable and long-term growth, accompanied by an adequate profitability for the benefit of all stakeholders: shareholders, customers, agents, employees, suppliers and communities.	Action for the recovery and rehabilitation of degraded areas of the country, interest-free loan to pay premiums in instalments cars, construction of a port in an environmentally sustainable investment plan, experimental process of certification of insurance products, life insurance.	Unipolis Foundation, Sustainability Committee / Ethics Committee, Ethics and Social Responsibility function (RES),	Partnerships with non-profit organizations (Freedom, Legambiente, BITeB, Gaia), participation in national and international networks (Procurement & Sustainability, CSR Manager Network, Forum for Sustainable Finance), organization of workshops on the territory	Indicators of economic, social and environmental sustainability

The data analysed reveals how deep and pervasive is the impact of employees welfare services on the business model of those companies who have adopted them intensively, also interiorising a deep social orientation that is also involving environmental as well as community social issues. Those companies who introduced a variety of employees welfare services have also introduced innovation in their business model that are directly associated with the latter. In particular the major impact is on business model value proposition and on stakeholders involvement model. In terms of social impact measures adopted, interestingly companies tend to focus on the measurement of sustainability impact rather than involving other areas of analysis and social impact. This element seems to confirm the relative difficulty in diffusing shared and easy to use social impact measurement systems.

9 Conclusions

The theoretical model and the empirical analysis has allowed to improve the understanding of the mechanisms that generate social innovation promoted by companies. In particular the paper highlights the role of employees' welfare services as one of the engine of business model and social innovation. Furthermore, the paper provides a complete and systematic picture of the introduction of employees' welfare services in Italian companies and a measure of their economic and social impact.

Do KIBS make manufacturing more innovative? An empirical investigation for four European countries

Daria Ciriaci¹, Sandro Montresor², Daniela Palma³

¹European Commission, Directorate General for Economic and Financial Affairs, ²Department of Economics, University of Bologna, ³ENEA, Rome

Abstract

The paper aims at estimating the innovation impact of the vertical integration of knowledge intensive business services (KIBS) into manufacturing. Referring to the vertically integrated sectors of an economy allows innovative knowledge, which is transferred directly and indirectly from KIBS to manufacturing in an embodied way, to be measured. Its impact on manufacturing innovation is then estimated. By merging OECD data on sectoral R&D and input-output tables with sectoral patent applications from the Pastat dataset, a panel of 18 manufacturing sectors is built up for the four largest European countries – France, Germany, Italy and the UK – spanning from the mid-90s to the mid-00s. The more innovative sectors are actually those making more intensive and extensive use of R&D embodied into KIBS production flows. In policy terms, strengthening the bridge between KIBS and manufacturing appears to be as crucial as supporting KIBS activities and service innovations.

Keywords: KIBS; vertically integrated sectors; embodied R&D flows.

JEL codes: L60, L84, O33, O32, P00.

1 Introduction

Two decades after the seminal contribution by Miles et al. (1995), Knowledge Intensive Business Services (KIBS) are still attracting a lot of attention. New important insights have been obtained about their role at different levels of analysis: micro and sectoral (e.g. Tether, 2005; Corrocher *et al.*, 2009; Consoli and Elche-Hortelano, 2010, Doloreux and Shearmur, 2010), urban and regional (e.g. Tödtling *et al.*, 2006; Savi and Lawton-Smith, 2013; Antonietti *et al.* 2013; Shearmur and Doloreux, 2014), macroeconomic and structural change (e.g. Mas-Verdú *et al.*, 2011; Hauknes and Knell, 2009, Di Cagno and Meliciani, 2005; Desmarchelier *et al.*, 2013).

A common aspect of these streams of research is the attention for the complex kind of knowledge-exchange that KIBS realise with their clients, especially with firms operating in manufacturing industries. Their knowledge interaction occurs through both disembodied and embodied flows, of codified and tacit knowledge, respectively, which overlap to a different extent with the production relationships between KIBS and manufacturing (Landry *et al.*, 2012)

The present paper focuses on and extends the investigation of “production-embodied” flows of knowledge between KIBS and manufacturing based on the use of input-output analysis (e.g. Baker, 2007; Tomlinson, 2000a, 2000b; Windrum and Tomlinson, 1999). In particular, it brings to it two pieces of value added. Firstly, rather than a simple input-output one, we adopt a more sophisticated vertically integrated approach based on the notion of subsystem. This perspective has recently proved quite useful in investigating the relationships between manufacturing and services, especially in the aftermath of the explosion of outsourcing practices from the former to the latter (Ciriaci and Palma, 2012; Montresor and Vittucci Marzetti, 2011). Secondly, rather than a standard production function approach to the impact of KIBS on the productivity of manufacturing (e.g. Antonelli, 2000; Katsoulacos and Tsounis, 2000), we use a “knowledge production function” with a long tradition in innovation studies at the firm level (Griliches, 1979; Crepon *et al.*, 1998). Using this original framework of sectoral analysis, we aim at investigating the extent to which KIBS’ innovative knowledge enters into the manufacturing subsystems (or vertically integrated sectors) through production-based flows, and in so doing increases their innovation capacity.

An empirical investigation is carried out with respect to four large EU economies, whose KIBS have been shown to be pivotal and have different intersectoral patterns of vertical integration (Ciriaci and Palma, 2012; Windrum and Tomlinson, 1999), that is: France, Germany, Italy and the UK, for a period which spans from the mid-90s to the mid-00s. In order to do so, the OECD Input-Output and the ANBERD databases are combined and merged with sectoral patent applications coming from the Pastat dataset. In a panel framework, country, sector and time specific effects are thus controlled for.

The remainder of the paper is organised as follows. Section 2 illustrates the theoretical background. Section 3 describes the methodological approach, Section 4 the data used and the empirical application. Section 5 comments on the results and Section 6 concludes.

2 Theoretical background

In nearly twenty years of intense research, the analysis of KIBS has become enriched with several definitions and approaches (for a review, see Muller and Doloreux, 2009). Some of them focus on the actors (companies or organisations) that deliver the services at stake (e.g. Miles et al., 1995; Bettencourt *et al.*, 2002) and treat “a KIBS” as the supply of a qualified, knowledge-intensive service (e.g. Amara et al., 2009; Rodriguez and Ballesta, 2010). Other definitions instead address the nature of these service activities (e.g. Den Hertog, 2000; Gallouj, 2002b) and deal with “a KIBS” as a particular kind of economic sector, with an important role in promoting innovation and growth at aggregate level (e.g. Baumol, 2002; Oulton, 2001).

Although it also draws on the first one, this paper is grounded in the second research stream. Hereafter, KIBS will be thus meant as “a category of service activities, which is often highly innovative in its own right, as well as facilitating innovation in other economic sectors, including both industrial and manufacturing sectors” (den Hertog, 2000, pp. 504–505).⁷⁴

This definition directly points to a function of KIBS, which is the focus of this paper (on the array of KIBS function, see Den Hertog and Bilderbeek, 2008). KIBS carry on key-activities in innovation systems (e.g. Muller and Zenker, 2001; Tether, 2005). Not only are they innovative *per se*, as they introduce new marketable services and technological applications. They also act as knowledge carriers with respect to other sectors, especially manufacturing ones, and in this way they work as “innovation propellers” at the system level (Castellacci, 2008).

Knowledge transfer constitutes the core activity that KIBS play (especially) with respect to manufacturing sectors (Leiponen, 2006). This is a manifold activity, which involves KIBS in the generation and diffusion of different types of knowledge, both codified and tacit, for developing problem-specific and innovative solutions to their manufacturing clients (Landry et al., 2012). In this process, two aspects require special attention, possibly more than in the extant literature: i) the production-based transmission of KIBS knowledge; ii) the techno-economic impact of this knowledge transmission.

2.1 The “production-based” transmission of KIBS knowledge

The production and use of KIBS knowledge occur through frequent and specialised interactions between KIBS and their clients (Koschatzky and Stahlecker, 2006). Not only in the form of explicit (e.g. contractual) knowledge transfers and cooperation agreements, but also via production relationships, like exchanges of intermediate services, commodities and capital goods. This latter kind of production flows between KIBS and manufacturing is beneficial in at least two respects. Firstly, it conveys to manufacturing sectors a tacit kind of KIBS knowledge, which can’t reach them in other ways but through the embodiment in the exchanged items (Hauknes and Knell, 2009; Papaconstantinou *et al.*, 1996). One can think of the purchase of a newly (KIBS) developed software product that encapsulates some “unwritten” functions, which the (manufacturing) client discovers by exploring its use.

Secondly, the production interaction between KIBS and manufacturing can also affect the diffusion of codified KIBS knowledge, even in the absence of an actual embodiment. As regional and urban studies have largely shown, by getting involved in (repeated) market relationships, their partners can build up and increase their “cognitive proximity” (Boschma, 2005), augment the overlapping degree of their learning routines and mental frameworks, and become able to better understand and absorb the explicit knowledge they exchange (Montresor and Vittucci Marzetti, 2008). One can think of a (disembodied) consultancy KIBS deliver to a (manufacturing) client in order to improve its market strategic positioning, benefiting of the experience accumulated by interacting with it in the exchange of more ordinary services, like accounting, logistics support and HRM.

All in all, an important “production-based” (and not only “embodied”) transmission of KIBS knowledge to manufacturing can be identified, for whose mapping input-output tables of production flows represent an important analytical tool. Indeed, the input-output approach to KIBS is one the first to have been adopted (Tomlinson, 2000a, 2000b; Windrum and Tomlinson, 1999) and its use has been recently extended (e.g. Mas-Verdú et al., 2011; Hauknes and Knell, 2009; Rodriguez and Camacho, 2008; Baker, 2007). However, in this research stream little attention is paid to the “complexity” of the production relationship between KIBS and manufacturing sectors: in particular, to the fact that KIBS knowledge can reach a manufacturing sector on a production basis, both directly and indirectly. The relative knowledge flow occurs also through the contribution of the former to an intermediate input of the product of the latter, or to a further intermediate input of this intermediate input, and so on and so forth, in the classical Leontievan sequence of production rounds (Miller and Blair, 2009). The ICT service that has served to ameliorate the component of an electronic device, which is then used in turn by an R&D agency-consulting for a PC producer, is just an example of this indirect, input-mediated relationship.

⁷⁴ KIBS thus include business-devoted activities such as consultancy, research and engineering, which are characterised by intensive professional knowledge (i.e. a technical area or discipline) and are dedicated to other productive sectors (providing them customized problem solving), rather than to final consumption (Miles et al., 1995). A more precise account of the identification of these sectors will be provided in the next section. On the classification of KIBS see, among the others, Miles et al. (1995), Muller and Zenker (2001), Martinez-Fernandez and Miles (2006).

This is a crucial aspect, which requires a move from a simple input-output perspective, to a more structural kind of perspective, which looks at the actual vertical integration of KIBS into manufacturing for serving its final demand, by capturing the direct and indirect relationships of the relative sub-systems. In previous studies, such an approach has been used to show that the latest stages of structural change (and the crucial role of outsourcing in it) have made this vertical integration of services into manufacturing quite substantial, with important implications for the blurring of the sectoral boundaries between KIBS and manufacturing (Ciriaci and Palma, 2011) and for the tertiarisation extent of their hosting economies (Montresor and Vittucci Marzetti, 2011).

Accordingly, our first bit of hypothesis is that the vertical integration of KIBS into manufacturing, which is realised through the direct and indirect contribution of the former to the final demand of the latter, represents a significant map of their production-based knowledge flows.

2.2 The “techno-economic” impact of production-based KIBS knowledge

The majority of the studies that, in an input-output framework, have looked at the economic impact of “production-embodied” KIBS knowledge flows – to be sure, not that many with respect to those focused on their sole mapping – have focused on the productivity gains that client manufacturing sectors can have from them (Tomlinson, 2000a, 2000b; Barker, 2007).⁷⁵ This is the natural consequence of their exclusive focus on the embodied way in which KIBS knowledge is supposed to reach manufacturing, and of the way in which the standard “embodiment hypothesis” (Jorgenson, 1966) assumes the knowledge obtained by the producer – typically through R&D – spills over the user. Indeed, according to this view, the knowledge of the former would only create a rent for the latter, to the extent at which the price of the sold commodities that incorporates such a knowledge does not entirely reflect its actual higher quality/value. The translation of these “rent spillovers” (Griliches, 1982) into productivity gains would thus be the most direct effect of production-embodied (KIBS) knowledge.

However, if we follow the wider production-based transmission of the previous section, the impact of KIBS knowledge acquired in this way is not only economic, but also and above all technological, in brief, “techno-economic”. As we said, the production exchanges that input-output tables map are also and above all the source of important learning-by-interacting (*à la* Lundvall, 1992) between the producer (KIBS) and the user (manufacturing) sectors. Through it, the user can make an innovative use of both the R&D embodied in the correspondent transaction and of the R&D, which is transferred irrespectively from it (i.e. in a disembodied way). Anecdotally, the case could be of a client that, by acquiring an ameliorated software benefits from the R&D the relative KIBS has spent in this amelioration, by introducing an innovative product/process based on its functioning. Furthermore, the market transaction of the software could increase the cognitive proximity between the KIBS and the client and, in so doing, make the latter more capable of assimilating other disembodied knowledge inputs from the former. Finally, although not necessarily, in order to increase its “absorptive capacity” of the transferred embodied knowledge, the client might be willing to increase its own investments in R&D (Cohen and Levinthal, 1989) and, in so doing, augment its invention capacity.

Summing up, a wider approach to the KIBS knowledge which is transmitted to manufacturing in a production-based way, makes of the former an important additional input of the inventive capacity of the latter: as it might be revealed by its patenting propensity and/or patent outcomes. In other words, we can expect that such an exchange of knowledge gets functional to the problem-solving process the manufacturing client faces in its technological innovations, and increases its capacity of making an innovative use of the customised solution it purchases from the KIBS provider. In brief, by acquiring from KIBS business-devoted services necessary for the realisation of their final products, manufacturing firms also learn by interacting and acquire technical knowledge and customized problem solving experience, which can have a positive impact on their innovation capacity.

On the basis of the previous argument, the second bit of our research hypothesis is that, the more vertically integrated KIBS are into a certain manufacturing industry (sub-system), the more the relative firms will have opportunities to introduce innovative products for the final consumers of their sector.

As we will see (in Section 3), the first bit of our research hypothesis (in Section 2.1) will entail the adoption of a particular intersectoral perspective, which represents the first value added of the paper.⁷⁶ Similarly, the second bit of our hypothesis will also entail the resort to other variables than standard productivity ones, and that rather account for the inventive capacity of the manufacturing sectors. This is an additional value added of the paper, which address a relatively neglected KIBS impact.⁷⁷

⁷⁵ Although these production relationships can be anchored to both domestic and international trade flows, the problems of accounting for the tradeability of services (and KIBS) has determined a certain focus on the former. Among the recent studies which also retain the latter see, for example, Nisioka and Ripoll (2012), and those reviewed in this article.

⁷⁶ To start with, such an improvement is obtained by limiting the analysis to intersectoral flows of intermediate commodities only, and without distinguishing their domestic or foreign origin.

⁷⁷ A possible explanation can be the need, in order to actually measure the innovation impact of production-based KIBS knowledge, of plugging into the analysis a variable of innovation output at the sectoral level (e.g. patents), which can only be obtained from less directly comparable datasets (than those for relating R&D efforts to input-output flows). Furthermore, a dataset of diachronic nature, rather than cross-sectional, is required to investigate the innovative impact of KIBS on manufacturing as a proper causal relationship.

3 Methodology

In order to address the aforementioned research question, we follow an extended input-output based methodology, which is focused on the notion of “subsystem” in production, and on the compact representation of it represented by that of a “vertically integrated sector”.⁷⁸ In brief, this can be defined as the set of all the economic activities directly and indirectly required to satisfy the final demand of each economic sector. Unlike the standard generic sector, j , which accounts for the economic activities that its firms carry out to contribute directly to their final demand, its vertically integrated equivalent also retain those activities of j which are necessary for obtaining their production inputs, and the production inputs of these inputs, and so and so forth in subsequent production rounds: in brief, those activities of j that contribute to its final demand indirectly, that is through other intermediate sectors.

Following the seminal work by Momigliano and Siniscalco (1982), the generic vertically integrated sector j can be represented by column j of the following $(n \times n)$ matrix (with n equals to the number of economic sectors of an economy):

$$\mathbf{B} = \hat{\mathbf{q}}(\mathbf{I} - \mathbf{A})^{-1} \hat{\mathbf{y}} \tag{1}$$

In Eq.(1), $\hat{\mathbf{q}}$ is the diagonalised vector of gross production, \mathbf{A} is the matrix of input-output coefficients, and $\hat{\mathbf{y}} \hat{\mathbf{y}} \hat{\mathbf{y}}$ is the diagonalised vector of total final demand. Given the conventional meaning of the Leontief inverse, $(\mathbf{I} - \mathbf{A})^{-1}$ (for which see Miller and Blair, 2009), each generic element, b_{ij} , indicates the total contribution, that is, direct and indirect, of sector i to the final demand of sector j .

The application of this perspective to the analysis of intersectoral embodied innovation/knowledge flows is then straightforward. Taking the expenditure in Research and Development (R&D) of sector j (r_j) as an input kind of proxy of the new knowledge generated by its firms (a standard assumption in innovation studies), the following $(n \times n)$ focal matrix, \mathbf{R} , can be obtained:

$$\mathbf{R} = \hat{\mathbf{r}}\mathbf{B} \tag{2}$$

where $\hat{\mathbf{r}}$ is the diagonal vector of sectoral R&D expenditure.

Under a number of hypotheses (for which see Leoncini and Montresor, 2003), the generic element of \mathbf{R} , r_{ij} , measures the amount of sector i 's R&D knowledge that gets embodied in the intermediate commodities required to i by sector j , both directly and indirectly (that is, in subsequent production rounds), in order to satisfy one unit of its final demand.⁷⁹ In other words, the correspondent knowledge flow, from i to j , takes into account that the former sector can contribute to the latter also being the intermediate input of a third generic sector, z , which is in turn an input for sector j . Furthermore, the knowledge flow which reaches sector j from sector i , is made possible also by the innovative knowledge that the latter has got from the former, again directly and indirectly.

In synthesis, the matrix \mathbf{R} appears suitable to deal with the complex relationships that link sectors to each other. In our case, \mathbf{R} allow us to retain that KIBS typically provide knowledge inputs that industries absorb, combine and transform into innovative products and processes, through multiple intersectoral rounds. Furthermore, it also accounts for the fact that the knowledge of the client manufacturing sectors is an essential knowledge input for KIBS' innovation too. The relevant knowledge interaction is in fact a “chain-one”, rather than linear (Kline and Rosenberg, 1986), in which the occurrence of feed-back is a crucial aspect of innovation diffusion.

The use of matrix \mathbf{R} for the analysis of production-based flows of KIBS knowledge into manufacturing is quite straightforward. In the aggregate, for the generic industry (or better to say, subsystem), j , this is given by:

$$KIBS_j = \sum_{i=k}^s r_{ij} \tag{3}$$

where the sectors which go from k to s are the KIBS sectors out of the n industries of the relevant economic system. In other words, $KIBS_j$ is nothing but the row-sum of the relevant column j of \mathbf{R} , with respect to the $(s - k)$ number of KIBS

⁷⁸ On the genesis of these ideas, dating back to the work of Sraffa (1960) and Pasinetti (1973), and on their application to the analysis of structural change and outsourcing in particular, see Montresor and Vittucci (2007).

⁷⁹ Among these hypotheses, the temporal reference of the variables that enter in the definition of Eq.(2) is an important one. As our time-neutral notation suggests, we hereby assume an instantaneous kind of diffusion process, in which the R&D expenditure of sector i at time t , gets totally embodied in (that is, it is proportional to) its input requirements by sector j of the same year. While this could actually happen at most partially, a temporisation of these effects would remain subject to a great amount of ad-hocness (on this point, see Leoncini and Montresor, 2003).

sectors. Of course, each of these addenda (from r_{kj} to r_{sj}) is, in turn, the production-based flow which pertain to each and every of the KIBS sectors.⁸⁰

4 Application

4.1 Empirical context

The issue at stake in the paper is investigated with respect to the four largest economies of the European Union (EU), that is: France, Germany, Italy and the UK. The choice is motivated by the relevance of the vertical integration of KIBS into manufacturing that previous studies have found in these four countries over the last two decades, and by their heterogeneity in the same respect. As shown by Ciriaci and Palma (2012), when the vertical integration of Eq.(1) is measured in terms of employment (that is, by substituting \mathbf{r} with a sectoral vector of labour, \mathbf{l} , in Eq.(2)), in France and Germany KIBS show an increasing degree of vertical integration into manufacturing from 1995 to 2005: a trend which is the more evident in the manufacturing subsystems of a higher technological intensity, though with differences between the two countries.⁸¹ In the UK, instead, the vertical integration of KIBS into manufacturing in the same period shows an inverted U-shape over time, with a turning point of its initial increasing trend in the early 2000s, at the take-off of the “service-based” economy.⁸² Finally, while still with an increasing trend, KIBS appear relatively less integrated in Italy than elsewhere, pointing to the influence of the specialisation patterns of one economy (notably low-tech in Italy) on the integrated role of KIBS.⁸³

Our empirical analysis of these four countries⁸⁴ refers to the same period of Ciriaci and Palma (2012) that is 1995-2005. More precisely, due to the discontinuous temporal availability of input-output data we refer, as they do, to two sub-periods of this temporal window: from the mid-90s (1995 and/or years around that) to the early-00s (2000 and/or years around that); from the early-00s to the mid-00s (2005 and/or years around that).

4.2 Econometric strategy and variables

In order to estimate the innovation impact of the vertical integration of KIBS into manufacturing, we use a standard “knowledge (log-) production-function” (Griliches, 1979) at the sub-system level. In so doing, we make the innovative knowledge obtained by each generic manufacturing sector j ($Inno_j$) depend on the flow of KIBS embodied knowledge ($KIBS_j$) – as from Eq.(3) - and on a set of theoretically consistent variables – i.e. its own knowledge (RD), physical (K), and human (L) capital – as follows:

$$\ln(Inno_{j,t+1}) = \alpha_0 + \alpha_1 \ln(KIBS_{j,t}) + \alpha_2 \ln(RD_{j,t}) + \alpha_4 \ln(K_{j,t}) + \alpha_5 \ln(L_{j,t}) + \omega_j + \varepsilon_j \quad (4)$$

where ω_j is the country/sector fixed effect, ε_j is an error term with standard properties, and the temporal notation (t) points to a lag between dependent and independent variables.

As far as the *dependent variable* is concerned, among the several available proxies of innovative output, we have opted to use patent applications and to resort to a proper counting of them. While we are aware of the still vivid debate about the *pros* and *cons* of using patent data as reliable innovation indicators (Watanabe et al., 2001)⁸⁵, and of the several and

⁸⁰ An important issue in building up these indicators is making them free from scale effects across sectors. Different relativisation procedures have been put forward for that in the literature, which all suffer from some kind of bias (for a discussion, see Montresor and Vittucci Marzetti, 2009). As we will see in the next section, the econometric strategy that we will follow enable us to control for size effects in R&D.

⁸¹ In France, for example, in 2005 KIBS accounted for 12.5% and 15% of the total employment needed to satisfy the final demand for low and medium/low-tech subsystems’ products, respectively, while the correspondent shares in 1995 were of 10.7% and 10.5%. The 2005 shares are significantly higher in the case of medium/high-tech (20.3%) and high-tech manufacturing subsystems (19.9%), whose values in 1995 were of 17.4% and 18.7%, respectively. In Germany, the increase of the same degree of vertical integration over the same period is even more accelerated – possibly in response to the policy support of services started in the late 80s (Windrum and Tomlinson, 1999). However, the same trend is more concentrated in the medium and high-tech manufacturing subsystems than in France.

⁸² The results for the UK are in line with other empirical studies sharing the same subsystem approach used in this study (Montresor and Vittucci Marzetti, 2010 and 2007).

⁸³ The previous picture is generally consistent with that found by Barker (2007), looking at the “simple” share of business service inputs of total intermediate inputs in manufacturing. France (13.9% in 1995), Germany (10.8% in 1995), and the UK (10.7% in 1998) stay apart from Italy (4.1% in 1992) and from other countries with a lower weight of KIBS in manufacturing (e.g., Denmark, 5% in 1997; Finland, 6.6% in 1995; Greece, 5.4% in 1995; Spain, 4.9% in 1995).

⁸⁴ Although this is a limited set of countries, their choice has been also inspired by the attempt at keeping a relatively high number of sectors when the different datasets that are needed for the application are merged. For the majority of the smaller European counties, this combination actually entails a substantial decay of sectors for which data are not available. Also the choice of the temporal span of the application has been inspired by the attempt at building up a panel with a satisfactory level of sectoral disaggregation.

⁸⁵ A debate that dates back at least to the famous Griliches’ (1990, p. 1669) concern.

interrelated options of patent-based proxies (Guellec and van Pottelsberghe de la Potterie, 2000), our focus on patent applications has two main motivations. Firstly, we wanted a proxy which could be retained logically and temporally close to the manufacturing use of the R&D-knowledge acquired from KIBS, rather than a more distant one (such as, for example, patent citations), possibly more volatile and affected by other antecedents than our focal one (e.g. local and international co-operation in the invention process) (Jaffe and Trajtenberg, 2002). In brief, we argue and expect that the production-based kind of KIBS knowledge flows we are investigating have a more direct effect on the client firms propensity to patent than of taking stock of the application (Brouwer and Kleinknecht, 1999). Secondly, and relatedly, the choice is also inspired by the evidence about the role of patent applications (possibly more than patent granted) as a key differentiating element of technological regimes and sectoral systems of innovation (Breschi et al., 2000; Malerba and Orsenigo, 1997) that is of our level of analysis.

On this basis, *Inno* is proxied with the (log of the) number of patent applications (*PAT*) available in the Worldwide Patent Statistical Database (PATSTAT) of the European Patent Office (EPO). Following conventional choices in the use of patents as innovative proxy at the micro-level (Acs and Audretsch, 1989), they have been obtained referring to the priority-date patents applied worldwide by inventors of the four relevant nationalities in 43 manufacturing sectors following NACE Rev. 1 classification (Tab. A1).⁸⁶

An important aspect in the patent measurement of *Inno* is its temporal specification. On the one hand, counted patent applications are subject to quite erratic year-by-year variations, which need to be smoothed for the sake of their econometric analysis (Wang et al., 1998). On the other hand, in spite of the arguments about their inventive-input nature, a substantial impact of R&D (and R&D spillovers) on patent applications can be expected only with a temporal delay, during which the acquired knowledge gets processed, absorbed and codified into a patent document: as much as a delay has been found for the impact of patent applications on changes of economic performance (Ernst, 2001). In order to account for these issues, we have considered the (log of the) average number of applications (*PATAVE_j*) in the three years after ($t+1$ in Eq.(4)) that of the retained KIBS flows and of the measurement of the other regressors (t in Eq.(4)). This means that we have used (i) the average number of patent applications during the period 1995-1997, with respect to KIBS vertical integration in 1995; (ii) the average number of patent applications during the period 2000-2002, with respect to KIBS vertical integration in 2000; and (iii) the average number of patent applications during the period 2005-2007, with respect to KIBS vertical integration in 2005.⁸⁷ The correspondence between Nace (Rev1) patent data, our key independent variable (*KIBS_j*) and the others variables in Eq.(4), whose sectoral level of disaggregation follows the ISIC Rev. 1 classification (see Table A2 in the appendix) and which are described in the following, has been obtained following the NACE-ISIC concordance table developed by the United Nations (UN). The sectoral disaggregation adopted in the econometric analysis (which includes 18 manufacturing sectors and 7 service sectors) is reported in the appendix (Table A3).

As far as the independent variables are concerned, the focal regressor, *KIBS_{j,t}*, has been obtained following Eq.(2) and by combining two sets of data: (i) the OECD STAN Input-Output dataset, from which we have drawn the matrices of total intermediate production flows (at current prices) for the 37 sectors of the ISIC Rev. 1 classification, for the three years covered by our analysis, 1995, 2000 and 2005; and (ii) the OECD Analytical BERD (ANBERD) dataset, from which we have collected data on R&D expenditures (PPP dollars at current prices) for the same years and 37 sectors of the ISIC Rev. 1 classification.⁸⁸ *KIBS_{j,t}* has been computed firstly in aggregate terms.⁸⁹ That is, for each sector (column) j of the 18 manufacturing ones we have been able to include, *KIBS_{j,t}* is the sum by row of the following sectors of **R**: Computer and related activities (*KIBS-COMP*, corresponding to sector C72 of the ISIC Rev. 1 classification), Research and Development services (*KIBS-RD*, sector C73) and Other business activities (*KIBS-BUS*, sector C74).⁹⁰ Secondly, in order to account for the diversity of KIBS sectors, we have also considered their corresponding rows of **R** for the aforementioned 18 manufacturing sectors separately - *KIBS-COMP_{j,t}*, *KIBS-RD_{j,t}*, and *KIBS-BUS_{j,t}* - and inserted them - alternatively to *KIBS_{j,t}* - in Eq.(4).

Coming to the other regressors of Eq.(4), the own knowledge capital of sector j has been proxied by referring to two kinds of R&D expenditure at time t . As an indicator of the innovation opportunities sector j can benefit from in a disembodied way, we have built up the R&D intensity of sector j at time t , *RD_INT_{j,t}*, as (the log of) the ratio of total R&D expenditure over total employment (source: OECD-STAN). Furthermore, we have distinguished from it the R&D

⁸⁶ Standard fractional-counting procedures have been used in the cases of patents with multiple co-inventors of different nationalities.

⁸⁷ A longer, forward temporal span would have suffered from the substantial decay, which is inevitably registered in the number of patent applications from the year 2007 onwards.

⁸⁸ In those few cases in which R&D data were available only at the next more aggregated level than the disaggregated one for the IO data, they have been artificially disaggregated in proportion of the correspondent value added. R&D sectoral data at current prices were the only available ones for the time period under study. However we believe that this does not represent a drawback for the analysis, as we controlled price variations while taking advantage of actual sectoral relevance of innovative activities through time in the estimation.

⁸⁹ As we have said, given the bias introduced by any relativisation procedure for **R**, the *KIBS* variables are built up with respect to the absolute values of the same matrix, leaving to the econometric model the control for size effects.

⁹⁰ Although sometimes also classified as KIBS, Post and Telecommunications (C64), and Finance and Insurance (C65T67) have not been considered in our analysis because of their lower impact on the kind of technological innovations we are considering, and because of the gaps in the available data. The remaining sectors out of the 37 are classified as: Primary sectors (P), Public Utilities (PU), Construction (C), Market services (MS), and Non-Market services (NM).

available in sector j at time t in an embodied way, as the result of the production flows occurring among firms belonging to sector j itself, by referring to the correspondent cell of the main diagonal of matrix \mathbf{R} in Eq.(2), $RD_INTRA_{j,t}$.

Finally, the physical and human capital inputs of the production function (Eq.(4)) have been proxied with, respectively, the fixed-capital intensity of sector j at time t ($K-INT_{j,t}$) obtained by relating its fixed investments to its total employment (source: OECD-STAN), and its total employment at time t ($L_{j,t}$) (source: OECD STAN).

The different data sources used for building our variables are summarised in Table A4.

5 Results

5.1 Some descriptive statistics

Table 1 reports the main descriptive statistics of the dependent and independent variables described in the previous section for the overall sample and by country. As preliminary insight on our research hypothesis, Figure 1 displays the relationship between the dependent variable ($PATAVE$) and our key explanatory variable (KIBS), by showing both the data scatterplot and the ordinary least-squares fitted line. As shown by the figure, there are evident traces of a positive relationship among the two.

Data are expressed in natural log.

Figure 1. Scatterplot and OLS fitted line.

As shown in Table 2, the pair-wise correlation among the adopted regressors is in general low. In particular, the KIBS variables are not significantly correlated with the R&D based ones, supporting our theoretical conjecture that the innovation impact of the former is not (necessarily) due to an induced increased of the latter. A notable exception is

represented by the correlation between *RD_INT* and *RD_INTRA*, which appear nearly collinear between them. Given that the largest sector contributions to each sub-system are normally those of the correspondent sector – that is, sector *j* vs. sub-system *j* - this is not unexpected and suggests to us that one of the two from the estimates should be dropped. As our focus on KIBS relies on the embodiment hypothesis, for the sake of consistence we have opted for retaining *RD_INTRA*. Finally, let us observe that, looking beyond pair-wise correlations, the variance inflation factors (VIF)⁹¹ are low, as it is symptomatic in the lack of multicollinearity.

Before presenting and commenting the results of the econometric analysis, it is interesting to note that the key explanatory variable of our study– that is, KIBS expenditure in R&D acquired by manufacturing sectors through vertical integration – has evolved differently over the retained period in the four countries at word (Figure 2).

⁹¹ Available from the authors upon request.

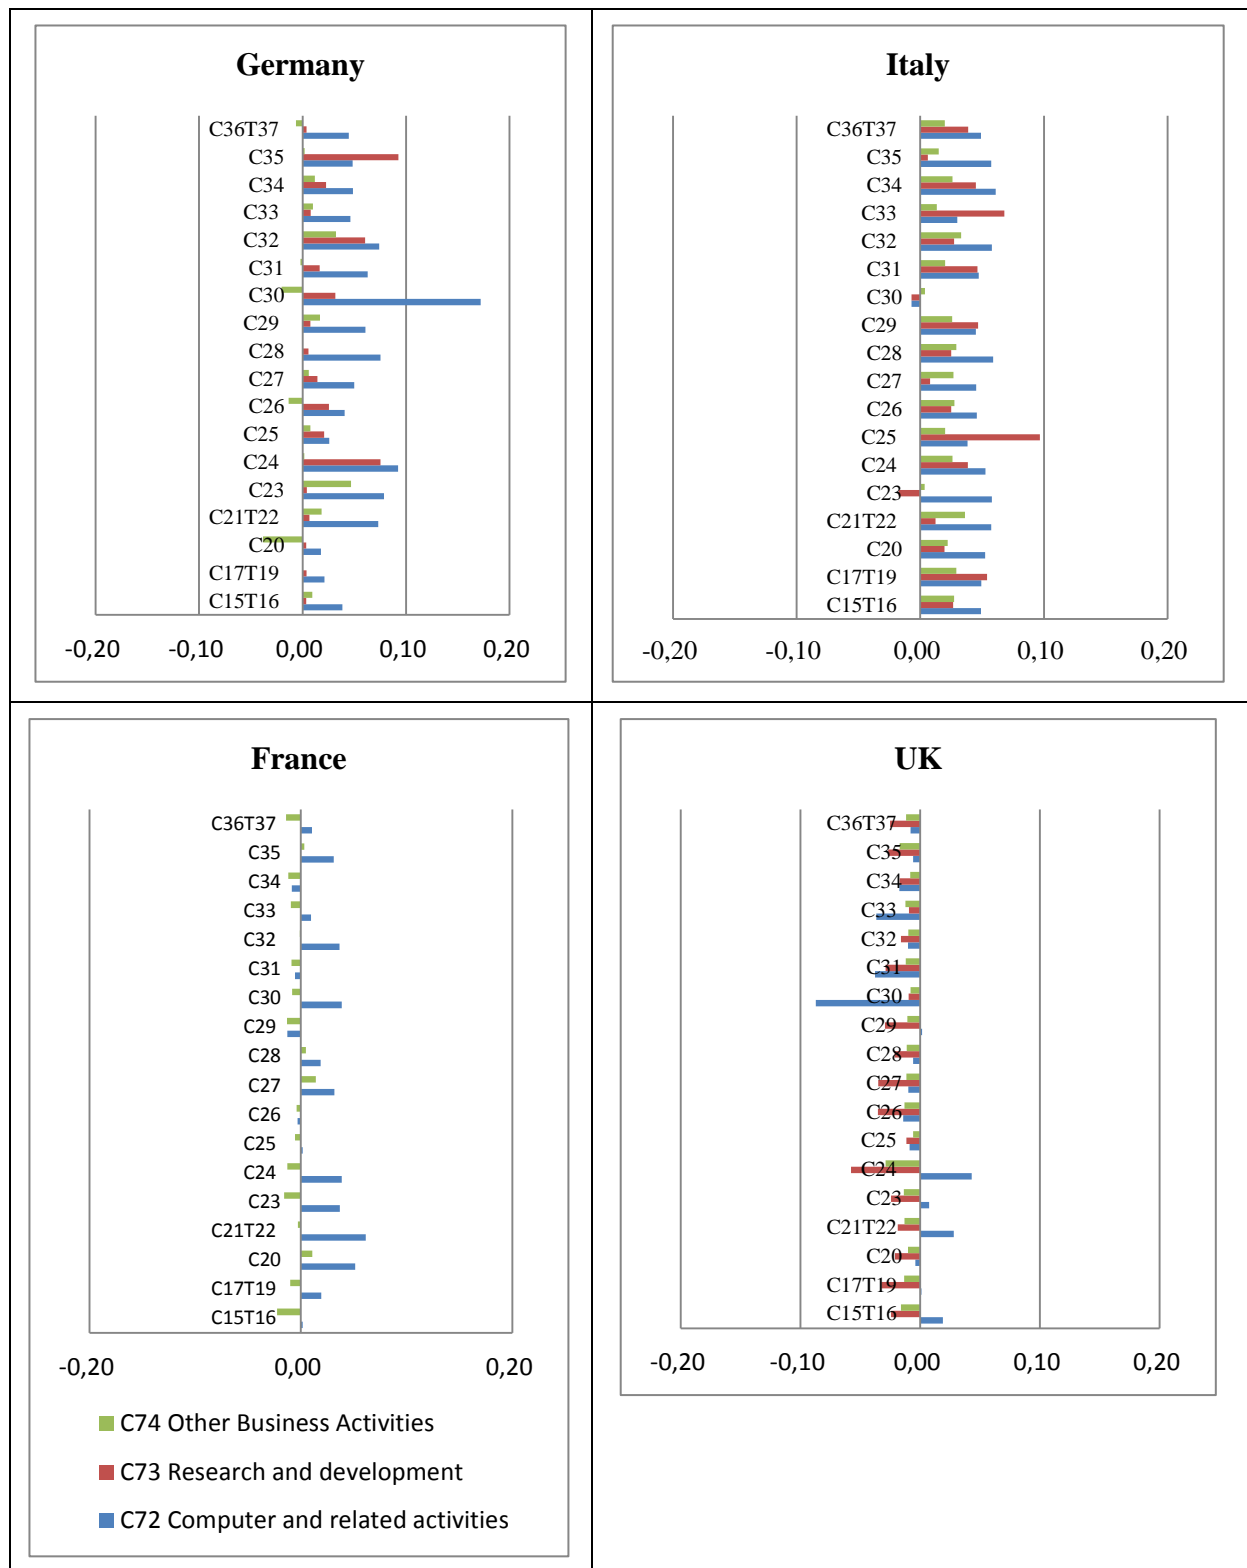

Figure 2. KIBS' R&D acquisitions by manufacturing sectors: 1995–2005 (% change of total intersectoral acquisitions).

On the one hand, although with some exceptions, in Italy and Germany nearly all the 18 considered manufacturing sectors increased the percentage points of their total embodied R&D acquired from KIBS in-between 1995 and 2005. More in particular, in Italy this increase appears relatively more homogenous across the three kinds of KIBS considered than in Germany. Here, the vertical integration of KIBS innovative knowledge into manufacturing has mainly concerned those produced by computer and related activities, especially with respect to technologically close sectors (e.g. sector C30, office, accounting and computing machinery). On the other hand, France and the UK show a completely different picture, with a decreasing reliance of manufacturing on KIBS-embodied R&D over the decade.

While in France this is limited to the percentage weight of other business activities – with that of R&D services remaining basically unaltered and that of computer and related activities generally increasing over time – in the UK it is indeed a general (with some few exceptions for computer and related activities) pattern. Thinking of the increasing weight that KIBS have gained in these economic systems over time, this last result might appear unexpected. However, in interpreting it, one should consider that the kind of knowledge diffusion we are considering is that of the production-based approach (see Section 2.1), which attributes a pivotal role to the underlying production transactions. In this last respect, the “generic” (e.g. in terms of employment) vertical integration of KIBS in manufacturing that previous studies have detected for the countries at stake over the focal period (see Section 4.1) is an important piece of information, and it is consistent with our results (Ciriaci and Palma, 2012). For example, in the case of the UK, the registered decrease does not exclude KIBS having increased their contribution to manufacturing in a disembodied way, exploiting a degree of development of the relative knowledge-interfaces that in the UK is quite established. To be sure, a sort of substitution in the resort to the two channels can be put forward and would deserve further testing in future research.

For the time being, our analysis focuses instead on the relevance of embodied R&D flows for the innovative performance of manufacturing sectors, as it can be captured by their patent applications. In this last respect, Figure 3 shows again heterogeneity across the four countries in the retained period, when we look at the cumulated number of patent applications in the retained manufacturing sectors. Germany and Italy are extreme cases, among the four, with the highest and lowest numbers of patent applications in the 18 considered sectors, respectively: a result that appears quite interesting for our research hypothesis, when we think of the high and low degree, respectively, of vertical integration of KIBS into manufacturing in the two countries. Both in Germany and in Italy, the machinery sector (sector C29) appears the most innovative one, followed by chemicals (sector C24) at a certain distance and by a narrow club of high-tech sectors. On the other hand, the UK and France are somehow in-between in terms of (cumulated) number of patent applications and share the dominant role of chemicals over machinery in the same respect. Even when cumulated patents are considered, their temporal variations across the considered periods remain quite erratic, confirming their well-known noisy nature (Jaffe and Trajtenberg, 2002). Overall, however, in the majority of the sectors, they increase from the beginning to the end of period, passing through a slight decrease in the intermediate one.

Figure 3. Cumulated number of patents in manufacturing: 1995–2005.

5.2 Econometric results

Before presenting the econometric results of the estimates of Eq.(4), it should be noted that the distribution of our dependent variable (*PATAVE*) is not substantially dissimilar from a normal one (see Figure A1). Accordingly, the resort to a probit or count model, of the kind usually adopted to estimate the knowledge production function at micro-level, does not appear necessary in our case.

A second important point concerns the possible endogeneity from which our focal regressor, *KIBS_j*, could suffer because of the complex relationships that link KIBS and manufacturing in the production-based transmission of knowledge (see Section 2.1), and that could persist even in the presence of a lag in the assumed impact of the former on the latter.⁹² In order to account for this issue, we have used as an instrument for *KIBS_j* the degree of vertical integration that KIBS reveal in sector *j* in terms of employment, following the relative estimator, *L_KIBS_j*, calculated by Ciriaci and Palma (2012). As we said in Section 4.1, this can be obtained by substituting *r* with a sectoral vector of labour, *I*, in Eq.(2). From a theoretical point of view, this appears an appropriate choice. On the one hand, as we have actually found in commenting the descriptive results of the previous section, manufacturing subsystems whose employed labour is largely accounted by its vertically integrated KIBS have higher chances to acquire larger shares of production-based KIBS (R&D) knowledge. On the other hand, as recent studies in innovation economics and industrial organization have shown (e.g. Mazzanti et al., 2007), a significant impact of the degree of vertical disintegration (i.e. as a consequence of outsourcing) on innovation could vanish in front of a number of conflictual forces. More in general, being the vertical

⁹² For example, *PATAVE* (1995-1997) may affect the KIBS knowledge flow in 2000. Then, the KIBS knowledge flow in 2000 affects *PATAVE* (2000-2002) in turn. We thank a reviewer for having raised this point.

integration in terms of labour a structural characteristic of an economic system, in our context it could be considered as exogenous and uncorrelated with the error term. Of course, this theoretical conjecture about our proposed instrument will have to be tested in the following.

In search for a suitable model for estimating Eq.(4), looking at the structure of our panel data, we first conducted a Breusch-Pagan Lagrange Multiplier (LM) test. The test rejects the null hypothesis that OLS residuals do not contain individual specific error components, thus confirming the presence of random effects. However, given that the simple presence of random effects does not imply that the relative model is more efficient than a fixed effect one, we have also run a Hausman test (Hahn *et al.*, 2011) to address the choice between the two (Table 3).⁹³ The results of the test suggest that the fixed effect estimation is the way forward, as we reject the null hypothesis of zero correlation between the regressors and the error term.⁹⁴

Table 3. Hausman test results. Ho: non-syst. difference in coefficients.

Prob>chi2 =			0.0000

Table 4 reports the results of our estimates in a step-wise fashion. In particular, columns from (i) to (iv) report the estimates of the model obtained inserting the regressors sequentially; column (v) reports the robust fixed effect estimates obtained when we consider the R&D acquired by manufacturing sectors through their vertical integration with KIBS (*KIBS_j*); column (vi) those obtained fitting the panel data model with a two-stage least-squares within estimator (that is, instrumenting (IV) *KIBS_j* with *L_KIBS_j*).

Columns (vii) and (viii) report the estimates obtained, instead, when the three KIBS-sectors - and their vertical integration with the generic manufacturing sector *j* (*KIBS-RD_j*, *KIBS-COMP_j*, and *KIBS-BUS_j*) - are considered separately. In this regard, it is worth noting that the very low level of vertical integration of *KIBS-RD* for France (close to zero), prevented us from obtaining reliable estimates at this sectoral disaggregated level. Therefore, in trying to overcome this problem, in column (vii) we report the estimates of Eq.(4) obtained for this sectoral level of disaggregation excluding France, and in column (viii) the estimates obtained considering all the four countries, but leaving *KIBS-RD* out. For the sake of clarity, our reference estimates are those reported in column (v).

At the aggregated level (Model (v) and Model (vi)), our research hypothesis is confirmed: our key variable is significant and enters the equation with the expected sign in both models. However, comparing the IV results with those in column (i) the coefficient on the endogenous variable is significant at a lower confidence interval (IV standard errors are larger)⁹⁵. Given the loss of efficiency observed, we have performed a Hausman test to detect systematic differences between the OLS and IV estimates, whose results lead us to accept the null hypothesis of not systematically different coefficients (Table 5).

In general terms, our results show that the larger the R&D that manufacturing sectors acquire through the integration with KIBS, the higher their innovative performance. In particular, a one-percent increase in the R&D that manufacturing sectors acquire through the vertical integration with the whole of KIBS at time *t* lead to a 0.19% increase in average patenting of the following three years. In other words, the flows of R&D coming from KIBS and used by the manufacturing subsystems to satisfy their final demand positively affects the sector ability to create new knowledge. This result is in line with the theoretical framework reviewed in Section 2, emphasising the manifold innovative role that KIBS play in an economic system. In spite of the structural differences we have detected among the four countries, KIBS appear in all of them an innovation effective carrier of embodied R&D towards manufacturing. In addition, it is interesting to notice that, when KIBS-embodied R&D is plugged into the knowledge production function, *RD_INTRA* is

⁹³ Let us remember that, unlike the fixed effect model, which assumes that individual heterogeneity can be captured by the intercept term, the random one identifies it as a part of the error term. The advantage of the fixed effect model is that the intercepts can be correlated with the regressors, allowing for a limited form of endogeneity. On the other hand, the advantage of the random effect model is that it yields estimates for all the coefficients. Accordingly marginal effects, even those of time-invariant regressors, can be estimated.

⁹⁴ As a rule of thumb, if both estimates are similar, we can use a random effects estimator, whereas if they differ the fixed effects estimator is preferred.

⁹⁵ Regarding the instrument chosen results from the first stage regression have corroborated *L_KIBS_j* as a relevant instrument.

not significant. This result suggests that, in the considered countries, the only kind of “embodied” R&D that allows manufacturing sectors to obtain commercially exploitable inventions is that invested by specialist knowledge producers and acquired from them through economic transactions related to the production processes of the recipient sector. On the contrary, as suggested by previous studies (e.g. Marengo and Sterlacchini, 1990), intra-sectoral embodied R&D flows can be deemed inputs of incremental/process innovations that usually do not find a patent outcome. Finally, attention deserves the significant negative sign that K_INT assumes in the “augmented” knowledge production function that we consider. A one-percent increase in manufacturing capital intensity at time t decreases manufacturing average patenting of the following two years by 0.13%. Apparently, by “deepening” their physical capital the manufacturing sectors at word decrease, rather than increasing, their invention capacity. Although apparently counter-intuitive, this interpretation is consistent with the findings obtained by other studies on the decreasing innovation returns that equipment investments face with the increase of the industrialisation level of the investing sectors/countries (e.g. De Long and Summers, 1991; Dullek and Foster, 2008). To be sure, in our case it seems that the switch from industrialisation to tertiarisation could have even made these returns negative (Montresor and Vittucci Merzetti, 2011).

The disaggregated analysis of the relationship at stake (Models (iii) and (iv)) reveals some interesting results about the contribution of specific KIBS sectors to manufacturing patenting activity, but should be interpreted carefully given the biased introduced by the aforementioned ad-hoc exclusions. When $KIBS-RD$ are retained along with the other two KIBS – that is, by focusing on the UK, Germany and Italy (Model (iii)) – what emerges is an remarkable external variation of the linear innovation mode: the only KIBS whose R&D incorporation seems to make manufacturing sectors more innovative in Germany, Italy and the UK are those offering R&D services as such. On the contrary, in these three countries the knowledge that manufacturing sectors accrue by interacting in the production realm with less innovation-dedicated services – that is, business services and ICT – does not significantly help with that. Taking into account the results on RD_INTRA (and on RD_INT in alternative specifications, available from the authors on request), it seems that in the countries at word, providing it occurs within the same sub-system (on which, see Montresor and Vittucci Marzetti, 2007), the externalisation of R&D from manufacturing to services appears, from an innovation point of view, a viable strategy.

Finally, when we impose an *ad-hoc* misspecification on the model by leaving $KIBS-RD$ out but considering all four countries, the other two KIBS regain a significant role as innovation predictors for manufacturing. In spite of the possible bias emerging from variables omission, it is interesting to note that the contributions of $KIBS-COMP$ and $KIBS-BUS$ are significantly different between them,⁹⁶ confirming the inner heterogeneity that KIBS have been found to have in the extant literature (see, for example, Consoli and Elche-Hortelano, 2010; Doloreux and Shearmur, 2010). In particular, the impact of the embodied R&D acquired from $KIBS-COMP$ is higher than that from $KIBS-BUS$: a one unit increase in the flow of vertical integrated R&D at time t increases average patenting by 0.07 and 0.05, respectively, in the following two years. Thinking of the typical embodiment mechanism that the complementarity between software and hardware realises, and the impact that this complementarity has been found to have on the relationship between manufacturing and services (Stanback, 1979; 1981), this result is not unexpected. Of course, this does not want to underscore the pivotal role of the services that business consultants (sectors) provide to manufacturing. However, their innovation contribution could be expected to be higher when the transmission of their knowledge is disembodied, rather than embodied as in the focus of this paper.

6 Conclusions

The connection between KIBS and innovation is by far an established one. On this basis, important policy initiatives have been promoted - at both national and European level - to increase their weight in economic systems and to develop the market conditions for manufacturing firms to be able to exploit them.

In spite of all the existing evidences, however, the multiplicity of channels through which KIBS can contribute to innovation has not been fully explored yet. In particular, while the direct innovative role of KIBS is quite understood, its indirect one still deserves analysis. This is especially so for the extent to which the innovative efforts undertaken by KIBS – typically their R&D expenditures – get acquired by manufacturing sectors, through the direct and indirect production relationships that constitute their vertically integrated sectors, and finally increase their innovation performance. The pervasive diffusion of outsourcing strategies by manufacturing firms towards service providers makes this issue an extremely relevant one to be addressed.

The present paper contributes to this research need with a new empirical application that has three original elements. First of all, it tries to retain both direct and indirect production relationships between KIBS and manufacturing, by making use of the sub-system methodology. Secondly, it goes beyond the simple mapping of these relationships and directly addresses their actual innovation impact. Thirdly, in order to do that, it combines different data sources to obtain a panel in which causality relationships can be more accurately identified.

Although limited to four European countries, over the period 1995–2005 – both because of data availability and continuity with previous research – the results we have obtained are quite interesting and have a number of policy implications. First of all, embodied R&D flows acquired from KIBS actually make manufacturing sectors more innovative. In other words, the innovativeness of manufacturing sectors could also be increased by exploiting the

features of the so-called Schumpeter Mark III model and reinforcing the (production) interactive linkage between industry and services. Innovation policies to foster R&D cooperation and technology transfer between the two realms could have a role in that. However, our results also suggest that the increasingly extensive processes of vertical integration of services into manufacturing that are occurring in the aftermath of the outsourcing strategies of industrial firms (Montresor and Vittucci Marzetti, 2011) can have an important innovation impact too. The same is thus true for those policies that address the specialisation patterns of countries and/or regions and that in so doing bring about structural changes in their vertically integrated sub-systems.

More generally, our results support the innovative importance of the so-called “rent” kind of R&D spillovers, which occur irrespectively from the public good properties of innovative knowledge and are rather due to the different contractual power of the interactive partners and the market structure they operate in. In this last respect, industrial policies (e.g. competition ones) find an additional leverage through which they can complement R&D ones in increasing innovation in manufacturing. Indeed, while within-sector R&D needs proper financing, that acquired from KIBS just requires manufacturing firms to face the production and the transaction costs to undertake the underlying economic exchange.

An additional interesting result of our application is the confirmation of the fact that KIBS are different among them, also in their capacity of conveying R&D to manufacturing sectors in such a way to increase their innovation capacity. In particular, the extent to which KIBS are related to an underlying production transaction – in a sort of software/hardware relationship – is a key aspect for their innovative impact on manufacturing. From a policy point of view, this result provides an interesting insight into the choice of the so-called key-enabling technologies through which manufacturing can be advanced towards more innovative developments.

Appendix

Table A1. Nace Rev.1 sectoral disaggregation of patent applications data.

15	Manufacture of food products and beverages
16	Manufacture of tobacco products
17	Manufacture of textiles
18	Manufacture of wearing apparel; dressing and dyeing of fur
19	Tanning and dressing of leather; manufacture of luggage, handbags, saddlery, harness and footwear
20	Manufacture of wood and of products of wood and cork, except furniture;
21	Manufacture of pulp, paper and paper products
22	Publishing, printing and reproduction of recorded media
23	Manufacture of coke, refined petroleum products and nuclear fuel
24	Manufacture of chemicals and chemical products
24.1	Manufacture of basic chemicals
24.2	Manufacture of pesticides and other agro-chemical products
24.3	Manufacture of paints, varnishes and similar coatings, printing ink and mastics
24.4	Manufacture of pharmaceuticals, medicinal chemicals and botanical products
24.5	Manufacture of soap and detergents, cleaning and polishing preparations, perfumes and toilet preparations
24.6	Manufacture of other chemical products
24.7	Manufacture of man-made fibres
25	Manufacture of rubber and plastic products
26	Manufacture of other non-metallic mineral products
27	Manufacture of basic metals
28	Manufacture of fabricated metal products, except machinery and equipment
29	Manufacture of machinery and equipment n.e.c.
29.1	Manufacture of machinery for the production and use of mechanical power, except aircraft, vehicle and cycle engines
29.2	Manufacture of other general purpose machinery
29.3	Manufacture of agricultural and forestry machinery
29.4	Manufacture of machine-tools
29.5	Manufacture of other special purpose machinery
29.6	Manufacture of weapons and ammunition
29.7	Manufacture of domestic appliances n.e.c.
30	Manufacture of office machinery and computers
31	Manufacture of electrical machinery and apparatus n.e.c.
31.1	Manufacture of electric motors, generators and transformers
31.2	Manufacture of electricity distribution and control apparatus
31.3	Manufacture of insulated wire and cable
31.4	Manufacture of accumulators, primary cells and primary batteries
31.5	Manufacture of lighting equipment and electric lamps
31.6	Manufacture of electrical equipment n.e.c.
32	Manufacture of radio, television and communication equipment and apparatus
32.1	Manufacture of electronic valves and tubes and other electronic components
32.2	Manufacture of television and radio transmitters and apparatus for line te
32.3	Manufacture of television and radio receivers, sound or video recording orlephony and line telegraphy
33	Manufacture of medical, precision and optical instruments, watches and clockS
33.1	Manufacture of medical and surgical equipment and orthopaedic appliances
33.2	Manufacture of instruments and appliances for measuring, checking, testing , navigating and other purposes, except industrial process control equipment
33.3	Manufacture of industrial process control equipment
33.4	Manufacture of optical instruments and photographic equipment
33.5	Manufacture of watches and clocks
34	Manufacture of motor vehicles, trailers and semi-trailers
35	Manufacture of other transport equipment
36	Manufacture of furniture; manufacturing n.e.c.

Agile New Service Development in an Interdisciplinary Context: KIBS as an Interface between Life Sciences and Engineering & Automation

Sabrina Cocca¹, Ann-Mareen Franke², Simone Schell²

¹Fraunhofer IAO, ²BioRegio STERN Management GmbH

A case study shows the role of services in a highly interdisciplinary context. The article describes how a new service offering is developed systematically using an agile development approach. Moreover, the knowledge gained for services research from the practical case study in the field of knowledge-intensive business services (KIBS) in an early phase is shown.

1 Introduction

1.1 Point of Departure

The present article shows a successful transfer of study results into the practical application of services and how these findings can be used for the theory of services research. BioRegio STERN Management GmbH is a German service company located in the federal state of Baden-Württemberg supporting the economic development of the life sciences industry. The service portfolio of the company falls within the category of the so-called *Knowledge-Intensive Business Services* (KIBS) and mainly consists of highly specialized consulting services for e.g. business development, grant applications and corporate finance. Their target groups are business founders, entrepreneurs and researchers in the life sciences industry. One of the main objectives is to initiate cross-sector cooperation between life sciences and engineering & automation to expose considerable synergy potential beyond their core businesses. Both represent economically strong and important industries in Baden-Württemberg. Combining these two industries should strengthen the industrial location and help life sciences to achieve an improved economic efficiency.

At present, the life sciences industry is predominantly producing small quantities using time-consuming manual processes. Since life sciences are highly subjected to requirements such as efficiency, quality, reproducibility and human safety, innovative automation solutions are gaining importance. Engineering & automation may develop customised, flexible automation solutions across the complete product creation process (e.g. automated cell cultures, regenerative implants).

The challenges for building up interdisciplinary cooperation activities include difficulties in finding suitable partners, stringent regulations due to current legislation, differences between the two industries in their ways of working, corporate cultures and specialized technical terminologies. To overcome these obstacles an appropriate service platform should be established in order to support projects at the interface between engineering and natural sciences. In this respect, a preliminary study was carried out to analyse the market potential and to assess cooperation conditions between the participating industries. The results of the study provide the basis for conceiving a service programme for active networking of two industries previously alien to each other.

The *New Service Development* discipline provides methods and tools for the development of KIBS. However, since this is about complex business services which are provided in close interaction with customers and since the present sample case additionally involves the factor of interdisciplinarity, the development process needs to be customised. In this way, services research is able to gain knowledge from practical application.

1.2 Methodical Approach

The present article is based on a sample case from BioRegio STERN Management GmbH and describes how KIBS can be developed systematically for a previously unknown market and introduced at only a minimum of risk by choosing an agile and prototypical approach. The methodology can be described along the phases of a new service development process (cf. Figure 1): Idea finding and evaluation, requirements analysis, service design, test, implementation and market launch.

The decisive factors for the recognition of a need were the preceding activities within the ELSA project ("Clusterinitiative Engineering – Life Sciences – Automation"). The prime questions derived there were included in the empirical survey identifying requirements for the new services to be developed.

A specific focus was on the compilation of requirements (combination of a broad survey and in-depth interviews for case studies) and on testing the service offerings, which can be structured according to two phases. Test phase 1 focuses on the prototypical test of the service concept while test phase 2 uses the lead-user approach for further trial and optimisation of the service offering. The company is currently still in the conceptualization and test phase. Along with the implementation and market launch, continuous optimisation and customisation of the offering to current requirements will be performed.

Industry-specific particular circumstances are considered both in the approach for new service development of the BioRegio STERN Management GmbH and for the development model chosen; these will be described in detail in another section below.

Figure 1. Approach used in the present case study.

Furthermore, findings that are useful for services research are reflected and shown explicitly in parallel to the practical development process. Hence, the sample case is a hands-on trial of a procedure model in the context of KIBS in a highly interdisciplinary environment. This results in new knowledge being fed back into the development process and makes it possible to recognise further need for the development of new services.

2 Interdisciplinarity in Cooperation Projects between Engineering & Automation and Life Sciences

2.1 Particular Characteristics of the Life Sciences Industry

Enterprises of the life sciences industry are active in the fields of biotechnology, medical technology or pharmaceuticals. They develop drugs, diagnostics or innovative substances. Although innovative products and processes of the life sciences industry involve very long development periods, they reach marketability step by step and generate an increasing demand. Enterprises of the life sciences industry must be competitive world-wide and comply with international quality standards and legal regulations. Requirements such as efficiency, quality and safety for human beings also apply to these products. Refer to Figure 2 for a detailed listing of the key words.

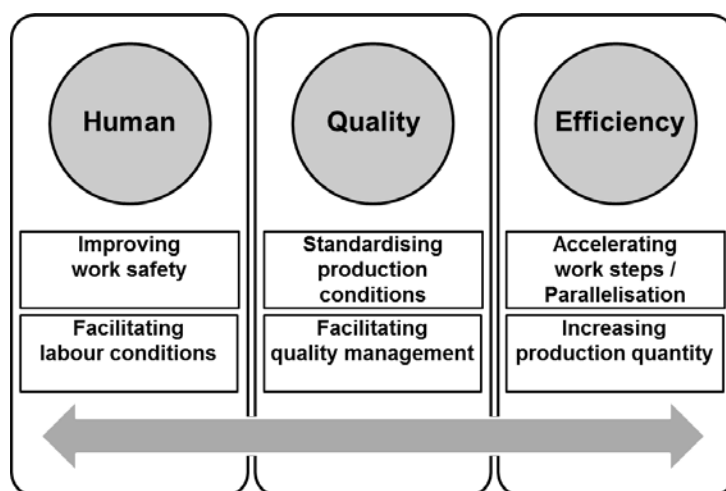

Figure 2. Key words characterising current challenges in the life sciences industry⁹⁷.

These products have usually been developed and manufactured at a laboratory scale, manually and in small quantities to date. This is an issue with regard to requirements. A possible solution to this may be using the services of engineers from the automotive supplier, mechanical engineering or automation industries. These develop equipment and processes together with the life sciences enterprises in order to attain readiness for marketing of the products more quickly. Hence, innovative automation solutions will become very important in the future. Engineering & automation may offer technical solutions for the complete process of product development or support process optimisation in life sciences. Some examples are miniaturised and more reliable diagnostic platforms or liquid handling systems. There will be a particularly high need of automation know-how especially in personalised medicine such as individual therapy, e.g. for tumour diseases. Personalisation will play an increasing role also for medical products: Therapeutic single-piece products such as artificial skin, intervertebral disc or cartilage replacements are developed and manufactured individually for specific patients. The individualisation is based on the single-piece production process. Furthermore, in compliance with the new EU chemical directive *REACH – Registration, Evaluation, Authorisation and Restriction of Chemicals*, cells in large volumes for testing of substances, chemicals and cosmetics need to be produced. The high demand for human cells can only be met with the aid of automated cell culture application or tissue factories. The use of automated processes becomes more and more important in order to reach the required quality standards such as GMP, DIN and ISO (cf. Ballesteros; Schell, 2012).

2.2 Particular Characteristics in the Engineering & Automation Industry

Enterprises of the engineering & automation industry are active in automation technology, machine building and mechanical engineering. While the concepts of automation technology, machine building and plant construction rather describe technical specialisations and the utilisation of technical solutions for production, the concept of engineering refers to upstream services and comprises activities such as consulting, planning and conceiving technical solutions. Many enterprises of the engineering and automation fields are currently predominantly active in the automotive industry. However, the life sciences industry offers a great economic potential for the automation industry, since particularly biotechnology is a key and interdisciplinary technology with a significant potential for growth, highly dynamic innovation and increasing demand. In order to be used successfully in the life sciences industry, automation solutions should be both miniaturised and flexible in use and, in addition, ensure that process costs can be reduced. The same is true for an intuitively operated and user-friendly control system. Usually, the production quantity is comparatively small. Automation can also be used to implement and optimise processes from the life sciences industry in parallel. Standardisation of automation, on the other hand, is relatively difficult in the field of life sciences due to individualized products. Potential opportunities appear in the area of production technologies that can be used to manufacture products for medical diagnostics in high volumes or for implants at a high precision. Other potential areas are liquid handling, statistic test planning for parameter optimisation or workflow control of laboratory processes using workflow management systems (cf. Ballesteros; Schell, 2012).

2.3 Cooperation between the two Industries – Current State of Affairs

Cooperation between the two industries is currently still in the fledgling stages. A few cooperation projects exist, with a tremendous potential for intensifying the matter. In order to promote such interface projects between life sciences and engineering & automation in a target-oriented way, the BioRegio STERN Management GmbH founded the "*Clusterinitiative Engineering – Life Sciences – Automation*", in short *ELSA*. Within this initiative, the existing regional

⁹⁷ Modified from Schraft; Kaun, 1998

clusters of the life sciences industry are linked with those of automation technology, machine building and automotive suppliers. Automation technology as well as machine building and plant construction are considered as key industries in the STERN BioRegion. The preconditions for cooperation between engineering companies and enterprises from the life sciences industry are therefore unique in this region. ELSA is intended to strengthen the industrial location, to help life sciences to achieve an improved economic efficiency and to open up a new market for the engineering and automation industry.

Albeit there is a high potential, the cooperation between engineers and life scientists at first glance involves a number of challenges that are due to the differences existing between the industries. This includes, among other factors, difficulties in finding suitable partners and stringent regulations due to current legislation. Moreover, special challenges are the different ways of working, the corporate cultures and the specialised technical languages. The differences are graphically illustrated in Figure 3.

Figure 3. Differences between the engineering & automation and life sciences industries⁹⁸.

As a result of these contrasts, interdisciplinary work is a prerequisite for realising interface projects between engineering & automation and life sciences. In this respect, an appropriate service offering is intended to provide support to both life science and engineering & automation enterprises in order to facilitate the link between these industries. In order to be able to develop such a suitable offering, it is necessary to first investigate the general market and cooperation conditions since these are completely uncharted economic waters (cf. Ballesteros; Schell, 2012).

3 Conceptual Design of the Study

3.1 Initial Situation and Objectives

The objective of the study was to determine the current state of affairs of cooperation projects between the engineering & automation and life sciences industries to convey market requirements.

The following individual issues were addressed:

- Determining the general attitude towards cooperation projects within and between the engineering & automation and life sciences industries
- Determining the potential for automation in the life sciences industry
- Deriving recommendations for the life sciences industry
- Deriving recommendations for the engineering & automation industry
- Supporting the cooperation of engineering & automation and life sciences as two industries which are still alien to each other

One particular characteristic of the project work is the high degree of customer focus (e.g. involvement of partners referred to as lead users). Another one is that it is an employee-driven project, which had a very motivating effect on the complete project team. Furthermore, the success factor of interdisciplinarity should be emphasized; it existed because of the close cooperation between an engineer and a biologist and facilitated mutual learning processes.

3.2 Survey Method and Data Basis

The study was structured according to two components: Broad survey (1) and case studies (2). The methodology is described in more detail below and illustrated in Figure 4.

⁹⁸ Cf. Ballesteros; Schell, 2012

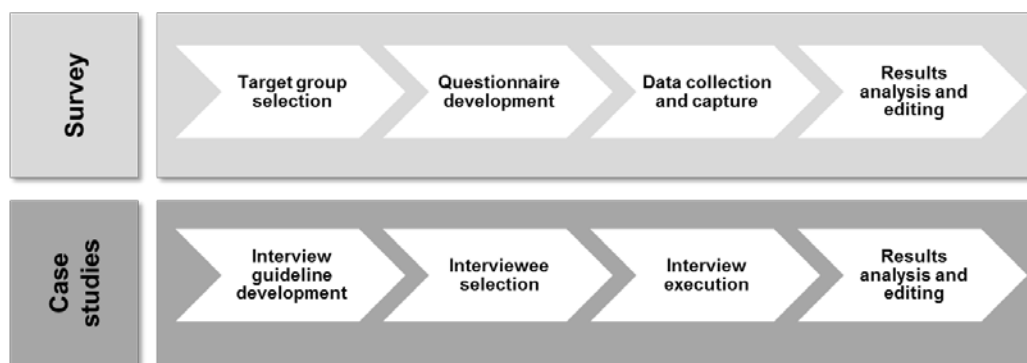

Figure 4. Methodology and components of the study.

(1) Survey

The survey was intended as the core foundation for determining market requirements and deriving a service offering to support cooperation between the two industries. Since it is a new field of study, i.e. cooperation between the two industries was uncommon before, and because of the promising prospects, this was a certain challenge and therefore highlights the explorative nature of the survey. Target groups for the survey were decision-makers (strategic positions) of enterprises from both industries. In order to safeguard comparability but also to be able to address the specific aspects of both industries, the representatives of the industries were addressed with questionnaires of the same structure but with individual questions customised to the target groups. The questionnaires were made available to the persons interviewed in both printed (sent by mail) and digital (sent by e-mail) formats and in an online version (Limesurvey®). In addition to cooperation between the life sciences and engineering & automation industries, also general issues relating to cooperation and specifically "cooperation within the life sciences industry" were subjects of the study in order to be able to derive the requirements and fields of action. The latter subject was particularly interesting in order to find out whether life sciences enterprises cooperate at all or do not usually enter into cooperation – neither within its own industry nor with other industries.

Table 1. Study outline of the broad survey.

Study Outline	
Target groups	Life sciences Engineering & automation
Areas of study	Cooperation in general Cooperation within the life sciences industry Cooperation between life sciences and engineering & automation industries Future development of cooperation projects between the two industries
Scope of study	131 enterprises
Period of study	September and October 2012

Both general factors for success and failure of cooperation projects and industry-specific issues which may have an impact on the cooperative behaviour were considered when preparing the questionnaire.

The following individual areas of study were subject of the survey:

- Cooperation projects by industries
- Attitude of the industries towards mutual cooperation
- Factors for successful cooperation
- Instruments for initiating cooperation
- Obstacles when initiating cooperation
- Need for support for initiating cooperation
- Reasons for cooperation with the other industry
- Successful cooperation projects between the industries
- Preferred forms of cooperation by industries
- Supply and demand of automation solutions for life sciences
- Fields of cooperation within the life sciences industry
- Attitude towards cooperation with the engineering & automation industry
- Fields of cooperation within the engineering & automation Industry

- Attitude towards cooperation with the life sciences industry
- Future cooperation projects between the industries
- Readiness to take action to support cooperation

The analyses were made using the statistics software IBM® SPSS® Statistics 20. The percentages specified refer to the valid answers. Rounding up or down may result in totals deviating slightly from 100 percent. Only those findings were included in the preparation and documentation of the study results which had a sufficiently high significance from the statistical point of view.

Target group profiles

43 percent of companies participating can be categorised to form part of the life sciences industry, 57 percent are from the engineering & automation industry. Most of the life science companies are from the fields of biotechnology (36 percent) and medical technology (38 percent), a smaller portion from pharmaceuticals (6 percent). The persons interviewed from the engineering & automation industry see themselves in the fields of automation technology (43 percent), machine building (35 percent) and engineering (24 percent), with some of the companies positioning themselves in more than one of the three fields, representing possible focuses.

(2) Case studies

In order to gain more profound knowledge about challenges and approaches in the cooperation between enterprises in the life sciences and engineering & automation industries, semi-structured in-depth interviews were made with two representatives each of both industries. All of the total of four case studies prepared from this are "lighthouse examples" of functional and fruitful cooperation. Nevertheless, obstacles surfaced which make it necessary to resort to external consulting and support in both industries from the point of view of the representatives of the companies interviewed (cf. Ballesteros; Schell, 2012).

The following individual areas of study were subject of the expert interviews for the case studies:

- Experience from cooperation projects with the other industry
- Opportunities in cooperation projects with the other industry
- Risks in cooperation projects with the other industry
- Solutions applied in the area of life sciences
- Utilisation of external support when initiating cooperation projects
- Criteria for the selection of cooperation partners from the other industry
- Criterion for success of cooperation with the other industry
- Specific sample case of cooperation with the other industry
- Nature and scope of the cooperation project
- Motivation and special characteristics of the cooperation project
- Channels and instruments used for initiation
- Barriers within the cooperation project
- Specific project objectives, competitive advantages and innovations achieved
- Future development of cooperation with the other industry
- Future potentials of engineering & automation solutions for life sciences

4 Results of the Study

The study revealed core findings which are fundamental to establishing a service offering tailored to the needs of the industry and target group. First, the synergies from cooperation of both industries are recognised and there is a substantial need for consulting services regarding mutual cooperation. The factors for success determined for cooperation activities can be outlined by these keywords: **building trust, interdisciplinarity, interface personnel and professional project management**. Moreover, it was possible to identify *obstacles and challenges* which may lead to conflicts between industry experts and which are intended to be specifically addressed by the service offering. This includes, above all, **financing issues, lack of contacts and ideas, lack of industry-specific know-how, different objectives and intentions, technical languages and time horizons**. It is necessary to try to find a common level of language between the two industries. In addition, **finding suitable partners** is an issue for many enterprises. For engineering & automation enterprises, a **lack of human resources** and **different corporate cultures** are additional obstacles for cooperation projects. Refer to figure 5 for a summary of the results.

Figure 5. Typical obstacles when initiating cooperation projects.

Important and useful *instruments for initiating cooperation projects* are, in particular, **recommendations from existing partners**. Hence, the personal component plays an important role and supports building trust. This is an interesting focus for new service development. The second rank among useful instruments is held by **personal networks of the enterprise's own employees**. Hence, it is important that individual employees are able to establish contacts autonomously in order to be successful in a cooperation project. Similarly, **events** (e.g. conferences, meetings, fairs, information and matching events) and **activities of industry associations and networks** (rated equally on an average) are among the top 3. The latter initiation instrument, however, is predominantly emphasized by enterprises with a tendency to a higher potential of innovation. Online platforms play only a minor role, the human factor is at the focus.

With regard to the *need for support when initiating cooperation projects* (see figure 6), particularly **contractual issues** and the **procurement of cooperation partners** are mentioned. In particular, enterprises from the life sciences industry expressed a need for support in the contractual arrangement of the cooperation (64 percent versus 41 percent among engineering & automation enterprises). Numerous enterprises from the engineering & automation industry find ratings of potential cooperation partners useful (35 percent). With regard to the need for support, there is also a difference between enterprises with a high and those with a slightly lower potential for innovation. The more innovative ones, for example, think that the procurement of cooperation partners (55 versus 36 percent) and support in the contractual arrangement of the cooperation (52 versus 39 percent) are more important. Enterprises with a lower degree of innovativeness usually rate content-related support in the arrangement of the cooperation higher than the more innovative ones (30 versus 18 percent). Although **training of employees** involved is at a very low rank (15 percent), there is a general agreement that support is needed in this area. However, enterprises with a lower potential for innovation emphasize this aspect more than those with a higher potential for innovation (27 versus 9 percent). With regard to the contractual arrangement of the cooperation, need for support is expressed rather by small and medium-scale enterprises (SME) than by large-scale corporations (52 percent of SMEs versus 21 percent of corporations). In order to determine the readiness of the enterprises to enter into cooperation projects with the other industry, specific potential activities were suggested. It is striking that enterprises from the engineering & automation industry show a higher readiness to take action relating to company strategy, organisation and human resources in order to give an impetus to such cooperation. The engineering & automation enterprises already acknowledge the significance of in-house interdisciplinarity and can easily imagine hiring specialists from the domain of life sciences directly. However, since the overall readiness is only average, it is evident that cooperation projects are currently rather based on loose constructs of individual enterprises than on close intermeshing of industries (cf. Ballesteros; Schell, 2012).

Figure 6. Need for support when initiating cooperation projects.

There are also differences with regard to supply and demand of automation solutions for the life sciences industry. The life sciences enterprises were asked about applications of such solutions in order to assess which ones are currently of interest. In order to compare the demand with the supply of automation solutions for life sciences, engineering & automation enterprises were also asked about their automation solutions being used by life sciences enterprises. The results differ. For example, life sciences enterprises are currently using predominantly solutions from the fields of measurement and electrical technology (65 percent), microelectronics and sensor technology (60 percent) as well as information and communication technology (55 percent). In contrast, there are engineering & automation enterprises specialising particularly in the fields of production technology (64 percent), robotics, development and manufacture of single special machines (47 percent). At first glance, the offering of the engineering & automation enterprises and the demand on the part of the life sciences enterprises for automation solutions for life sciences diverge, however, the opinions with regard to the future importance of individual solutions are very similar. This means that the industries will probably show a sufficient amount of future connecting factors and do not move into entirely different directions at least with regard to their expectations.

The results from the expert interviews are useful as a supplement to the broad survey and for the development of good practice examples. All in all, there is still work to be done to make the two industries aware of each other. It has also been confirmed that engineering enterprises getting into the life sciences industry need support in order to familiarize themselves with **licensing regulations**, market requirements, **business models** and **market access options**. Moreover it is important to find a suitable partner who understands one's own industry. This may involve that engineering & automation enterprises have competencies in the specific fields of application of life sciences – or vice versa that life sciences enterprises are staffed properly to recognise their potential for automation. **Joint networking events** and **fairs** play an important role to facilitate meeting each other. However, representatives of both industries frequently tend to go to fairs of their own industry. Especially biotechnology and medical technology specialists need to be brought closer to automation fairs by platforms like ELSA. With a view to increasing the cooperation between engineering & automation and life sciences, enterprises with a think tank function play a core role. They can complement the lack of interdisciplinary work in an enterprise and generate new automation solutions for life sciences.

5 Transfer of Results to the Practice of Services

The following requirements and needs for the development of a service offering to support cooperation between the two industries can be derived by considering the service concept and the results of the study:

Bringing together the demand and the offering

The offerings of engineering & automation enterprises and the demand of life science enterprises for automation solutions differ. This is a starting point for new service development. This divergence can be adjusted by addressing individual companies directly. For example, a campaign could be launched to directly attract new companies from

measurement and electrical technology to the market of life sciences since the need in the life sciences industry is greater than the current supply.

Personal contacts

The human factor and direct interaction play a core role in supporting the initiation of cooperation. Merely sending information material or providing a service on call (e.g. telephone hotline, online platforms and chats) will not get a service provider very far. It is much more important to actively facilitate interaction between potential cooperation partners. Other program-specific services such as “business speed dating” or cooperation exchange may be offered as future services in addition. An on-line platform may be implemented. However, the personal component should be reinforced, for example, by information events or video presentations.

Training and workshops

This aspect is closely related to the previous one (personal contacts). Although only a minority of the persons interviewed mentioned qualification issues explicitly, a need for training can be deduced implicitly. In addition to the transfer of knowledge to employees involved, particularly in companies having less experience with cooperation, or about companies of the other industry, the subject of awareness raising also plays an important role. In particular, such trainings and workshops can support engineering & automation enterprises in reducing fear of differences in corporate cultures. In this regard, a training or joint workshop proves to be more helpful than written materials (e.g. information brochures). Other content that may be offered are subjects specifically tailored to the enterprises such as: "*Production and Automation for Natural Scientists*" or "*Life Sciences for Engineers*". Training about the economic efficiency of projects or the design of requirements specifications and detailed specifications is also interesting.

Differentiation by industries

It has become evident that the two industries are more similar as expected. This facilitates the arrangement and organisation of shared offerings (e.g. events). However, there are also industry-specific needs and obstacles that have to be addressed in different ways. While for life science enterprises (especially for SMEs) support in the contractual arrangement of cooperation projects tends to be important (designing the cooperation), enterprises in the engineering & automation industry rather need support for the evaluation of potential cooperation partners and to reduce constraints (initiating contacts). Hence, automation companies need support at an even earlier stage in the process before entering into the cooperation. However, providing an evaluation of cooperation partners as a service turns out to be difficult because usually there are no indicators yet about the enterprises from the life sciences industry. Nevertheless it is interesting to offer external project management for interface projects as a service. This service considers obstacles and constraints in the cooperation and includes them into the project management task.

Interdisciplinarity and communication

Interface personnel is an important issue on two levels: first within the enterprises themselves, second with a view to the consulting services. Not only the two industries need an interdisciplinarity approach to understand the other industry and to be able to cooperate better, but also external service providers intending to support cooperation projects between the two industries. For example, a "translation service" between the two industries could be considered: Either in terms of a dictionary or in terms of a personal translation that can be requested for project meetings. Such a service addresses the different specialised languages which are often a cause for failure of interdisciplinary cooperation.

Visualisation

Visualisation can be viewed as another interesting field. For example, laboratory processes can be visualised for a better presentation. The biotechnology specialist recognises the processes and can identify with automation more easily. A biotechnology truck or exhibition events organised at enterprises which are able to show that lab automation products are also interesting. Rapid prototyping could also be used to present ideas visually in a quick and efficient way.

Since the sample case of the BioRegio STERN Management GmbH deals with the development of new services in an entirely new market – support of cooperation between two industries, which are (still) fairly unknown to each other – the uncertainty and the risk of undesirable developments are particularly high. The company therefore is using a systematic approach to avoid developing services that "miss the market" but rather align them with the requirements of both industries. The development and testing activities were geared to a procedure model (see figure 7) which takes all phases of new service development into account: idea management, requirements analysis, service conceptualization, test, implementation and market launch.

The research disciplines *New Service Development* and *Service Design* did not become known before the Eighties of the 20th century. In the Nineties, the concept of *Service Engineering* emerged. This concept describes the systematic development and design of services using suitable models, methods and tools – and thus adopts to some extent the approach of product and software development common in the engineering sciences. Since the time when the research

discipline emerged, numerous methods and instruments for the design of services have been developed (e.g. Bullinger; Fähnrich; Meiren, 2003; Bullinger; Scheer; 2003; Salvendy; Karwowski, 2010; Scheer; Spath, 2004).

Figure 7. Service Engineering process (according to Burger; Kim; Meiren, 2010).

In contrast with other concepts from services research (cf. Scheuing; Johnson, 1989; Ramaswamy, 1996; Edvardsson, Olsson; 1996; Shostack; Kingman-Brundage, 1991; Jaschinski, 1998), which are usually structured either sequentially or iteratively (cf. Schneider; et al., 1998), this model features modularity as a property. At first glance, the chosen procedure seems to be rigid and linear, i.e. without any iteration or optimisation loops provided. For this reason, the model was slightly modified *in application*, without making any change to the fundamental idea. The background for this is the concept of **agile development** such as it is known, for example, from software engineering. Here, iterations are provided which permit returning or jumping to other phases in order to be able to respond to errors and any optimisation opportunities at an early stage; so an incremental availability of the result is possible (Moran, 2014). In the sample case, for example, iterations were inserted between idea management and the requirements analysis, between service conceptualization and test as well as between service implementation and market launch.

Further, the present case is about KIBS. KIBS and the associated sectors and sub-sectors are usually defined on the basis of the *Classification of Economic Activities in the European Community (NACE)* and mapped to the parameters 71 to 74 (see figure 8).

Figure 8. Classification of KIBS in the NACE (Hertog; et al., 2006).

KIBS are generally defined as services provided on the basis of specialised knowledge. Their provision and use could lead to a growth of knowledge (cf. Muller; Doloreux, 2007; Schnabl; Zenker, 2013; Schricke; Zenker; Stahlecker, 2012). Particularly consulting services fall into this category, for example, business consulting, technology consulting, engineering and market research. Knowledge-intensive services, also referred to as knowledge-focused services, are usually characterised by a high contact intensity with customers and a high number of variants (cf. Baumgärtner; Bienzeisler, 2007). For the present sample case of BioRegio STERN Management GmbH, this results in a certain complexity (e.g. specific nature of the customer's problem and of the technical or scientific field) and interactions with the customers become necessary in the service processes (e.g. analysis of the initial situation, data collection at the customers, acceptance of the result by the customer). These particular characteristics should be taken into account as early as possible during the development process.

The individual phases of the procedure model as well as the backgrounds for customisation are described below.

Idea management and requirements analysis

In order to be able to develop and select sustainable ideas, the company first required to know the market and its requirements. This is particularly important because the market is fairly unknown with regard to cooperation between industries. In addition, the differences between the industries had to be addressed in this phase. Each industry has its specific requirements which have to be considered. After the first collection of ideas on the basis of various informal interviews and a workshop with representatives of potential target groups, specific requirements were established (see survey and case studies). The ideas were subsequently refined by supplementing, delimitation and evaluation before making a selection. It was worked out in detail which advantages result for "customers" from using the service. In the context of BioRegio STERN Management GmbH, the "customers" are the cluster protagonists. Since the objective is to establish further cooperation projects at the interface of life sciences and engineering & automation, the services are defined in such a way that this objective can be achieved. Those enterprises which will use the services are to be enabled to enter into a cooperation more easily.

Service conceptualization and test

It is not possible to cover all customer groups of the target industries and service scenarios with an initial service concept because of the individual nature of the need for support between the industries and the large number of possible cooperation constellations. In order to align the service offering with the real customer needs, which may be higher than evident from the information obtained from the requirements analysis, an early concept test of the planned offerings is made with pilot customers in workshops and individual interviews. Subsequently, the service concept is aligned with the more detailed requirements. This prototyping method prevents the enterprise from being too late in recognising needs for adjustment and unnecessary costs (e.g. for production of sales brochures, procurement activities, purchasing external consulting services or recruitment of new employees) which would have been incurred by a service concept that might have failed in the market.

Service implementation and market launch

Iterations involving re-testing and re-engineering or a further development of the service offering are also provided between the last two phases – the implementation of the service and its rollout in the market. Hence, the agile approach runs throughout the complete new service development process. The BioRegio STERN Management GmbH is currently preparing for the transition to the two phases of conceptualization and test as well as implementation and market launch. The close cooperation with pilot customers or partners with a lead user role makes it possible to run these two phases nearly in parallel and upscale them for additional customers in case of successful adaptation. A critical factor may be that the market does not accept the service in spite of the conducted market analysis. A risk assessment is carried out and accompanies the new service development.

6 Summary and Conclusion

The application of the selected procedure model worked in the sample case without any problems. The modular nature allowed individual adjustments and jumping between phases even though this is not depicted in the process model itself. The degrees of freedom that were utilised in the model are described below. They show points of departure for the further development of procedure models for new service development.

Agile new service development, testing and prototyping

Owing to the completely unknown market and the risk that the target groups are not yet ready for the subject-matter (cooperation with a different industry), the sample case is used to approach the solution by way of prototyping. For this reason, the test phase is particularly intensive in addition to the requirements collection. All in all, an agile approach, i.e. an iterative procedure, plays an important role in the development of complex services. Accordingly, a more detailed investigation of the relationships and an extension of known development models by an agile concept is an interesting starting point for future services research.

Lead user approach and high customer focus

Moreover, close cooperation with lead users has turned out to be useful, particularly in connection with testing a first concept and a first specific offer. This can help to minimise the risk of developing offerings that "miss the market" since future needs are anticipated in time and correctly. Hence, customer focus is not only "glanced at superficially" by a compilation of obvious requirements but ensured by developing more substantial requirements into the service. In this way, customers develop from the passive role of mere informants and objects of study into development partners. Since such lead users want to actively drive the development of innovative products and services themselves, the development project becomes more dynamic and economically more efficient for the service provider. An interesting subject of study in this context is how such lead users are identified and how points of interaction within the development process of a service can be defined and visualised.

Awareness raising and marketing in "early markets"

The model includes the establishment of a marketing concept for the new services in parallel to the development of the service concept. In the case of BioRegio STERN Management GmbH, the focus is predominantly on raising the awareness of the target groups (life sciences and engineering & automation enterprises), most of which first have to be made aware of the advantages of cooperation with the other industry. In this respect, the functions that e.g. business communication, marketing and sales and, in particular, collaboration in close development partnerships with potential customers can take in the development process may also be studied. It should be demonstrated which variation of the development model allows an early push into markets, which do not yet know their own needs. It is also possible to show mechanisms of how experience gathered by lead users can be communicated efficiently to other potential customers in order to facilitate the roll-out of the service in the market.

Interdisciplinarity

The example has shown that the interdisciplinarity requirement can be covered by service offerings, in this case for the collaboration between the engineering and natural scientific disciplines. In the sample case, interdisciplinarity already exists in the service development process. Other research activities could investigate the role of services at interfaces and, on the other hand, optimum compositions of developer teams for services in different areas (e.g. joining designers with natural scientists).

7 Supplementary

7.1 About BioRegio STERN Management GmbH

BioRegio STERN Management GmbH is a skill-sharing network, providing a help and advice centre for founders of new businesses, entrepreneurs and researchers in the life sciences sector in the cities of Stuttgart, Tübingen, Esslingen and Reutlingen and the Stuttgart and Neckar-Alb regions (Baden-Württemberg, Germany). BioRegio STERN Management GmbH represents the interests of these market players in dealings with political circles, the media and associations and provides advice on grant applications and corporate financing. Key focal points include regenerative medicine, medical technology and the automation of biotechnology. Managing Director Dr. Klaus Eichenberg is a molecular and cell biologist and investment analyst.

7.2 Acknowledgements

The results outlined in the present article are based on partial results of the project titled "Clusterinitiative Engineering – Life Sciences – Automation (ELSA)". ELSA is supported by the Ministry of Finances and Economy of Baden-Württemberg with funds from the European Regional Development Fund (ERDF).

Knowledge intensive sectors in Mexico: An international comparison

Leonel Corona-Treviño
National University of Mexico UNAM,

One of the essential components of the knowledge society is the economic role of Knowledge Intensive Services (KIS), which have become engines of economic growth and high quality job creators. However, Mexico's policies have been focused mainly on technological innovations in goods, disregarding service innovations and thus the relationship of technology infrastructure with knowledge intensive services. The paper is exploratory in nature: First, an international comparison of Mexico is made -in terms of employment, value added and productivity- with the USA, France, Spain and Finland, looking at the knowledge and technology intensive sectors. For this purpose national data are aggregated in two sets: goods and services. On the one hand, services which are divided into traditional, intensive knowledge and innovation centered. On the other, goods are divided into manufacturing, which comprises low, medium and high technology. For the remaining goods sectors, mining and construction are included in low tech industries while agriculture is dealt with separately. Finally, considering Mexican's relatively weak economic structure in high technology goods and innovative and knowledge service sectors, this paper outlines a number of insights that could contribute to policies aimed at fostering innovation processes.

Index Terms KIS, Knowledge intensive services, Mexico, International comparisons.

1 Introduction

Schumpeter's approach of "creative -destruction" allows, in a context of crisis, to relate the economic swings to the changes in technology and institutions. So, the innovations involving new products, processes, markets, resources and organizations, complemented by the entrepreneur (the decision maker) are key concepts for theoretical and empirical research. The process of creative-destruction can be analyzed at firm or industry level, as the process of industrial change and renewal is fundamental for economic growth and development. For contemporary societies, the long term process of economic waves of prosperity-recession, and depression- improvement, nowadays results in the development of service economies that is, economies with half or more jobs in services.

To understand the evolution towards knowledge societies, it is necessary to follow up the emergence of the Technology goods and Knowledge service sectors and the decline of different industries over time, along with the commercialization of innovations in their entrepreneurial context. However, in developing countries, besides looking at the evolution of their industries, a comparison is required to detect the gap between these countries and developed nations with respect to the relative number of innovations and their diffusion, as well as the relative awareness of the importance of both technology based goods and knowledge based services.

2 Literature Review

The economic analysis of services and particularly of service innovation is growing and will be more important in the future (Expert Panel European Union, 2011), according to the following evolution stages approaches: assimilation, demarcation and synthesis (Coombs & Miles, 2000). In the assimilation approach, service innovation is regarded as similar to innovation in manufacturing, while in the demarcation approach, which considers that services are different, a specific definition and method is required. Finally, anticipating a synthesis approach, the interrelations between technology and service innovations involve a combination of new and old theories and concepts (Djellal & Gallouj, 2013). Thus, for the emerging integrated approach, the interrelationship between good & services innovations is becoming more important (Omachonu & Einspruch, 2014). It is also important to note that the 'reverse innovation cycle' in contrast to the classical one, explains the innovation stages for consumer services industries, beginning with the efficiency of delivering the service, secondly the process innovation that develops service quality, and thirdly, service product innovation achieved through new kinds of services (Barras, R, 1986).

In order to classify innovation services four dimensions are proposed: service concept, client interface, service delivery, and technology which are related to personal, organizational, marketing and competing capabilities (Hertog, 2000). Another point of view involves considering which services are undergoing most change or being transformed: physical (goods), information, Knowledge-based or people, or stressing intra-services differences in terms of the patterns of technologies used, relevant market characteristics and technical skills required (Miles, 2008).

Different service sectors correspond to different knowledge intensity and R&D input, depending on the supplier. On the one hand, if the suppliers are goods businesses, then R&D services and engineering and computing relate to high innovative intensity; or, other goods could be inputs for a service provider which has a low innovation rate such as land

and sea transport, security, cleaning and other businesses. On the other hand, it is important to know whether the service has a service provider as in the case of technical consultancy, which corresponds to high innovation; or low innovation for example, advertising; banks, insurance; trade, repair of motor vehicles and hotels (Evangelista, Rinaldo, Maria Savona, 2003). Some services participate in the innovation processes as sources or support for innovation, and as agents of diffusion (Miles, 2005).

3 Methodology

Industries of Knowledge Intensive Services (KIS) are an important to the innovation and progress of modern economies. In order to make a structural analysis of KIS evolution, a general classification is made differentiating between industries which produce services and goods industries (the latter including agriculture, mining, energy and manufacturing). Goods are classified as high (HT), medium or low technology (Annex1). Services are divided into traditional, knowledge intensive and innovation services. Innovations services (IS) are those which generate innovations based on high tech services and highly qualified personnel; knowledge intensive services (KIS) use information intensively, qualified personnel and knowledge in standardized processes based on standard or high tech, but with less innovation. Traditional services (TS) are based on standardized processes and equipment, technology and personnel, but these could also generate incremental innovations (Annex 2). Services are a major challenge to the concept and measurement of productivity (Djellal & Gallouj, 2013).

Based on these aggregated industries, the evolution of relative employment, value added and productivity is presented for Mexico and compared with the USA, France, Spain and Finland.

4 Results

In 1950 was the first economy in the world to have more than half of the jobs available in service the service sector thus making it a predominantly service economy. Nowadays, it is the world’s largest tertiary economy with an employment level of 85% in 2012. For the same year, the percentage of employment in services for France was 78%, Spain 73%, Finland 72% and Mexico 52%. Therefore, the shift to service employment continues to grow and it is positively correlated with national GDP per capita (Schettkat & Yocarini, 2006) and (Fuchs, 1968).

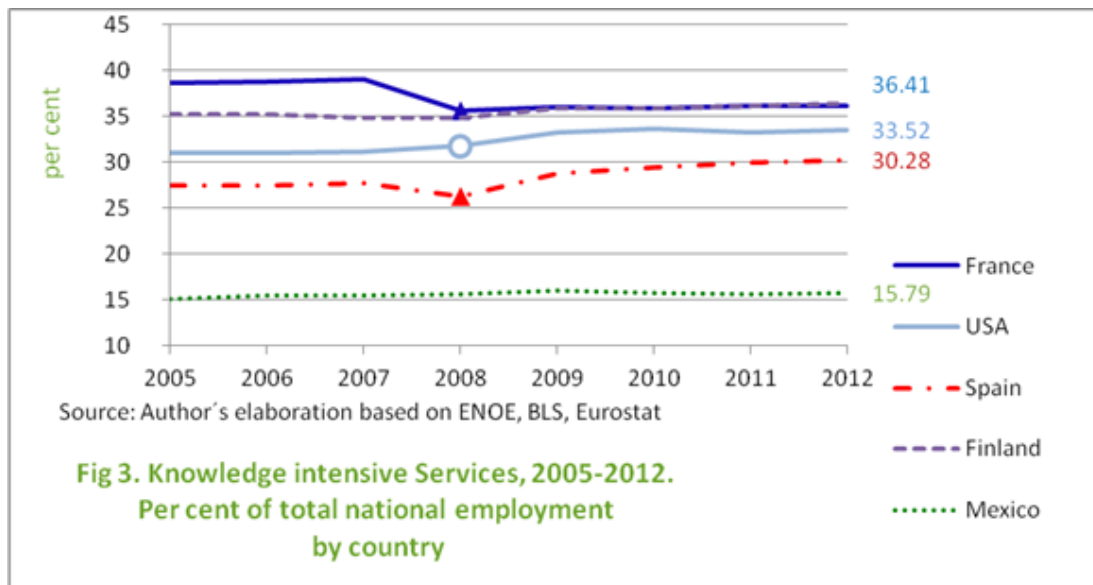

In 2012, the five countries selected showed a diminishing tendency in the goods industries, that is mainly agriculture and manufacturing. Mexico has the highest employment participation in goods, 38%, which is about double that of the USA which has the lowest rate of only 17%. Spain has the highest rate of change, reducing the share of employment in the goods sector from 35% in 2005 to 24% in 2012. This reduction could be due to the impact of 2008 crisis which caused a greater drop in manufacturing and agriculture employment compared with job losses in services. The reduction of employment in the goods industries for the period 2005 to 2012 was 4 points in France, and only 2 points in Finland. (Fig. 1).

In the traditional service sector there is a general tendency for four countries to maintain and converge with a proportion of jobs around 40%. As a matter of fact, all the countries selected are in the range of 37% for France and as high as 44% for Mexico. The USA and Spain are in the order of 43% and Finland has a constant proportion of 31% of the traditional services jobs with respect to their total national employment figures. (Fig. 2).

France has a higher participation of jobs in “knowledge-intensive services” 36%, above that of the USA, which is in second place with 34%. This is due to the fact that France has a higher proportion of jobs in health, education and government sectors. Despite the 2008 crisis, all countries increased their participation in the KIS sector for the period 2005 to 2012: Spain 3%, USA 2.5%, Mexico and Finland have been practically static at 1%. In contrast, France dropped 4 points from 39% in 2005 down to 35% in 2012 (this is partly due to the change in the Eurostat methodology in 2008, see footnote 5) Fig. 3.

In the sphere of “innovative services”(IS), the USA. is the country with the highest proportion of employees, 6.8% in 2012, increasing nearly 1 point since 2005, a fact correlated with research and development activities. Also, the impact of the crisis on employment in this sector has been less than at national level over all, so the participation of this sector increased. The other countries are quite a long way behind the US, in the range of 3.5% for France and 2.3% for Mexico which has an important gap with respect to the other countries. France reveals a tendency to decrease from 4% in 2005 down to 3.5% in 2007, with a large drop to 3% in 2008; later, there is a recovery up to 3.5% in 2012. The USA shows an increase of nearly 1% for the 2005 to 2012 period, with a marked slow-down in 2008 correlated with the crisis. Mexico has a small rise in IS from 2.1% in 2005 up to 2.3% in 2012, while Finland shows no change during this period with a 4% participation in Innovation services (Fig. 4).

Fig 4. Innovation services, 2005-2012.
Per cent of total national employment by country

Summing up the results (Table 1), the largest negative impact on employment of the 2008 crisis is on the “goods sector” (GS), for all five countries, with an average rate of -7.6%. If we look at each country individually, the largest impact is in Spain (-15.8%), the USA (-12.4%) and Finland (-6.4%). In KS, except for the USA with a slight drop of -0.5%, we can see that for the other four countries there is an increase particularly in Mexico (2.2%) which, in spite of the crisis also shows an important increase in IS (5.9%) and in France (3.9%). In contrast, the IS sector goes down in the USA (-4.3%) and in Finland (-3.8%).

4.1 Value added and productivity for each country

.4.1.1 Mexico

In 2012, Mexico reached 2/3 of the total value added in areas including traditional services (41.5%) and low technology industry goods (24.6%). The remaining 1/3 was generated by the knowledge intensive sector (14.4%), medium tech goods (9.1%), innovation services (5.9%), agriculture (3.9%) and the high tech goods sector (1.4%) which in fact reduced its participation from 1.8% in 2003. However, this sector achieved its highest productivity of 86.4 thousand constant dollars per worker in 2008 and its highest growth rate of 37% during the period 2003 to 2012. The other sectors are far behind with half that productivity, 41.7 thousand for high technology goods industries and nearly a quarter of that highest productivity, 22.8 thousand constant dollars for knowledge intensive services in 2008. In addition, these other sectors remain on a more or less on a constant plateau with respect to productivity. Agriculture is the weakest sector with 4.4 thousand dollars per worker, nearly 20 times less than the highest productivity in innovation services (Fig. 5).

Source: Author’s Elaboration based on INEGI (Mex).

So, to explain why there is such a large sectorial productivity gap we need to take additional factors into consideration: 1) the dual economy characterized by a wide gap in agriculture between very low value added activities in seasonal rain dependent agriculture versus irrigation agriculture. There are also divisions in traditional services, i.e. retail commerce, on one hand, the informal market and on the other, modern trade. 2) Mechanisms of value transfer which could explain the productivity gap between innovation services, with productivity in 2012 of 86.7 thousand dollars, and high tech industry with half this level of productivity, that is 41.7 thousand dollars per worker.

4.1.2 United States of America

The USA shows 2/3 of its value added in Traditional (35.6%) and Knowledge intensive service sectors (33.1%). The rest is in innovation services (9%) and good industries (22%). For the period of 1997 to 2012, the High Tech goods sector has the highest growth (2.6 points) with Innovation services (0.4) in second place. The other sectors more or less maintain their value added (KIS and Agriculture); and Medium Tech (-2 points) and Low Tech (-4.3) diminish their participation. The productivity range in 2012 is between 221 for High Tech goods and 95 and 98 for Knowledge intensive and Traditional services, respectively, in thousand 2008 dollars per worker. In 1998, Innovation services show a productivity of 124, and High tech goods of 54, in thousand-2008 dollars. That is to say, lower values compared with 2012 and also less pronounced differences between sectors (Fig. 6).

Source: Author’s elaboration based on BEA (USA)

4.1.3 Spain

Similarly to the USA, Spain covers 2/3 of its value added with Traditional (36.4%) and Knowledge service sectors (28.9%). The rest is in low tech (20.6%) and medium tech industries (6.9%). For the period of 2002 to 2012, the KIS sector had the highest growth rate (4.5 points) and in second place, Innovation services (0.5). Value added diminishes for the other sectors: Medium Tech (-2.9 points) and Low Tech (-1.3) and falls slightly in high tech (-0.1) and agriculture (-0.6). The productivity range for 2012, is 115 for Innovation services and 43 for Agriculture, in thousand 2008 dollars per worker. In contrast, in 2002 productivity was both lower and with smaller differences between sectors that is, in the range of 79 for innovation services and 25 in Agriculture, in thousand-2008 dollars. (Fig. 7)

Source: Author’s elaboration based on EUROSTAT and INE.

4.1.4 France

By 2011, France covered 3/4 of its value added in Traditional (41.1%) and Knowledge intensive service sectors (33.3%). The rest is in low tech (11.5%), medium tech industries (5.8%), Innovation services (5.3%), and with a small participation in agriculture (1.8%) and high tech industry (1.5%). For the period of 2002 to 2011, the KIS sector has the highest growth rate (4.5 points) with Innovation services (0.5) in second place. The other sectors’ value added diminishes: Medium Tech (-2.9 points) and Low Tech (-1.3): and fall slightly in the case of high tech (-0.1) and agriculture (-0.6). The productivity range in 2012 is between 115 for Innovation services down to 43 for Agriculture, in

thousand 2008 dollars per worker. In 2002, productivity is lower, in the range of 79 for innovation services and as low as 25 in Agriculture in thousand-2008 dollars, which is a less pronounced difference than in 2012. (Fig. 8).

Source: Author's elaboration based on EUROSTAT

4.1.5 Finland

In 2012, Finland has nearly 2/3 of its value added in Traditional (35%) and Knowledge intensive service sectors (28.8%). A quarter of it is in Low tech (16.1%) and medium tech industries (10%). We find the other sectors in decreasing order: Innovation services (5.4%), Agriculture (3%) and High tech industries (1.7%).

For the decade 2002 to 2012, Finland shows a slow change in value added structure, diminishing for the goods industry (-3.1%), and increasing in the case of traditional services (2.6%) and innovation (1.4%) services. However, there are noticeable reductions including high tech (-1.3%) and knowledge base (-1.0%) sectors. Productivity comes full circle in the case of High tech industries as it is nearly the same at the beginning and end of this period (67 vs. 69 thousand dollars 08) with a sound high productivity of \$208 thousand dollars-08 in 2008, alerting to a need to counteract non-positive tendencies to become a knowledge society (Fig. 9).

Comparing the 5 countries selected, productivity per worker is higher in the USA in all sectors, except in traditional and innovative services where France has the highest value added per worker, and is in second place in H Tech and Medium Tech, KIS and Agriculture. Finland is second in Low tech. Mexico has the lowest value added per worker in all sectors. Therefore, in function of their respective national productivity the countries analyzed appear in the following order: USA, France, Finland, Spain, and Mexico (Table 2).

Table 2. Productivity by sector and country, in value added per worker.
Thousand dollars 2008.

Country	USA	Mexico	Spain	France	Finland	
SECTOR/year	2012	2012	2009	2011	2012	Average

Author's elaboration base on author's classification (annex1) based on Eurostat for EU's countries and NACE for USA and Mexico statistics.						

4.2 Discussion

As countries moved towards becoming modern societies the services sector increased. However, considering that services are more heterogeneous than goods activities (Howells & Teller, 2004), the literature reports different approaches to classifying services industries (See literature review section). One way is the use the innovation intensity vs. the interactivity axes (Evangelista & Savona, 2003). Choosing only the first axis, innovation intensity, a classification of services in three sectors is proposed: Innovation services, Knowledge intensive and Traditional services (Annex 2). Applying a similar criterion, goods industries are classified into High, Medium and Low technology sectors (Annex 1). The remaining sectors are the primary industries of agriculture and mining. This broad taxonomy in 7 sectors allows a comparison between countries and could position them in terms of their respective structure and dynamics.

However, the approach is limited in the sense that the sectors have different innovation intensities depending on the country being studied. So it is necessary to make adjustments with complementary sector information for each country and a more detailed analysis based on firms' innovations. For example, Mexico's modernization based on maquiladora assembly plants downgraded the content, for instance, of aeronautics, from High to Medium technology. Similar adjustments must be made for each country, an analysis which is not included in this paper.

Conclusions

Changing the structure of goods and services is a slow but sustained process. In the Schumpeter framework an implicit question is that as services are an increasingly important part of the economy as a whole, how integrated goods & services productivity will develop. (Maroto-Sánchez & Cuadrado-Roura, 2009). Up until now there is no clear answer as to how a service-goods production revolution similar to the historic industrial revolution will come about. Thus, analyzing the evolution of knowledge services and technology sectors, some partial understandings could help find a way in the future to really overcome the 2008 economic crisis. Then, the analysis of service innovation is in fact a modest contribution towards that larger goal.

Comparing the selected countries, four have about 2/3 of its value added in Traditional and Knowledge service sectors in 2012: USA (68.7%), Spain (65.3), France (74.4) and Finland (63.8), whereas Mexico achieves it (66.1%) by combining the same traditional services with low tech industries.

The productivity per worker is the largest in the USA for all sectors, with the exception of the highest productivity in innovative services which is highest in France, the country that comes in in second place with respect to High and Medium Tech, KIS and Agriculture. Finland is second in Low Tech. Mexico has the lowest value added per worker in all sectors. Therefore, the countries selected fall into the following order: USA, France, Finland, Spain, and Mexico, in function of their respective national productivity (Table 4).

Finland shows certain stagnation in its sectorial structure, with an important number of businesses in the high tech goods sector shutting down since the 2008 crisis. The lesson is that it is risky to base on economy too much on one tech niche (Nochia).

Mexico is lagging behind the selected countries. Thus a policy of developing internal capacities mainly for Knowledge and Innovative services is urgent.

Annex 1: Agriculture and Manufacturing Industries

Agriculture (Natural Resources and mining)	High-technology industries	Medium-technology industries	Low-technology industries
Agriculture, hunting and forestry (A) [111-113, 115] {A1-A2}	Aircraft and spacecraft (353) [3364] {C30.3}	Machinery and equipment (29), [333 excl. 3333], {C28 excl. C28.2.3, C33}	Mining and quarrying* (C) [21], {B}

Visiting experiences and behavioural types in cultural audiences: an analysis of two museums in Lisbon

Pedro Costa, Margarida Perestrelo, Giles Teixeira

Lisbon University Institute (ISCTE-IUL) – DINAMIA’CET-IUL

Audiences of cultural events are subject to diverse kinds of experiences in their exercise, which are determinant to structure their consumption practices and cultural habits. Mapping and analysing visitors’ experiences and their visiting styles is thus fundamental to enhance museums’ offer.

Drawing on a conceptual framework which identifies four main kinds of experiences in cultural practices – (i) intellectual experience (ii) emotional experience; (iii) social experience; and (iv) recreational experience, the audiences of two museums in the city of Lisbon (Fado Museum and Puppets Museum) are analysed in this paper.

Considering a typology of diverse audience categories (permanent collection, temporary exhibitions, other events), a detailed study of the assessment of different experiences is pursued, with the aim to confront and identify relevant discriminant categories such as socio-demographic characteristics (e.g. age, gender, qualifications, professional status, nationality, residence, previous artistic practices) and cultural habits (considering their visits to other cultural facilities and events). The final aim is to draw some policy-oriented recommendations from this analysis.

Keywords: Museums, Museum experience, Cultural audiences, Cultural experience, Visiting experience, Culture, Lisbon.

1 Introduction: Research problem and context

Audiences of cultural events are subject to diverse kinds of experiences during their cultural practice. These experiences are determinant to structure their consumption practices and cultural habits, and thus fundamental to be understood and worked on the management and programming of cultural venues. Several recent studies have been pointing out the importance of mapping and analysing visitors’ experiences and their visiting styles in order to enhance museums offer (e.g. Falk 2009). This literature has been highlighting the existence and importance of several visitor identities within the museum experience and therefore, stressing the importance of analysing and predicting visitors’ different behavioural patterns.

This paper aims to analyse the audience of two particular museums in the city of Lisbon, Portugal (Fado Museum and Puppets Museum), crossing the assessments of the quality of the individual experiences declared by their visitors on a recent survey with some of the socio-demographic characteristics of those visitors, their motivations and cultural habits.

The paper was conceived within the scope of a wider study conducted by Dinâmia’CET (Centre for Socioeconomic Change and Territorial Studies, from University Institute of Lisbon) for EGEAC (Lisbon Municipality’s Enterprise for Management of Facilities and Cultural Animation). This audience development study, conducted between July 2013 and July 2014, involved a thorough survey to nearly 6000 visitors of cultural venues and events under EGEAC’s management. The main purpose of the research study was to better overview and understand visitors’ profile for each event and venue, in order to ultimately plan more successful audience engagement strategies in the near future, addressed to both visitors (real) and non-visitors (potential). More specifically, the research focused on the following key topics: (i) Visit and cultural habits (ii) Frequency of visiting (iii) Nature of visit (iv) Reasons and motivations for visiting (v) Visit experience (vi) Communication (vii) Branding (viii) Socio-demographic profile.

As far as the present paper is concerned, it takes a more detailed and focused approach, whereby rather than addressing all these eight topics within all the EGEAC venues and events, we looked solely at the 2 museums (Fado Museum and Puppets Museum) in order to specifically analyse visitors’ profile in the light of their museum experience.

Based on literature review, we identified four main kinds of experiences in museum visiting practices: (i) learning (intellectual experience); (ii) emotional (emotional experience), social (social experience) and fun (recreational experience). Drawing on this conceptual framework and considering three different programming settings - (i) permanent collection, (ii) temporary exhibitions; (iii) other events - the research seeks to identify, confront and assess which of the following relevant discriminant features - (i) visitors’ socio-demographic characteristics (e.g. age, gender, education level, nationality, artistic practices and professional status) and (ii) cultural habits (social nature of visits, visits to other cultural venues and events) - will mostly influence visitors four main types of museum experience.

After this brief introductory framing of the problem and of the context of the empirical study, the next section will analyse the museum experience at the light of literature and propose an analytical framework based on these 4 kinds of experiences. Section three will sum up the methodological issues of the study, whilst section four will present the main

results achieved and analyse the data in regard to the conceptual framework. A final section will draw some conclusive remarks concerning policy-oriented principles.

2 Museums audiences and museum experience(s): a framework for analysis

Evolving museums in evolving societies: challenging visitors' experiences

In today's post-modern world, museums are constantly redefining themselves to respond to the demands of shifting and complex societies in which they exist. Because of social, economic and political imposing agendas, museums are permanently not only challenged to revise their missions, roles and activities, but are subject to question their own purpose of existence. Since the birth of museums, collections and people have always been at the centre of their identity making, i.e. they are at the core of why museums are and exist. Nevertheless, because of historical circumstances, museums have given dissimilar emphasis to either people or collections, depending on the perspective at the time (e.g. Benhamou, 2011; Towse, 2003). In fact, intense reasoning and debate about museums' *raison-d'être* and the path they should embrace has long since been held within the museum studies community.

In spite of the debate's everlasting nature and complexity, in the last 30 years, 'museums have striven to become more democratic in their structure and more responsive at all levels to the interests of a broad-based public' (Hein 2000:2). In order to be less static and better mirror contemporary society, museums have been encouraged to change and become not only more open and communicative, but more appealing and socially responsible, in compliance with their inherent social nature. As a result, issues such as public access, accessibility and social inclusion could no longer be left unaddressed and key areas, such as education and audience/marketing research, have thus far become crucial factors in museums' success and survival. In other words, visitors and their museum experience have become the prime concern for museums worldwide. By shifting from the presentation of collections to the production of experiences, the emphasis is now placed on what museums enable people to do and in what people want to do in museums.

This new museum democratic approach in making collections more welcoming, accessible and comprehensible to as many people as possible, has been taking place due to a greater awareness of visitors' ever so changing expectations and attitudes towards museums. In fact, visitors today are increasingly expecting a greater degree of involvement and participation in museums. As such, 'it is not enough for museums to present collections and information in a passive way. Museums have to engage interest through active involvement with their users and build on it to achieve their objectives' (Ambrose and Pain 1993:16). Furthermore, today visitors call for a greater variety of experiences within museums, be they intellectual, emotional, social, recreational or educational, for instance. In order to provide these different layers of experience, museums today are embracing a multitude of roles and constantly creating new interpretive frameworks, thus allowing visitors to have multiple readings and different personal meaningful experiences. By offering assorted perspectives on their collections, museums act as mediators, as they encourage visitors to freely interact with objects and pursue their own meanings. It is fundamentally this rich meaningful mediation between the object and the viewer that outlines the relevant and irreplaceable role of the museum in our society.

Marketing Research and Audience Development

One of the resources through which museums found to help grasp the different meaning and decision-making processes and strategies that each visitor employs in its interaction with the museum is marketing research. Aimed at better comprehending and recognizing these processes, the museum studies research community have increasingly been conducting numerous comprehensive audience development studies, which have confirmed that there are indeed differentiated responses to the museum experience. In addition, it was found, that alike regular consumers, not only do museum visitors have similar cultural habits and patterns of behaviour within museums, but they also have individual different needs and motivations for visiting these leisure institutions (McLean 1997). More importantly however, is that museums have learnt that it is those specific personal needs that will shape a person's visiting motivations, which in hand are accounted for ultimately affecting the overall enjoyment and quality of the museum experience (Falk 1992, 2009).

Marketing research is therefore a tool to 'provide information on people's preferences, attitudes, likes and needs to help companies understand what consumers want' (Hannagan 1992:49). As far as museums are concerned, 'understanding the public's interests and concerns, likes and dislikes, needs and wants, is of critical importance in providing successful museums and services' (Ambrose and Pain 1993:16). With such knowledge and insight, museums are then able to 'develop its products accordingly to facilitate the exchange process' (McLean 1997:89). In other words, by helping pinpoint and understand existing discrepancies between what is offered and visitors' wishes that need fulfilling, marketing research has allowed museums to provide improved tailored products and services and give 'maximum customer satisfaction through the most effective deployment of resources' (Hannagan 1992:54).

As reasoned, museums have been striving to be more sensitive and aware to the specific interests of its visitors. The aim is not only to motivate and engage visitors but consequently, to build long-lasting mutually beneficial relationships with audiences. This new approach has allowed audiences to become empowered, as they now have a highly respected saying in what they expect to find, see, learn and experience in a museum. Marketing research is therefore a key tool to help gain new audiences and bridge the gap between museums and the public they serve. This tool is leading museums forward and reinforcing their purpose as institutions that exist for the benefit of society, i.e. the people.

Museum Experience

In order to understand how visitors' characteristics may shape the museum experience, one must also grasp how visitors produce meaning when interacting with objects and what other endogenous or exogenous factors interfere in that same interaction. As Falk and Dierking have pointed out, within a Museum, 'whatever the visitor does attend to is filtered through the personal context, mediated by the social context, and embedded within the physical context' (Falk and Dierking, 1992:4).

Each viewer or visitor is a singular distinct person who has its own personal context. This unique context 'incorporates a variety of experiences in and knowledge of the content and design of the museum. The personal context also includes visitor's interests, motivations, and concerns' (Falk and Dierking 1992:2) and therefore, help to mould what and how an individual appreciates, understands and interprets. In addition, these personal qualities are extremely important because, as the cultural approach to communication has contended, in meaning construction process, shared by a viewer and an object, specific features of both elements interfere and are determinant in the negotiated production of meaning. The message is no longer defined only by the sender (object) but also by the receiver (viewer), who is now regarded as an active and essential element of communication, being at the core of the interpretative equation (See Hooper-Greenhill 1997, 2000). Moreover, this communication theory is supported by a new exciting way of understanding learning: constructivism. According to Hein, this educational theory argues that knowledge is constructed by the learner and therefore, 'both knowledge and the way it is obtain are on the mind of the learner' (Hein 1996:75).

The underlying argument that permeates these theories is that meaning and subsequent knowledge is something that is always personally constructed, which will thus affect the extent of the engagement and enjoyment of the experience. As knowledge is 'always built on, and consolidated with, previous knowledge', visitors tend to engage more when the experience is somewhat familiar, i.e. when it recalls 'directly to an interest or concern that existed before the museum visit' (Falk and Dierking 1992:119-120). This occurs because visitors 'assimilate events and observations in mental categories of personal significance and character, determined by events in their lives before and after the museum visit' (Falk and Dierking 1992:123). It is this personal significance within the visitor's personal context that will ultimately create and mould motivations for visiting or not visiting a museum. The challenge is then set for museums, as 'visitors come with such a broad range of interests and backgrounds that no single recipe for motivating them could possibly apply across the board.' (Csikszentmihályi and Hermanson 1995:37).

As far as the social context is concerned, it is known to also influence a visitor's experience and interpretation (e.g. DiMaggio and Hirsch, 1976, Becker, 1982; DiMaggio, 1987; Bourdieu, 1994; Caves, 2002; Benhamou 2011). The social and cultural background of the visitor, which is linked to his socio-demographic profile (e.g. social class, age, household and gender) plays a significant role in shaping and forging its character. This way, a visitor interprets both as an individual and as a member of a broader community that interprets socially, i.e., as a member of an interpretative community. Finally, the physical setting is also of importance, as the gallery space, 'which includes the architecture and feel of the building' (Falk and Dierking 1992:3), can also strongly influence a visitor's overall museum experience. In fact, the gallery space of a museum, which may be regarded in some instances to be non-neutral at all, can therefore act and become in itself a meaningful exhibition interpretative tool.

An operational analytical framework

As reasoned above, today visitors expect a great range of experiences within museums that they can relate to and enjoy. Being each visitor a person who not only carries individual and social features, but also has personal specific needs and motivations, one could only assume the countless variety of visitor experiences that may take shape and place within the same museum. However, although recognizing the complexity of this reality, when carrying out visitor surveys, researchers have to try and summarize the universe of possible museum experiences into simple few categories for practical and methodological reasons.

As such, we chose to identify and consider four main kinds of museum experiences that people may have within museums: *learning* (intellectual experience); *emotional* (emotional experience); *social* (social experience); *fun* (recreational experience). We regarded the following four categories as unavoidable because we felt they comprised the majority of the reasons given in numerous national and foreign museum visitor surveys. Moreover, they are inspired by the present definition of museums by the British *Museum Association*: '*Museums enable people to explore collections for inspiration, learning and enjoyment. They are institutions that collect, safeguard and make accessible artefacts and specimens, which they hold in trust for society.*' (<http://www.museumsassociation.org/faq>).

3 Methodological Issues

As explained beforehand, the present paper focuses on visitors of two distinct Lisbon museums: Fado Museum and the Puppets Museum. Before addressing methodological and technical issues, it is of importance to outline each Museum's history and mission, as well as examine the nature of their collections and activities they promote.

The Fado Museum

Although Fado has over 200 years of existence, Lisbon's Fado Museum only opened its doors to the public in 1998. According to the museum's official website, its mission is to research, gather, document, preserve, interpret, promote,

exhibit and learn about Portugal's most traditional music genre. (<http://www.museudofado.pt>). The Museum aims to celebrate Fado's exceptional value not only as a symbol of Lisbon, but as an art that is deeply rooted in the cultural traditions and musical history of the country. Moreover, it aims to praise an art that shapes and promotes Portugal's cultural identity, both nationally and overseas. This goal was to some extent accomplished in 2011, when Fado was proudly added to UNESCO's list of World's Intangible Cultural Heritage.

Since its opening, the Museum's permanent collection has incorporated items belonging to hundreds of artists, musicians, composers, authors, poets, instrument manufacturers and researchers. These items not only include material objects e.g. music instruments, phonograms, records, clothes and documents (periodicals, pictures, photographs, posters, musical scores), but also immaterial (intangible) patrimony, such as the memories and testimonies of hundreds of personalities that witnessed, played and wrote the history of Fado. It is because music belongs to the realm of immaterial heritage that visitors' interaction and engagement with exhibition contents, via technology, has always been a huge priority and concern for the museum.

In addition to the *permanent collection*, the Museum has developed a vast programme of activities which include regular *temporary exhibitions* (held outside the Museum gallery space in different cultural venues, providing extra visibility and reaching non-regular visitors) and *other events*, which mainly consist of live performances, musical guided tours (available inside and outside the Museum), books and album launches, workshops, presentations and conferences.

The Puppets Museum

Since 2001, the Puppets Museum is located at the *Bernardas Convent*, in Lisbon. However, the Museum was founded long before in 1987, by the *Companhia de Marionetas de S. Lourenço*, a travelling puppet theatre company which had successfully performed both in Portugal and abroad since 1973. Up until today, the Museum continues to be the sole Portuguese institution to feature the history of puppets and puppet theatres companies across the world, in spite of focusing more on Portuguese puppetry traditions and objects.

As such, it dedicates itself to the collection, conservation, research, exhibition and interpretation of different puppet collections (<http://www.museudamarioneta.pt>). By means of exploring multiple collection approaches, the Museum aims to spread knowledge and provide insightful yet pleasurable fun experiences for its visitors. In addition, because it attracts a large number of young visitors, the Museum fosters numerous educational and children's edutainment activities, mostly concerning live puppet shows and museum guided tours⁹⁹.

The Puppet Museum has been progressively acquiring new items for its main permanent collection, which are a depiction of different puppetry practises that derive either from ancient traditions or from modern artistic expressions. These acquisitions have only been possible due to the admirable contribution, help and support of various individuals, authors, collectors and puppeteers, who have donated their collections or personal objects to the Museum. As a result, it now houses one of the most significant and complete collections of Portuguese traditional puppets. In addition, it also comprises an outstanding wide collection of over five hundred African and Southeast Asian puppets and masks bestowed by the famous Portuguese collector, Francisco Capelo.

Besides its *permanent collection*, the Puppet Museum also holds two to three *temporary exhibitions* per year, in a proper devoted gallery space within the Museum. These exhibitions naturally relate to the art forms of puppetry and theatre, which may often be expressed through painting and photography. In addition, the Museum holds several *other events*, which principally include serving as a host to two notorious Lisbon festivals called: *FIMFA - International Festival of Puppetry and Animated Forms (performing arts)*; and *MONSTRA - Lisbon Animated Film Festival (cinema)*. Finally, several performances, conferences and theatre shows also take place occasionally within the Museum.

Survey implementation

The implementation of the survey data collected by questionnaire was held at the Fado Museum and the Puppets Museum in a pre-defined one year period (July 2012 to June 2013), after a pre-test was previously conducted in June 2012. All interviews were conducted face to face by a team of interviewers, following a proportional quota sampling, which is a non-probabilistic technique used to ensure equal representation of visitors in each group.

The questionnaire was held in several languages (Portuguese, English, Spanish and French, depending on the language spoken by the respondent) and situations (when entering the event, during, or when leaving), covering a variety of days and times of the week depending on the programme of activities and events being held at each venue.

A proportional quota sampling method was used to recruit museum visitors, with quotas based on the events' categories defined by the Fado Museum and the Puppets Museum. By applying a quota sampling method where the sample is not chosen using random selection, it becomes impossible to determine the possible sampling error. In addition, it is also not possible to make statistical inferences from the sample to the population. Therefore, as usually

⁹⁹ Although students/children are a considerable part of the museum's audience, visitors that took part in any educational activities were not targeted by this study, due to the fact that it was centered on people that visited the museum voluntarily, i.e. not part of organized groups. This exclusive approach was also adopted in all other surveyed EGEAC's venues and events, including the Fado Museum.

done in this kind of studies, we can't generalize the results and conclusions for the total number of visitors of the two museums.

Sample Design

The control variables underlying the definition of quotas are the events' categories defined by the Fado Museum and the Puppets Museum, which consist of permanent collection, temporary exhibitions and other events (Table 4.1 in Annex IV presents the events included in each of these categories).

In order to calculate the sample size, it was assumed a dispersion of 0.16 for the characteristics of the universe being studied, a 95% confidence level and a sampling error of 3.8%. Considering the Fado Museum population of 49385 visitors, a sample of 423 visitors was obtained. The sample distribution is proportional to the weight of each category previously mentioned within the universe of the Fado Museum public. After collecting the information, we accomplished a sample of 545 subjects and therefore the sampling error decreased to 3.34%. Considering the Puppets Museum population of 12308 visitors, a sample of 411 visitors was obtained. The sample distribution is proportional to the weight of each category previously mentioned within the universe of the Puppets Museum public. After collecting the information, we accomplished a sample of 404 subjects and therefore the sampling error increased to 3.83%.

Distribution of the sample by quotas by event category	FADO MUSEUM				PUPPETS MUSEUM			
	Permanent Collection	Temporary Exhibitions	Other Events	TOTAL	Permanent Collection	Temporary Exhibitions	Other Events	TOTAL
VISITORS -POPULATION	34 117	4 144	11 124	49 385	7 712	2 580	2 016	12 308

Statistical Reliability

The purpose of this research is to understand whether there is a difference in average terms between the four main kinds of experiences in museum visiting practices, considering three different programming settings - *permanent collection*, *temporary exhibitions* and *other events*. Moreover, it seeks to identify and assess which of the visitors' socio-demographic characteristics and cultural habits mostly influence the identified four main types of museum experience. Each experience was considered the dependent variable, whilst each museum and each socio-demographic characteristic and cultural habit were the independent variables.

Although we are dealing with samples that were not chosen using random selection, which would not allow us to extrapolate the results to the Universe, the data were treated by a two-way ANOVA. The dependents variables are metric and the independent variables are categorical. However, real issues occurred when considering the asymmetric distribution of the variables, the absence of homoscedasticity between groups with unequal sample sizes and the absence of residuals normality. Therefore, the two-way ANOVA model was not suitable.

Thus, the following methods were applied: descriptive statistics, contingency tables with means and standard deviations of the dependent variables, bar graphics (dependent variables standardized with the Museum mean and standard-deviation) and boxplot.

4 Main Results

The main results that were achieved by carrying out a thorough analysis are systematized in this section. As stated before, our aim was to confront the 4 types of experience considered (intellectual experience; emotional experience; social experience; recreational experience) at the light of the following hypothetic relevant discriminant features: on the one hand some visitors' socio-demographic characteristics (e.g. age, gender, education level, nationality, artistic practices and professional status); and on the other hand, some indicators on cultural habits of visitors (social nature of visits, visits to other cultural venues and events).

For both museums, our operative framework for the analysis compared 3 categories of "cultural offers": (i) *permanent collection*, (ii) *temporary exhibitions*; (iii) *other events*. The basis of this analysis is the rating of the 4 kinds of experiences each targeted visitor had. By considering the answers to a specific museum experience question of the questionnaire (see operationalization of the experiment, on the figure presented at annex 1), this data was then crossed

with all the potential discriminant features, which were in turn provided by answers given in accordance to several other questions of the same questionnaire.

Global general results

Global comparative analysis, without the consideration of discriminant variables can be consulted on figure 2. Some of the main features of the analysis can be outlined as follows.

All 4 kinds of experiences picked up high marks in all the cases considered (3 types of events in each museum). As such, they show small distinctions among them, with scores mostly concentrated at the top of scale (4-5), and with means between 3.2 and 4.3. The overall results show just one outlier: the social experience on temporary exhibitions on Fado Museum, which was rated 2.76. Despite differences not being too relevant in general, it is still worth to perform a more in-depth analysis in the next section.

Fado Museum has more variability of results than the Puppets Museum. It is particularly noticeable when considering the *Temporary Exhibitions* in Fado Museum, which recurrently reports lower scores. This can be explained by the fact that these exhibitions are held outside the premises of the museum, in central touristic places, thus attracting less frequent audiences.

The *emotional* experience is generally the most valued kind of experience, with the exception of the Puppets Museum's *Permanent Collection* and the *Temporary Exhibitions* at the Fado Museum, where the *fun* experience overrates it. *Fun* and *intellectual* experiences (with diverse patterns) are usually the 2nd and 3rd most rated kinds of experiences, within the different kinds of events, on both museums. The *social* experience is regularly the one that is considered the least important, with lower mean scores.

As far as the *intellectual* experience is concerned, the results reveal a dichotomy: although it scored higher marks in the Fado Museum's *permanent collection* and *other events*, in the Puppets Museum, however, the high scores were registered on the *Temporary Exhibitions*, which can be explained perhaps by the exceptional quality of their contents.

The *emotional* experience is consistently more prized on the Puppets Museum than in the Fado Museum, which can be eventually seen as relatively natural due to the nature of the collection and exhibitory devices of each museum (although this can be arguable).

Although the *social* experience is, as mentioned, the less valued experience on both museums, its importance differs considerably when it comes to the *Temporary Exhibitions*: it rates as the worst experience in the Fado Museum (2.79), but improves to a much better (3.4) average on the Puppets Museum.

Lastly, the *fun* experience seems consistently more cherished on the Puppets Museum too.

The next sub-sections will examine the results of our specific analysis, in order to try and find significant differences considering the several discriminant variables. It should be noted that many other variables dealt with in the survey could be used in a similar analysis (e.g. professional status, expressed motivations for the visit, recurrence of the visit), but they are not to be taken into account in the specific scope of this paper, bearing in mind its particular conceptual framework. However, some of them were yet tested, without convincing results. A full analysis of these crossings can be developed in future opportunities.

Figure 2. Degree of importance of each kind of experience assigned to the event, by event category (Global Results) (from min=1 to max=5).

Degree of importance assigned to the event	FADO AND PUPPETS MUSEUMS			FADO MUSEUM									PUPPETS MUSEUM								
				Permanent Collection			Temporary Exhibitions			Other Events			Permanent Collection			Temporary Exhibitions			Other Events		
	Nº	Mean	Standard-deviation	Nº	Mean	Standard-deviation	Nº	Mean	Standard-deviation	Nº	Mean	Standard-deviation	Nº	Mean	Standard-deviation	Nº	Mean	Standard-deviation	Nº	Mean	Standard-deviation
Learning (intellectual experience)	921	3,90	0,85	327	3,98	0,79	79	3,39	0,97	120	3,97	0,93	214	3,88	0,86	93	4,09	0,75	88	3,85	0,78
Emotional (emotional experience)	923	4,07	0,89	325	4,01	0,95	79	3,57	1,01	122	4,24	0,81	215	4,08	0,84	93	4,20	0,82	89	4,34	0,67

Orange shading - the average importance given to the events in this age group is different from others

Crossings with socio-demographic variables

- Gender

Crossing results between the importance assigned by visitors to each kind of experience (by event category, in both museums) and gender can be observed on the tables and figures presented on section II.1, on Annex II. The differences registered between male and female genders are not very relevant. Some slight differences do exist in particular cases (e.g. women rate *learning*, *emotional* and *fun* experiences higher than males on *other events* in the Fado Museum), which could be more related to programming and sampling issues than to specific gender traits. *Social* experience data shows slightly greater differences (particular in temporary exhibitions), as male results are more expressive in several types of events. Overall, the Puppets Museum displays less consistent gender differences than the Fado Museum, as far as the assessment of the experiences are concerned.

- Age

Crossing results between the importance assigned by visitors to each kind of experience (by event category, in both museums) and age can be observed on the tables and figures presented on section II.2, on Annex II. Again, the results are quite similar and not very striking. The pattern of results between age groups seems to be not very diverse, and when differentiated, they seem to be related to each specific type of event, which in turn, influences in a consistent way the different kinds of experiences. In effect, just three things can be outlined: (i) the *temporary exhibitions* in Fado Museum represent (again) an exception (with progressive relative valuations with age); (ii) extreme age groups (younger and older) show higher evaluation standards across the board concerning the Puppets Museum; (iii) the *social* experience, at large, once again, registers more fluid and diversified results (by age) for the different kinds of experiences.

- Education level

Crossing results between the importance assigned by visitors to each kind of experience (by event category, in both museums) and educational level can be observed on the tables and figures presented on section II.3, on Annex II. Once more, the results are not significantly diverse amongst the different educational level groups. Although we could expect, based on the literature review, that educated groups (with higher cultural capital, by proxy) would highly value the *learning* experience, these differences were not consistently found, as this type of experience seems to be homogeneously acknowledged across educational levels. On the other hand, as expected, *emotional* and *fun* experiences assessments seem to consistently decrease as the level of education rises. Lower levels of qualifications declare consistently higher levels of assessments for these kinds of experiences, particularly on the Puppets Museum. The *social experience* (across the board) and *temporary exhibitions* (especially the Fado Museum's ones), once more, revealed more inconsistent and disperse results.

- Nationality

Crossing results between the importance assigned by visitors to each kind of experience (by event category, in both museums) and nationality can be observed on the tables and figures presented on section II.4, on Annex II. This could be an interesting distinctive indicator, as tourist audiences are considerably large in both museums and are one of the most discriminant variables in many of the other survey questions. However, the results are not conclusive at all, with very similar patterns amongst Portuguese and foreign visitants, concerning their valuation of experiences. With the exception of some sporadic cases (probably related to sampling issues), such as the higher assessment of *fun* on the Puppets Museum's *other events*, there are no consistent differences. Once more, only on the Fado Museum's *temporary exhibitions* is the average importance given to the events by the two groups more different.

- Place of Permanent Residency

Crossing results between the importance assigned by visitors to each kind of experience (by event category, in both museums) and place of permanent residency can be observed on the tables and figures presented on section II.5, on Annex II. This indicator complemented the previous one by distinguishing tourist audiences from the people residing in the city of Lisbon and its suburban areas. Once again, the results are not distinctive at all, showing very similar patterns amongst the 3 groups of visitants, concerning their valuation of experiences. Only the Fado Museum's *temporary exhibitions* seem to, more than often enough, present more distinctive patterns. This fact may be related to the specific features of these audiences, since they were surveyed outside the conventional museum space, and are therefore, presumably, less likely to be the usual Fado Museum public.

- Artistic practices

Crossing results between the importance assigned by visitors to each kind of experience (by event category, in both museums) and previous contact with artistic practices can be observed on the tables and figures presented on section II.6, on Annex II. It could be assumed that people with previous regular personal contact with artistic practices (people

who have studied, practiced or have been engaged in any form of artistic activity during their lives) would have more distinct assessments regarding their experiences, than other subjects questioned. However, again, differences are not quite substantial at all. On the Fado Museum, “*non-artistic*” subjects have slightly greater *fun*, *social* and *emotional* experiences, particularly on *other events*, whilst they rate worse the learning experience in *temporary exhibitions*. On the Puppets Museum, people with artistic backgrounds seem to slightly overrate *learning* and *emotional* experiences, whilst “*non-experts*” slightly overrate *social* and *fun experiences*, comparatively.

Crossing with cultural habits of visitors

- Social nature of visits (accompanied or not)

Crossing results between the importance assigned by visitors to each kind of experience (by event category, in both museums) and the fact of being accompanied or not during the visit can be observed on the tables and figures presented on section III.1, on Annex III. These results are a little more enlightening than most of the previous ones, although once more, they display differences that cannot be considered very relevant. In effect, naturally, visitors tend to highly value the *social* experience when people are accompanied, in all types of events. A similar increase occurs regarding the *fun* experience, but solely in the case of *other events* on the Fado Museum. In contrast, *fun* experiences decrease in the Puppets Museum’s *temporary exhibitions*, when accompanied. Results on the *emotional* experience are not too consistent either: whilst in the Puppets Museum there are no significant differences, in the case of the Fado Museum, results seem to improve when people are alone, in both kind of exhibitions, but worsen, when alone in the *other events*. Finally, the *intellectual experience* tends to be, in most cases, a little bit more valued if people visit alone.

- Visits to other cultural venues and events

Crossing results between the importance assigned by visitors to each kind of experience (by event category, in both museums) and the cultural place(s) most frequently cited as the most important in Lisbon (used as proxy of visiting other venues) can be observed on the tables and figures presented on section III.2, on Annex III. These results are not very easy to assess, as it concerns an open multiple answer question (here we just reproduced the most popular ones in each case) and the variable seems not to have a considerable discriminant capacity. There are no clear patterns that can be easily defined by these results. However, an interesting result worth mentioning is that two most universally cited cultural places (Centro Cultural de Belem and Fundação Calouste Gulbenkian) seem to present more distinct evaluations from the rest, as far as the *intellectual* experience is concerned. The difference between people that rated other (less cited) cultural places and the two above mentioned venues, seems to be bigger in the *intellectual* experience, which may indicate the existence of specialized audiences with more discriminant capacity.

5 Conclusions

This paper intended to examine and analyse the audiences of two particular museums in the city of Lisbon, Portugal (Fado Museum and Puppets Museum), by correlating the assessment of the quality of each visitor’s individual experience, with some of its socio-demographic characteristics, motivations and cultural habits. Four types of visiting experiences were considered on this study: (i) *learning* (intellectual experience); (ii) *emotional* (emotional experience), *social* (social experience) and *fun* (recreational experience).

Our purpose was to empirically test some of the most spread conceptual developments on museum audiences, which made us expect that the various types of experiences considered would vary significantly in response to the different kinds of events that took place in each different museum. To see which features would mostly influence visitors’ experience and why, we took into account not only the socio-demographic characteristics of those visitors (gender, age, educational level, nationality, local of residency, and previous artistic practice), but also their motivations and cultural habits (social nature of visits - accompanied or not; and visits to other cultural venues and events).

However, the differences that were found are much less visible than what we expected, considering the literature. In fact, all museum experiences are generally very well rated and so the differences in numbers are quite narrow. In addition, is it especially striking that the average grades are not even transversally consistent amongst the categories analyzed. As such, the discriminant variables were not so discriminant as we anticipated.

Some of the outcome results may even represent significant challenges towards some conceptual approaches on museum audiences. For instance, the low variability of the intellectual experience’s rating in regard to cultural capital (measured by the educational level) contradicts a somewhat commonplace expectation that higher educated visitors expect foremost an intellectual experience within museums. Many assumptions could be made as to why this is so, either because people, regardless of their cultural capital, feel compelled to say what they think might be the most *correct and socially approving* answer and/or because museums are in fact changing and being less elitist in their nature and approach towards the public.

On the other hand, however, as expected, visitors with lower educational levels seem to value more fun and social linked experiences. As reasoned, even these examples, shaped by the particularities of specific events and settings, express very slight differences, and so we have yet to further explore many other links and meanings and try to shed some more light into the matter in future museum experience research work.

As far as the differences between the 3 types of events or programming settings are concerned, they are more expressive and relevant in the Fado Museum than in the Puppets Museum, which present to be more homogeneous. Fado Museum shows more distinct results not only because events are more diverse in nature (including concerts, openings, guided visits, inside and outside the museum facilities), but also especially because temporary exhibitions were held outside the museum in other Lisbon's cultural locations and thus more keen to attract tourists or occasional visitors. These factors are likely to have been the main reason why visitors rated their experience slightly more unevenly, rather than because of the contents of the events themselves.

In terms of policy and action-oriented principles, these results make us aware of the need to deepen our audiences' analysis, making clear that we should progress towards the disentanglement of these "black boxes" in their functioning and to be a little more doubtful on some apparent long-term consensus on these audiences' mechanisms.

Innovation in Brazilian landfills: A ServPPIN perspective¹⁰⁰

Silvia Cruz¹, Sônia Paulino², Faiz Gallouj³

¹State University of Campinas, ²University of São Paulo, ³University of Science and Technology (Lille1)

This paper is devoted to the discussion of public services innovation in the Brazilian municipal solid waste sector, with emphasis on multi-agent participation within Clean Development Mechanisms (CDM) projects. The empirical context is based on six landfill CDM projects located in the São Paulo Metropolitan Area, Brazil. CDM projects have a dual purpose: reducing GHG emissions and promoting local sustainable development in host countries – through the promotion of local co-benefits. The discussion is based on the analytical model provided by the ServPPIN concept (public-private innovation networks in services). It focuses on the characterization of the landfills selected and on the identification of the stakeholders involved within these landfills, pointing out the participation gaps. The results indicate that the participation of associations and cooperatives surrounding landfills is still marginal. Pulling this theoretical (ServPPIN) and empirical research (landfill CDM project) together, one can identify the main factors affecting the establishment of basic conditions for service innovation: a) interactions and the building of social relations aimed at innovation among various stakeholders; b) the development of competences on several fronts; especially relational and organizational; c) the role of the public sector (mainly the coordination role) in supporting the development of successful public-private innovation networks in services.

Keywords: ServPPIN; public service innovation; clean development mechanism; solid waste sector; landfill.

1 Introduction

This paper is devoted to the discussion of public services innovation in the Brazilian municipal solid waste sector, with emphasis on multi-agent participation within Clean Development Mechanisms (CDM) projects. The empirical context is based on six landfill CDM projects located in the São Paulo Metropolitan Area, Brazil. It comprises 39 municipalities, and approximately 20 million inhabitants, generating around 16 thousand tonnes of solid waste per day (Cetesb, 2013).

The discussion is based on the analytical model provided by the ServPPIN concept (public-private innovation networks in services) (Gallouj and Weinstein, 1997; Bučar et al., 2013; Djellal and Gallouj, 2013; Gallouj et al., 2013; Labarthe et al., 2013). Beyond the relational aspect (interfaces and feedbacks) among various public and private actors, the ServPPIN concept emphasizes third sector organizations' (associations, NGOs etc.) participation in different ways. It highlights the important institutional and regulatory role of the public sector, decisive in the success and sustainability of the network; and it points out the importance of non-technological innovation.

CDMs encompass activities aimed at reducing greenhouse gas (GHG) emissions by establishing projects across a wide range of sectors, including landfill sites. In line with article 12 of the Kyoto Protocol, these projects must also contribute to promoting sustainable development in their host countries, through the establishment of local social and environmental co-benefits. Although the CDM projects have a dual purpose (reducing GHG emissions and promoting local sustainable development in host countries – through the promotion of local co-benefits), the United Nations Framework Convention on Climate Change (UNFCCC) does not establish indicators to evaluate social and environmental co-benefits.

According to the Marrakech Accords (Decision 17/CP. 7) the responsibility for determining whether a CDM project activity contributes to sustainable development is defined by the host country and resides with its Designated National Authority (DNA) (UNFCCC, 2001). The Letter of Approval (LoA), a document which confirms that the project contributes to the sustainable development of a particular country, is issued by the DNA and is exclusively based on the objectives of local contributions to sustainable development, as set out by the proponents of the project.

In Brazil, the specifications of a project in order to promote local sustainable development are based on information from Annex III of Resolution n.1 of the Inter-Ministerial Commission on Global Climate Change¹⁰¹. This establishes both the benefits to the local area and how project activities contribute to each of the following aspects: environmental sustainability; improvement in working conditions and net job creation; income distribution; training and technological development; and finally, regional integration and working in conjunction with other sectors (Brazil, 2003). However, analyzes performed on the promotion of local development, based on the CDM projects in the solid waste sector, indicate that most of the projects do not contribute significantly to the achievement of local sustainability (Sutter;

¹⁰⁰This work was supported by Grant 2011/00081-5, São Paulo Research Foundation (FAPESP); CAPES Foundation/Ministry of Education of Brazil; and Centre Lillois d'Études et de Recherches Sociologiques et Économiques (CLERSÉ).

¹⁰¹ Inter-Ministerial Commission on Global Climate Change is the Designated National Authority (DNA) in Brazil.

Parreño, 2007; Siebel et al., 2013). In this direction, the importance of civil society's effective participation throughout the approval process of a CDM project is noticeable.

CDM projects are not implemented with the explicit goal of promoting service innovation; however, these projects can create leverage and open new possibilities to improve services related to urban solid waste, converging with the National Policy on Solid Waste (Brazilian law nº 12,305/2010) requirements and social and environmental co-benefits generation from carbon market projects.

In this manner, there is need for the development of activities which focus on the steps for generation and treatment of solid waste, preceding the final disposal of waste, searching for alternatives to reduce the generation of waste, encouraging actions for reuse, recycling, and treatment.

Besides these, landfill CDM projects can improve management practice during the operation of landfills (air pollution, groundwater contamination, biogas management, visual, freight vehicle access arrangements, etc) as well as improve on activities carried out after landfill closure, in order to fulfil with the closure plan of the landfill area (maintenance of the vegetation, landfill cover system etc.).

Activities carried out in the projects developed in landfills involve various agents: concession-holders responsible for managing the landfill and capturing landfill gas (LFG); municipal departments; and representatives of associations from the communities surrounding the landfills. The importance of civil society's effective participation throughout the approval process of a CDM project cannot be overstated. Indeed, project proponents should send letters of invitation to all project stakeholders. The following agents should be considered in the case of Brazil: local authorities and chamber of deputies for all municipalities involved; municipal and state environmental departments; NGOs and social movement forums; community associations both directly and indirectly involved in project activities; and State and Federal Public Prosecution Offices.

In this context, this paper intends to analyze how the promotion of local co-benefits is linked to the promotion of innovation in urban solid waste services, emphasizing the participation of civil society, highlighted in the Kyoto Protocol and in the ServPPIN concept. The paper is structured into four sections. Following the introduction, section 2 discusses the public services through the ServPPIN concept¹⁰², focusing on the multi-faceted and heterogeneous nature of the public sector and on the role of the civil society in innovation in public services. Section 3 is devoted to the presentation of empirical cases, focusing on the characterization of the landfills selected and on the identification of the stakeholder involved with these landfills, pointing out participation gaps, taking into account the following criteria: consultation, benefits, and interaction/interface. Our conclusions are set out in section 4.

2 ServPPIN concept and the role of the civil society in innovation in public services

The purpose of this section is to present: 1) specific characteristics of public sector and public service innovation; 2) the concept of public-private innovation networks (ServPPIN), highlighting the importance of multiple links and feedbacks between the public and private sectors, and also with service users and; 3) the role that third sector organizations/end users (citizens) have to play in the ServPPIN context.

Innovation in Public Services

There is an increasing scientific literature on innovation in the public sector. However, the literature generally neglects or underestimates the role of the public sector in the innovation process (Djellal et al., 2013; Windrum; García-Goñi, 2008; Brandão; Bruno-Faria, 2013; Osborne; Brown, 2013).

The public sector is often portrayed as a facilitator of innovation activities, merely drafting the legal framework, among other actions which do not include a leading role in the innovation process (Gallouj; Weinstein, 1997; Mulgan; Albury, 2003; Hartley, 2005; Halvorsen et al. 2005; Koch; Hauknes, 2005; Windrum; García-Goñi, 2008; Potts; Kastle, 2010; Fuglsang, 2010; Sundbo, 2013; Djellal; Gallouj, 2013; Djellal et al. 2013; Osborne; Brown, 2013).

Although the idea has long been prevalent that public services are produced, predominantly, by the public sector, more recently there is improved clarity that public service provision generally involves a more complex and broad range of actors and institutions: public services can be provided by public actors, private actors, or both (Di Meglio, 2013). In this manner, systematic efforts will be required to foster innovation in the public sector (Bloch; Bugge, 2013), and, therefore, in public services.

Djellal and Gallouj (2012) highlight the importance of public services according to the output produced by these services, which can be called social or civic outputs. According to the authors "These 'outputs' contribute to social cohesion, solidarity and collective and civic identity" (p. 11).

Another aspect of public service provision is the difficulty of identifying and demarcating activities that should be attributed to the public sector as opposed to the private sector, as many services and activities in the public sector are integrated with the activities of the private sector and vice versa (Bugge et al., 2010; Potts; Kastle, 2010). This aspect is observed also for services related to municipal solid waste that generally is carried out through concessions to the private sector.

¹⁰² This concept was developed in the ServPPIN project funded by the European Commission. The main results of that project are published in Gallouj, Rubalcaba and Windrum (2013).

According to Bugge et al (2010) and Bloch and Bugge (2013) the multi-faceted and heterogeneous nature of the public sector is a result of the multiple interfaces which characterize public organizations: 1) the interface with the private sector; 2) the interface between the public sector and citizens; and 3) the internal interfaces within the public sector (between government levels and between different areas of activity). These various interfaces, illustrate public sector heterogeneity, and also the permeability between organizations (private, public, and third sector) (Gallouj et al.,2013).

Having outlined the characteristics of multiple interfaces and heterogeneity of the public sector, the public-private innovation networks in services (ServPPIN) concept can be useful in understanding the logic of public service innovation.

Public-Private Innovation Networks in Services (ServPPIN)

One of the factors encouraging interest in examining Public-Private Innovation Networks is the growing recognition of the important role played by public sector organisations in the innovation process. Public administrations are thus no longer restricted to playing a supporting role in the innovation process. They may be active participants in that process, particularly insofar as their own activity is concerned.

Just like public-private partnerships (PPPs), ServPPINs are networks of collaborative partnerships between public and private organizations. However they are more comprehensive, open and flexible than traditional PPPs, which entail relations between actors that are more rigid, with predefined functions, rules and formal procedures (particularly contracts) that can bureaucratize the process, and limit the potential for innovation.

The high number, and diversity, of participants in a ServPPIN can lead to a complex and intensive process of interaction in which a large amount of heterogeneous information and knowledge (tacit and non-tacit) are likely to be exchanged, since plenty of channels are opened for interaction. In other words, ServPPIN can be thought of as a multi-agent service relationship system (Djellal and Gallouj, 2013).

The innovation network¹⁰³ concept is biased towards manufacturing and technology. This concept, in the traditional sense, suffers from a certain number of shortcomings; namely: a technology bias (with largely predominance of tangible technological innovation), a manufacturing bias (linked to the previous one), and a market bias (the private sector is central to innovation dynamics). This means in short that innovation networks are mainly focused on technological innovation produced by the collaboration of private actors in the manufacturing sector.

The ServPPIN concept provides a way of overcoming these various biases (Djellal and Gallouj 2013; Gallouj et al., 2013; Labarthe et al. 2013, Windrum, 2013). It goes beyond the technologist view of innovation¹⁰⁴. Its perspective is broader, incorporating non-technological types of innovation such as: organizational, ad hoc (defined by Gallouj and Weinstein [1997] as the interactive solution to the specific problems of particular clients), social, and bricolage innovation (defined as innovation through non-programmed activities, trial-and-error processes and adaptation to random events – [Fuglsang, 2010]).

Through the ServPPIN concept, Gallouj et al (2013) emphasize the importance of multiple links and feedbacks (interfaces) between public and private sector, and also with users – in our case, representatives of associations from the communities' surrounding landfills – and policy makers for service innovation. As pointed out by Djellal and Gallouj (2013):

ServPPINs are multi-agent service relationship systems. The actors involved in interaction have to deal with the ill-defined nature of their respective products, their non-stockability, a diversity of systems of interaction, the multiplicity of possibly competing value systems and the fact that their products are located in different spatial and temporal scales. ServPPINs introduce the traditional research questions of service economics into network-based analyses of innovation. (Djellal and Gallouj, 2013 p. 30. highlighted by the authors).

According to Bučar et al. (2013), ServPPINs can be understood as a place for social interaction and the construction of social relations aimed at innovation. Nevertheless, of all case studies provided by the ServPPIN research project¹⁰⁵, several were not explicitly oriented towards the innovation target. For example, in some hospital case studies the main objective was to reduce costs in the use of technologies.

Similarly the CDM landfill projects we examined were implemented in order to reduce GHG emissions, rather than having the explicit goal of promoting service innovation. In fact, the technology and innovation outcomes appear to be additional results of the local co-benefits generation. Interesting changes and innovations are likely to arise out of such networks – which can then be retrospectively labelled 'innovation networks'. Taking into account non-technological,

¹⁰³ Innovation networks and systems have been the subject of an extensive literature in economics, sociology and management (Callon, 1992; Edquist, 1997; Latour, 1999; Lundvall, 1992; Nelson, 1993 among others).

¹⁰⁴ The technology issue is taken into account in the designs of the carbon market projects and regarding the promotion of social and environmental local co-benefits, in the cases studied, all Project Design Documents (PDD) and Validation Reports indicate the development and diffusion of technologies through the project's implementation, highlighting the following aspects: training, technology development and transfer.

¹⁰⁵ ServPPIN is an EU-funded research project which focuses on the role of public and private services on growth and welfare and the particular role of public-private innovation networks. For more information: <http://www.servppin.com/>. The main results of the project are also published in Gallouj, Rubalcaba and Windrum (2013).

incremental and non-programmed innovations (ad hoc, *bricolage*, rapid application etc.) it is also possible to consider even those networks which are not explicitly (or immediately) oriented towards innovation to be ServPPINs.

The ServPPIN contributes to opening up the traditional innovation network concept to new actors: all market services, as well as third-sector organisations (NGOs, associations etc.). It extends potential forms of participation for certain actors, for example, the involvement of civil society in the decision-making and consultation processes. This is particularly the case with regards to the role civil society plays in the ServPPIN context – helping to translate social preferences which are not merely reflected by market prices (Fuglsang, 2013).

Public Service Users and Their Involvement in Service Innovation

The innovation process involves several players who contribute in different ways in the development of service innovations. In this sense, the involvement of customers/service users as ‘partners’ in the process of service innovation development is highlighted, which can be achieved through dialogue with service users, joint experimentation, panels and other communication tools (Hertog et al; 2010). It is noteworthy in recent years that the participatory governance mechanisms have been widely promoted in developing countries (Speer, 2012). These mechanisms seek to involve citizens in decision-making regarding the allocation of public resources among communities, shaping public policy, as well as involvement in the monitoring and evaluation of government expenditure.

According to Speer (2012), one of the key reasons cited for participatory governance mechanism implementation is related to the improvement of public services. Given that when citizens are empowered and democracy strengthened there is a tendency to an increase in local government responsiveness and accountability. This process tends to improve the efficiency and sustainability of public service delivery, since it might have the ability to match public services to user preference.

Participatory governance mechanisms can improve information flows in two ways: from citizens to governments about citizen preferences/demands; and from governments to citizens about government decisions and actions, as well as about service provision outcomes.

Lehtonen and Tuominen (2013) emphasize the collective preferences of citizenship, with a broader vision of the citizen, not only as a public service receptor, but also active in the production, control and planning of these activities. The authors note that active dialogue is required to negotiate and mediate under different citizen preferences. In this context, the relevance of user integration in the service innovation process it is brought to attention.

However, ServPPIN research Project results (Gallouj et al., 2013) show the limitation of the third sector organizations’ participation and that the involvement of service end users (citizens) is marginal. Thus, especially regarding to the role that civil society has to play in ServPPIN – assisting in the translation of social preferences – there is a need to empower public users in order to foster successful cooperation.

Schilling (2011) points out that improvements in cooperation among the agents is coupled with the need to manage knowledge from different sources for successful service innovation, and also requires the capacity to sustain a constant flow of communication between the many agents (Green et al., 2013), which can be achieved through the establishment of routines and communication channels¹⁰⁶. The important role of information technology in the communication and processing of information in the service innovation process is also emphasized (Di Meglio, 2013).

Thus, to analyze the participation as well as the role of civil society in public-private service innovation networks it is important to sustain an adequate standard of public services, taking into account the quality of service and social needs, particularly with regards to municipal solid waste services from the case of landfills with CDM projects.

In order to explore participation in the empirical context studied, as well as proposed by Labarthe et al (2013), the end-users are not individual users that are integrated within the networks. It is rather some collective organizations representing them (here representatives of associations from the communities surrounding landfills), which are members of the ServPPINs, as presented in the empirical results section.

3 Empirical results: the Brazilian landfill CDM projects

Of the 325 Brazilian CDM projects registered, 50 are developed on landfills, 23 of which are located in the State of São Paulo (UnepRisoe, August 2014). Our research focuses on the São Paulo Metropolitan Area, which is one of the five largest urban conurbations in the world, and the largest in Brazil, with the city of São Paulo as the main nucleus. It comprises 39 municipalities with, approximately, 20 million inhabitants, 55.4% in the city (municipality) of São Paulo.

The landfills for the empirical research were selected on the basis of the following criteria: a) carbon market Brazilian projects: regulated and voluntary carbon market; b) projects scope: landfill projects; c) Localization: São Paulo Metropolitan Area; d) Methodology used to measure GHG emission reduction: ACM0001 – flaring or use of landfill gas; e) Monitoring period verified: with at least one monitoring period verified until the beginning of the empirical research (February, 2014). Through the prior criteria mentioned, the landfills selected are: Bandeirantes, São João, Caieiras, Itapevi, Pedreira, and Lara.

¹⁰⁶ In the majority of ServPPINs cases analyzed by Djellal and Gallouj (2013) it is clear that organizational innovations are related to better sharing of information, establishment of communication channels, etc. Examples: Capacity Planning (UK) – in the health sector; ITS Vienna Region (AT1), DoRIS (AT3), VIATIC (FR1), and Compano (AT2) – in the transport sector.

The data on the CDM landfill projects, from 2003 to 2014, were obtained through documentary research in three databases: United Nations Environment Program (UNEP/WHO), and UNFCCC CDM Registry, for accessing monitoring reports and project design documents; and The Ministry of Science, Technology and Innovation (Ministério da Ciência e Tecnologia e Inovação- MCTI) database for accessing the project documentation, based on Annex III of Resolution No. 01/ 2003 of the Inter-ministerial Commission on Climate Change (CIMGC) (document that describes the promotion of social and environmental co-benefits).

Particularly for the analysis of the participation of associations, representatives of associations from the communities surrounding landfills, and recycling cooperatives, data were collected through semi-structured interviews organised into three categories to discuss opportunities for service innovations: consultation, benefits, and interface/interaction (Table 1).

Table 1. Categories and items addressed to discuss opportunities for service innovations.

Category	Items Addressed
Consultation	Participation before and after project implementation; public consultation (public audiences, surveys, questionnaires, workshops, visitation, panels); PDD comments; language and clarity of documents; language used; community engagement
Benefits	Cooperatives benefiting from CDM revenues; contributions of CDM projects to environmental education programs
Interaction/Interface	Proposed meetings; disclosure of the annex III activities to stakeholders; channels for recording complaints; the coordination role achieved by the public sector

Source: The authors

The interviews were conducted, in the first semester of 2014, with 4 associations and 3 waste-picker cooperatives engaged in the solid waste issue.

3.1 Stakeholders Participation under the Carbon Market Projects

With regards to participation, specifically for carbon market projects, the CDM Executive Board requires stakeholders' participation in the whole process of the activity development, fulfilling: 1) Project proponents should send letters of invitation to all project stakeholders; 2) Summary of information should be presented by the stakeholders; 3) Confirmation by the host country that the project assists in the achievement of sustainable development; 4) Report made of DNA justifying how the comments provided were taken into account.

The project information must be available in an appropriate manner, ensuring data accessibility, in a language and framework that can be understood by all stakeholders.

Even though stakeholder participation is explicitly considered by the CDM Executive Board, the process is still considered insufficient, in terms of contemplation of the actors, and in terms of measuring participation throughout the project cycle.

The participation of stakeholders in CDM projects has been widely challenged at the international level also (CAN, 2011; CDM WATCH, 2010; Foronda et al., 2010; Subbarao; Lloyd, 2011; Kolmuss, 2012) indicating that there is still a gulf to be breached, due to the intense asymmetrical information among stakeholders and the lack of a clear understanding about how the resources from the sale of Certified Emission Reductions (CERs) should be applied, added to the unpreparedness of public bodies to clarify questions regarding the carbon market. Table 2 shows some elements related to public consultation, openness and transparency of information to support improvements in the participation of stakeholders.

Table 2. Elements for stakeholder participation in carbon market projects.

Topic	Public Consultation	Openness and transparency of information
Elements	Quality and range of communication tools between the project proponent and stakeholders (public audiences, surveys, questionnaires, workshops, visitors, panels, among other); Quality and range of publicity needed to achieve stakeholders; Frequency and timing; Period for Consultation; Place and time selected	Anticipation in the disclosure; means of divulgation; accessibility of language and language used

Source: based on Monzoni (2004) and CDM Watch¹⁰⁷ (2010).

¹⁰⁷ The CDM Watch is an organization created in 2009 with the purpose of supervising the actions performed under the CDM, particularly aimed at strengthening civil society participation processes.

In 2011, through public consultation, the United Nations Framework Convention on Climate Change (UNFCCC) conducted a study aiming to contribute towards the inclusion of different actors in CDM projects. The key findings of the public consultation were:

- The comments of the stakeholders should be considered during the design of the project;
- The first meeting with the stakeholders should be taken prior to the submission of the PDD;
- Validation and verification of the project to ensure the required benefits; and
- The establishments of mechanisms for affected stakeholders to express their demands.

The elements outlined may contribute towards the fulfillment of the requirements related to the complete and effective involvement of communities surrounding landfills (and other stakeholders) on the project, through access to information and participation in the decision making process.

According to Decision 3/CMP.1 (Marrakech accords), UNFCCC defines stakeholders as: “the public, or any individuals, groups or communities affected or likely to be affected, by the proposed CDM project activities”. Therefore the Designated Operational Entity (EOD), independent audit, responsible for the validation and verification of projects, should revise the PDD and other relevant documents for the validation and verification of the project, in order to evaluate, beyond the technical issues, if the requirements outlined by the CDM executive board in relation to stakeholders’ participation¹⁰⁸ are being met.

3.2 Characterization of the landfills and identification of stakeholder

The characterization of the landfills selected for the empirical research is shown Table 3.

Table 3: Characterization of the landfills related to operation and CDM Project.

Landfill	Location (São Paulo Metropolitan Area)		Year of beginning landfill operation / closure	Landfill area (ha)	Public / Private landfill	Tons of waste / day	Project registration date on CDM Registry	Crediting period	Average tCO ₂ e / year*
Bandeirantes	São Paulo	District of Perus/ Zona Oeste	1979/ 2007	140	Public	5,000	20 Feb 06	1st: Sep 06 - Sep 13 2nd: Dec 10 - Dec 17	1,000,000
São João	São Paulo	District of São Mateus/ Zona Leste	1992/ 2009	84	Public	6,000	02 Jul 06	May 07 - May 14	800,000
Pedreira	São Paulo	District of Tremembé/ Zona Norte	2001	56,2	Private	1,200	12 Feb 08	Feb 08- Feb 15	185,000
Caieiras	Caieiras		2002	350	Private	7,000	09 Mar 06	Mar 06 - Mar 13	770,000
Itapevi	Itapevi		2003	20,5	Private	900	17 Aug 07	Aug 07 - Aug 14	90,000
Lara	Mauá		1987	30	Private	1,500	15 May 06	1st: Sep 06 - Sep 13 2nd: Dec 10 - Dec 1	750,000

Source: The authors

* These data are based on the preliminary modelled/projected emission reductions from the PDD

The PDD section named “Stakeholders consultation¹⁰⁹” was investigated for each landfill selected as an empirical case, in order to map the stakeholders. A weakness was verified in the PDD, particularly in relation to the actors considered as “potentially affected populations”, i.e, communities surrounding landfills.

In the PDD “Stakeholders consultation” section, the stakeholders representative of civil society largely cited was the Brazilian Forum of NGOs and Social Movements for the Environment and Development; in other words, although the Forum is widely recognized for actions and activities aimed at protecting the environment and promoting sustainable development, it is generally for the purpose of this research to consider it as a stakeholder.

Thus, specific information about representatives of associations from the communities surrounding landfills directly affected by the activities of the enterprises was researched beyond the project design documents and the UNFCCC website, as well as direct searches on *Google* being used (web search engine tool) with the keywords: landfills name; cooperatives; associations/communities surrounding landfills.

In addition, the following databases were checked:

¹⁰⁸ The requirements are: Project proponents should send letters of invitation to all project stakeholders; Summary of information presented by the stakeholders; Confirmation by the host country that the project assists in the achievement of sustainable development; Report of DNA justifying how the comments provided were taken into account.

¹⁰⁹ This section includes: A brief description of how comments by local stakeholders have been invited and compiled; a summary of the comments received; and a report on how due account was taken of any comments received.

- ✓ Recyclable material Cooperatives listing, available in the website Department of Environment of São Paulo State – SMA¹¹⁰;
- ✓ “Registration of civil society organizations – database of 2009-2011” listing, available in the integrated Water Resources Management System (SIGERH)¹¹¹, taking into account mainly the data related to the watershed committee of *Alto Tietê*, regarding the geographical area selected for study;
- ✓ Websites of the municipalities at Itapevi, Mauá, and Caieiras;
- ✓ Websites of the subdistricts São Mateus, Perus, and Tremembé (city of São Paulo);
- ✓ Minutes of public audiences related to carbon credits;
- ✓ FEMA (Environment and Sustainable Development Fund) and Confema (Special Fund for the Environment and Sustainable Development Council) resolutions related to CDM projects (in this case, only for Bandeirantes and São João CDM projects).

Figure 1 shows, specifically, the stakeholders’ mapping of the representatives of associations from the communities surrounding landfills.

Figure 1. Stakeholders’ Mapping – associations from the communities surrounding landfills
Source: The authors.

From this mapping (addressed previously in Figure 1), Table 4 shows the representatives of associations selected.

Table 4. Representatives of associations selected.

Landfill	Representatives of Associations	Description
Bandeirantes	Perus and Anhanguera Forum for local sustainable development	Founded in 2003 with the purpose of organizing the popular participation and demand improvements for the region of <i>Perus</i> .
São João	Chico Mendes Cooperative	Founded in 1999 with the purpose employment generation for people on low income in the East Zone of São Paulo
	More Life, Less Rubbish Campaign (<i>Campanha Mais Vida Menos Lixo</i>)	Initiative of the residents of <i>São Matheus</i> district that have mobilized against the bad odours and the possibility of accidents occurring due to the activities performed by the landfill

¹¹⁰ <www.ambiente.sp.gov.br>

¹¹¹ <www.sigrh.sp.gov.br>

Landfill	Representatives of Associations	Description
Caieiras	Pinheiros Philanthropic Association	Founded in 1993 with the purpose to assist the local residents of <i>Caieiras</i> region (around 450 families)
Pedreira	Cantareira Viva Cooperative	Founded in 2006 with the purpose to enable the selective waste collection, income generation, and stimulate improvements in <i>Vila Albertina</i> the region (a neighborhood in the <i>Jaçanã/Tremembé</i> district, São Paulo)
Itapevi	Itapevi Cooperative	Founded in 2003 supported by the Municipal Department of Environment. Currently with 20 registered cooperative members
Lara	Association of Literacy Movement for Youth and Adults (AMOVA)	Founded in 2002 in the city of <i>Mauá</i> ; is focused on providing housing to low income people, through partnerships with <i>Caixa Econômica Federal</i> (Brazilian bank) and the Ministry of Cities

Source: The authors.

For the public sector, stakeholders include the city halls and municipal sub districts, as well as the departments related to CDM projects issues. For the private sector, the stakeholders include the concession-holders responsible for landfill management in the case of public landfills, the company that owns the landfills in the case of private landfills; and the concession-holders responsible for biogas recovery and power generation.

3.3 Participation Gaps

The role and participation that civil society has to play in the ServPPIN – helping to translate social preferences – are fundamental to promote service innovation. Besides that, within the CDM projects context, participation is considered a core issue for the project to comply with the goal of promoting local sustainable development.

According to data collected from the representatives of civil society, the communities surrounding landfills lack information regarding the existence and operation of the CDM landfill projects; in addition there is no knowledge about local benefits promotion that the projects must perform. The major gaps identified are addressed in the following topic.

a) Consultation

The period designated for stakeholders to manifest their opinion about the project (30 days, set by UNFCCC) is considered inappropriate by the interviewees’ representatives of *Bandeirantes*, *São João*, and *Itapevi* landfills. The interviewees of the other landfills were unaware about the availability of documents related to the CDM projects to be accessed and commented on.

Other issues raised are related to: difficulties in obtaining documents in the UNFCCC and MCT&I online platforms; the lack of documents available in the native language; and the technical language used in the documents related to the projects. Without a common language, surrounding communities may remain unaware of any possible benefits arising out of project implementation. Furthermore, the establishment of a common language can improve exposure of the different interests at stake. The asymmetric information problem diminishes, or even hampers, an effective participation of the associations of residents surrounding landfills.

With the exception of the *Bandeirantes* and *São João* landfills, which both held public audiences and meetings, there is no information on the existence of meetings, workshops and other types of mechanisms to facilitate the participation at the other landfill sites. However, even in the *Bandeirantes* and *São João* landfills cases, it is emphasized that the respective communities suffer difficulties to voice their claims in an effective manner: the views of the municipality and the operating company’s technicians usually prevail.

It is thus necessary to develop the competence of the associations (from the communities surrounding the landfills) to discuss technical indicators about landfill operation and closure plans, as well as other alternatives for final waste disposal. There is a need on the part of technicians at the municipal departments, concession-holders, and CDM project developers to ensure that data communicated about CDM projects can be easily understood by the communities surrounding the landfills.

With regards to the PDD section named “Stakeholder consultation”, only the *Bandeirantes* landfill did not receive comments from stakeholders. For other landfills, the comments were generally performed by Municipal Departments of Environment, Public prosecution, and state and municipal environmental bodies.

Only the *Itapevi* landfill received comments from the Brazilian Forum of NGOs, pointing out the need for improvements in local stakeholder involvement and the importance of setting up transparency mechanisms related to the projects; and *Itapevi* Public Prosecution declaring that the PDD of the landfill was not submitted in a local consultation process. Therefore, it is observed that the comments received mostly do not regard the stakeholders as set

out by the Kyoto Protocol: individuals, groups or communities affected or likely to be affected, by the proposed CDM project activities.

b) Benefits

According to the preferences of representatives of civil society, the projects should contribute to reduce or to avoid negative externalities generated by landfills. That is, to reduce pollution; to reduce risks (related to the activities performed by landfills); to increase quality of life; to ensure cooperatives and environmental education programs benefit from the resources of CDM.

In the PDDs, only Caieiras and Lara landfills mentioned the proposition of future projects to be carried out from the CER resources. Despite this, the absence of means for monitoring/supervising, if these proposals are to be implemented, is brought to attention.

The cooperative of Itapevi, was awarded with equipment for compacting waste; and the Caieiras landfill transfers 1% of the CER resources (Candiani et al 2013) to the Municipal Social Fund to be invested in the areas of education, health and environment. For the other landfills, there is no information about cooperatives and associations that benefited with the resources of the projects. Specifically for Bandeirantes and São João landfills, problems of access to revenue from the sale of Certified Emission Reductions are noteworthy. The access to CER resources intended for FEMA¹¹² occurs through public tenders. However, sub-districts need to develop their competence in order to be able to publicize good quality projects and thus access revenue from the sale of carbon credits.

ServPPINs require increased flexibility from the public sector. Therefore, particularly in relation to the means for accessing the resources from CER (public tenders), it is recommendable to review the public tenders, adapting the requirements to the real situation of the cooperatives; to propose ways to support the cooperatives (i.e. action plans to capacitate the cooperatives to be able to design good quality projects and thus access the revenues from the sale of carbon credits); to prevent that bureaucratic issues hinder access to CER resources.

c) Interaction/Interface

While evaluating the existence of communication channels for receiving complaints, inquiries and comments from stakeholders, it is pointed out that there are no effective channels for participation of civil society associations and cooperatives surrounding landfills throughout the stages of the project cycle. Some of the complaints mentioned by the interviewees affected by the São João, Bandeirantes, Itapevi, and Caieiras landfills are related mainly to: the odor from the landfills; the misdirection of the resources derived from the sale of CERs; and the lack of benefits generated from the projects for the community. Moreover, it is observed that there is a need to publicize activities related to CDM projects and implement an effective communication channel that would improve discussions, negotiations and disclosure to the various stakeholders via public consultations and dialogue mechanisms.

Largely, the interactions are restricted to public audiences and meetings concerning the application of the resources from the sale of the carbon credits generated by Bandeirantes and São João CDM projects. At the other landfills, the interface is considered only by the availability of documents in the UNFCCC and MCT&I online platforms to receive stakeholders' comments about the projects. As highlighted by the ServPPIN concept, it is essential to empower the public sector and civil society for cooperation. In addition, it is important for the public sector to perform network coordination in an appropriate manner.

4 Conclusion

The ServPPIN concept highlights the importance of interaction/interface among public and private organizations and mainly, third sector organizations, for developing innovative services.

In this way, through the application of the ServPPIN concept, it was possible to identify and analyze the factors related to the establishment of fundamental conditions for public service innovation in the municipal solid waste sector through the implementation of landfill CDM projects.

For the analysis, the following variables were considered: consultation; benefits; interaction/interface.

- ✓ ***Regarding consultation***, the main gaps identified are related to the period for stakeholders to voice their opinion about the project – 30 days, as set out by UNFCCC, is considered inappropriate. Other issues raised are related to: difficulties in obtaining documents in the UNFCCC and MCT&I online platforms; the lack of documents available in the native language; and the technical language used in the documents related to the projects (generating asymmetric information). The comments pointed out in PDD section “Stakeholder consultation” in general, do not regard the stakeholders as set out by the Kyoto Protocol (individuals, groups or communities affected or likely to be affected, by the proposed CDM project activities).

¹¹² 50% of the revenues from the Certified Emissions Reductions (CER) of the Bandeirantes and São João landfills are allocated to municipal government, specifically to the Environment and Sustainable Development Fund – FEMA, which is administered by the Municipal Department for the Environment.

- ✓ **Regarding** the benefits provided by project implementation, the absence of means for monitoring/supervising is highlighted, if the proposals described in the documents related to the projects are to be implemented. Additionally, and specifically for Bandeirantes and São João landfills, problems are noteworthy of access to revenue from the sale of Certified Emission Reductions, which occurs through public tenders, and the need to develop competences is highlighted, in order to make the cooperatives able to design good quality projects and, thus, access the revenue from the sale of carbon credits.
- ✓ **Regarding** the interaction/interface, the absence of effective channels for receiving complaints, inquiries and comments from stakeholders and the need to publicize activities related to CDM projects throughout the whole crediting period are noteworthy. For the Bandeirantes and São João landfills, interactions are restricted to public audiences and meetings concerning the application of resources from the sale of carbon credits. For the other landfills, interface is only considered from the availability of the documents in the UNFCCC and MCT&I online platforms.

Overall, the results presented corroborate with the results shown in the international literature regarding stakeholder participation under the carbon market projects (CAN, 2011; CDM WATCH, 2010; Foronda et al., 2010; Subbarao; Lloyd, 2011; Kolmuss, 2012), and in the ServPPIN research Project results (Gallouj et al., 2013) pointing out that service end user (citizen) involvement is marginal.

ServPPINs enable potential complementarities and synergies to be explored in various modes of cooperation between public, private and civil society organizations. In this way, in the instances studied, it is essential to empower the public and private sectors and civil society. Besides this, it is important the public sector performs the coordination of the network in an appropriate way. The proactive role of the public sector as a network leader turns out to be a very important determinant of success in the CDM landfills cases, as instruments capable of contributing to public service innovation in the municipal solid waste sector.

Pulling this theoretical (ServPPIN) and empirical research (landfill CDM project) together, once can identify the main factors constraining and affecting the establishment of the basic conditions for service innovation. Based on the set of case-studies investigated, lessons have been drawn concerning:

- a) The interactions and the building of social relations aimed at innovation among various stakeholders involved
- b) The development of competence on several fronts, especially, relational and organizational
- c) The role of the public sector (mainly, the coordination role) in supporting the development of successful public-private innovation networks in services

Evidence on the role of user orientation for innovation and productivity in Finnish service firms

Matthias Deschryvere¹, Luis Rubalcaba²

(Draft version with preliminary results from August 2014, do not cite without permission of the authors)

¹VTT Technical Research Centre of Finland, Tekniikantiet 2, 02044 Espoo, Finland (corresponding author: matthias.deschryvere@vtt.fi)

²Department of Applied Economics, Faculty of Business and Economics, University of Alcalá, Plaza de Victoria 2, 28.802 Alcalá de Henares, Spain (luis.rubalcaba@uah.es) and VTT.

Acknowledging user needs as important for the success of the firm has been common practice both at innovation policy level and in academic literature. But empirical evidence on the role of user orientation for firm performance is still scant. This paper contributes to the empirical user innovation literature by analysing the role of user orientation for innovation and productivity at the firm level. Our unique dataset from Finland allows us to analyse how the intensity of user orientation affects the above complex innovation-productivity relationships following a CDM model. Our first results show differences between service firms and manufacturing firms. Only for service firms user orientation has a significant positive association with innovation output. But not any kind of user orientation is significant in services. Only combinations of user orientations and the intensity of user orientation matter: active user innovation is more relevant than passive user consideration. Despite significant impacts from services innovation on productivity, there are no direct significant impacts from user involvement.

Key words: services, innovation, productivity, user orientation, user innovation, interaction with customers, open innovation, CIS

Acknowledgment: This working paper has been written in the context of the SDL-INNO and SOPPI projects financed by VTT and/or Tekes. We thank Statistics Finland for the access to the data.

1 Introduction

Most existing literature conclude on a positive relationship between investments in knowledge, product innovation output and labour productivity, both in development and in developing economies (e.g., Mairesee and Robin, 2010, Crespi and Zuñiga, 2012), not only for manufacturing but for services too (Cainelli et al., 2006, Loof, 2004, Criscuolo, 2009). However, evidence on the role of customers and users for firm performance is mixed and no clear picture exists on the issue (Laursen and Salter 2006, Belderbos et al. 2004, Harhoff et al. 2014). Given the stylized fact that understanding user needs are crucial for the success of the firm this is a surprising observation (SPRU 1972, 1974; Von Hippel 1976, 1978).

In the case of services, empirical evidence is particularly needed since case studies and service literature has shown the extremely important role of users in service co-production and service innovation (Gallouj, 2002; Sundbo and Toivonen, 2010), even if external sources for innovation, in which users are a major actor, play a major role for incremental innovation but not necessarily for radical innovation in Europe, where size or R&D investment can be more relevant (Battisti et al., 2014). Therefore the focus of this paper is on analyzing if and how user orientation contributes to innovation and productivity at the firm level.

To be able to reach the above objective the paper builds on the CDM model from the economics literature where it is used to empirically study the impact of innovation on productivity. CDM allows us to model the complexity of the innovation process. The outcome of our analysis will shed light on the relationship between user orientation and innovation and between user orientation and productivity. Because open innovation practices such as user orientation are important for functions of the firm beyond R&D, such as HRM, procurement and manufacturing and IT its relationship with innovation output and production output can differ (see Vanhaverbeke et al., 2014). Moreover, in services, innovation sources are far beyond a relatively less important use of R&D (Tether, 2005, Rubalcaba et al., 2010) and the relationship between innovation and productivity is far to be simple given the problems for measuring service productivity inputs and outputs (Gallouj and Savona, 2009, Djellal and Gallouj 2013).

To incorporate user orientation as a source of innovation in our model we build on the research on open innovation and user innovation from the innovation management literature (Laursen and Salter 2006). Open innovation is a relatively new field of research; although it has been influential in the field of innovation studies it has had limited impact upon broader disciplines of management and economics West et al. 2014). Based on that literature hypotheses will be developed and different measures of user orientation will be constructed. It is for example useful to distinguish

between different degrees of user involvement as they are expected to have different impact on the performance of the firm.

We address the above research questions empirically based on a recent and unique set of Finnish firm level data. Using data on the CIS2010 linked to business register and financial data the analysis allows for analysing more reliable measures of labour productivity (i.e., based on real data not on CIS-like perceptions of productivity growth). In addition it allows for testing the impact of lag structures. Recent empirical evidence on the role of user orientation for firm performance is still very scant, supposedly due to the lack of available data. Our paper offers new empirical evidence and contributes to filling the empirical research gap on user orientation and firm performance. The motivation for the paper is to look for empirical evidence on the role of different means and intensities of user orientation in the performance of firms in services and manufacturing and to shed more light on the mechanisms at work.

The remainder of the paper is organized as follows: section two gives an overview of the previous literature on user orientation and firm performance. Section three describes the data and the empirical model Section 4 presents the results and the robustness checks and section 5 provides a discussion of the conclusions.

2 Literature review

This paper builds on two stretches of literature. From the economics literature on innovation, and productivity we borrow our empirical set-up that combines decisions on innovation inputs with outcomes in innovation and productivity, following the existing recent CDM works in for the area of services. From the innovation management literature on open innovation and user innovation we take into account the knowledge on how open innovation and user innovation has been described to affect firm performance. This included the impacts of users on innovations and the impacts on firm performance; both from the consideration of passive users in innovation and from the user co-innovation as well. Our approach will cover both aspects of user orientation for services while integrating both under the CDM framework.

2.1 Innovation and productivity

The empirical analysis of innovation and productivity has built continuously on the CDM model of Crépon, Duguet and Mairesse (1998) that takes into account innovation inputs, innovation outputs and production outputs and that corrects for selectivity and endogeneity (see Hall 2011 for an overview, Criscuolo 2009, Love et al. 2011, Crespi and Zuniga 2011, Hall et al. 2012). Variants of this structural model are to be preferred to single equations as it takes into account the innovation process and its complexity. However the focus in these models have often been on the unbiased estimation of the innovation input on the innovation output and of the innovation output on productivity while other variables of interest have been added in as controls. As our primary interest in this paper is on user orientation and firm performance we aim to integrate this focus in the context of a CDM model variant.

The relationship between innovation and productivity has already been explored for the case of services, even if at a limited extent compared to the large literature on the topic proving the positive relationship for manufacturing (e.g., Crepon et al., 1998, Crespi and Zúñiga, 2012). The two ways approach by Cainelli et al (2006) showed how innovation led to positive impact in productivity levels in the three years after. Mairesse and Robin (2009) compare manufacturing and services in France to find significant positive effects of product innovation on productivity and no effect or very little when process innovation is considered; impact from product innovation on services productivity are even higher than impacts on manufacturing productivity. However, Criscuolo (2009), based on the CDM model and using a CIS data for 14 mostly OECD countries shows that the productivity effect of product innovation is larger in manufacturing than in services in most of the countries. In developing economies positive impacts from innovation on productivity have also been reported following a CDM model, than in the case of Chile (Alvarez et al.,2012) and Uruguay (Aboal and Garda, 2012). The Uruguayan case has shown how in manufacturing technological innovation are more relevant for productivity while in for services non-technological innovation have a more important role.

Beyond the approached for the whole of set of services, a particular attention has often been paid to business services and knowledge-intensive business services. For the US business services firms, Mansury and Love (2008) find positive effect of service innovation on growth but not on productivity, what is coherent with the European results underlining the impacts on service innovation is quality and market differentiation but not so much on costs and productivity given the often increases of costs related to business service innovations (Rubalcaba et al.,2010) leading to major positive impacts on employment (Evangelista and Savona, 2003). For the Swedish case, Löf (2004) finds that knowledge intensive manufacturing and knowledge intensive services present similar regression positive results when analysing innovation and productivity, suggesting that R&D and innovation contribute very little to explain the large productivity differences between those major knowledge intensive branches.

2.2 The role of users on innovation and performance

A key finding of the influential SAPPHO project from the seventies was that successful innovators have a better understanding of user needs than their unsuccessful counterparts (SPRU 1972, 1974; Rothwell et al. 1974). With

success these early authors referred to market share and profitability¹¹³ induced by single innovations. In addition to understanding user needs also the insights in user involvement matter (Radosevic and Yoruk 2011). Further key dimensions of successful innovators are attention to marketing, use of external knowledge sources and leadership. The overall conclusion of the above research is that successful innovations do combine technology with market needs. Von Hippel further analysed the SPRU data and underlined the importance of (lead) user/customer involvement in the innovation process (Von Hippel 1976, 1978, 1988; Urban and von Hippel 1988).

The technology sourcing literature and innovation management literature have revealed a tendency towards more distributed innovation processes both geographically and external partners wise (Chesbrough 2003, Laursen and Salter 2006, Chesbrough and Bogers 2014, West et al. 2014). Dahlander and Piezunka (2014) examine external suggestions by customers and find that external cooperation by customers is an unusual case with less than 10% of the firms receiving multiple suggestions per month. However there is little evidence available for corporate decision makers of how the different forms of opening the innovation process impact firm-level outcomes.

User innovation research and open innovation research both encourage firms to look beyond their borders for sources of innovation. Hence it does not come as a surprise that user innovation researches are increasingly at play in the arena of open innovation research. However, a clear difference in both traditions relates to their diagonal stance on appropriability. The user innovation researchers did criticize appropriability because it limits innovation and welfare and because the inventors are anyway better off if they reveal inventions for free. While open innovation is a firm centric theory of innovation, user innovation focuses on consumer, individual and societal welfare (West et al. 2014).

Belderbos et al. (2004) studied the relationship between cooperative R&D and firm performance for a sample of 2056 innovative Dutch firms in a two cross sectional approach for the years 1996 and 1998. They use two alternative measures of performance, the growth in net value added per employee (labour productivity growth) and the value of sales per employee of product and services that are new to the market (innovation sales productivity growth). Customers and universities are important sources of knowledge for firms pursuing radical innovations, which facilitate growth in innovative sales in the absence of formal R&D cooperation. Or in other words, customer cooperation is not significant but customer spill-overs are significant for growth in new to the market sales per employee.

Harhoff et al. (2014) find cooperation with customers and competitors not appear to help technology sourcing. However, they underline that their findings do not imply that cooperation with customers is not beneficial for the firms. After all they only measure effects on total factor productivity. It is indeed recommended to use multiple measures of firm performance as to test the robustness of the findings, especially in the light of policy implications. Cooperation with customers can be a boost to selling the products abroad, even if it does not increase the productivity at home. They underline that cooperation with customers are often entered in order to adapt existing products to new markets. Companies have the opportunity to learn about the demand and preferences of customers and adapt to local tastes (von Hippel, 1988).

2.3 Customers, users and performance in services

There is a wide range of empirical studies that used Europe's Community Innovation survey (CIS) to measure firm open innovation practices and the use of external sources and collaboration in the innovation process (Laursen and Salter 2006; Ebersberger et al. 2010; Love et al. 2011). Love et al., prove the role of customers in innovation output at the exploratory stage of the innovation process for UK service business (not so much on the transformation or developments stages). Previously, Laursen and Salter (2006) analysed how openness explains innovation performance among UK Manufacturing firms. They find that lead users are significant for radical and incremental innovation and use innovative sales shares of new to the world and new to the firm products as dependent variables, testing a U-inverted shape curve for external sources. A different result is obtained by Wimdrum *et al* (2013) and Battisti *et al* (2014) both for manufacturing and services companies at EU and sector-aggregated level, where external sources are proved to be important for incremental innovations but not for radical innovations; internal sources such as R&D and company size play a more relevant role.

For a sample of 800 UK firms Mina et al. (2014) examine how manufacturing and service firms differ in their use of 14 different approaches to open innovation collaboration. They find that informal collaborations are predicted by the importance of services and market-based knowledge, while formal collaborations are predicted by the importance firms place on formal appropriability. External sources play also a role for cooperation agreements in the EU case (Gallego et al., 2013)

The Innovation Value Chain (IVC) approach (Hansen and Birkinshaw 2007) encouraged Love et al. (2011) to empirically analyse the process through which business service firms source knowledge, innovate and then exploit or commercialise innovation to generate business growth. Using in essence a variant of the Crépon et al (1998) model the authors do not find any effect of customers on sales growth nor on innovative sales. More interestingly their result highlight that the importance of the link to customers often found based on Community Innovation Survey (CIS) data could be explained by the exploratory linkages to customers in the knowledge sourcing stage of the innovation process.

¹¹³ Successful innovations are those that managed to establish a worthwhile market or profit while unsuccessful innovations are those that failed to establish a worthwhile market or profit, despite being a technical success. Radosevic and Yoruk (2011) define successful innovations as reaching a sales growth of more than 10% (1 year) after the launch of the innovation.

Their results should be carefully read as they only apply to UK based business services and a limited number of self-reported contemporary sales growth figures.

Ashok et al. (2014) analyse the role of end-user collaboration for process innovation in services. For a sample of 166 I.T. firms they find that benefits from collaboration are not automatic, as the firm's commitment of internal sources fully mediates the impact of the intensity of end-user collaboration and breadth of external collaboration on process innovation. In line with the above results for process innovation, Foss et al. (2011) concluded that impact of customer collaboration on product innovation performance was mediated through organisational practices.

Based on the above findings from the economics literature on innovation and productivity and the innovation management literature and we will develop a set of hypotheses. At this early stage of our analysis we will explore four hypotheses.

Hypothesis 1: "User orientation has a positive relationship with innovation output".

Hypothesis 2: "Innovation has a significant impact on productivity but user orientation may have no significant impact on labour productivity".

Despite the aforementioned mix evidence on the users' role on innovation and output, we can work under the hypothesis of a positive impact on innovation output and a non-significant one on labour productivity. The first hypothesis is based on the fact most service innovation literature stresses the importance of users in service co-productions and innovations (Gallouj and Weinstein, 1997; Sundbo and Toivonen, 2011) and the problems of measuring productive and innovation in services have been explained by the statistical under-representation of non-observable service innovation and non-observable service performance (Djellal, and Gallouj, 2013), that may heavily affect the understanding of the role of users through statistics. The new Finnish data on user should allow us to mitigate part of the major gaps struggling previous CIS-based analysis on services. New data should make service innovation and performance more visible and inter-linkages more observable.

The second hypothesis stresses the expected relationship between innovation and productivity in services in the line of the CDM models reported before but focuses again on the interactions between services suppliers and users: these interactions are ones more likely to generate positive impacts on quality and employment (Rubalcaba et al., 2010, Evangelista and Savona, 2003) and not so much on productivity. Moreover, service innovation impact could have a little or non-significant impacts on productivity if just short-term effects and only technological innovation is considered. Long-term effects and the consideration of non-technological innovations, as done in Aboal and Garda (2012) should lead to more positive effects. This hypothesis is also coherent with the non-significant results from customers in innovative sales found by Crepon et al (1998) and the non-automatic results found by Ashok et al. (2014).

The Finnish data allow a distinction between different types of user orientation. In particular, we can distinguish between user consideration for innovation (customer feedback, market studies, etc.), users as resources of innovation activities (brainstorming, user communities, crowdsourcing, etc.) and user innovation (products developed by users at the early stage before development or at development stage). According to the literature on user driven innovation in services (Sundbo and Toivonen, 2011) we can expect a higher impact on both innovation and production outputs from users innovation than the mere users consideration for innovations. User innovation can be enlarged to some extent to the concept of users as resources of innovation activities since users are providing ideas in this way that can be essential for innovation.

Hypothesis 3: "User innovation plays a more crucial role than user consideration for innovation and production output".

Finally, the existence of 6 Finnish-CIS categories of users involvement in innovation allows us to the breadth and depth categories that Larsen and Salter (2006) used for the analysis of external sources in innovation. In this case, we analyse different alternative or complementary ways of user involvement. However, we cannot make of hypotheses of a U-inverted form in the use of users ways of involvement as Larsen and Salter did for the use of external sources. There is no reason to expect a decrease in the marginality of additional more intensive engagement of users on innovation since different types of user engagement relate to different phases not necessarily cumulative (Kuusisto et al., 2013). Hypothesis 4 establish that user depth can be more important than breadth since the intensive if the user engagement deems to be more relevant than the variety of ways of engagements according to the previous literature on services (Gallouj, 2002, Sundbo and Toivonen, 2011) and to the role of external sources depth in services business performance (Battisti et al 2014).

Hypothesis 4: "User depth is more important than user breadth both for innovation and production output".

3 Data and empirical set-up

The analysis in this paper is based on the Finnish CIS data from 2010 that contains more extensive (related to previous data sets used in the literature) and hence unique data on the innovation knowledge channels between users and firms. These data have undergone a preliminary descriptive exploration (Niemi and Kuusisto 2013; Kuusisto et al. 2014). The descriptive analysis concluded that the work of users to modify or develop products has often been important for product innovators in sample. Roughly one third (one seventh) of the firms reported that users contribution was important in adapting (developing) innovative products the firm commercialised. Based on correlations it was further found that firms reporting product innovations with significant user involvement are also more often involved in

launching new to the market products. Finally they refer to fine-tuned CIS2012 surveys currently being processes at Portugal and Switzerland including user orientation questions following the Finnish example.

3.1 Data and descriptives

This paper explores a unique firm-level dataset from Finland containing extensive information on user orientation practices of firms both from manufacturing and services. When the 2010 Community Innovation Survey (CIS2010) was send out to a representative sample of EU firms only the Finnish firms were asked about the importance of user orientation practices. The first descriptive results on these user orientation practices were recently published (Niemi and Kuusisto 2013, Kuusisto et al. 2014). However, no analysis has been undertaken based on a richer dataset that merges the unique survey data with hard firm level data. To address the relation between user orientation, innovation and productivity at the firm level we did construct such a database that linked the Finnish CIS2010 survey to Business Register data and Financial Statement statistics from Statistics Finland. The CIS2010 is a cross section referring to the period 2008 to 2010 while the merged administrative data contain the most recent available information on firm performance for the period 2008 to 2012.

Data source: Statistics Finland. *For these variables tabulated descriptive statistics refer to 793 firms with strictly positive innovation expenditures (350 from services and 443 from manufacturing).

After cleaning out firms with insignificant turnover and tiny employment from the merged dataset the representative sample of service and manufacturing firms contains 2058 firms of which 24% were categorised as innovative firms (firms with strictly positive innovation expenditures and sales of innovative products and services). As a background to our econometrical analysis Table 1 describes the key input and output characteristics and additional control characteristics of the firms in sample. Almost half of the firms (44%) reported to perform in-house R&D and also for service firms in sample this innovation input related figure was rather high (37%). The average expenditure on innovation inputs crossed the 6 million EURO gap or 7% of total sales. The average manufacturing firm has 7 times higher innovation expenditures than the average firm from the service sector. The innovative activities these firms

undertook could either have been related to product innovations (39%), process innovations (36%), organisational innovations (38%) or marketing innovations (32%). Innovative sales from new products for the average firm accounted for 18% percent of the total sales. Production output of the average firm was 323 thousand EURO in terms of turnover per employee and a much lower 67 thousand EURO in terms of value added per employee. Our analysis will correct for intermediate inputs and will analyse both production output measures.

Table 2. Importance of user orientation dimensions for innovation activities by industry.

User innovation index	0.126	0.215	0.144	0.225	0.135	0.221

Note: The first part in the above table contains the shares of firms that reported a certain user orientation dimension to be of medium to high importance to them. Data source: Statistics Finland.

Table 2 includes the importance of ways and modes of including customers and users in innovation activities and production of innovative products. The first block in Table 2 shows the self-reported importance of different dimensions of user orientation. Focusing on individual user orientation measures may miss to capture the general user orientation strategy of the firm and therefore the second block contains general measures of user orientation. Overall two key findings emerge: (1) the more intense the interaction with users, the less frequent it is of importance. (2) In services user orientation is slightly less frequent of importance than in manufacturing, except in the case of user ideas (users as a resource of innovation activities), what support the idea of having ideas as part of the user innovations in services; user engagement is different to users engagement in manufacturing. Definitions of all user orientation and other regression analysis variables are presented in Table A1 while Table A2 and A3 present the descriptive statistics for the innovator sample only.

However, looking at more detailed sectors shows that the importance of user consideration especially lights up in the service sectors such as ICT, the financial sector, the scientific activities industry and the wellbeing sector and to a lesser extent in manufacturing industry (results not tabulated). The importance of user innovation is roughly in line with that of user consideration but it shows up to be less important in the wellbeing and financial sector. The more technology is involved in the manufacturing firms or the higher the knowledge base of the service firms, the more often the firms report user orientation to be for their innovation activities. In addition we found users to be twice as important for the biggest firms than for the small firms. As such firm size can be expected to play an important role in explaining the importance of user orientation. When plotting the importance of user orientation dimensions by firm age no big differences emerge between firm age categories although overall a higher share of young firms indicate user orientation to be of importance for their innovation activities.

Following Laursen and Salter (2006) Table 3 tabulates the external search breath and search depth for our firms in sample. In a comparable way we also calculated what we call the *user orientation breath* and *user orientation depth* and further added the R&D collaboration breath and R&D collaboration depth figures. The tabulated measures are informative as they summarize the average firm strategy on openness and user orientation for innovation and their role for innovation and production output will therefore be tested in our regression analysis.

Table 3. Openness and user innovation strategy measures of the firms in sample.

SAMPLE	Services		Manufacturing		Full sample	
	1031 obs.		1027 obs.		2058 obs.	
VARIABLE	Mean	S.D.	Mean	S.D.	Mean	S.D.
External search breadth	0.350	0.414	0.471	0.435	0.411	0.429
External search depth	0.067	0.102	0.094	0.128	0.080	0.117
User orientation breadth	0.287	0.352	0.313	0.350	0.300	0.351
User orientation depth	0.059	0.130	0.061	0.142	0.060	0.136
Collaboration breadth	0.134	0.330	0.247	0.381	0.190	0.348
Collaboration depth	0.026	0.076	0.046	0.103	0.036	0.091

Data source: Statistics Finland.

The correlations matrix in Table A4 shows that user consideration variables and the “users as an innovation source” variables do correlate to a limited degree. Furthermore especially user consideration and not users as an innovation source correlates heavily with clients and customers as a source of innovation. Surprisingly the correlation between user orientation variables and cooperation with clients and customers diminishes the more intensive the consideration of users becomes. The correlation between the client cooperation variable and the client as innovation source variable is relatively strong. Looking at the correlations between the variables of our regression analysis does not reveal any correlations higher than 0.5, except for the correlations between the R&D cooperation variables (0.75) and between the group and the size variables (0.52) (correlations not tabulated).

After this short description of the firms in sample and the introduction of our measures of user innovation the next section introduces the empirical set-up to analyse the role of user orientation for innovation and production output. The model will allow linking the self-reported importance of user orientation for innovation activities and for the production of innovative products to the real importance of user orientation for innovation and output performance.

3.2 Empirical model for user innovation and productivity

For the analysis of the relationship between user innovation and productivity we build on the CDM model (Crépon et al. 1998, Griliches 1979) that was fine-tuned for a set of OECD countries by Criscuolo (2009). This OECD core model described below allows for comparisons between multiple countries. The advantage of building on this core model will fully materialize when comparative user innovation data from Portugal and Switzerland will soon become available for comparative research (Kuusisto et al. 2014).

The CDM model is a structural model incorporating the innovation investment decision, the innovation process and the role of innovation in the production of output. It takes care both of selectivity, the fact that only a subset of firms engages actively in innovation activity, and endogeneity, due to the fact that some of the explanatory variables in the model might be simultaneously determined as the dependent variables.

Like the CDM, this model has three stages and consists out of four equations (see Criscuolo 2009). The first stage explains firms’ decision to engage in innovation activities, and the amount of innovation expenditure chosen. It is composed of two equations and it is estimated using a generalised Tobit model (Heckman, 1979).

The first equation accounts for firms’ innovative effort (*innov**) and can be formally written as follows:

$$Innov_i^* = X'_i \mathbf{b} + u_i \tag{1}$$

Where the subscript *i* refers to firms; *X* is a vector of regressors described below and *u* is the error term that is assumed to be normally distributed. As firms will only innovate if the expected net gains from this activity are positive, the observation is a discrete event (innovative or not)¹¹⁴ rather than a latent variable *Innov**. Therefore, the first equation models the probability that the firm is innovating using a probit model:

$$Prob(Innov_i = 1) = Pr(Innov_i^* > 0) = Pr(u_i > -X'_i \mathbf{b})$$

Where *X'*_{*i*} is a vector of variables affecting the innovation investment decision and includes: size of the firm, measured as log employment; a dummy for whether the firm is part of a group; a dummy for whether the firm is an exporter; a variable that captures the importance of obstacles to innovation due to knowledge, costs and market; and industry dummies. These variables are largely those used in previous CDM works (e.g., Crespi and Zúñiga, 2012)

¹¹⁴ An innovative firm is strictly defined as having positive (*x*>0) innovation expenditures and positive (*x*>0) innovative sales.

Conditional on the firm being innovative, one can observe the amount of investment and thus the intensity of investing in innovation. The second equation of the first stage is an innovation expenditure intensity equation, where the dependent variable is innovation expenditure per employee. It estimates the role of exogenous covariates on the amount of innovation expenditure:

$$\begin{aligned} \text{InnExp} &= X'_2 d + e_i && \text{if } \text{Innov} = 1 \\ & && \text{and} \\ \text{InnExp} &= 0 && \text{if } \text{Innov} = 0 \end{aligned} \tag{2}$$

It is assumed that the error terms u and e are jointly normally distributed with mean zero and covariance ρ and the two equations are estimated as a generalised Tobit equation, by maximum likelihood. Additional regressors are used with respect to the first equation. In the second equation the vector of covariates X' includes a dummy for belonging to a group; a dummy for whether the firm is an exporter; a variable that captures R&D co-operation activities; and a dummy for public financial support. For the parameters of interest to be correctly identified, a crucial assumption is whether there are variables that affect the decision to invest in innovation but not the intensity of the innovation effort, *i.e.* whether exclusion restrictions exist. In this model the variables included in the first equation, but excluded from the second, are firm size and obstacles to innovation. The idea is that while it is well known in the literature that larger firms are more likely to invest in innovation (see for example Cohen and Klepper, 1996), the intensity of investing in innovation – measured as the ratio of total innovation expenditure per employee – is already scaled and therefore less likely to be correlated to size. Finally from this first step the inverse Mills ratio is estimated and used as an additional regressor in the second and third step of the model to control for selectivity. In addition the predicted value of innovation expenditure is calculated.

The second step consists of the estimation of the knowledge production function, where the dependent variable, log innovative sales per employee (selected by Criscuolo versus other alternatives such as the introduction of product and process innovation, Crespi and Zúñiga, 2012 or all different types of innovation as in Aboal and Garda 2012), depends on a vector of covariates X'_3 containing log employment; a dummy for SME's; a group dummy; a dummy for process, organisational and marketing innovation; a set of user orientation variables; a set of R&D co-operation variables and innovation source variables as to control for other incoming knowledge flows not due to user orientation; a set of innovation hampering measures; the Mills ratio; industry dummies; and actual log innovation expenditure per employee (or predicted values when correcting for potential endogeneity). Given that the model is estimated only on innovative firms, the Mills ratio, estimated in the first stage, is added to correct for selectivity. The identification restriction here is that public financial support only affects innovation outcomes through increased investment in innovation and, similarly, that – once one conditions for the co-operation activity of the firm – serving foreign markets (measured by export dummy) only affects innovation outputs through increased innovation expenditure.¹¹⁵ The innovation outcome equation can therefore be written as:

$$\text{Innov_output} = X'_3 g + v_i \tag{3}$$

In the third stage the innovation output productivity link is estimated using a Cobb-Douglas production function in our case augmented with measures of user orientation (Griffith et al. 2006).

$$\text{Ln}(\text{sales per employee}) = X'_4 p + v_i \tag{4}$$

The dependent variable is log sales per employee. The right-hand side variables are: firm size; a dummy for SME's; a group dummy; a dummy for foreign ownership; a dummy for process, organisational and marketing innovation; a set of user orientation variables; the Mills ratio, to correct for selectivity; and log innovative sales per employee. To account for the potential endogeneity of log innovative sales per employee, the output production function is estimated using instrumental variables 2-stage least squares (IV 2SLS). All variables used in the empirical set-up and their definitions are listed in table A2. The next section summarizes the results of the empirical analysis.

4 Results and robustness testing

The results of the CDM model variant described in the previous section will be presented by model stage. The focus in the description of the results will be on the role of user innovation for innovation output (stage 2) and production output (stage 3). To measure innovation output in the service sector researchers have often used simple innovation dummies (see for example Crespi and Zuniga 2011). However, because of the imprecision and noisiness of innovation dummies we use instead the share of sales of innovative products for measuring innovation output. The latter measure is useful for goods and services and gives a good indication of how important the innovation(s) were for the firm (see Hall 2011). We underline that at stage one the empirical model is estimated on the full sample while during subsequent stages it is estimated for the sample of innovator firms only.

¹¹⁵ The latter is a very strong assumption since one does not allow international technology transfer to have any other potential role than those arising through formal co-operation agreements.

4.1 Innovation expenditures equation with selection

In stage 1 of the CDM variant we estimated a full two equation model by maximum likelihood (see table A3). Recall from the previous section that the selection equation models the probability of having both positive innovation expenditures and innovative sales while the intensity equation models innovation expenditures per employee in logs. The results for the full sample confirmed the presence of selection, with a significant correlation coefficient of 0.3. This result also clearly holds for services but does not seem to hold for manufacturing. This result means that in case we unexpectedly observe innovation expenditures for a firm than the innovation expenditure intensity will be relatively high given its characteristics.

A glance at the innovation intensity equation learns that for services the selection appears to have biased the coefficients towards zero and that it affected the significance levels. For manufacturing the bias ran into the other direction but no effects on significance levels were detected (results of the independent equations not tabulated). For service (manufacturing) firms innovation intensity increases (falls) with firm size. Firms who receive subsidies of some kind tend to have higher innovation intensities as do firms that collaborate on innovation. Being part of a firm group only tends to return higher innovation intensities in the service sector. These results suggest financial frictions may be at play. Based on these explorative results of the selection issues we will use the predicted values of innovation intensity where appropriate (the expectation of innovation intensity conditional on the other firm characteristics). For analysing restricted samples of innovators we will include inverse Mill's ratios in our regressions to correct for selection.

4.2 Innovation output and user orientation

Table 4 shows results for two versions of the innovation output equation by industry, where innovation is defined as the log of sales of innovative products by employee. For each industry sample the table compares the regression results using actual innovation expenditures versus predicted innovation expenditures. To capture user orientation we use all available info from the survey by making a sum of all the answers to the user orientation questions scaled by the maximum score possible. The higher the score of this user orientation index (USERS), the more important user orientation is for the innovation activities of the firm.

Table 4. Second stage estimation: Innovation output equation, with user orientation index USERS.

The table shows that user orientation tends to play a positive significant (albeit weak) role for the innovation output in the service sector but not in the manufacturing sector. We recall that for the UK Manufacturing sector Laursen and Salter (2006) found users to have a positive significance for the fraction of the firm's turnover related to new to the world market products and incrementally improved product but not for related turnover fractions of new to the firm products. However, their dummy proxy variable of users was actually based on the customer's as innovation source information. To control for other possible knowledge sources for innovation we included two general standard measures of openness, namely external sourcing breadth and depth. Results show that for Finnish firms it is not the breadth of external search but rather the depth of the external search that has a significant positive impact on innovation output. For R&D collaboration measures no clear significant effects were found. In the case of R&D intensity clear positive effects are found but they turn negative or insignificant once we controlled for endogeneity. A final result of interest is that organizational innovation tends to have a positive effect on innovation output in the manufacturing sector.

As we expect the intensity of the user interaction to play a role for its importance on innovation we created a set of new measures that we wanted to test. The first measure captures the user consideration stance of the firm (user consideration) while the second reflects the user innovation activities of the firm (user innovation). In addition, in a similar fashion as earlier innovation openness measures were computed, we calculated the breadth of user orientation

activities (user breadth) of the firm and the depth of those activities (user depth). Apart from the alternative sets of user orientation variables the regressions ran included the same controls as these in table 4.

Table A6.1 and A6.2 offer empirical evidence that user orientation strategies turn out to be significant in the service sector only. For services we observe user innovation to have a positive relationship with innovation output. However, in the case of user consideration the relationship turns out to be negative. Further it was found that for service firms it is the user breadth that has a positive significant relationship with innovation output, not the user depth. Table A6.3 shows that when single user orientation dimensions are considered, only the application of user feedback systems turns out to have a positive significant relationship with innovation output in the manufacturing sector. The next section looks at the results of the third stage of the applied CDM model.

4.3 Output production and user orientation

In the last part of the analysis we look at the productivity impacts of innovation activities and user orientation. Table 5 shows estimates of equation (4) for two alternative indicators of innovation activities: the actual and predicted innovation sales per employee as instruments for innovation output. Using the predicted probability instead of the actual innovation is more appropriate to account for possible endogeneity issues concerning knowledge inputs. Therefore we have instrumented the innovation output measure using inputs to innovation and other firm characteristics. Conventional variables such as capital, employment are included in each specification and usually their estimates are not much affected by the inclusion of innovation variables.

Data source: Statistics Finland.

Our results show that user orientation tends to negatively affect the productivity in manufacturing firms but that it has no significant effect for service firms. Innovation output has a robust positive effect on our productivity measure. The remaining variables in the productivity equations are fairly standard and not very affected by the choice of innovation variables. Capital intensity has a somewhat low coefficient, albeit still reasonable in light of the included industry dummies, which will tend to depress it. Process innovations have a negative impact on productivity in the manufacturing sector. However, unlike previous results productivity does not fall with firm size as log employment stays insignificant. Being part of a group has a positive impact on productivity for service firms as has being foreign owned for manufacturing firms.

Looking into more detailed measures of user orientation shows that the negative relationship between user orientation and productivity in the manufacturing sector is mainly driven by user innovation rather than by user consideration (Table A7.1). In addition it is the depth rather than the breadth of the user orientation that tends to exert a

significant impact. Interestingly, that impact is negative in the manufacturing sector and positive in the services sector (Table A7.2). A final results flows from the specification with individual user orientation measures for which the results are tabulated in Table A7.3. In the manufacturing sector it is the use of market studies, consumer panels, focus groups and interviews that have a positive relationship with productivity. Further measures turned out to be insignificant. However, the above results have to be interpreted with care as coefficients from different subsamples under investigation indicate a complex relationship and due to the relatively weak significant levels applying to small sample sizes. Results will be discussed after some extra robustness tests.

4.4 Robustness tests

To check how robust our presented first results are we plan to do a series of robustness tests.

Our CDM model variant follows the OECD core model of innovation and productivity (Criscuolo 2009) in defining an innovative firm as having both strictly positive innovation expenditures and innovative sales. An alternative less strict definition could be used that requires only positive innovation expenditures for a firm to be defined as innovative.

As comes to the measurement of innovation output we deliberately preferred the superior measure of sales of innovative products and services to simple innovation dummies. Nevertheless one could argue that the sales measure is too narrow as it does not capture organizational and marketing innovations for which user orientation could also play a role (e.g., impacts on non-technological innovations found for services in Aboal and Garda, 2012). One could indeed look at different kinds of innovation dummies but recent evidence from the literature indicates that here the use of only one broad innovation measure capturing product, process, organizational and marketing innovation maybe optimal (Hall et al. 2012).

A third set of robustness tests relate to alternative measures of the conventional productivity measure we use. Although widely used in CIS based research, the log of turnover per employee is only a rough proxy for productivity due to the role of intermediate inputs that vary greatly over industries. Therefore we will use instead the log of value added per employee as a measure of labor productivity (see Belderbos et al. 2004). It goes without saying that to take into account the time structure of the effects one should also check for alternative lags.

A last set of robustness tests relates to coping with the endogeneity issues. The CDM model is an appropriate structural model to build our analysis on as it takes into account the nature of the innovation process and pays attention to selection and endogeneity issues. The standard focus of the model and on the correction of biases is on how innovation inputs relate to innovation outputs and production outputs. Indeed, augmenting the model with user orientation variables does not automatically correct for additional potential endogeneity issues. Therefore additional attention is required to analyse the possible endogeneity of user orientation variables.

5 Discussion and conclusions

Our first results based on the Finnish unique set of data for 2010 show that user orientation seems to play a significant role for the innovation output in the service sector, confirming our first hypothesis. These results are not the same for each kind of service engagement. Individual user involvement variables do not report a particular significant effect. However, it is on the overall integration with users combining different ways when services firms get a higher impact on innovation, mainly with user innovation is pursued, not just user consideration. This result supports the previous theoretical (Gallouj, 2002, and Weinstein, 2007) and case study results (Sundbo and Toivonen, 2011) on strong role of users in service innovation when there is a strong involvement. In addition, no clear significant relationship was found between user orientation and innovation output in the manufacturing sector.

Regarding the second hypothesis, we confirm positive impacts of service innovation in service productivity as notices in previous work (Aboal and Garda, 2012) but we did not find significant evidence that user orientation would affect the productivity of service firms, at least when roughly measured by turnover per employee. Our results support this hypothesis for the service sector, according to the characteristics of services innovation and impacts on quality (Rubalcaba et al., 2010) and employment (Evangelista and Savona, 2013) in contexts of complex and non-visible transmission mechanisms between service innovation and service productivity (Djellal and Gallouj, 2013). At the other hand, results for the manufacturing sector show that user orientation tends to have a significant but negative impact on productivity. The interpretation of these results is challenging as complex relationships are at work and certainly also dynamics play their role. This key results show that the relationship of user orientation and firm level output measures is substantially different between service firms and manufacturing firms.

The user orientation profile of a firm can differ along several dimensions. In the context of innovation activities it is useful to distinguish between the more passive interaction between the user and the firm and the more intense or active interaction. Therefore we looked at user consideration versus users being active innovation sources or developers (co-innovators). We recall that our third hypothesis stated that more intense interaction profiles would have a stronger relationship with our output measures than more passive interactions. Our results support our hypothesis in that user innovation indeed turns out to be more significant than the more passive user consideration. But the relationship differs depending on the output measure. User innovation has positive relationship with innovation output in the service sector and a negative relationship with the production output measure in manufacturing. The services results may back the previous theoretical and case studies results for service innovation while the manufacturing results may be related to the

role of external sources for incremental innovation rather than for radical innovations (Windrum et al., 2013). Higher manufacturing innovation in terms of sales from innovation products may rely more on internal sources or other factors than on the users innovation that may be useful for incremental but less profitable innovations in manufacturing.

Turning to the aggregate role of different means of user orientation our analysis produces mixed results. User breadth has a significant positive relationship with innovation output in the service sector while user depth has a negative relationship with production output in the manufacturing sector. The mixed evidence does not support our hypothesis 4. When detailed means of user orientation are considered it was found that the feedback of users and the market studies turned out to have a positive impact on output in the manufacturing sector. Overall our results show the complex relationship between different dimensions of user orientation and that practices and channels differ substantially between services and manufacturing firms, but not in what we expected from previous literature on breadth and depth (the relationships do not follow Larsen and Saulter 2006 or Battisti et al 2014).

As overall conclusion, new empirical evidence from the Finnish survey on user's role in innovation proves their importance for innovation products, but not whatever kind of user's role. Impacts are significant when there are right combinations of user orientation and active involvement, so some sort of user innovation is produced even at a preliminary phase of the innovation process. The manufacturing sectors hold higher shares of companies engaging users in their innovation activities, and users innovation is more visible from descriptive statistics, but impacts from users into innovation are not significant according to the CDM model, what may suggest the higher role of other external and internal sources in goods innovation performance. Although we have found positive impacts from innovation outputs on productivity, the role of users is not directly linked to productivity gains in a significant way.

The limitation of our current analysis boils down to the fact that some of our results on user orientation have to be interpreted as associations rather than as effects. Additional robustness test will have to be focusing on correcting for endogeneity issues.

Further research should compare the Finnish results with results for other countries. In the near future data will become available of innovation surveys from Portugal and Switzerland that have incorporated the unique Finnish user orientation question from the CIS 2010 survey. We argued that the CDM model set-up we used would be a fruitful start for further cross-country comparative analysis.

Appendix

Table A1. Description of variables used in the regression analysis.

No	Variable name	Definition
Potentially endogenous variables		
1	Innovator	Firm has strictly positive innovation expenditures and strictly positive innovation sales (binary)(from CIS)
2	Innovation intensity (IE)	log innovation expenditure per employee (from CIS)
3	Innovation output (LISPE)	Log innovation sales per employee (from CIS)
4	Productivity	Log turnover per employee (from business register)
5	Productivity (second measure)	Log value added per employee (value added from financial statement statistics, employment from business register)
6	process innovation	The firm reported a process innovation for the period 2008-2010 (binary).
7	organisational innovation	The firm reported an organisational innovation for the period 2008-2010 (binary).
8	marketing innovation	The firm reported a marketing innovation for the period 2008-2010 (binary).
Exogenous variables		
Firm general characteristics		
	Log employment	Log employment (business register)
	SME	Small or medium sized company (binary)(business register)
	Industry	TOL2008 one digit industries (binary)(business register)
	Exporting	firm active in international market (binary variable)(business register)
	Public support	firm received financial support from government for innovation (CIS)
	Group	Firm is part of a larger organization (binary) (CIS)
	Foreign	Foreign-owned enterprise (business register)
Firm innovative capabilities		
<i>Detailed user orientation variables</i>		
	Feedback	<i>Use of customer feedback systems</i> has been of medium to high importance for the innovation activities and the production of innovative products in the 2008 to 2010 period (binary)(CIS)
	Market studies	<i>Use of market studies, consumer panels, focus groups and interviews</i> have been of medium to high importance for the innovation activities and the production of innovative products in the 2008 to 2010 period (binary)(CIS)
	Survey needs	<i>Surveying of user needs by research methods</i> have been of medium to high importance for the innovation activities and the production of innovative products in the 2008 to 2010 period (binary)(CIS)
	Ideas	<i>Development forums and platforms to collect ideas from users and user communities</i> have been of medium to high importance for the innovation activities and the production of innovative products in the 2008 to 2010 period (binary)(CIS)
	Product adaptation	Customers and user moulding of existing products that your firm developed, produced and commercialised has been of medium to high importance for the innovation activities and the production of innovative products in the 2008 to 2010 period (binary)(CIS)
	New products	Customers and user development of new products that your enterprise produced and commercialised has been of medium to high importance for the innovation activities and the production of innovative products in the 2008 to 2010 period (binary)(CIS)
<i>General user orientation strategy measures</i>		
	User innovation	The answers on how important feedback, market studies, survey needs, ideas, product adaptation and new products are to the innovative activities of the firm (3 high, 2 medium, 1 low or 0 not used) bundled into one sum divided by the maximum possible score 18.
	User consideration	The answers on how important feedback, market studies and survey needs are to the innovative activities of the firm (3 high, 2 medium, 1 low or 0 not used) bundled into one sum divided by the maximum possible score 9.
	User innovation	The answers on how important ideas, product adaptation and new products are to the innovative activities of the firm (3 high, 2 medium, 1 low or 0 not used) bundled into one sum divided by the maximum possible score 9.

	User breadth	If one of the 6 above detailed measures of user orientation has been used by the firm it is scored one otherwise zero, after which the sum of all scores is made and divided by 6.
	User depth	If one of the 6 above detailed measures of user orientation is of high importance to the firm it is scored one otherwise zero, after which the sum of all scores is made and divided by 6.
<i>Other innovative capabilities of the firm</i>		
	Cost hampering factors	Sum of the importance (3 high, 2 medium, 1 low, 0 not relevant) of cost hampering factors divided by maximum possible score (CIS)
	Knowledge hampering factors	Sum of the importance (3 high, 2 medium, 1 low, 0 not relevant) of knowledge hampering factors divided by maximum possible score (CIS)
	Market hampering factors	Sum of the importance (3 high, 2 medium, 1 low, 0 not relevant) of market hampering factors divided by maximum possible score (CIS)
	Total hampering factors	Sum of the importance (3 high, 2 medium, 1 low, 0 not relevant) of cost, knowledge and hampering factors divided by maximum possible score (CIS)
	Cooperation index	Sum of all cooperation dummies by location divided by maximum possible score 42.
	Inward R&D cooperation	Sum of cooperation dummies for all locations of competitors, clients, suppliers and other firms within the group by maximum possible score 24.
	Outward R&D cooperation	Sum of cooperation dummies for all locations of consultants, universities and polytechnics and government and public research institutes divided by a maximum possible score of 18.
	National R&D cooperation	Sum of all domestic cooperation dummies by location divided by maximum possible score 7.
	International R&D cooperation	Sum of all international cooperation dummies by location divided by maximum possible score 35 divided by the total cooperation index.
	External search breadth	If one of the sources of innovation has been used by the firm it is scored one otherwise zero, after which the sum of all scores is made and divided by the total amount of innovation sources 11.
	External search depth	If one of the sources of innovation is of high importance to the firm it is scored one otherwise zero, after which the sum of all scores is made and divided by the total amount of innovation sources 11.
<i>Production factors and prior productivity measures</i>		
	Capacity	Log capital per employee (capital from the financial statement statistics and employment from the business register)

Table A2. Descriptive statistics of innovative firms (firms with strictly positive innovation expenditures and innovative sales).

SAMPLE	Services 216 obs.		Manufacturing 279 obs.		Full sample 495 obs.	
	Mean	S.D.	Mean	S.D.	Mean	S.D.
Firms that performed R&D	0.94	0.25	0.98	0.16	0.96	0.20
Firms with product innovation	1.00	0.00	1.00	0.00	1.00	0.00

Societal challenges in the back office of farm advisory services: the case of pesticides use reduction in the French seed potato industry

Hana Dhiab, Pierre Labarthe, Catherine Laurent

INRA-UMR SAD-APT

This paper examines how agricultural advisory service organizations such as Knowledge Intensive and Business Services (KIBS) generate the knowledge needed by farmers to reduce the use of pesticides. A case study was conducted within the French seed potato industry based on structured interviews with advisory organizations that supply different forms of KIBS and are involved in the production of knowledge with farmers. The results show how societal issues related to the reduction of pesticide use are taken into account in these different forms of KIBS. We conclude that the numerous investment rationales in the back offices of KIBS tend to better integrate market information than the societal challenges associated with a sustainable use of pesticides.

Introduction

The agricultural development model based on intensified production techniques with high levels of chemical inputs, especially pesticides (phyto-pharmaceutical products), has been strongly challenged since the 1990s. As the harmful effects of pesticides on human and animal health (e.g. certain cancers, skin conditions, etc.) and on the environment (air and water pollution, effects on fauna and flora) have been shown, several regulations have been passed and initiatives taken to promote the sustainable use of pesticides in the EU and its Member States.

Directive 2009/128/EC specifies that national plans to manage and reduce the risks of pesticide use must be established in every Member State. The States must facilitate the adoption of integrated farming methods and must take measures "to reduce risks and impacts of pesticide use on human health and the environment and to encourage the development and introduction of integrated pest management and of alternative approaches or techniques in order to reduce dependency on the use of pesticides". These plans, which are intended to promote the development of measures to reduce pesticide use, require several types of intervention: regulations, control, advisory services, and training. Article 5 of Directive 2009/128/EC emphasizes the fact that the aim is both: (i) to guarantee access to training: "Member States shall ensure that all professional users, distributors and advisors have access to appropriate training by bodies designated by the competent authorities" and (ii) to set up a system to certify that advisors, farmers and users have access to all the information needed for their activity.

This emphasis on the role of advisory services is consistent with a more general goal of the European Commission, which is to improve the offer of Farm Advisory Services in the Member States (Regulation (EC) no 73/2009 of the Council).

In France, European regulations concerning pesticides have been incorporated into a specific action programme (Ecophyto 2018) funded by a pesticide tax. Several objectives of this programme specifically concern knowledge production to meet challenges in terms not only of outputs and income, but also of health and the environment.

Yet the scope of these actions is still limited and the various public- and private-sector advisory organizations are expected to contribute directly to the production and dissemination of knowledge to meet the goal of pesticide reduction. Are the advisory service providers meeting these expectations?

We will see in the first section that agricultural advisory services are knowledge-intensive business services (KIBS) which can come in various forms. The research presented here focuses on a particular case study, the seed potato industry (Section 2), and studies the performance strategies of thirteen advisory organizations in France, corresponding to different forms of KIBS (Section 3). The results show how the societal issues related to the reduction of pesticide use are taken into account in these different forms of KIBS (Section 4).

1 Understanding the strategies of organizations that invest in KIBS

1.1 Agricultural advisory services are KIBS

By definition, knowledge-intensive business services (KIBS) are services in which knowledge production is the most important component. Gallouj (2010: 105) defines KIBS as "activities whose knowledge is both input and output", while Miles (1995: 18) defines KIBS as "services that involve economic activities which are intended to result in the creation, accumulation or dissemination of knowledge". Bettencourt et al. (1999: 100) define them as "firms whose primary value-added activities consist of the accumulation, creation, or dissemination of knowledge for the purpose of developing a customized service or product solution to satisfy the client's needs".

Our findings on agricultural advisory services converge with this theoretical definition. Labarthe et al. (2013, 11) define the agricultural advisory sector as "the entire set of organizations that will enable farmers to co-produce farm-level solutions by establishing service relationships with advisers so as to produce knowledge and enhance skills".

According to this definition, agricultural advisory services are provided by organizations that, with farmers, co-produce solutions to problems relating to the productive, sanitary, and/or environmental objectives of their farm activity. Their advice helps farmers to comply with the regulations and to change their practices, by providing them with adequate knowledge relevant to their farming conditions. As the aim of advisory services is to produce and coproduce knowledge with and for farmers, they clearly are KIBS.

Several authors have highlighted the diversity of kinds of knowledge used in KIBS (Muller and Zenker, 2001): diversity in the nature of knowledge (tacit, codified, mixed), in its sources (external, internal, organizational, individual), and in its domain of specialisation (economic, technical, etc.). To respond adequately to the client's request, advisory organizations must combine internal and external knowledge, tacit and codified knowledge, knowledge particularly relevant to the client's problem, and so on. These combinations stem from a highly interactive relationship between the KIBS and their clients (Muller and Zenker, 2001; Den Hertog, 2002; Muller and Doloreux, 2009; Strambach, 2010; Rodriguez, 2013) but also require knowledge processing skills.

KIBS are thus caught in a dialectic between the need to contextualize knowledge in order to solve specific problems, and the necessity to capitalize on codified and validated knowledge (Toivonen, 2004). This twofold necessity is found in the distinction between front and back office. Front-office work is performed in the beneficiary's presence and involves the co-construction of the request and/or of the response. Back-office work standardizes the service offer, gathers and includes scientific and technology monitoring, advisors' training, the storage of technical reference (construction and use of databases, etc.), and even the production of original knowledge (through experiments and R&D).

We find this combination of activities and types of knowledge in agricultural advisory services. To solve a farmer's problem, for example an outburst of mildew (a disease of potatoes), advisors need specific knowledge that is relevant to this particular situation (the climatic conditions of the farm, the farmer's previous practices in every field, etc.) as well as more general technical and scientific knowledge on diseases, methods to control them, cropping techniques, etc. They will thus base their action on knowledge related to a wide range of subjects, such as pesticide regulations, economic knowledge on crop management, and so on. Faced with certain problems, the transfer of available codified knowledge may not be sufficient, and the advisor will be asked to help the farmer to develop new skills. This will involve the integration, into the advisory service, of tacit knowledge related to the farmer's know-how, experience, practices, etc. As in KIBS generally, the distinction between front and back office is therefore very important.

Over the past few years the range of organizations providing farm advisory services has grown: chambers of agriculture, consultancy firms, producer organizations, upstream or downstream industries, etc. As a result, a part of the service offer is provided no longer by traditional service providers but by organizations proposing advisory services associated with the purchase of farming inputs or technologies (seeds, fertilizers, pesticides, GPS, etc.). Front- or back-office activities are thus combined differently, depending on the type of service provider and their strategies.

1.2 Towards a typology of KIBS specific to agricultural advisory services

Several classifications of services have been put forward (Miles et al., 1995; Evangelista and Savona, 2003; Hollestein, 2003). Miles et al. (1995) propose a taxonomy based notably on the link between technologies and the service delivered:

- P-KIBS (traditional professional services): services based on specific occupational skills. These include firms providing services such as consultancy, marketing, training, management and accounting, as well as legal, environmental and certain financial services.
- T-KIBS (new technology-based services): services related to information and communication technologies (ICT) and to the technical activities connected to these technologies. This includes firms providing certain telecommunication services, software and other information technology-related services (e.g. equipment management), training in new technologies, and so on.

Yet this taxonomy centred on firms seeking to make profits by developing a service offer does not allow for all types of service provider investing in agricultural advisory services to be included. We need to add (Table 1):

- Embedded or Integrated KIBS (E-KIBS or I-KIBS) (Barcey and Bonamy 1999, Djellal and Gallouj, 2010) developed primarily as a secondary service to accompany a commercial activity concerning a good: sale of inputs to farmers, or collection of their production. The main objective of these services is to improve the sale of goods (quantity, quality) by providing farmers with related services. These services may be proposed by private firms or cooperatives, and are currently growing fast.
- Client-owned KIBS (C-KIBS): services offered by farmers' associations or enterprises owned by the farmers. The aim is to provide services that solve clients' problems or improve the performance of members' farms, without seeking any other form of profit. The beneficiaries of these services belong to the association, to which they pay a membership fee. This contribution is a collective investment of farmers in advisory activities (both front and back office).

Facing different constraints, these different types of KIBS may have different economic behaviours. An analytical framework is proposed to analyse the strategies of these different types of advisory service providers.

1.3 Understanding service providers' strategies

Academic debates on performance measurement of services abound. They focus primarily on the limitations of traditional productivity measurement and aim at analyzing the relations between service production and the means necessary for its delivery. Indeed the productivity and growth indicators used in industry do exclude several dimensions of service firms' performance (Gadrey, 1996; Djellal and Gallouj, 2008, 2010, 2012; Du Tertre, 2010), for instance those linked to the co-production of services. However, productivity improvement is still part of the strategy of the service providers, as attested for example by the efforts to standardize the services (Gadrey, 1994). This tension is also found in agricultural advisory services, which may be standardized (collective advice, production of standardized decision tools, etc.) or alternatively be considered as an activity that is typically rooted in a face-to-face relationship. These issues are the subject of general debate on the analysis of service activities: should we develop an assimilation perspective (by using the same analytical frameworks as those used in industry) or rather a demarcation perspective (by developing specific frameworks), or else an integration perspective (Gallouj, 2010). The latter perspective has led to the creation of multi-criteria frameworks for analysing the performance of KIBS, which facilitates our understanding of these service providers' strategies: *"the idea is that, in services to a greater extent than elsewhere, performance cannot be captured solely through the notion of productivity"* (Gallouj, 1999).

The analysis of agricultural advisory services' performance requires us to take into account objects not only in the economic world but also in the environmental, regulatory, social and industrial worlds. *"Dealing directly with the difficulty of representing the product of a service activity such as advisory services requires one to recognize that there are various types of service production, and that the product is not a technical reality per se, but results from a social construction"* (Labarthe, 2006). Therefore, various authors have pointed out (Djellal and Galouj, 2010, 2012; Labarthe, 2006; Labarthe et al., 2013; Viitamo and Toivonen, 2013; Janeschek et al., 2012) that a multicriteria analysis seems to be the most appropriate method for analyzing advisory services' performance strategies.

2 Survey and framework for analyzing the strategies of advisory services in the seed potato industry

This study explores the ways in which societal issues (i.e. societal demands to reduce pesticide use) influence the performance strategies of agricultural advisory organizations in different types of KIBS. In order to secure the accuracy of the empirical evidence collected for the research, we chose to focus the analysis on a case study, the seed potato industry in France. This production was chosen for three reasons:

- The sanitary quality of the seeds is a priority, to protect the farmers' crops and to comply with international trade regulations in the industry.
- The seed potato industry is subject to high risks of parasites that can cause the entire crop to be lost. Farmers therefore use high levels of pesticides (the "Treatment Frequency Index" is very high). Hence 1) the decrease of the amount of pesticides used may generate specific risks and demand for farm advice; 2) it is a sensitive area for societal issues related to pesticides.
- Various types of actor are involved in providing advice in this industry (producer organizations, chambers of agriculture, pesticide firms, potato seed companies, etc.).

The different types of farm advisory service providers were identified through an analysis of the supply chain, and a snowball sample methodology. The main ones were interviewed, i.e.:

- "Producers' organizations" (PO), to which all seed potato producers have to belong. There are three PO in France: one for producers in the Nord-Pas-de-Calais, Upper Normandy, Picardie, Champagne-Ardenne and Île de France regions; a second for producers in the Centre region; and a third for producers in Brittany. They provide advisory services to members and are funded primarily by producers' membership fees.
- "Potato seeds companies", which are private-sector firms producing and commercializing potato seeds. They have contracts with the farmers producing seed potatoes.. They offer advisory services free of charge to these farmers, to ensure that they use recommended practices to secure the quantity and quality of potato seeds production.
- "Chambers of agriculture", which are para-state advisory services financed by public and private funds. The service may be free of charge or not, depending on the case.
- "Centers for agricultural studies", which are collective organizations (or clubs) funded by the farmers and which enable them to receive advisory services.
- "Firms producing pesticides and fertilizers", which are private-sector businesses that combine advisory services with the sale of products.
- "Independent advisory bodies", which are private consultancy firms commercializing services to farmers. They are financed exclusively by the sale of these services.

The analysis presented here is based on surveys conducted with a semi-structured questionnaire that included:

- A general description of the organization (date of creation, status, membership numbers, etc.)
- A description of the advisory service offer (number of advisors, format and modality of service, themes, number of clients, etc.)
- An analysis of the back-office configuration (back-office activities, team, themes, governance, etc.).

All the interviews were transcribed in full and used to fill in an analysis framework that enabled us to understand the advisory organizations' performance strategies as well as the orientation of their back-office investments. This framework was inspired by the work of Gallouj (1999) and Labarthe (2006). Five dimensions of advisory service performance are considered: the financial, technical, relational, innovation, and civic dimensions (see Table 1).

- The financial dimension is related to the profitability of the firm's advisory services. It analyzes the added value of advisory services and its generation.
- The technical dimension relates to the optimization of the advisors' productivity. The indicators used to evaluate performance here are: productivity of advisory services in terms of time (number of farmers/advisors), of surface area (surface areas cultivated/advisors) and of quantity (quantity of potato seeds sold/advisors); level of standardization (standardized/personalized message); and rate of dysfunctioning (advisory service evaluation system).
- The relational dimension focuses on the relationship between the advisor and the farmer. Through this relationship the farmer's problem can be defined clearly and his/her needs met adequately. The service quality depends on the quality of the relationship, and is guaranteed by the personalization of the advisory services offer. The evaluation indicators adopted to analyze this dimension are: personalization (frequency of visits, duration of visits), client loyalty (producer turnover, advisor turnover), nature of the contract (standard, personalized).
- The innovation dimension is centred on the back office. It examines the firm's capacity to invest in knowledge acquisition and production and renewal, and analyzes the back-office activities (R&D, training, etc.), the human and material resources deployed, the themes, etc.
- The civic dimension analyzes the firm's capacity to integrate the values of equity or societal issues.

These performance dimensions cannot be thought of independently; there are synergies and contradictions between them. A cross-cutting analysis of all five enabled us to identify the service providers' strategies and to present them synthetically. In particular, it furthered our understanding of the choices that are made by different types of service provider in the distribution of the activities and the investments between front- and back-office.

3 Results

The research enabled to analyze the performance logics of each of the four types of advisory service: C-KIBS (client-owned KIBS: producers' organizations), E-KIBS (embedded KIBS: services proposed by seed companies), T-KIBS (technological KIBS, in these cases companies selling software or using decision support technologies for farmers) or P-KIBS (professional KIBS, in these cases chambers of agriculture and private consultants). Each strategy is illustrated by means of a multicriteria analysis template described in the preceding section.

3.1 C-KIBS logic (producers' organizations)

The sanitary quality of potato seeds is a competitive advantage for the French industry. Producers' organizations (PO) have therefore been set up to better meet this objective, with the State's support. They are funded by the seed potato farmers' annual membership fees. The profitability of this collective investment of farmers in a service activity depends on the advisory services' contribution to the production of healthy and certifiable potato seeds. The advisors' aim is to identify the members' problems and to provide them with solutions to guarantee their plants' good health, from sowing to storage. Their strategy is essentially based on the relational and innovation dimensions.

- The relational dimension is crucial. The number of producers per advisor is low (18 in the case of PO1), and the frequency of advisor-farmer interactions is high (see Table 3). There is therefore a real personalization of advisory services, as opposed to a striving for productivity in the technical dimension. This strategy is thus somehow similar to the one of consultancy cabinets described by Labarthe et al. (2013), characterized by the importance of the face-to-face relationship between advisor and producer (front office) for the co-production of advice. In the case of C-KIBS, the membership fee is however pooled into a collective investment whose aim is to develop any advisory activities (front- and back-office) that is relevant for the purpose of the association. Thus, the added value of the services is not conceived exclusively at the individual level of the interactions between farmers and advisors, as it might be the case for small consultancy cabinets. In the case of C-KIBS, the activity of the advisors is not assessed only by measuring the intensity of the direct relationship with the farmers. The advisors can also devote themselves to back-office activities, both types of activities are considered complementary as the direct interaction with the producer contributes to the back-office in so far as it enables the producers' problems to be identified better.

- The innovation dimension also occupies a central place in the POs' strategies. Their back-office activities are multiple: research and development, experimentation, science and regulations monitoring, training, production of technical advice, etc. The POs devote significant financial and human resources to this: they have specific teams dedicated to these activities and their back-office budget is large (€1.4m in the case of PO1). Experimentation is the POs' main investment, but its implementation depends on the size of each PO and their investment capacity. It is less developed in PO2 and PO3, where it is carried out mainly through partnerships with research institutes, than in PO1 which, in addition to partnerships, runs its own experimental projects. The research themes vary and cover more than the testing of new varieties' potential. They include sanitary aspects (treatment of crops, seeking new pest control methods, improvement of the potato varieties' resistance to pests, decontamination of water, etc.), agronomic aspects (fertilization, production techniques), economic aspects (irrigation management, improvement of crop yields, etc.) and regulatory aspects (new pesticides). The PO accumulate and renew their knowledge by involving themselves in formal and informal research networks, notably with public- or private-sector research institutes, and by way of a science and regulations watch based on subscriptions to scientific and trade magazines and journals. The advisors moreover participate in training, both in-house and organized by research institutes.

The POs' advisory services' performance logic is therefore centred on the relational and the innovation dimensions, via joint investments in front- and back-office activities. The back-office investments are orientated by the advisor-farmer relationship. These investments are at the heart of the solutions proposed to farmers.

3.2 E-KIBS Performance rationale (potato seeds companies)

The performance of advisory services proposed to farmers by potato seeds companies is driven by a standardization rationale. These firms' core business is to create new potato varieties and/or to commercialize the seeds of these varieties. The aim of their advisory services is to secure both the quantity and the (sanitary) quality of the production. Indeed the services' profitability depends directly on the quality of the plant production of the farmers for whom they cater. The strategy chosen by these firms is to reduce front-office expenditures and to invest in back-office in order to produce technical references. Their justification is therefore in technical rather than relational terms. Unlike the POs, the role of quantitative outputs is important in the assessment of the activity of the advisors. Both the content and the form of the services are standardized (standardized technical forms to fill in, software, decision aid, technical message service, standard service package, etc.). The standardization of front-office advisory services frees up time of advisors as well as financial resources, that can be used for back-office activities (science monitoring, R&D, creation of databases, training). Justification in terms of innovation is important for these actors because it enables them to produce technical references that reduce working time spent in the front-office. But it also plays a significant commercial role for these firms and includes profitability objectives of its own, which do not necessarily correspond to the expectations of the farmers receiving the services: the back-office activities are centred on testing the potential of new varieties and on characterizing modes of production of these varieties. This enables these firms to broaden the range of varieties they can offer and to conquer new markets and new areas of application (crisps, chips, etc.).

The case of the pesticide firm is different. Rather than offering advisory services directly to farmers, it caters for PO technicians who act as intermediaries between the firm and many farmers, especially by organizing training sessions for farmers. The back office is oriented towards testing the effectiveness of pesticides in order to produce and disseminate knowledge to maximize the sale of pesticides. This approach corresponds to a rationale of standardization, through the formatting of knowledge on the effectiveness of pesticides.

This standardization rationale lies at the interface between justification in terms of technical aspects and in terms of innovation. It is based on significant back-office investments but on reduced front-office expenditures. The performance of the advisory services depends on these firms' ability to standardize their offer by producing technical references enabling them to reduce their front-office expenses.

3.3 The T-KIBS' Performance rationale (consultancy firms)

The T-KIBS are independent consultancy firms whose aim is to develop and sell advice to farmers, based on new technologies. Their services may be in the form of software, a decision aid tool, a recommended technique, etc.

Their profitability depends on guaranteed and increasing income from the sale of technical solutions to farmers. To ensure this profitability, T-KIBS grant more importance to back-office activities, where they invest in the acquisition of new technical references enabling them to broaden their network of service sales. To this end, they develop experimental activities, science and regulations monitoring, the creation of databases, development of software, etc. The back-office themes vary: testing of pesticide treatment programmes, of fertilization programmes, of soil-related techniques... This enables them to broaden their service offer. In the case of CC1, farmers have internet access to technical and regulatory databases. They also receive a technical manual distributed by the advisors at the beginning of the campaign. The CC2 develops decision aid tools (DAT) for managing fertilization and irrigation, software, etc.

Investment in knowledge production is very important for these consultancy firms, but the cost is high. This impacts on the technical and relational dimensions, as the former is given priority over the latter. Technical results are considered very important (125 farmers per advisor in the case of CC1). The direct face-to-face advisor-farmer

relationship is not central: advice is either collective or delivered remotely via information technology tools. This makes it possible to reduce front-office expenses and to save time and resources, which can then be invested in back-office.

The T-KIBS performance logic is based on the innovation and technical dimensions. It is driven by the back office to create new references and to sell solutions to farmers.

3.4 The P-KIBS performance logic (chambers of agriculture)

The chambers of agriculture are para-statal organizations which cooperate with the public authorities in promoting agricultural development. They assist farmers in several respects: technical, economic, regulatory, etc.

The advisory service performance rationale of chambers of agriculture is based on the innovation and technical dimensions. Due to compromises between the chambers of agriculture and the state, justification is situated mainly at the innovation dimension. The back office is therefore important in chambers of agriculture. In collaboration with state agencies, they fund activities (experimentation, science monitoring, training, etc.) on several research themes (research to find new pest and disease control techniques; development and monitoring of decision tools, e.g. plant health report; training). This research is undertaken under national or local programmes in partnership with public institutions (Ministry of Agriculture, INRA, Regional Council, etc.). Their purpose is to produce agronomic knowledge.

These investments are at the core of the chambers of agriculture's activity. Over the past few years there was a tendency to reduce public funding of advisory services. This has had repercussions on their front-offices activities that included free advice for farmers. The chambers of agriculture have sought to develop other sources of funding along with a commercial range of increasingly standardized services (standard packages in the case of CA1). These services are now delivered for a fee and are based on collective advice via Internet messaging, rather than on direct interaction with farmers. This enables the chambers of agriculture to reduce their expenses and thus to carry on investing in their back-office activities.

The P-KIBS' performance rationale is at the interface between the innovation and the technical dimensions. The back office is very important for the actors for these dimensions and is at the heart of their activities and their commitments to the State. At the same time, this principle enables them to meet national and regional objectives, and to inform the front-office activity. The standardization of front-office advisory services to finance the back office not only shows the importance of knowledge-production for these organizations, it also reflects the situation of public cost containment in agricultural advisory services in France.

3.5 The diversity of performance rationales

Although they have points in common, the advisory services' performance rationales differ considerably, depending on the type of actor, especially in terms of back-office investment choices. The C-KIBS orientate their investments towards knowledge-acquisition to ensure that competitive advantages are sustained nationally (in the French seed potato industry) and to guarantee the quality of both the potato seeds and the soil. On the other hand, E-KIBS' back-office investment choices are determined above all by the objective of moving into new markets, including internationally, by creating new varieties for which there is a demand. For the T-KIBS, the performance rationale is designed in order to produce new solutions and to increase the number of clients. In the case of P-KIBS, it is the compromise with the State that guides back-office investment choices and orientates them towards investments in research projects to achieve national or regional objectives.

These actors are embedded into power relationship. They have different positions in the supply chain. The traditional service providers (the T-KIBS and the P-KIBS) are being marginalized to some extent by the E-KIBS and the C-KIBS, which are moving into a dominant position. The latter have specific strategies related to the organization of the industry. The POs assist farmers to guarantee the quality of French production by identifying farmers' problems and providing them with solutions, while the E-KIBS assist producers to monitor and ensure the quantities and the sanitary and commercial quality of their production. These strategies impact on the way in which societal issues are integrated into the advisory services' back office.

4 Rationale of performances and societal issues

The reduction of pesticide use is taken into account in different ways depending on the performance strategies of the different KIBS. Issues relating to pesticide residues in food, the air, the soil and water may be integrated to a certain degree into back-office objectives. It is nevertheless possible to refine the analysis and to show the effect of performance rationales in the integration of societal issues into back-office configurations. For this, we based our study on the analysis of the innovation dimension. We thus cross-compared the different actors' performance strategies with the societal issues relating to pesticide reduction (Table 5).

The results are homogeneous for the C-KIBS. All of them integrate pesticide reduction issues into their back-office investments. Environmental issues are included in the objectives of their internal research projects and their projects with outside partners. They do research on new disease control techniques, on the creation of new varieties that are resistant to diseases, etc. When it comes to economic and regulatory issues, these actors test new pesticides in partnership with the pharmaceutical firms producing them. The integration of all issues into their back-office strategies

is justified by their relations with plant producers and with the entire industry, as guarantors of the sanitary quality of both the soil and the seeds. As these KIBS are financed by producers, they are not compelled to show profits or to have any objectives other than devoting their resources to R&D and seeking solutions to the producers' problems. The volume of these investments depends only on the size of the organizations.

In the E-KIBS, the potato seeds companies do not integrate societal pesticide-reduction issues into their strategies. Instead, they prioritize commercial objectives. They invest in the creation and testing of the potential of new varieties, to meet the different needs of various segments of the market.

The situation is completely different in the case of the pesticide producer, which invests to meet the different challenges regarding not only the environment but also users' health. The firm puts forwards its investments in research to develop new products (for instance replacing powders by liquid products) which are less dangerous for human health. These investments are fully integrated into its commercial strategy and serve as sales arguments to counter criticism and controversy over pesticide use.

The T-KIBS invest very little to develop services integrating the issue of the reduction of pesticide use, as they do not foresee a potential for the commercial development of such services. Moreover, investments in back-office are very costly for such firms, considering their small size. Thus, as pesticide reduction is not a priority for them and their client, they rather dedicate their resources to issues more directly related to the profitability of their clients.

P-KIBS prioritize investments in the production of agronomic references that meet the societal goals of reduced pesticide use. These investments are part of the compromises between the chambers of agriculture and the State. They are made in the framework of national or local research projects in partnership with institutions in both the public sector (the Ministry of Agriculture, the public research institutes, etc.) and the private sector. The P-KIBS benefit from the support of public funds for these investments. However, as this support is decreasing, they are increasingly orienting their investments towards the acquisition of references enabling them to create and sell standardized services to farmers.

We thus find that the more the performance rationale is controlled by the clients, the more the R&D will be oriented towards the acquisition of agronomic references that integrate environmental goals of pesticide reduction into the organization's investments (the case of the C-KIBS). One might imagine that the C-KIBS would develop specific actions to better guarantee producers' health, notably by seeking to reduce risks of exposure to toxic products during their application on the crops. Yet that is not the case at all. This may be because, in Europe, the organizations providing agricultural advisory services give very little thought to preventing chemical risks (Laurent 2014).

Tables and figures

Table 1. Proposed classification of services, to enrich the taxonomy proposed by Miles (1995).

Type of KIBS	Activity (share of advice in the activity)	Organization's objective	Status	Relations with clients (the role of advisory services in these relationships)
Professional KIBS (P-KIBS) (Miles 1995)	Service = 100% of the activity	Making profits via the commercialization of services	Private firm	<ul style="list-style-type: none"> - Contractual relationship - Service provision at the heart of the relationship (what is sold is above all the advisors' working time) - Advisors' core competencies
Technological KIBS (T-KIBS) (Miles 1995)	Service = 100% of the activity	Making profits via the commercialization of services	Private firm	<ul style="list-style-type: none"> - Commercial relationship revolving around the sale of an intangible good (software, tool to help decision making, map, etc.) - Service and advice accompany this sale - Revolves around R&D (ICT, etc.)
Embedded or Integrated KIBS (E-KIBS or I-KIBS) (Barcey Bonamy 1999, Djellal and Gallouj 2010)	The services are above all developed to accompany a commercial activity concerning a good (input or output)	Improving the commercial activity on goods (quantity, quality) by providing clients/suppliers with these goods and related services. Note: a tendency is developing to seek profits on the service activity itself	Private firm or cooperative	<ul style="list-style-type: none"> - Commercial relationship (contract on the sale of products or on the collection of the farmer's produce) - The services accompany this commercial relationship (notably to guarantee the quality and quantity of the goods) - There is a tendency to separate the offer of these services from transactions on goods
Client owned KIBS (C-KIBS)	Services = 100% of the activity	Improving the performance of the clients/owners of the organization	Association (or firm whose capital is owned by farmers)	<ul style="list-style-type: none"> - The beneficiary of the services is a member of the association (and pays a membership fee) - This fee is a pooled investment in advisory services (front and back office) - Additional services can be invoiced individually

Table 2. Analysis framework for advisory service performance.

Dimensions	Indicators
Financial	*Profitability of the advisory service
Technical	*Productivity of the advisory service: -Ratio farmers/advisor -Surface areas under crops/advisor -Quantity of seed potatoes sold/advisor *Level of standardization -Is there a standardization of advisory services? *Rate of dysfunctions -Are there indicators of the advisory services' success?
Relational	*Personalization -Frequency of visits -Duration of visits *Client loyalty -Turnover of producers -Turnover of advisors *Nature of the contract
Innovation	*Share of the total budget devoted to the back office *Number of back-office staff *Back-office activities -Experiments -Databases -Scientific monitoring -Training
Civic	*Taking into account controversies over the use of pesticides -Health -Equity

Value (co)creation in emerging KIBS industries: Absorptive capacity matters. Evidence from Russia

Marina Doroshenko¹, Dmitri Vinogradov²

¹*Institute of Statistical Studies and Economics of Knowledge, National Research University – Higher School of Economics, Russian Federation. Email: mdoroshenko@hse.ru*

²*Essex Business School, University of Essex, United Kingdom. Email: dvinog@essex.ac.uk*

The paper focuses on knowledge-intensive business services (KIBS) to study the determinants of the successful value creation. We argue that value creation is not always efficient: the value of services could be lost due to an inefficient absorptive capacity of service consumers, who must be value adders together with providers due to the nature of services. The origins of inefficiency are elucidated by a thorough study of the interaction between KIBS producers and consumers (co-production). The methodology includes the study of observable patterns in Russian KIBS sector performance in 2007-13 obtained from specialised surveys of Russian executives who were asked to answer questions both on their own company and on market developments. We provide both cross-section and generalised analysis of survey data.

Introduction

The notion of absorptive capacity was initially introduced in macroeconomic dimension and characterized the ability of a national economy to absorb and exploit external resources, information, and knowledge (Adler 1965). In their classic paper Cohen and Levinthal (1990, p.128) redefined the concept on microeconomic level by labeling absorptive capacity as “the ability of a firm to recognize the value of new, external information, assimilate it, and apply it to commercial ends”. It is generally considered an imperative for business success.

From their thorough review of literature on the fundamentals of absorptive capacity concept, Roberts et al. (2012) reconstruct major assumptions of a firm’s ability to recognize and to utilize external knowledge. Among them two are of vital importance for our study:

First, absorptive capacity depends on prior related knowledge. Without some prior related knowledge, a firm will not be able to accurately determine the potential value of external knowledge.

Second, absorptive capacity is path-dependent. Accumulating absorptive capacity in one period will permit its more efficient accumulation in the next. Likewise, in an uncertain environment, absorptive capacity affects expectation formation, permitting the firm to predict more accurately the nature and commercial potential of technological advances. These two features of absorptive capacity—cumulativeness and its effect on expectation formation—imply that its development is path dependent.

The exact configuration of absorptive capacity, though generally accepted, differs in details. Bibliometric study of Lane et al. (2006) present absorptive capacity is a multidimensional construct that consists of three interrelated competences: knowledge identification, knowledge assimilation/transformation, and knowledge application. Zahra and George (2002) emphasize four dimensions: acquisition, assimilation, transformation and exploitation of knowledge. In our paper we shall use three-dimensional approach suggested by Lane et al. because we consider it closer to the original Cohen and Levinthal’s definition and includes the recognition stage, which is important for our purposes.

Scholars have leveraged Cohen and Levinthal’s original work on absorptive capacity in several ways. The application of absorptive capacity in such areas as innovation, interorganizational learning, mergers and acquisitions, and new product development signifies its substantial contribution to competitive advantage and firm performance (Lane et al. 2006). Meanwhile along these variety of research field we made two important observations.

First, the search of valuable external knowledge often appears as the specially organized process of monitoring of a firm’s environment. E.g. Cohen and Levinthal (1989) and Lichtenthaler and Lichtenthaler (2009) show that a firm develops collective knowledge about certain areas of markets, science, and technology through its research and development activities, and screen those areas for the sake of improving its products and services.

Second, among all components of absorptive capacity, most authors put the main emphasis on the final stage. Intensive studies are devoted to a variety of applications of the newly absorbed knowledge; e.g. replenishment of a firm’s knowledge base (Van den Bosch et al. 1999), forecasts of technological trends (Cohen and Levinthal 1994), reconfiguration of existing capabilities (Pavlou and El Sawy 2006), and creation of innovative products and services (Tavani et al., 2013). Neglected are the first stages of recognition and acquisition of new knowledge.

Empirical studies support these deductions from theoretic literature. Measuring of absorptive capacity involve self-explanatory proxies. E.g. Cohen and Levinthal (1989) tested the general predictions of their model using business unit data for 1975 through 1977 from the FTC’s Line of Business Program, and used R&D sales as a proxy for absorptive capacity, though they obviously measure the final outcome of absorption.

Zahra and George (2002) suggested a series of indicators for all elements of absorptive capacity:

- Knowledge acquisition capability (the number of years of experience of the R&D department, the amount of R&D investment)
- Assimilation capability (the number of cross-firm patent citations, the number of citations made in a firm's publications to research developed in other firms)
- Transformation capability (the number of new product ideas, the number of new research projects initiated)
- Exploitation capability (the number of patent, the number of new product announcements, the length of product development cycle)

The first two sets of proxies picture the corresponding stages of knowledge absorption as the process of external monitoring.

The purpose of our study is to present a slightly different view on absorptive capacity. First, we study the sources of external knowledge that appear in core business activities of a firm through interaction with its suppliers. This approach is in line with an augmenting tradition within the studies of new product development. E.g. Rindova and Fombrun (1999) emphasize that a knowledge exchange process during product development process demands strong customer learning capabilities. Tsai (2009) also proves that high levels of absorptive capacity would allow a customer firm to incorporate fruitful knowledge and capabilities of suppliers. The empirical study of Tavani et al. (2013) introduces customer's ability to learn from their suppliers among other proxies of absorptive capacity. These studies bring up the problem of absorptive capacity for new knowledge transfers within everyday businesses rather than for knowledge obtained through special monitoring efforts.

Second, we intend to put special emphasis on the beginning stages of knowledge absorption because they are crucial for the entire process. The literature review above shows that these stages are little explored in general. Few relevant studies associate recognizing of new knowledge with screening of open external sources like patent bases and conference outcomes. Again, the recognition of value of the new knowledge arriving from everyday interaction between suppliers and customers is practically out of view.

We study the problems of "everyday" absorptive capacities by the example of firms who use knowledge-intensive business services (KIBS). This paper is aimed to examine the ability of Russian companies to appreciate and to apply external novelties they face when obtain KIBS. KIBS are widely known as users, carriers and sources of innovation (Miles et al 1995). The KIBS sector appears as a set of activities aimed to help other companies to solve problems than need external sources of knowledge. In particular, the existing literature stresses that (a) provision of KIBS links the knowledge of the consumer with the knowledge that exists elsewhere, thus improving the exchange, availability and usability of the knowledge, and (b) each KIBS provides a solution to a specific problem of the customer and thus embeds and transfers knowledge that would be otherwise unavailable to or neglected by the customer. (Thus, for example, Muller & Zenker, 2001, p.1504, subdivide knowledge processing within KIBS firms into the integration of external knowledge, acquisition of available problem specific knowledge, and elaboration of the new problem specific knowledge; see Landry et al., 2010, for a discussion of these and other characteristics of KIBS).

Therefore KIBS are information services by nature. Sometimes their rendering is accompanied by producing of a material object, but even in this case the value of informational constituent exceeds the one of subjoined artefact essentially. The use of KIBS hence means the use of external non-profile knowledge, and the problem of absorptive capacity faces the user in its entire complexity.

Data and Methodology

The data used here derive from specialised surveys that have been undertaken in Russia, covering 600-800 producers of KIBS annually for each year across 2007-13.¹¹⁹ The core of the surveys was replicated across this period, but some questions were only asked in particular years, so our reporting below will use data from various years according to availability. The sample consists of Russian-based producers of KIBS¹²⁰ selected annually based on their reported turnover. Companies were invited to take part in the survey consecutively. If the invitation was rejected, the next invitation (to a company with the next highest turnover) was sent out. Occasional severe delays with replies or replies from firms that earlier rejected the invitation resulted in minor deviations from 60 firms per sector, which does not affect the total sample quality. Executives of these firms answered questions on their own company and on the more general market developments. All surveys are anonymous, some firms may be included in several surveys (not

¹¹⁹ The surveys are designed by the Institute of Statistical Studies and Economics of Knowledge (ISSEK) and are conducted by ROMIR Monitoring using original topic guides and questionnaires developed specially for this research.

¹²⁰ KIBS production in Russia is strongly concentrated, with 20 per cent of the companies accounting for around 80 per cent of the market. Respondents in each segment were recruited from the top 200 companies in each sector (as measured by their turnover). While some of the same companies will feature in more than one year, this was not designed as a panel survey. Since data are provided to us anonymously, we cannot exclude such multiple representation. However, ROMIR, the survey firm, has indicated to us that in each year around 15–20% of companies have participated in earlier surveys, though our respondents do not participate in the survey more than once every two years. Foreign-owned companies are excluded from the study, since the large multinationals who do supply Russian markets are believed to provide highly standardized services – as was confirmed by our expert interviewees. Russian companies compete with these multinational firms, in part, through providing more customized services; they would generally fail to compete on the basis of economies of scale.

necessarily successive), but it does not alter the generalised results. We cannot prevent one and the same firm from taking part in several consecutive surveys, therefore this dynamic double-counting, or potentially misbalanced panel, has no effect for any particular year reported.

The KIBS sectors covered in the surveys are advertising, marketing, audit, IT-services, recruitment, engineering, financial advice, legal advice, property development services, and business design. This choice includes most of the industries described as KIBS in the existing literature. While there is some disagreement as to the precise statistical identification of KIBS sectors (see e.g. Hipp, 1999; Koch and Stahlecker, 2006; Muller and Doloreux, 2007), it has been common to include most of the industries covered in NACE (Revision 1) divisions 72–74.¹²¹ Our sample contains a good range of these industries, including both long-established professional services and newer technology-related and management services. The samples for all of these sectors were dominated by relatively small firms – 60% of more of the cases in each sector in 2011, for example, had 50 or fewer employees. It is common in other countries, too, for service firms, and KIBS, to be relatively small in scale (CRIC/IDSE/ISE, 2001).

While we cannot match specific users and suppliers, we have also opportunities to draw on data about KIBS users. In 2007 and in 2011, a survey parallel to that of KIBS suppliers covered over 700 business consumers of one or more of the KIBS services discussed above. Each of the business consumers were asked about their experiences with each of the types of KIBS used by the company. In 2007 the average client company used 4.7 services, and in 2011 4.2 services, so we have about 3300 observations by customers about their experiences.

Later we present results from these surveys, addressing the hypotheses set out above, and providing other relevant information concerning innovations in KIBS. But first, we need to discuss the role of KIBS in Russia, and consider how one aspect of this context affects our research strategy.

Main findings

This paper aims primarily to fill in the gap both in theoretical and empirical literature by examining thoroughly the first component of the absorptive capacity, i.e. the ability of KIBS customers to recognize the value of new knowledge which is embodied in KIBS due to their knowledge intensity.

Two patterns of consumer value creation are commonly observed: standardisation and customisation of products. An important value-creating feature of standard products is reduction of consumer costs, both direct (prices of standard products are lower) and indirect (costs of recognising, selecting and learning-to-use). Personalised production, on the contrary, is costly, but the decrease in value due to a complexity of choice and use is compensated by an additional value from the perfect fitting to THE consumer needs. Service industry provides a good example of both standardisation and personalisation with a wide range of intermediate solutions.

Many studies confirm that KIBS are more prone than most other sectors - including most other service industries - to produce customized services. Hipp et al (2000) and Tether et al. (2001) prove it using German survey data, Sundbo (2002) – using Danish ones, Evagelista and Savona (1998) – Italian, Hortelano and González-Moreno – Spanish, Nahlinder (2005) – Swedish.

Our surveys show that Russian KIBS sector also provides an excellent empirical support to the hypothesis about wide spectrum of variously customized decisions. Following the above-mentioned European empirical approaches, we asked KIBS providers to divide the total amount of their services into three groups: standard (replicable with minor replication costs), customized (highly bespoke, hardly replicable) and intermediate group having “standard shell with individualised nucleus” (partially customised), Table 1 shows that in all sub-sectors these three groups are well filled.

Table 1. Distribution of KIBS in terms of degree of standardisation, 2010.

Responses to the question: "What share of your services in 2010 falls into each of these categories?" (mean shares shown; standard deviations in brackets)

	Overall	Sectors									
		AD	MKT	ADT	IT	REC	ENG	FIN	LEG	DVP	DSGN

¹²¹ To be precise, the NACE codings for the sectors studied here are 72.1-72.4 (hardware, software and database consultancy, supply and processing – grouped as IT-services), 73.1 (for engineering), 74.1 (for legal advice, audit and marketing), 74.2 (building, machinery and industrial plan design), 74.4 (advertising), and 74.5 (labour recruitment). The study also included two sectors that are not usually considered KIBS - NACE divisions 70.1 and 70.3 (property development and real estate intermediation) and 65.2 (financial intermediation) with 67.1 (activities auxiliary to financial intermediation). The latter two are often provided jointly by the same entity and it is hard to separate them. With regard to these we specifically focus on companies that provide financial intermediation and associated services to business customers.

Meanwhile customers do not recognize perfectly the degree of service customization (see Table 2, where we use more fractional scale of customization for more precise estimations). They tend to treat a visible part of customized services as standard ones. These customers do not understand the value of efforts that were made by providers to tune the service to individual needs, and thus do not recognize the value of the resulting customization.

Table 2. Standardisation of Services in Russia as seen by service providers and consumers, 2007.

Responses to the question: "What was the share of standard services in the total volume of services provided/ordered by your company?" (standard deviations shown in brackets). Consumers could answer questions for multiple KIBS sectors resulting in the high number of total responses, N, in the final row)

Note that N means different things for providers (it is here the number of firms, which equals the number of answers), and for customers (it is the number of valid answers, which exceeds the number of firms).

Source: ISSEK-ROMIR surveys, 2007.

Consumed KIBS are considered to be on average less tailored than produced ones; sometimes the difference is substantial (up to two times). We named this observable fact *perception asymmetry*. It differs from widely known information asymmetry because a customer may be fully informed about the rendered service, but consider it as equivalent to services provided to other consumers. Then the customer believes to purchase a standard service though actually the service was tailored.

In other words perception asymmetry means that a producer understands what differs his service from services provided by other producers, but a consumer may not recognise the difference. Producers know the technology of service production objectively, but consumers subjectively compare the provided service with similar ones ("services of the same name") supplied to other consumers. This effect cannot be explained by asymmetric information (see e.g. Gallouj (1997), for asymmetric information in services), because it does not depend on how well the customer is informed about the service itself. In a standard asymmetric information setting (Akerlof, 1972) knowledge of the quality of products delivered to other customers is irrelevant. The problem of asymmetric perception only arises in an economy with highly heterogeneous products, which is the case with KIBS. In particular this can lead to a distorted pricing in a market where consumers expect prices for seemingly homogeneous products to be levelled, whereas providers of highly heterogeneous services would seek for a pricing mechanism suitable for unique products targeted at individual customers.

Due to perception asymmetry producers know their services are tailored, but consumers consider them standard. We discovered this phenomenon and labelled it the "turbid glass" effect. When one looks through a turbid glass, similar though different objects may seem identical. Likewise KIBS customers see the vague picture of rendered services where differentiation and individuality are indistinguishable.

The "turbid glass" effect prevents customers to distinguish between a tailored service and a standard one, i.e. they underestimate the bespoke characteristics of services and overestimate their standardized characteristics. In other words, we observe partial losses of value embodied in customization.

We do not mean that all KIBS customers look at the sector through the “turbid glass”, otherwise we observe zero demand for customized services, - in the absence of perceptible differences between the services, less expensive standard services crowd out more expensive customized ones. We only claim that KIBS users have different abilities to recognise the which is embodied in services by the technologies of their production. Some customers have better absorptive capacity since they recognise heterogeneity of services and treat them as customised solutions for their businesses. Other customers imagine services as commoditised and thus less prepared to assimilate their actual complexity.

Seeking for the origins of the “turbid glass”, we appeal to Cohen and Levinthal’s (1990) remark about path-dependence of absorptive capacity. They also highlighted the importance of accumulated expertise for proper absorption of non-profile knowledge. We explored perception asymmetries to test this hypothesis with reference to KIBS, which are always beyond customer’s principal activities. Even if a customer firm delegates service provision only partially, and the “make-or buy” trade-off is settled by combination of in-house production of services and purchasing it from an external supplier, service production remains a non-profile business for the customer. innovations beyond its principal activities. Their implication impels the firms to special efforts [Cohen and Levinthal, 1990, 150]: “When, however, a firm wishes to acquire and use knowledge that is unrelated to its ongoing activity, then the firm must dedicate effort exclusively to creating absorptive capacity (i.e., absorptive capacity is not a byproduct)”

KIBS customers should make especially serious efforts in their service appropriation activities when dealing with customised or partially customised KIBS production. Bespoke, particularised, KIBS require detailed information about the customer’s needs; generic knowledge about a representative consumer is not sufficient. Drawing on evidence from several surveys, Miles (2008) argues that innovative KIBS providers rely on the information obtained from their customers more heavily than do innovators among manufacturing firms and most other service businesses. The particularisation of a service normally requires that the client supplies, at a minimum, relevant information about the business processes problems that the KIBS firm is helping to address. Quite often, the client is engaged in prolonged dialogue with the KIBS firm concerning the nature of the problem and the applicability of possible solutions. (These may be discussed more abstractly, or actually prototyped or trialled in practice.) The roles of KIBS in knowledge transfer are widely recognised and studied in the literature (see e.g. Hipp, 1999, for an early review, and Strambach, 2008, for a more recent contribution), but there is little research on just how this knowledge is transferred¹²². One exception is Landry et al. (2010), studying the types of knowledge transferred from KIBS providers to customers, and examining the factors that facilitate such an exchange of knowledge. In the present study, we extend their findings in terms of the innovative impact of KIBS on their customers

A term often employed in the context of service relationships is “coproduction” – signifying the role of the customer in generation of the service product. Much of the literature on coproduction has concerned public services (Percy, 1983, Whitaker, 1980 are early examples); a smaller volume of studies bring the perspective to bear on consumer and business services (e.g. Marion, 1997, Spohrer & Maglio, 2008). The basic point is that the customers and users of services often have to contribute greater or lesser amounts of effort to the service production process. Sometimes physical presence is enough, but often the client is required to input information and to interact more intensively with the service provider (and sometimes with other clients).

In the KIBS case, as noted above, the client has, at the very least, to specify its business problem and provide relevant information to the provider. Often, higher levels of engagement are required. KIBS services products can be seen as having two producers. The service provider inputs mainly its intellectual labour resources. The customer firm inputs information about itself, and participates in a process of change (which may involve various stages, including, as suggested above, stages of testing solutions and obtaining feedback on them). Koch and Strotmann (2006) showed that the market success of KIBS firms crucially depends on the quality of coproduction. In other words, co-production is vitally important to create proper consumer value, especially in the case of highly bespoke services because Imperfect information hinders proper bespeaking. The better the service is tailored, the better it suits the customer’s need, and the easier should be its application. This is the reason why the quality of co-production appears as an essential determinant of absorptive capacity.

Surprisingly, co-production rarely appears in absorptive capacity studies independently, but rather in the general context of interaction between suppliers and customers. In this paper we discuss it as a separate topic because imperfect co-production may hinder the customers from proper absorption of services even under excellent potential absorptive capacity.

To study the level of coproduction, KIBS providers were asked to estimate the level of customers’ involvement in the service production on a scale ranging from 1 (minimum participation, no inputs provided except the terms of reference for the service contract) to 10 (maximum participation, joint project implementation). Table 3 presents data from the 2007 and 2011 surveys: the overall score for coproduction in KIBS, and that in most sectors exceeds 6 out of 10 in both periods, despite the recent economic downturn. (Furthermore, though not displayed here, some 30 per cent of KIBS firms report scores of 8-10, in both samples.)

¹²² We will use this common formulation, though resist the notion that knowledge is a “thing” that can be moved from one location to another. We would rather see knowledge as a property of knowing agents, and that acquisition of this property involves processes of assimilation of information and building this into cognitive frameworks.

The conclusion is that these KIBS firms do see their as often participating quite substantially in coproduction of their services. Overall, there is little change between periods. Individual sectors move in different directions, but generally to very limited extents, despite the economic downturn.¹²³ It may be that some firms are pushed towards more light-touch service provision, while others seek more coproduction, as a result of economic stringency. In both the 2007 and 2010 samples, F-tests on an analysis of variance of results indicate statistically significant differences (at the 99% confidence level) in the degree of customers' involvement in production of services across economic sectors. This evidence is provided by ANOVA test (differences are significant at level of 99% confidence interval).

Substantial score for coproduction does not nevertheless guarantee its quality. Bettencourt et al. (2002), who consider coproduction to be a defining characteristic of KIBS, accordingly point out that clients may not sufficiently recognize the necessity of coproduction, Our surveys also show that the degree of co-production, though high enough, is nevertheless substantially beyond providers' needs. Table 4 compares actual and desired levels of customer involvement, using the same 10-degree scale as Table 3.

Table 4. Actual vs desired levels of co-production.

Our survey asked about the quality of coproduction, and the factors that were involved when this was low. No wonder than in 2013 only half (50.7 per cent) of the Russian KIBS producers considered that they received excellent coproduction from their counterparts.

Insufficient coproduction inevitably leads to mismatch between a customer's needs and the final quality of service even if the contribution of provider was perfect. The potential customer value of service is therefore partially destroyed. The service becomes less appropriate and less useful for further stages of absorption (transformation and exploitation). Figure 1 supports this argumentation by emphasizing two important observations. First, Russian KIBS consumers failed to absorb KIBS in full amount; the share of respondents who reported full absorption (vertical axis) is beyond 100 per cent for all groups (cross-section analysis, though not shown on the chart, confirms incomplete absorption in all observed sectors). Second, the largest share of absorbed services corresponds the largest score for coproduction.

¹²³ We do not have panel data; it is possible, but unlikely, that there is more volatility at the firm level.

Responses to the question: "Please estimate the degree to which the customers are actually involved/desired to be involved in the production of services, on the scale 1 to 10" vs. Responses to the question: "Please estimate the of customers' absorption of rendered services", 2013.

Figure 1. Relationship between co-production and absorption of KIBS, 2013.

Coproduction and actual absorptive capacity are therefore closely related (Spearman's correlation is 0,48 at 10 percent significance level). The correlation is not as strong as one could expect, because the groups with lowest scores for coproduction also show good absorption. The explanation (both intuitive and empirical) is that weak coproduction corresponds standard services, whose absorption demands less efforts from the customer.

The results of Figure 1 may be interpreted alternatively: despite of proper co-production, KIBS providers failed to supply services of necessary quality. This assumption is nevertheless not supported by evidence. Our survey of KIBS customers show that over 90 per cent of them are happy with rendered services. Beyond 10 per cent reported that they are not satisfied and rather not satisfied with the quality of services (with results varying from 4 per cent for users of auditing services to 18 per cent for services of business design). Only few cases of improper absorption could thus be explained by bad KIBS production. The main imperfection lies on the customers' side.

Co-production is thus crucial for proper absorption of services because it is crucial for proper tuning of services to THE customer's needs, especially in the case of customized services. Providers fail to create perfect consumer value without necessary customer cooperation. This causes not only microeconomic value losses, but macroeconomic s well. Our surveys show that in 2007-2013 from 30 to 45 per cent of rendered services were not absorbed completely. Resources that providers spent for their production were partially or completely wasted. Having in mind that KIBS production involves mostly highly qualified human recourses (as argued by Miles, 2007, and Strambach, 2008, among others, and supported by our surveys in Russia), their misuse moves the whole economy back from Pareto optimality both in quantitative and in qualitative terms.

The ability of customers to absorb KIBS may therefore be improved not only by improving of their ability to assimilate innovations, as widely shown in literature (see Zahra and George (2002) for discussion), but also by making KIBS themselves more appropriate. Cohen and Levinthal (1990) insist that absorptive capacity is strongly dependent from previous customer experience. This argument could hardly be supported empirically in developed economies whose customer firms have dozens years of practice with KIBS. But younger markets provide solid selections of both experienced and inexperienced customers. At least Russian KIBS providers deal actively with both groups, as Table 5 shows.

Table 5. Customers' expertise in KIBS, 2011.

Relying on their experience, Russian KIBS providers strongly support the idea that experience in KIBS consumption generally makes their inexperienced customers better coproducers (see Table 6). Almost three quarters of them support the suggestion that their customers make significant progress, and only 12 per cent do not notice any improvement in their customers' expertise.

Having in mind the close relation between coproduction and implementation in services, and relying on Cohen's and Levinthal's (1990) argument about the crucial role of prior experience for customers' absorptive capacities, we may include that extending experience in KIBS coproduction and consumption is a promising mechanism of improving the service absorption (see also Doroshenko, 2012). Experienced customers are more able to recognize the necessary level of coproduction and to coproduce properly depending on their desired level of service customization. We expect that the extension of customer involvement may visibly improve the absorptive capacity of KIBS consumers by improving their ability to recognize and to co-create proper customer value of services.

Conclusions

Cohen and Levinthal (1990) introduced the concept of absorptive capacity to describe the ability of a firm to adopt and to make good use of external knowledge. We use the empirical data to track the main components of KIBS users' absorptive capacity, i.e. their ability to recognise and to evaluate the value of services, their ability to implement services and their ability to put the services to commercial end in their core businesses. We find the value losses in all above mentioned components.

First, we prove that KIBS consumers are unable to recognise the individualisation of service properly, and they underestimate the value added by customised services and overestimate the value added by commoditised services. Both distortions deteriorate absorptive capacity and cause latent value losses due to improper choice of service supplier.

Second, we show that KIBS users are often unable to be perfect co-producers for various reasons. As a result, they obtain excess value of standardisation and lacking value of bespeaking; in both cases the value of service is beyond expectations, and its proper absorption is inhibited.

Third, we provide evidence that service implementation is not perfect, partially due to insufficient expertise of KIBS users, partially due to their insufficient motivation. Some services of proper quality are not used at all or used only partially. Consequently, direct (observed) value losses appear, especially in emerging markets for services.

We conclude that absorptive capacity of KIBS users is imperfect at all stages of their consumption cycle: supplier selection, service (co)production and final implementation. Open and latent value losses result from poor absorption, in terms of both consumer and social welfare. We prove that learning-by-doing in co-production is the main source of upgrading the customers' absorptive capacity at all stages.

HOUSE OF SECURITY (HOS) – From Attacks Scenarios to Security System Components

Shuki Dror, Emil Bashkansky, Rachel Ravid

Industrial Engineering and Management Department, ORT Braude College, Israel

In the past organizations have tended to address various aspects of security separately, often assigning different responsibilities to different distinct departments such as Information Technology (IT), physical security and fraud prevention. Today, there is a greater recognition of the interconnected nature of security requirements and that a holistic approach is needed for preventing different types of hazards. This growing awareness informs our development of a comprehensive methodology for organizational security decision making processes and security system design.

1 Introduction

With terrorism threatening targets around the world, especially in unstable regions, and the growing sophistication of criminals and their machinations, the tasks of security managers have never been more formidable. The security system design process involves a difficult and complex balancing act that must take into account many different interests and values such as risk probabilities and costs. Each system component requires separate consideration, in tandem with analysis of the interaction between components. Understanding a client's risk perceptions and effectively communicating risk is critical in helping clients make informed decisions regarding the security system needed. Disciplines such as operations research, statistics and quality management are usually applied in order to provide a framework for constructing models of security decision making.

A variety of analytical methodologies and algorithms has been developed for this purpose. Transportation security systems have received special attention in the literature, particularly since the September 11 terrorist attacks on the U.S. (Stewart; Mueller, 2011) presented a cost-benefit analysis of Advanced Imaging Technologies (AIT) for passenger screening. (Majeske; Lauer, 2012) developed Bayesian decision models of two passenger prescreening systems: two-way and three-way classification schemes. (Xiaofeng, 2012) studied the case where passengers are categorized as one of several risk classes, according to their risk characteristics. (Lee; Jacobson, 2011) introduced passenger assignment procedures that balance the tradeoff between maximizing security and minimizing the expected duration of the passenger security process. (Hasoun et al., 2011) used elements from queuing theory in order to model illegal border crossing and security agents' reactions. (Niyazi, 2011) applied game theory to security system modeling. He implemented a Stackelberg game for analyzing resource allocation strategies to improve cargo container transportation security. (Keeney; Von Winterfeldt, 2011) developed a value model for evaluating homeland security decisions and allocating the security resources' costs effectively, using estimated values of the probability of various types of threats, vulnerability, consequences and costs.

In the main, previous research related to security decision making has focused on specific systems such as aviation transportation systems and aimed to provide deep insight into the effectiveness and utility of some devices or operation policies. The security standard (ISO 28000; 2007) was developed to organize security operations within the broader supply chain. The standard specifies the requirements for a security management system, including the aspects critical to security assurance for any organization or enterprise wishing to manage its security and activities.

The methodology proposed herein—the HOS methodology—uses a generic QFD based framework to organize security decision making and streamline the process. The QFD technique is well-known for creating a linkage between product design, customer needs and process requirements and is extended here for methodology needs. The methodology provides the client with an objective assessment of potential vulnerabilities and gaps that enable him or her to construct a risk profile. Based on the risk profile, the security engineer can propose optional security systems. The effectiveness of each security system is evaluated using the appropriate measure. The latter is based on the expected loss measure, which was developed earlier by the authors (Bashkansky et al., 2007). An ANOVA procedure is implemented to divide the set of security components into a group of dominant vital components and a complementary group of less important items. The methodology implementation is demonstrated by a detailed example of a hotel security decision making process.

2 The Methodology

Leading companies around the world have been using QFD since 1966. Its two-fold purpose is to assure that true customer needs are properly deployed throughout the design, building and delivery of a new product, and to improve the product development process itself (Akao, 2003). Typically, the approach is described in terms of a four-phase model consisting of four successive stages or matrices: (1) an overall customer requirement planning matrix (also called the HOQ); (2) a final product characteristic deployment matrix; (3) a process plan and quality control charts; and (4) operating instructions. An HOQ maps the WHATs representing desired customer product attributes define VOC Voice

of Customer (VOC) into the HOWs, the technical characteristics as viewed by the R&D staff; see (Chan, 2002) for an extensive review of the QFD literature.

This paper builds on the HOQ framework by developing a HOS that translates the security needs of an enterprise into the relative importance of the components of its existing security program according to their relative importance in meeting these needs.

The general building sequence of the HOS comprises the following six major steps:

1. Relevant Scenarios (WHATs) – Identify and classify the attackers' intentions and the relevant (plausible) attacks to the organization (the walls). Specify scenarios for every place in the organization that may be attacked.
2. Likelihood and severity of these scenarios – Assign assessments observed from security surveys; include scenario possibilities and losses when a scenario occurs.
3. System components (HOWs) – Select a structured set of relevant system components (the ceiling), i.e. technologies, people, and procedures, which are capable of preventing the identified scenario.
4. Interrelationship matrix – Evaluate the reduction in the risk of each scenario as a result of using each security component (the house's main contents). An appropriate scale is applied, illustrated by symbols.
5. Synergy/tradeoff between the system components (the roof) – For each scenario, identify which system component supports (or obstructs) another system component. These synergies can highlight innovation opportunities or bring to the fore areas that need reorganization.
6. System priorities – Calculate the system component priorities as a one bloc and for every specific place that may be attacked (the floor).
7. System effectiveness – Estimate the overall effectiveness of the security of the analyzed system. This value could be used as a selection criterion when several security systems are introduced for the same set of scenarios.

The calculation of the system components priorities takes into account the possibility that a scenario occurs, the reduction in the risk of each scenario as a result of using each security component, the loss when a scenario occurs, and the synergy between security components, given a specific scenario. The last part of this formula differentiates it strongly from the classic QFD formula. The classic QFD has one roof that presents correlations between the technical characteristics. Here we assume that correlations between the system components might change for each scenario, i.e., there are several roofs, corresponding to the number of rows in the HOS matrix.

The Analysis of Variance (ANOVA) method is utilized here for selecting the vital security components to be improved. The method is used for selecting the components to be improved. ANOVA is a method for decomposing the total variability in a set of observations, as measured by the sum of the squares of these observations from their average, into component sums of the squares that are associated with specific, defined sources of variation. (see, e.g., Montgomery, 2004). (Dror and Barad, 2006) utilized the MSE criterion as a quantitative tool for implementing the Pareto Principle. This principle was presented by Juran as a universal principle he referred to as the "vital few and trivial many". (Dror, 2010) showed that the one-way ANOVA tools, i.e., MSE, MSB and the F-statistic, are equivalent when used for dividing a group of ordered items into two groups: the vital few and the trivial many.

3 Constructing the HOS for Hotel Terrorist Attack Protection

The Relevant Scenarios (WHATs)

Hotels have often been the object of terrorist attacks. The most common kinds of such attacks are suicide bombers, car bombs, explosives, grenade assault and the taking of hostage(s). Potential attack locations: front of the hotel, entrance check point, parking area, lobby and anywhere inside the building. The left wall of the HOS includes 5 x 5-1 possible scenarios (the combination of "a car bomb inside the building" is not feasible).

The Likelihood and Severity of the Scenarios

In the second step of building the HOS (right wall), scores, based on security surveys, were assigned by experts who assessed the likelihood and severity of every scenario. In order to emphasize the dramatic character of terrorist attacks, the geometrical and not arithmetical scale of scores was used according to:

- Scenario likelihood: unlikely/weak – 1, likely/medium – 3, very likely/strong – 9
- Severity of damage to people or/and property: light – 1, medium – 3, high – 9

The System Components (HOWs)

The relevant hotel security system "hows" (components) include:

Technologies:

- Prevention devices: cameras (LPR,TV), video information analysis (VIA), entry control tools, boulders
- Alarm devices – detectors, distress/trouble buttons, siren

Human resources:

- Personnel: external, internal
- Police

Security system procedure & operating instructions

The Interrelationship Matrix

This stage of constructing the HOS is very essential, but is also almost the most painstaking and laborious part of the process. 24 what (rows) and 12 how (columns) form 288 cross cells ($I=24$, $J=12$ and $IJ=288$). Each cell contains the assessment of the extent to which the specific how might reduce the risk of occurrence or damage caused by a corresponding scenario (what) measured, as is customary in QFD, on the basis of four degrees of interaction: high interaction (=9), medium interaction (=3), low interaction (=1) and no interaction (= blank, further considered as zero). This assessment is usually based on experts' knowledge and experience. Consensus decision making based on the Delphi method (Linstone; Turoff, 1975) was selected as the most appropriate for arriving at the final scores.

Synergy/tradeoff between the system components (the roof)

The HOS roof construction here differs somewhat from the usual QFD technique. In the context of this paper synergy/tradeoff means that two hows functioning together produce a combined result not independently obtainable. Positive or negative synergy can exist. The latter often appears as a result of tradeoff between two hows. Positive synergy occurs if interactions between two hows produce a joint effect, which is greater than the sum of the parts acting alone. In contrast to standard QFD, the presence of positive/negative synergy must be analyzed for each scenario separately.

The experts' assigned positive synergy between:

- cameras TV and VIA,
- policemen and operating instructions
- external personnel and operating instructions.

System components priorities

A system components priority can be calculated according to (1) by multiplying three score columns: likelihood, severity and the corresponding column of the interrelationship matrix. Empty cells are considered as zeros. A simple Excel© function, such as SUMPRODUCT (array1, array2, array3) can be used for this purpose.

The ANOVA based MSE method described above, when applied to these data, emphasize the following five (from twelve) components as dominant for the hotel security system: Operating procedures; TV cameras; internal personnel; entry control; visual information analysis.

The dominant components destined to protect a certain place—parking, for example—can also be partially analyzed. In this case, we utilize only the relevant part of the common matrix obtained by deleting unnecessary scenarios.

Now the dominant components preventing parking area threats are operating procedures and internal personnel.

3.7 Overall effectiveness of the security system

This value could be used as a selection criterion when several security systems are introduced for the same set of scenarios.

4 Conclusions

QFD, is a product-oriented quality technique supported by (ANOVA), a statistical technique, was applied in an innovative way to reveal the requirements of the security system to be adopted by an individual organization or the suitability of a security system already in place. The method provides useful information and understanding regarding the relative importance the management of an enterprise should attribute to its security system components as dictated by attacks scenarios as well as by its internal capabilities. QFD provides a mechanism for leveraging the security system of an individual organization. The HOS highlights potential attackers' intentions and the relevant attacks to the system and translates them into the relative importance of the security system components.

The HOS method is different from the classic QFD. In the classic QFD, a single roof presents correlations between the technical characteristics. In HOS we assume that correlations between the system components might be changed for each scenario, i.e., several roofs, corresponding to the number of rows in the House of Security matrix. Hence, the calculation of the relative importance of the system components takes the synergy/tradeoff between security components given a specific scenario into account. For comparing different security systems designed to prevent the same threats, a new effectiveness measure is proposed. Analysis of Variance (ANOVA), supports pinpointing of the vital security system components. It divides a group of items (here a set of security system components) into two groups: vital few and trivial many.

A QFD matrix is typically carried out by teams of multidisciplinary representatives from all stages of product development and manufacturing. For building the HOS, a cross functional team is established. It might include security

experts, managers, technical engineers and maintenance technicians. Among its assignments, the team would be tasked with organizing the process of extracting input information for the HOS matrix.

This paper describes the implementation of the above methodology for hotel protection from a terrorist attack. The QFD team identifies the most common kinds of attacks: suicide bombers, car bomb, explosives, grenade assault and taking of hostage(s), and potential locations of the attack in or around the hotel: front of the hotel, entrance check point, parking area, lobby, and anywhere inside the building. The HOS pointed out five vital components of the security system: operating procedures, TV cameras, internal personnel, entry control, and visual information analysis. A partial analysis to identify the most important component for protecting a certain area of the hotel (parking area) showed that the number of the vital components decreases and the dominant components for preventing parking area threats are operating procedures and internal personnel.

Our method (the HOS supported by the ANOVA method) reveals the most suitable security system structure to be adopted by an individual organization. In the case study, vital five security components were found to be the best tools for reducing the risk of attack scenarios.

The method applied in this work effectively supports the selection of vital security system components. It emphasizes adopting a systemic approach for selecting the vital security system components in response to attack scenarios.

Technology adoption in service organizations: a framework proposal for studying ICT diffusion in healthcare and hospital services

Josivania Farias, Juliana de Almeida

Universidade de Brasília

The aim of this paper is to outline a framework for the study of Information and Communication Technology (ICT) diffusion in healthcare and hospital services having Rogers's innovation decision process (1983) as a background. To do so, we sought publications on the topic from the last 10 years. After gathering dozens of organizational and individual determinants of technology adoption, the next step was to lay these factors throughout the stages of this adoption's decision-making process. This study aims to contribute with research efforts that address facilitating or inhibiting factors of ICTs adoption getting the Innovation Diffusion Theory close to the many conditioning factors of the adoption of ICTs.

1 Introduction

Innovation is defined as a well succeed exploitation or transformation of ideas into products, processes, business models, or more profitable services when it deals with taking higher risks, being essential to competitiveness (Tether, 2003). Its development process encompasses decisions and impacts that come from the recognition of problems through research; development and commercialization of an innovation; and the diffusion and adoption of innovations by users. Diffusion, in turn, assumes the role of a process by which innovation is transmitted to the members of the social system through communication channels (Rogers, 1983).

In this context, the diffusion of technologies goes through an important innovation decision process supported by the IDT in Rogers (1983). It seems to be about a sequential linear stage model of the innovation decision-making process, which simplifies the complexity that may exist in the adoption of technological innovations and innovations in services, including the intrinsic to hospital services.

Barlow (2013) argues that the diffusion of innovations can be explained by the making of individual decisions, linking innovation and the adopters who make up the organization.

According to England and Stewart (2007), innovation can be interpreted as a process of adopting new technologies, methods and ideas, which is essential to the development of healthcare organizations. Innovation in this area comprehends the development or improvement of the clinical practice, of the support services design, of the physical infrastructure and of technologies. It also affects the health care delivery models and the demand for hospital beds. Therefore, the diffusion and adoption of innovations in health care is a challenge, because it deals with the complexity of health services and involves multiple stakeholders (Barlow, 2013). In the case of healthcare services, innovations are responsible for major changes in the results and obviously for an increase in expenditure (Rye, Kimberly, 2007).

The studies on factors that condition the adoption of innovations are capable of making the decision-making processes more effective, both at an individual organization level or at an organizational system level, through more effective political decisions. For this reason, it is essential to understand the facilitating and inhibiting – or conditioning – factors of its diffusion in this context (Rye, Kimberly, 2007).

The ICT is a linkage between telecommunications and computing technologies, which is able to improve work routines and is influenced by organizational, technological, economic and individual factors (Bouwman et al., 2005). In the extent of this work, it is timely to discuss and understand that on the one hand, the organizational perspective addresses all factors related to the nature of the organization and to the environment in which it operates, and on the other hand, the individual perspective considers all factors associated with the acceptance, the attitude, the intention, the propensity and readiness to use technology and the after-use of the individual, as well as, factors related to the users perception of technology (Bouwman et al., 2005).

Due to the importance of the innovation decision process developed by Rogers (1983), employing the same logic to studies on technology adoption in health services organizations can be helpful. However, it was noticed, as a gap, the need to catalogue, discuss and allocate factors that intervene in the process of adopting technologies, so that they were arranged in each one of the adoption stages, since, although the idea is not to propose hermetic boxes that enclosure sets of variables as corresponding only to each particular step, it is perceived as relevant to organize and distribute them among the process steps in order to guide upcoming research work.

Thus, this paper aims to outline a framework for the study of the diffusion of ICT in healthcare and hospital services, having as background the innovation decision process proposed by Rogers (1983), which involves the prior conditions and five decision stages (knowledge, persuasion, decision, implementation and confirmation), and suggesting which conditioning factors of the diffusion of ICT from the organizational and individual (attitudinal, cognitive and behavioural) perspective are evident in each phase of this process.

2 Method

This work relies on a method of logical and descriptive exposition of the scientific literature about the diffusion of technologies in healthcare and hospital services, in a mainly qualitative, essayist and reflexive approach. For this, the literature review that guided this study used the descriptors ‘diffusion’, ‘adoption’, ‘acceptance’, ‘innovation’, ‘health’, ‘hospital’, ‘information’, ‘technology’ and ‘ICT’ (Information and Communication Technology). These searches were done in journal repositories in scientific databases that encompass the Science & Technology, Social Sciences, and Health & Medicine areas. The selected databases were: Applied Social Sciences Index and Abstracts (ASSIA); ERIC; Library and Information Science Abstracts (LISA); Social Services Abstracts; Sociological Abstracts; and Technology Research Database, taking into consideration a ten-year period, the period between 2004 and 2014. The kinds of sources used were dissertations and theses, academic journals and conference procedures and works, and the kinds of documents were articles, conference articles, dissertations and theses. The searches were done through the ProQuest database.

Following these parameters, the search returned 51 publications, 37 among them were full texts that could be accessed, from which 21 were considered appropriate to the research topic, as shown in Table 1. To avoid finding many unrelated publications, the authors worried about making small searches, alternating descriptors and rotating between terms that should be in the titles or in the abstracts of the publications. With this, a greater adherence of results to the theme was assured.

Table 1. Results of scientific publications based on searches in ProQuest database.

Searches	Descriptors	Result	Accessible	Adequate

5	Abstract (acceptance) AND title (innovation) AND title ((health OR hospital))	3	2	1
Total		51	37	21

All choices in the literature searches reported in Table 1 were based on knowledge of the diffusion of innovations present in Rogers (1983). Thus, it was possible to see, for example, the proximity between the words ‘diffusion’, ‘adoption’ and ‘acceptance’, which lead to the possibility of alternating them in each one of the searches. For that reason, it is possible to notice that in a way the searches complemented each other, as to cover all the initial parameters and decrease the occurrence of possible gaps left by one or another.

After collecting the full texts, all of them went through the first recognition stage, reading the titles, abstracts and keywords. The publications that were outside the scope of the research were discarded and, then, the remaining publications underwent a second sorting, a complete reading. Thereafter, the selected publications were registered and detailed according to the kind of publication, authorship, affiliation, country, journal, year, keywords, classification methodology, objectives and results.

Most publications (61.8%) were from Taiwan (23.8%), from the United States (19.0%) and from the UK (19.0%), 13 publications in total, considering the country of origin of the first and the second author’s institutions identical in all cases. It was also observed that most of the publications came from authors affiliated to the National Chung Cheng University (Taiwan), to the Harvard Medical School (USA) and to the University of the West of England (UK) tied with the University of Wisconsin-Madison (USA), considering all authors of each publication. In addition, the highest production years, based on the found publications, were 2007, 2009 and 2012.

It is also important to mention that other studies, apart from those selected, were used to build this essay, directly promoting the objective of the research, or establishing concepts and knowledge needed to achieve it.

3 Innovation Diffusion Theory

With the Innovation Diffusion Theory (IDT), Rogers (1983) deepened the understanding of the diffusion and adoption of innovations, which he sometimes uses as a synonym to technology, process.

According to Rogers (1983), the decisions and events prior to the first adoption of an innovation strongly affect the diffusion process. To the author, an innovation is like an idea, practice or object seen as new to an individual or to another party involved in the adoption and has five basic attributes, namely: relative advantage: “the degree to which an

innovation is perceived as better than the idea it supersedes”; compatibility: “the degree to which an innovation is perceived as being consistent with the existing values, past experiences, and needs of potential adopters”; complexity: “the degree to which an innovation is perceived as difficult to understand and use”; trialability: “the degree to which an innovation may be experimented with on a limited basis”; and observability: “the degree to which the results of an innovation are visible to others” (Rogers, 1983, 15, 16).

According to Rogers (1983), the innovation adoption process covers decisions, activities and impacts that come from needs or problems, through either research, development or commercialization of innovations. In this process, the individual or other decision-making units, initially, strive to gain knowledge about an innovation to, then, take an attitude towards it. From that moment, it is possible to decide to accept or reject it, and if it is accepted, the decision implementation and confirmation phases follow (Figure 1).

Thus, the process of adopting technological innovations involves a number of choices and actions in the midst of uncertainties and their conditioning factors.

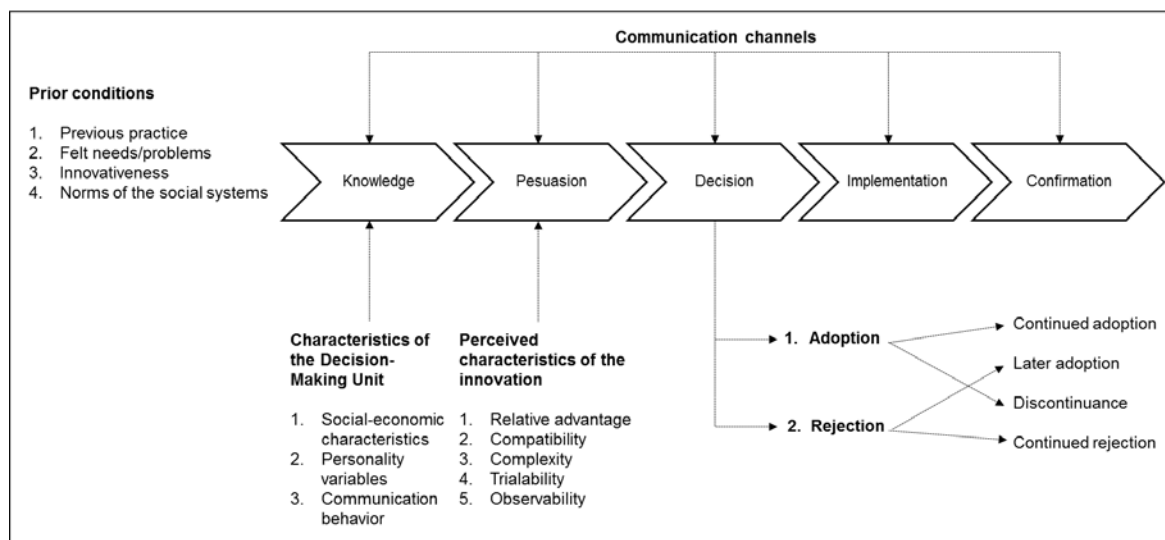

Figure 1. Innovation-Decision Process
Source: Rogers (1983).

Observing the initial conditions that can affect the innovation decision process, Rogers (1983) gives four kinds of necessities to the understanding of prior conditions, which includes the set of existing practices, the perceived needs and problems, the innovativeness and the social systems standards. Innovativeness is the degree to which an individual unit or another adoption unit is relatively incipient in adopting new ideas from other members of a system. The degree of innovativeness and the ranking of the members of the system into categories (innovators, early adopters, earlier majority, late majority and laggards) are based on the relative time in which an innovation is adopted (Rogers, 1983).

After understanding the prior conditions, the process goes through five phases or stages (Rogers, 1983), as follows:

1. Knowledge: happens when an individual or another decision-making unit is exposed to an existing innovation and understands how it works. This step includes the characteristics of the decision-making units in relation to the socioeconomic aspects, to the personality variables and to the communication behaviour.
2. Persuasion: happens when an individual or a decision-making unit forms a favourable or unfavourable attitude to the innovation. This phase is influenced by the perceived characteristics of the innovation (relative advantage, compatibility, complexity, trialability and observability).
3. Decision: happens when the individual or the decision-making unit creates efforts in activities that lead to the choice between the adoption and rejection of the innovation.
4. Implementation: happens when an individual or a decision-making unit puts into use a new idea. Implementation problems are more serious when it comes to an organizational adoption, because it involves many individuals, who can be more resistant than one. Rogers (1983) also mentions the reinvention, which is an innovation that undergoes changes made by its many adopters.
5. Confirmation: happens when an individual seeks reinforcement to an innovation decision already made. Here, attitudes have a relevant role.

The model also proves to be very useful for both theory and practice, because its sequential linearity simplifies the complexity intrinsic to the process, which, naturally, in practice, when the transition between stages happens, is not always so clear or easy. According to Oxford Dictionary of English (2010), diffusion as a noun is the spreading of something more widely (i.e. the rapid diffusion of ideas and technology). However, the diffusion should not be naively understood (Latour, 2000). If we search the meaning of the term ‘diffused’ in other sources, we will see that something diffused is something without a clear shape, something that is, many times, confusing (Dicionário Online de Português, 2014). Therefore, it is believed that the diffusion process, taking into consideration each one of its stages, drawn

according to Rogers (1983), is permeated by the organizational and individual factors that will hinder or contribute to the success and fluidity of the process and its consolidation.

4 Theoretical Approaches on Technology Adoption

For Rogers (1983), technology has two key components: (1) hardware, which is a tool that incorporates the technology as a physical material or as objects, and (2) software, which is the database for the tool. According to this author, a technological innovation can incorporate information and reduce uncertainties about the cause and effect relationship in solving problems, and, at the same time, it can create uncertainties for the potential adopters.

Thus, from the 1960s until 2014, several studies were developed with the intent of understanding the attitudes, the use intentions and the behaviour towards the adoption of technologies. Seeking an explanation for the impact of the intentions on the individuals' behaviour, two major theories have been developed, the Theory of Reasoned Action (TRA) and the Theory of Planned Behaviour (TPB). They were dealt with in Agarwal (2000) and in Ajzen and Fishbein (1977).

In 1989, Davis introduced the Technology Acceptance Model (TAM), aiming at the validation of measurement scales for two different constructs: perceived usefulness and ease of use, which mean, respectively, how much an individual believes that a system is useful for improving their performance at work and how much he believes that using a system would require less effort. The author dealt with the users' acceptance, linking the variables 'perceived usefulness' and 'ease of use' to the use intention and to behaviour, theories elucidated in TRA and TPB.

Then, Venkatesh and Davis (2000) proposed extending TAM to TAM2, which incorporated new constructs, since the TAM model explained around 40% of the variance in use and behavioural intention (Davis, 1989). The new constructs include processes of social influence and cognitive instrumental processes, including subjective norms, voluntariness, image, job relevance perception, output quality and demonstrability of the result.

Considering the various existing models and theories, Venkatesh et al. (2003) compared eight information technology acceptance models, for the development and validation of a unified model, called the Unified Theory of Acceptance and Use of Technology (UTAUT). In this model, the use behaviour is created by a series of interactions between intention and use determinants, namely: intention of use, performance expectancy, effort expectancy, social influence, facilitating conditions and key variables that moderate the relationship between influencing variables and the technology use intention: gender, age, experience and voluntariness of use. Thus, the UTAUT established itself as a support to managers in ascertaining the success probability of the technology adoption, in a more targeted to the context of the organizations way. Recently, it has been extended to the UTAUT2 model, which emphasizes the more focused on the technology user perspective study, adding three constructs to the basic model, namely: hedonic motivation, price value and habits (Venkatesh; Thong; Xu, 2012).

Parasuraman and Colby (2001) also contributed to the study of technology adoption, regarding the readiness of individuals, when they proposed the Readiness Technology Index (TRI), in which they presented facilitating (optimism and innovativeness) and inhibiting (discomfort and insecurity) factors of technology adoption.

In a sort of evolution of the TRI, although the authors claim that this was not their purpose, Ratchford and Barnhart (2012) developed the Technology Adoption Propensity Index (TAP-I), whose suggested scale consists of 14 items that combine the evaluation of attitudes and beliefs, of people who may or may not be users of technologies, using as analysis dimensions two inhibiting factors (vulnerability and dependence) and two facilitating factors (optimism and proficiency).

All these approaches emphasize the concerns with acceptance, readiness, use propensity, attitudes and use intention shown by technology users or potential users, but they focus heavily on prior to the adoption or implementation phases.

Jasperson, Carter and Zmud (2005), discussed research about behavioural use on the post-adoption phase of Information Technology (IT) and suggested a research agenda on the factors that influence users to explore and expand the technologies contained functionality. These authors define the post-adoption behaviour as feature adoption decisions, feature use behaviours and feature extension behaviours use, all made after the adoption of the technology, when it is accessible to users and adopted to fulfil their work routines.

In another way, Rogers (1983) offers a very similar to this one by Jasperson, Carter and Zmud (2005) discussion, even though he does not directly talk about post-adoption. He deals with the reinvention, which in his proposal is addressed in the implementation stage of the innovation process. Therefore, Rogers (1983) did not establish a post-implementation or post-adoption phase, but talked about the flexibility of certain innovations, which gives the opportunity of reinvention for the users who try the process of adopting a technology. Thus, an innovation is not invariable and the adoption experience contributes to how it will be used in the user routines.

Advancing on the discussions of what can also be called post-adoption, Bagayogo, Lapointe and Bassellier (2014) sought to understand how individuals can improve the use of IT, after its adoption. Thus, they interviewed users of different applications of IT in different situations and showed that the improvement of the use and of its patterns is defined by variables associated with the technology, the users and their tasks.

5 Conditioning Factors of ICT Adoption and Diffusion in Healthcare and Hospital Services

According to Burke et al. (2002), the skills acquired through the adoption of ICTs in the health services area in the 2000s, provided the development of computerized processes of data and integration of administrative and clinical information. Therefore, the chances of increasing the adoption of IT and of expanding its functionalities become high (Burke et al., 2002).

Cresswell and Sheikh (2013) state that the diffusion and the adoption of IT in healthcare reveal many difficulties related to the diversity of technical, social and organizational factors. They contributed with a description of the main results on each of the three factors, as shown in Table 2. They also observed some gaps in the currently developed research on technologies diffusion, which need to be investigated in the future: environmental influences, connection between adopters and organizational attributes; and noticed that the final users are not opposed to the technologies, but resist their use. This happens because the final users see the technologies as inadequate or invasive to their values, aspirations and personal or social rules (Alexander; Staggers, 2009, Boonstra; Broekhuis, 2010, Gagnon et al., 2010, Keshavjee; Bosomworth, 2006, Ludwick; Doucette, 2009, Yarbrough; Smith, 2007, Yusof, Stergioulas, Zugic, 2007 apud Cresswell; Sheikh, 2013). Cresswell and Sheikh (2013) gathered information found in several studies published between 1997 and 2010.

*Table 1. Determinant factors that influence innovation diffusion or adoption.
Source: Cresswell and Sheikh (2013, e76, e81).*

Factors	Descriptions and references
Technical	Early demonstrable benefits; perceived ease of use; costs; the extent to which a system is interoperable with existing technology; the extent to which technology fits in with existing organizational processes; and the extent to which it can be trialled (Gagnon et al. (2010), Yarbrough; Smith, 2007 apud Cresswell; Sheikh, 2013).
Social	Information technology literacy and general competencies of users (Keshavjee; Bosomworth, 2006, Ludwick; Doucette, 2009, Yarbrough; Smith, 2007 apud Cresswell; Sheikh, 2013); personal and peer attitudes toward an innovation (Gagnon; et al., 2010, Yarbrough; Smith, 2007 apud Cresswell; Sheikh, 2013); financial considerations (Boonstra; Broekhuis, 2010, Gagnon, et al., 2010 apud Cresswell; Sheikh, 2013); the extent to which the technology supports inter-professional roles and working; on-going involvement of key stakeholders (management, developers and users) at the conception and design stages (Gurses; Xiao, 2005 apud Cresswell; Sheikh, 2013); and opportunity for field testing of early prototypes and open communication channels (Gagnon; et al., 2010, Keshavjee; Bosomworth, 2006, Yusof; Stergioulas; Zugic, 2007 apud Cresswell; Sheikh, 2013).
Organizational	Organizational leadership; and Support to boundary spanning and reduction of the gulfs between technology, users, managers and clinicians (Boonstra; Broekhuis, 2010, Gruber et al., 2009, Gagnon; et al., 2010, Keshavjee; Bosomworth, 2006, Ludwick; Doucette, 2009, Yusof; Stergioulas; Zugic, 2007 apud Cresswell; Sheikh, 2013).

As it can be observed, the study by Cresswell and Sheikh (2013) presents several variables previously considered in the works proposed by Rogers (1983), Davis (1989) and Venkatesh and Davis (2000), although it does not mention them directly.

Furthermore, for the diffusion of technological innovations in healthcare and hospital services, it is essential to know the key values that the technologies are able to create, which according to Ghodeswar and Vaidyanathan (2006), are the disease prevention, the ease of suffering and the improvement of the quality of life of people who seek some kind of treatment. In line with this, a Health Information Technology (HIT) is able to change healthcare services, because it involves data processing at a hardware and software level to store and share information that supports the decision (Thompson; Brailer, 2004 and Kim, Park, 2012).

Alkrajji, Jackson and Murray (2011) studied the process of adopting technology (HIT) in Saudi Arabia, and exposed various factors that affect the decision for its adoption. The most relevant factors, according to the mentioned authors, are: network externalities related with communication channels; external pressure of the government; integration of system with the existing ones; accreditation of technology adoption; standards benefits; organization characteristics – organization size (i.e. number of beds, employees), organization type (i.e. research centre, university hospital), organization structure (i.e. regional or corporate structure), organization culture (i.e. turnover rate, absence rate, nationalities), organization complexity; the degree of politics in the organization and the degree of bureaucracy in the organization; policy and procedures; clinician engagement; standards cost (direct and indirect); and external support (vendors or consultants).

Holden and Karsh (2009) conducted a literature review on the adoption of HIT in order to ascertain whether the use of existing theories to develop testable models of HITs benefited both research and practice and found that this is true. Specifically, they found that

ease of use (or usability) may be the result of HIT that fits with user abilities and task requirements. To achieve it: (1) adjustments can be made to the HIT interface to make it more user friendly by building in help features or by making design more consistent with clinicians' mental models, (2) clinicians can be provided with more training or time to practice using the system, perhaps in a separate room used for carrying out HIT emulation, or (3) the task can be redesigned in any number of ways.

Lin, Lin and Roan (2012) set out to investigate the physicians' reactions to the electronic medical record with emphasis on managerial issues, specifically regarding the barriers, threats and inequality, all perceived in relation to technology. 115 physicians from six different hospitals were interviewed and the results revealed that a perceived threat directly and negatively affects the usefulness and the behavioural intention. The Perceived inequity has a direct and positive effect on the perceived threat and a negative effect on the perceived usefulness, and an indirect impact on the behavioural intention.

Emani et al. (2012) conducted a survey with 760 patients in order to apply the innovation diffusion model for the study of the Personal Health Records (PHRs) technology, this way, they tested and confirmed several predictors of the value of this HIT pointed out by Rogers (1983), Davis (1989), Venkatesh and Davis (2000) and others, namely: relative advantage, ease of use, trialability, perceptions of privacy and security, age and computer use. They got to the conclusion, therefore, that the innovation diffusion model fits in the PHR perception study and provides an appropriate basis to identify factors that distinguish PHR users from non-users.

Lai, Lin and Tseng (2014) identified determinants in the adoption of the Radio Frequency Identification (RFID), a technology that performs automatic data collection and tracking of assets and people, including in hospital services. In a sample of 102 hospitals, the authors found that cost; ubiquity that is the capacity to transmit communicate, monitor, and control signals to individuals or objects to perform various functions, regardless of users' whereabouts (Lai; Lin; Tseng, 2014, 5); compatibility (Rogers, 1983); security and privacy risk; top management support; hospital scale, large-scale hospitals are more likely to adopt innovative technology than the small ones, according to Chang et al. (2007 apud Lan; Lin; Tseng, 2014); financial readiness, installation costs, implementation and maintenance (Kim and Garrison, 2010 apud Lai, Lin and Tseng, 2014); and government policy, government's financial support, training curriculum, specification and policy stability, according to Chang et al., (2006 apud Lai; Lin; Tseng, 2014); are the critical factors most impactful in the adoption of RFID technology in hospitals.

Hung et al. (2010) proposed and tested an integrated model that incorporates organizational and technological or systemic factors as key determinants of the adoption, in healthcare institutions, of the Customer Relationship Management System (CRMS), an ICT that makes the process of establishing, developing and maintaining the relationships with customers in medical centres, regional hospitals and community hospitals, easier. Through carrying out a series of surveys in medical centres, regional hospitals and community hospitals in Taiwan, the authors found out that the attributes hospital size, the system capabilities of staff, innovation of senior executives (senior executives are the critical people in determining the organizational attitude towards innovation, so, their ability, preferences and readiness to change are critical to the innovation decision), knowledge management capabilities, and relative advantage, have significant influence on the CRMS adoption.

Vasileiou, Barnett and Young (2012) conducted in-depth interviews with 18 main informants of 15 successful innovations in health services in the UK, innovations awarded by the Health Service Journal, with the aim of studying the usefulness of the innovations in health services. The results showed that the innovators articulated concepts related to the main existing in the British National Health Service approaches, namely: clinical trials and improvement cycles. They found out that health services need individuals who have technical knowledge.

Marsan and Paré (2013) developed research on the antecedents of the decisions to adopt OSS (Open Source System) in healthcare organizations. Through 18 semi-structured interviews with IT experts from the health and social services sector in the Province of Quebec, Canada, they found eight factors that influence the adoption of this technology, grouped as follows: software characteristics (low cost, right to use and compatibility with organizational needs); characteristics of organizations to absorb OSS (internal IT resources availability and internal expertise in open source software); and characteristics of external environment in relation to institutional pressures and public discourse about OSS (external expertise in OSS, vision and leadership by departmental authorities with regard to software adoption, community interest and clarity, consistency and richness of the OSS public discourse).

Chen et al. (2008) aimed to verify the behaviour intention of nurses tied to public health (Public Health Nurses - PHNS) in relation to web-based learning in pre-implementation stage. They also aimed to identify the nurses' intervener factors, based on TAM, by means of a 202 nurse's sample. They noticed great chances of technology adoption. Moreover, they found that perceived usefulness is the factor that most directly affects the behaviour intention, which is indirectly influenced by the factors perceived ease of use, individual's computer competency and Internet access at workplaces. All these factors that directly or indirectly impact have a positive effect for a greater behaviour intention, in the nurses' case.

Hung Tsai and Chuang (2014) studied nurses' use behaviour of the Primary Health Information System (PHIS) technology, which supports primary health care with the ability to improve the practice and delivery of healthcare services quality. Through the application of 768 questionnaires with primary healthcare nurses, they found that the compatibility factor has a positive impact on the perceived usefulness and trust in relation to the ICT. They got to the conclusion that if the nurses see the technology as reliable, they become more prone to the perceived usefulness and, with this, it is possible to establish a favourable attitude.

Focusing on individual perceptions, Aggelidis and Chatzoglou (2009) set out to develop and test a modified version of the TAM model (Davis (1989)), they also considered other models presented in the literature based on the Hospital Information Systems (HIS). On the main data collection phase, 341 users of these systems from the main public hospitals of the East Macedonia and Thrace region answered the questionnaire via personal interviews. The results showed that perceived usefulness, ease of use, social influence, attitude, facilitating conditions, self-efficacy (individuals with higher self-efficacy are more likely to experience positive effects than individuals with lower self-efficacy) and, indirectly, training significantly impact the behaviour intention of the people in accepting technologies in healthcare organizations.

Kim and Park (2012) made a study aimed at developing and testing a model that described the behaviour intention and the health behaviour of various HIT consumers. The proposed model, which the authors called Health Information Technology Acceptance Model (HITAM), is an extension of the TAM. Kim and Park (2012) interviewed 728 members of the three largest online health portals in South Korea and, based on the results, categorized factors that affect the behaviour intention for measurement, storage and healthcare data management, in the health zone, in the information zone and in the technology zone. The first one is processed from the health status to perceived threat, to perceived usefulness, to attitude and to behavioural intention. In the information zone, the factors are the perceived usefulness, which gets subjective norms influences. Finally, in relation to the technology zone, it has technology use forms, technology reliability, output quality and result demonstrability, which affect the perceived usefulness (Kim, Park, 2012).

Ketikidis et al. (2012) also tested the TAM model with some new proposals in order to investigate the beliefs and acceptance of the HIT with health professionals. Thus, Ketikidis et al. (2012) conducted 133 valid interviews with doctors and nurses from three clinics of the city of Skopje, Republic of Macedonia, in order to evaluate the intention of use of HIT predictors and found that ease of use, relevance norms and subjective norms could directly predict the intention of use of this technology.

According to Holden and Karsh (2010), the growing interest in the reactions, behaviours and attitudes of technologies users in healthcare indicated the importance of theories focused on technology acceptance, use, readiness, propensity, among others. The authors made a literature review of 16 data sets analysed in over 20 health clinical studies. In relation to the application of the TAM model (Davis, 1989; Venkatesh and Davis, 2000), the authors decided to evaluate the future of the TAM applied to health services based on its past. The results showed that the model is able to predict a considerable part of the acceptance of technologies in healthcare, and that the theory can generate benefits to the original model, either through its amendment or extension.

Kijsanayotin, Pannarunothai and Speedie (2009), stating the relevance of the acceptance and use HIT in community health centres of Thailand theme, applied the UTAUT (Venkatesh et al., 2003) in order to test and confirm factors involved in the adoption of this technology. Thus, through questionnaires administered in 12 Thailand provinces, with 1,607 Community Health Centres (CHCs), they found out that individuals who worked in the health centres showed a high level of acceptance and use of the technology. The researchers confirmed that the factors performance expectance, effort expectance, social influence, voluntariness, previous experiences with technology, intention of use and facilitating conditions are able to predict the acceptance and use of a health IT system in community health centres.

In view of the studies reviewed until here, two tables are elaborated. They gather all conditioning factors presented separately in organizational (Table 3) and individual factors (Table 4) and their respective references. Initially, the idea was to divide the tables into facilitating and inhibiting factors to the organizational and individual perspective, but when making the process of cataloguing the variables, it was noticed that the same factor can play both roles, creating redundancies. Therefore, we used the terms: conditioning factors.

It is important to highlight that Ward et al. (2007) conducted a literature review on factors that impact the attitudes related to the technologies in health services and verified that the Health Care Practitioners (HCPs) are important for the acceptance and use of technologies. Therefore, they stressed that there is a gap in the study of the subject, which is little exploration of the factor 'change of attitudes' of the HCPs regarding adoption of technologies.

38. Vulnerability	Ratchford and Barnhart (2012)
39. Use of computer	Emani et al. (2012)
40. Use forms	Kim and Park (2012)

6 Discussions

The consolidation of the conditioning factors of the diffusion and adoption of technologies made it possible to see that some of them like external pressure of the government, community interest in technology, government policy and social economic characteristics are not part of the internal environment of the adopting organization, but make up its macro environment, surpassing the level of the firm. Cresswell and Sheikh (2013) suggested the study of the environmental influences as a gap in the research on innovations diffusion. Thus, reflecting on the organizational perspective proposed by Bouwman et al. (2005) it is noticed that it is important to consider exogenous factors in coming studies.

The set of conditioning factors of the adoption of technologies reported in this work shows the strength of the Innovation Diffusion Theory (Rogers, 1983), as well as of the studies of Davis (1989) and Venkatesh et al. (2000, 2003, 2012), considering its effect on the great amount of research discussed. It has been found that many studies still test, modify and confirm the findings of these authors. Holden and Karsh (2010), for example, noticed the importance of the theory in generating benefits to the original technology acceptance model (TAM), through its alteration or extension, directing for further research in this way.

The most cited factors still have a strong connection to those proposed by Rogers (1983) – compatibility, complexity, observability, relative advantage and trialability – and the perceived usefulness (Davis, 1989; Venkatesh and Davis, 2000). These refer to factors often considered in studies on technology adoption.

By observing the set of conditioning factors analysed, an interesting proposition for the decision model developed by Rogers (1983) would be to consider the individual alignment of the decision makers and users to the innovation, i.e. to promote a change in attitudes according to the needs of the process and of the technology, as suggested by Ward et al. (2007). The attitudes make up a very important factor cited in several reported studies (Aggelidis; Chatzoglou, 2009, Hung; Tsai; Chuang, 2014, Kim; Park, 2012, Rye; Kimberly, 2007, Rogers, 1983, Ward et al., 2007) and in the proposal presented in the framework (Figure 2), they pervade all stages of the decision making model of Rogers (1983).

It is observed, through the studies of Cresswell and Sheikh (2013), England and Stewart (2007), Hung et al. (2010), Lai, Lin and Tseng (2014), Marsan and Paré (2013) and Rye and Kimberly (2007), the importance of the manager's role in the adoption of technologies. The leaders' views, beliefs, knowledge and expertise have to be focused on innovation and, more than that, a manager has to be able to promote the necessary conditions to the organizational learning, to the climate and to the attitude, adapting them to an enabling environment to the diffusion of innovations and technologies.

In view of the discussion developed so far, this paper proposes, on the following page 16, a framework (Figure 2) to the study of the ICT diffusion in health and hospital services, having as background the process of innovation decision, based on the factors listed before. The factors proposed by Rogers (1983) were kept according to the original model and the others were logically distributed to the most appropriate stages of the process according to the knowledge acquired in the literature.

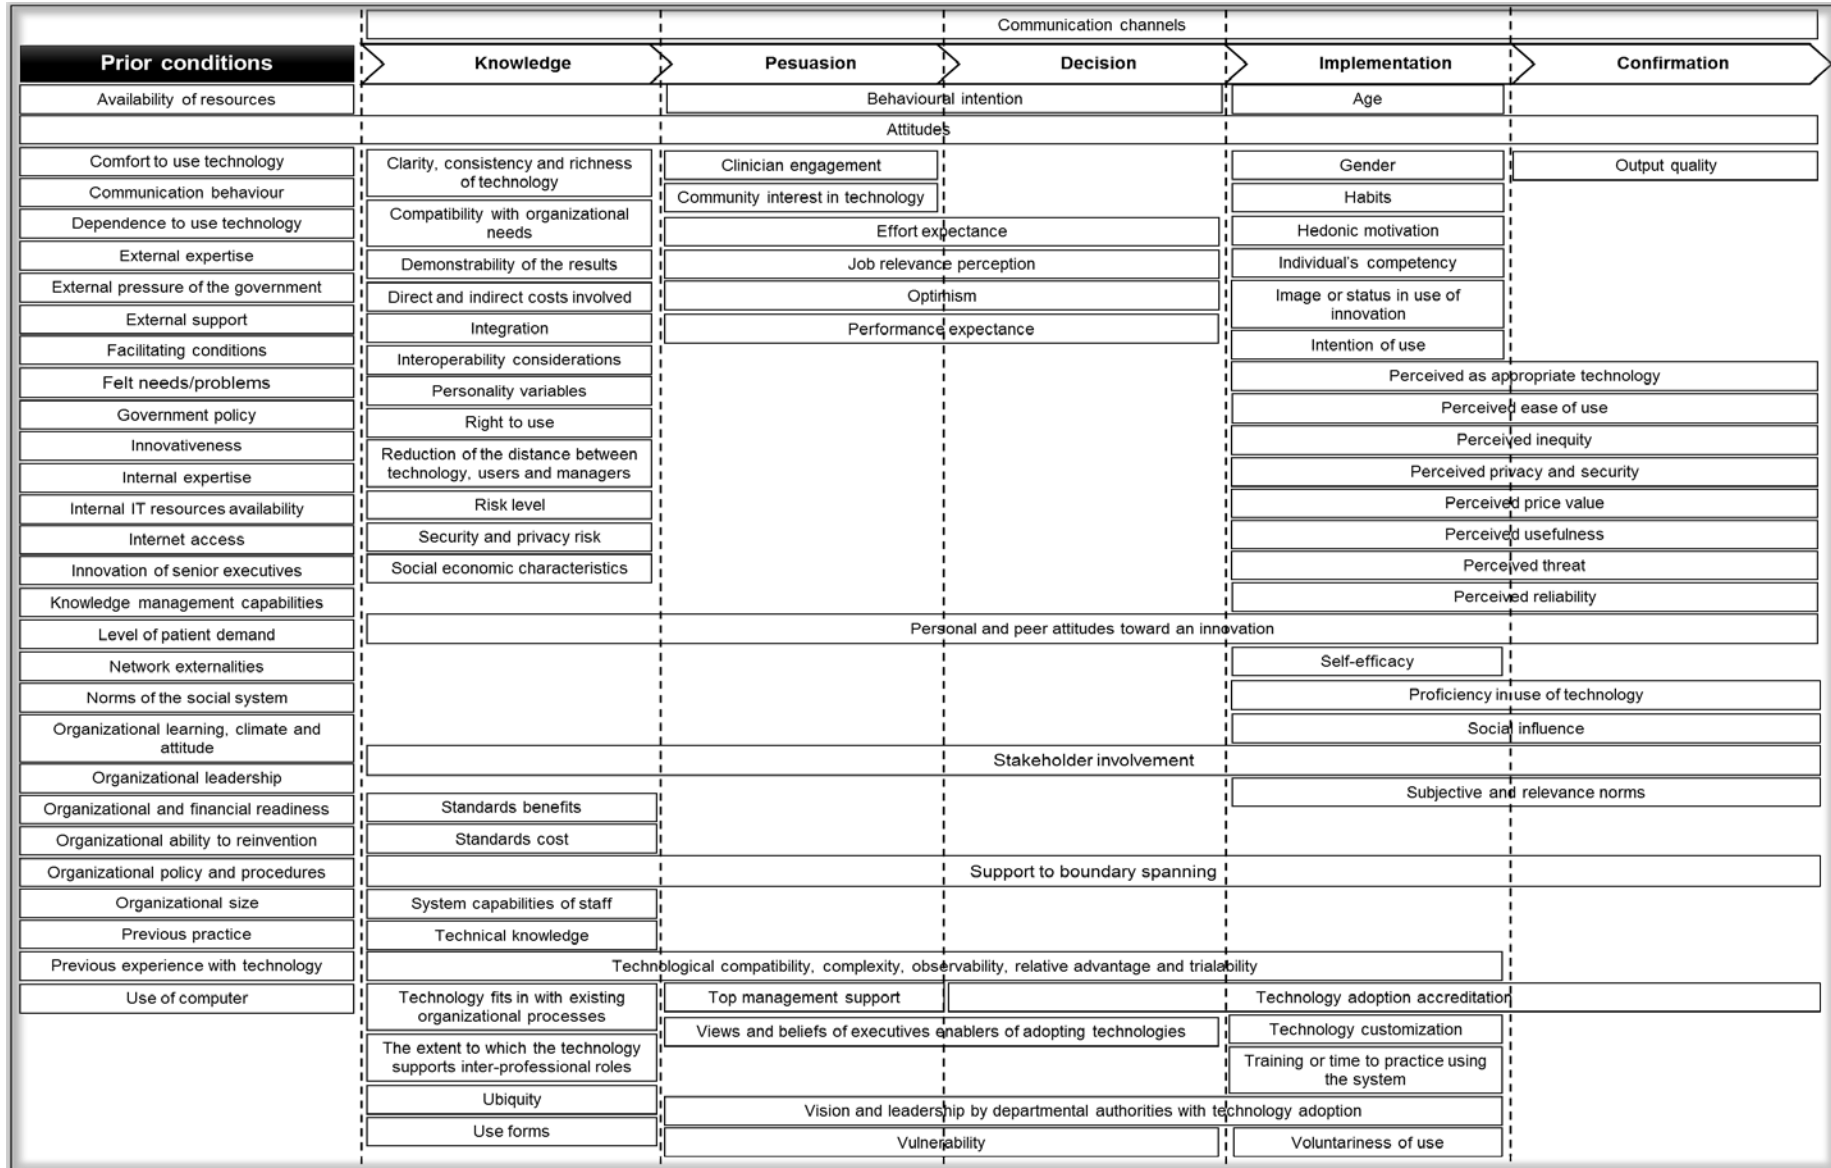

Figure 2. Proposed framework to ICTs diffusion in healthcare and hospital services.

7 Final Considerations

This paper is the result of an effort of readings and reflections focused on the discovery and discussion of existing concepts in research on the facilitating and inhibiting factors of the adoption of Information and Communication Technologies or ICTs in health and hospital services, getting, for it, closer together the Innovation Diffusion Theory and the various conditioning factors of the ICTs adoption.

It is our intent, in a theoretical and investigative work to be developed in the future, to revise, improve and implement the framework proposed here. There are still many questions about the disposition of the factors in the innovation decision-making process, about the existence of new factors to be integrated, and still other considerations that may arise during the development of field investigations from this framework directed at the diffusion of ICTs in health and hospital services.

Technology Adoption: A review of the Information Systems' approaches, theories and models

Josivania Farias, Lear Vieira

Universidade de Brasília

The evolution of studies on acceptance and adoption of technologies is occurring in a fragmented and poorly ordered way, which leaves room for redundancy on variables and on the composition of conceptual models. This study, through the mapping of approaches and critical analysis of its contents, gathered part of the literature production on the subject, creating a common body of knowledge on the proposed models, illustrating points of similarity or conceptual overlaps, major disparities and complementarities. Finally, presents a research agenda proposing the application of variables apparently little applied in the most recent studies of acceptance and adoption of technologies in conceptual models applicable to future studies.

1 Introduction

Studies on information systems have been seeking explanations to questions like how and why individuals accept and adopt new technologies (Venkatesh; Morris; Davis; Davis, 2003). Within this perspective, several theoretical approaches have emerged, aiming to solve the inherent puzzle in this theme.

However, as in any complex phenomenon (social, technological, economic, among others), the acceptance and adoption of technologies have been studied by various theoretical approaches, generating hundreds of variables with their complex relationships of prediction or correlation, in an attempt to explain beliefs, attitudes, and intention to use a certain technology. Thus, the evolution of studies in this area occurs, as expected, in a poorly ordered way, making room for redundancies in the choice and definition of variables and in the composition of conceptual models, and using, moreover, a renaming practice of variables already known and used for decades.

In most of these studies, it is possible to trace a connection with the first approaches on the acceptance and adoption of technologies, such as the Innovation Diffusion Theory (Rogers, 1983), the Theory of Reasoned Action (Fishbein; Ajzen, 1975), the Theory of Planned Behavior (Ajzen, 1991), the Social Cognitive Theory (Bandura, 1986), and, specifically in studies on acceptance and adoption, the Technology Acceptance Model (Davis, 1989; Venkatesh; Davis, 2000) and the Unified Theory of Acceptance and Use of Technology (Venkatesh *et al.*, 2003; Venkatesh; Thong; Xu, 2012).

Thus, we realized the need to catalog, regroup and reorganize variables, and to discuss the composition of constructs on acceptance and adoption of technologies in the 2009-2014 period, in order to identify the main points of similarity, duplicity, disparity, overlaps, and complementarities between the component variables of the different used approaches.

The main objective of the present paper is to identify the theoretical trajectory of studies on the acceptance and adoption of technologies, specifically discussing the main variables that influence or maintain some kind of correlation with the intention to use technologies. It is also an objective to present inputs to the establishment of research agendas on this issue, listing possible gaps related to the arrangement originating from the choice of constituent variables of theoretical models that encourage the development of new research papers on this area.

2 Method

The survey of papers was based on the analysis of published production on five journals of the Senior Scholars' Basket of Journals of the Association for Information Systems (AIS) from January 2009 to May 2014. AIS's Basket indicates eight journals considered to be the best in the IS area and publicly supported by the Association (AIS, 2011). The five journals consulted were: Management Information Systems Quarterly (MISQ), Journal of Strategic Information Systems (JSIS), Journal of Management Information Systems (JMIS), Journal of the Association for Information Systems (JAIS) and Information Systems Journal (ISJ). These journals provided 1100 publications, distributed in the following way: MISQ with 416, JSIS with 196, JMIS with 204, JAIS with 164, and ISJ with 120. In a first selection, we chose to analyze the papers' titles, abstracts and keywords in search of combinations of the following key terms: technology, information technology, information and communication technology, adoption, acceptance, diffusion, readiness, propensity, implementation, purchase, intention and use.

This initial analysis led to the selection of 40 publications on MISQ, 19 on JSIS, 26 on JMIS, 24 on JAIS and 27 on ISJ, totaling 136 papers, i.e. 12% of the total found, to be read and analyzed in a second step, consisting of mapping of the proposed models, and reading, rereading and cataloging their variables. Papers that didn't present models and those describing or explaining phenomena not directly related to the acceptance and adoption of technologies were discarded. At this stage, we discarded 97 publications that didn't have adherence to the theme, corresponding to 71% of the selected papers of the first step, leaving 39 articles whose models and variables were analyzed in the present paper, which added up to 213 constituent variables in the models, approaches and theories studied.

3 Presentation and discussion of theoretical approaches on acceptance and adoption of technologies

The reading of the papers selected for analysis led to the identification of a significant range of variables that comprise theoretical approaches applicable to studies of acceptance and adoption of technologies, whose models are recurrently presented as references to ground researches on the theme. The most widely used model is the Technology Acceptance Model, which, among its versions TAM (Davis, 1989) and TAM 2 (Venkatesh; Davis, 2000), is adopted in 67% of the articles. Next, the Unified Theory of Acceptance and Use of Technology, in its versions UTAUT (Venkatesh *et al.*, 2003) and UTAUT2 (Venkatesh *et al.*, 2012), appears as conceptual model in 26% of the analyzed studies. With lower rates of application, we identified the Innovation Diffusion Theory (IDT) (Rogers, 1983) in 18% of the papers, the Theory of Reasoned Action (TRA) (Fishbein; Ajzen, 1975) also in 18%, the Theory of Planned Behavior (TPB) (Ajzen, 1991) in 15% and the Social Cognitive Theory (SCT) (Bandura, 1986) in 8%. These models and theories represent the approaches considered of reference on the present paper.

We perceived a lower rate of use of more traditional approaches such as IDT, TRA, TPB and SCT in comparison to the more recent TAM and UTAUT. However, we also verified that the more recent approaches, in general, incorporate variables previously established in other models and theories, using different labels. Thus, we assume that classical approaches are considered, even if not directly cited on the papers. We also have to consider the fact that the present paper uses the bibliography for the 2009-2014 period in IS specialized journals, so the appearance of models specific to information technology contexts, such as TAM and UTAUT, is expected.

Other approaches were mentioned, but only once in the 39 studies. Among them are: Elaboration Likelihood Model (ELM) (Petty; Cacioppo, 1981, 1986), Expectation Disconfirmation Theory (EDT) (Oliver, 1977, 1980), Status Quo Bias (SQB) (Samuelson; Zeckhauser, 1988), Institutional Theory (DiMaggio; Powell, 1983), Social Exchange Theory (SET) (Homans, 1958), Contingency Theory (Thompson, 1967), Human-Computer Interaction (HCI) (Card; Moran; Newell, 1983), Structuration Theory (Giddens, 1984), Actor Network Theory (ANT) (Latour, 1987), Technology Threat Avoidance Theory (TTAT) (Liang; Xue, 2009) and Protection Motivation Theory (PMT) (Rogers, 1975). These approaches, due to their low incidence on the studies, were not analyzed in depth by the present review.

3.1 Technology Acceptance Model's (TAM) constructs

The TAM (Davis, 1989) presents variables that help explain the attitude, intention and beliefs of IS acceptance, such as: 1) Perceived Usefulness, defined as “the degree to which a person believes that using a particular system would enhance his or her job performance” (Davis, 1989, 320); and 2) Perceived Ease of Use, defined as “the degree to which a person believes that using a particular system would be free of effort” (Davis, 1989, 320).

Later, Venkatesh and Davis (2000) extended TAM, formulating TAM2 with the addition of five new predictors of intention to use and actual use of technologies: Subjective Norms, taken from TRA; Image, taken from IDT; Job Relevance, defined as an individual’s perception regarding the degree to which the target system is applicable to his or her job; Output Quality, which refers to when people take into consideration how well the system will perform and; Result Demonstrability, also taken from IDT.

TAM, on its first version, is a model composed of few variables when compared to other approaches discussed below. However, it was the most cited model on the papers appreciated in this study, which shows that its smaller number of variables is a good starting point for the discussion of new models.

3.2 The Unified Theory of Acceptance and Use of Technology (UTAUT)

The UTAUT represented a systematic effort to compare and unify the many existing models of technology acceptance. From the theoretical comparison and empirical application of eight models, including IDT, TRA, TPB and TAM, Venkatesh *et al.* (2003) consolidated the referred unified theory, establishing four predictors of the intention to use and usage behavior of technology: 1) Performance Expectancy, defined as “the degree to which an individual believes that using the system will help him or her to attain gains in job performance” (Venkatesh *et al.*, 2003, 447); 2) Effort Expectancy, defined as “the degree of ease associated with the use of the system” (Venkatesh *et al.*, 2003, 450); 3) Social Influence, defined as “the degree to which an individual perceives that important others believe he or she should use the new system” (Venkatesh *et al.*, 2003, 451) and; 4) Facilitating Conditions, which refers to “the degree to which an individual believes that an organizational and technical infrastructure exists to support use of the system” (Venkatesh *et al.*, 2003, 453).

Later, Venkatesh *et al.* (2012) extended the theory, formulating UTAUT2 and adding three predictors: 1) Hedonic Motivation, defined as the fun or pleasure the user gets from using a technology (Brown; Venkatesh, 2005); 2) Price Value, defined as consumer’s cognitive tradeoff between perceived benefits and monetary costs relative to an application (Dodds; Monroe; Grewal, 1991) and; 3) Habit, defined as the extent to which a user tend to perform behaviors automatically (Limayem; Hirt; Cheung, 2007).

UTAUT, unlike TAM, presents a model with many variables and relationships, possibly because it is an attempt to unify various approaches. It is undeniable that this model explains significantly the technology acceptance

phenomenon, however, it may be important to check in future studies if there is potential risk of saturation due to its large number of parameter and variables.

3.3 Contributions of the Innovation Difusion Theory (IDT)

The IDT was proposed in the 1960s by Rogers (1983) with the objective to organize studies on the diffusion of innovations. This theory proposed five general attributes that influence the adoption of innovations: 1) Relative advantage, defined as “the degree to which an innovation is perceived as being better than the idea it supersedes” (Rogers, 1983, 213); 2) Compatibility, defined as “the degree to which an innovation is perceived as consistent with the existing values, past experiences, and needs of potential adopters” (Rogers, 1983, 223); 3) Complexity, defined as “the degree to which an innovation is perceived as relatively difficult to understand and use” (Rogers, 1983, 230); 4) Trialability, defined as “the degree to which an innovation may be experimented with on a limited basis” (Rogers, 1983, 231) and; 5) Observability, defined as “the degree to which the results of an innovation are visible to others” (Rogers, 1983, 232).

Subsequently, Moore and Benbasat (1991) adapted IDT to the IS contexts. Relative Advantage, Compatibility and Trialability were kept. Some variables with different names from those proposed by Rogers (1983) are presented, but have the same definition, and, therefore, we can infer a rename. This is the case of Ease of Use, which uses the same definition of Complexity, and Results Demonstrability, which uses the same definition of Observability. The author also present Voluntariness of Use, which is defined as “the degree to which use of innovation is perceived as being voluntary, or of free will” (Moore; Benbasat, 1991, 195).

Two new variables were proposed: Image, defined as “the degree to which use of an innovation is perceived to enhance one’s image or status in one’s social system” (Moore; Benbasat, 1991, 195) and; Visibility, referring to the degree to which one can see others using the system (Moore; Benbasat, 1991).

IDT is the oldest approach considered on the present study, but its variables are still used in studies on the acceptance and adoption of technologies, even if sometimes they are used under different labels. This is one of the indications of possible redundancies in more recent approaches.

3.4 The Theory of Reasoned Action (TRA) and Theory of Planned Behavior (TPB) perspectives

The TRA is defined, essentially, by two key variables: Attitude Toward Behavior, which refers to “an individual’s positive or negative feelings (evaluative affect) about performing the target behavior” (Fishbein; Ajzen, 1975, 216), and Subjective Norms, defined as “the person’s perception that most people who are important to him think he should or should not perform the behavior in question” (Fishbein; Ajzen, 1975, 302). TRA was considered with a focus on individual acceptance in the works of Davis (1985) and Davis, Bagozzi and Warshaw (1992).

One of the proponents of TRA proceeded to extend it, thus organizing TPB (Ajzen, 1991), which also sought to explain the intention to use and usage behavior of subjects in a variety of fields. Thus, he added, to TRA, the variable Perceived Behavioral Control, defined as “the perceived ease or difficulty of performing the behavior” (Ajzen, 1991, 188).

The TRA/TPB variables were incorporated into UTAUT and TAM. As in IDT, we see that these variables remained relevant to studies of acceptance and adoption of technologies, indicating possible redundancies and duplicities between recent approaches and those regarded as references on the present paper.

3.5 The approach of the Social Cognitive Theory (SCT)

The SCT was proposed by Bandura (1986), and emphasizes dynamic interactions between people (personal factors), their behavior, and their environments. Compeau and Higgins (1995) and Compeau, Higgins and Huff (1999) applied and extended SCT to the context of computer use. Even though it was used only for computer use studies, the nature of the proposed model allows it to be extended to research the acceptance and use of information technologies in general.

Compeau and Higgins (1995) composed their approach using the variables: Outcome Expectations – Performance, defined as the performance-related consequences of the behavior; Outcome Expectations – Personal, which refers to the personal consequences of the behavior; Self-efficacy, which is the judgment of one’s ability to use a technology to accomplish a particular job or task; Affect, defined as an individual’s liking for a particular behavior and; Anxiety, which means evoking anxious or emotional reactions when it comes to performing a behavior.

It is possible to draw a parallel between TAM and SCT variables. This theory was also used in the elaboration of UTAUT and is, as in the case of IDT and TRA/TPB, still relevant to studies of acceptance and adoption of technologies. SCT was, initially, a general theory to be applied in the research of human behavior, and then went on to be useful in the study of computer use, currently becoming an approach used for the research on technology adoption.

3.6 Constituent variables of theoretical approaches on acceptance and adoption of technologies

Altogether, the five different reference approaches (IDT, SCT, TRA/TPB, TAM/TAM 2 and UTAUT/UTAUT2) define 29 variables as influencing, directly or indirectly, the acceptance and adoption of Technologies. A summary of these variables, in alphabetic order, is shown on the Table 1 below:

Table 1. Constituent variables of theoretical approaches on acceptance and adoption of technologies.

<i>Codes</i>	<i>Constituent Variables</i>	<i>Sources</i>
01	Affect	Compeau and Higgins (1995)
02	Anxiety	Compeau and Higgins (1995)
03	Attitude Toward Behavior	Fishbein and Ajzen (1975), Ajzen (1991)
04	Behavioral Control	Ajzen (1991)
05	Compatibility	Rogers (1983), Moore and Benbasat (1991)
06	Complexity	Rogers (1983)
07	Ease of Use	Moore and Benbasat (1991)
08	Effort Expectancy	Venkatesh <i>et al.</i> (2003)
09	Facilitating Conditions	Venkatesh <i>et al.</i> (2003)
10	Habit	Venkatesh <i>et al.</i> (2012)
11	Hedonic Motivation	Venkatesh <i>et al.</i> (2012)
12	Image	Moore and Benbasat (1991), Venkatesh and Davis (2000)
13	Job Relevance	Venkatesh and Davis (2000)
14	Observability	Rogers (1983)
15	Outcome Expectations – Performance	Compeau and Higgins (1995)
16	Outcome Expectations – Personal	Compeau and Higgins (1995)
17	Output Quality	Venkatesh and Davis (2000)
18	Perceived Ease of Use	Davis (1989)
19	Perceived Usefulness	Davis (1989)
20	Performance Expectancy	Venkatesh <i>et al.</i> (2003)
21	Price Value	Venkatesh <i>et al.</i> (2012)
22	Relative Advantage	Rogers (1983), Moore and Benbasat (1991)
23	Results Demonstrability	Moore and Benbasat (1991), Venkatesh and Davis (2000)
24	Self-Efficacy	Compeau and Higgins (1995)
25	Social Influence	Venkatesh <i>et al.</i> (2003)
26	Subjective Norms	Fishbein and Ajzen (1975), Ajzen (1991), Venkatesh and Davis (2000)
27	Trialability	Rogers (1983), Moore and Benbasat (1991)
28	Visibility	Moore and Benbasat (1991)
29	Voluntariness of Use	Moore and Benbasat (1991)

4 General set of constituent variables of theoretical approaches on acceptance and adoption of technologies

From the reading of the analyzed papers, we identified variables complementary to the previous list presented on Table 1. The expanded list, presented in alphabetic order on Table 2, reveals a great quantity of variables that, although they constitute a valuable reference, need to be reorganized in order to fit properly to the operationalization of future studies.

Table 2, below, presents the extended list of variables obtained from the 39 analyzed articles added to the constituent variables from the five reference approaches listed on Table 1 and brought into this extended set (Table 2) highlighted in bold.

Table 2. Extended General Set of constituent variables of theoretical approaches on acceptance and adoption of technologies.

<i>Codes</i>	<i>Constituent Variables</i>	<i>Sources</i>
01	A Priori Attitudes	Sarker and Valacich (2010)
02	Access Facilitation	Datta (2011)
03	Achievement Emotions	Beaudry and Pinsonneault (2010)
04	Activity Support	Junglas, Goel, Abraham and Ives (2013)
05	Actual Usage	Lu, Deng and Wang (2010)
06	Adjusted Beliefs	Sun (2013)
07	Affect	Compeau and Higgins (1995)
08	Affective Quality	Benlian, Titah and Hess (2012)
09	Age	Lu, Deng and Wang (2010), Wattal, Racherla and Mandviwalla (2010), Venkatesh, Sykes and Venkatraman (2014)
10	Agreeableness	Venkatesh, Sykes and Venkatraman (2014)
11	Anxiety	Compeau and Higgins (1995)
12	Appropriations	Al-Natour and Benbasat (2009)
13	Argument Frame	Angst and Agarwal (2009)
14	Assistance	Chan, Thong, Venkatesh, Brown, Hu and Tam (2010)
15	Attitude Toward Behavior	Fishbein and Ajzen (1975), Ajzen (1991)
16	Attitude Toward Outsourcing	Messerschmidt and Hinz (2013)
17	Avoidance of Personal Interaction	Chan, Thong, Venkatesh, Brown, Hu and Tam (2010)
18	Awareness	Chan, Thong, Venkatesh, Brown, Hu and Tam (2010)
19	Behavioral Beliefs	Al-Natour and Benbasat (2009)
20	Behavioral Control	Ajzen (1991)
21	Concern for Information Privacy	Angst and Agarwal (2009)
22	Challenge Emotions	Beaudry and Pinsonneault (2010)
23	Coercive Pressures	Messerschmidt and Hinz (2013)
24	Cognitive Absorption	Cheng (2011)
25	Colletivism	Lowry, Cao and Everard (2011)
26	Comfort with Change	Hong, Thong, Chasalow and Dhillon (2011)
27	Communication Effectiveness	Lu, Deng and Wang (2010)
28	Compatibility	Rogers (1983), Moore and Benbasat (1991), Chan, Thong, Venkatesh, Brown, Hu and Tam (2010)
29	Competitive Pressure	Li, Troutt, Brandyberry and Wang (2011)
30	Complexity	Rogers (1983)
31	Complexity of a Technology	Sarker and Valacich (2010)
32	Compliance	Datta (2011)
33	Computer Self-Efficacy	Brown, Dennis and Venkatesh (2010), Cheng (2011)
34	Concurrency	Brown, Dennis and Venkatesh (2010)
35	Confirmation	Hong, Thong, Chasalow and Dhillon (2011)
36	Conscientiousness	Venkatesh, Sykes and Venkatraman (2014)
37	Consistency with User Knowledge	Hong, Thong, Chasalow and Dhillon (2011)
38	Consumer Review	Benlian, Titah and Hess (2012)
39	Content Quality	Cheng (2011)
40	Context Support	Junglas, Goel, Abraham and Ives (2013)
41	Contextual IT Needs	Walsh (2014)
42	Contractual Restriction	Li (2009)
43	Control	Lowry, Gaskin, Twyman, Hammer and Roberts (2013)
44	Coping Motivation	Herath, Chen, Wang, Banjara, Wilbur and Rao (2014)
45	Convenience	Chan, Thong, Venkatesh, Brown, Hu and Tam (2010)
46	Culture of Innovativeness	Messerschmidt and Hinz (2013)
47	Curiosity	Lowry, Gaskin, Twyman, Hammer and Roberts (2013)
48	Demand Characteristics	Baird, Furukawa and Raghu (2012)
49	Desire for Online Interpersonal Awareness	Lowry, Cao and Everard (2011)
50	Deterrence Emotions	Beaudry and Pinsonneault (2010)
51	Disconfirmation	Venkatesh and Goyal (2010)
52	Discounting Own Information	Sun (2013)
53	Distraction	Guinea, Titah and Léger (2014)
54	Dyadic Object-Based Beliefs	Al-Natour and Benbasat (2009)
55	Ease of Use	Moore and Benbasat (1991)

4.1 Variables related to phenomena different from acceptance and adoption of technologies

In this first analysis, the goal was to eliminate variables that, according to our perception, had poor adherence to the set of relevant variables to the study of acceptance and adoption of technologies because they related better with other phenomena, such as post-adoption, continued use and usage behavior. Thus, in this condition we identified and discarded 16 variables (7,5% of the total), whose codes enable the identification of their labels on Table 2, namely: 05, 12, 15, 24, 35, 51, 64, 72, 82, 120, 123, 165, 172, 183, 195 and 208.

In this task, some variables related to situations of post-adoption were identified, such as: Actual Usage (05), Cognitive Absorption (24), Confirmation (35), Disconfirmation (51), Feedback (72), Satisfaction (172), System Use (195) and User Satisfaction (208). We also discarded variables related to the characterization of systems or organizations which were research locus, such as: Hedonic Systems (82), Power Distance (156), Spatial Network (183) and Stock Ownership (184).

Acceptance and adoption of technologies are intertwined phenomena, since they associate with several other phenomena. Therefore, it is not surprising to find the existence of variables in studies on the subject, but that are not sufficiently adherent to it. These variables may be useful for general purpose studies on human-technology interaction, but in more specific cases, as it is on the present paper, which focus on acceptance and adoption, its relevance to the study of the phenomenon must be tested, thus avoiding a low degree of relevance in the composition of conceptual models to study the phenomenon of acceptance and adoption of technologies.

4.2 Adequacy of variables to different contexts of acceptance and adoption of technologies

Continuing the examination of constituent variables of approaches used in studies on acceptance and adoption of technologies, we attempted to identify their adequacy to different context, be they cultural, geographic or technological, thus having applicability to studies of any technology. In this task, the following variables were identified (the codes presented are the same used on Table 2): 01, 04, 13, 16, 17, 25, 27, 34, 37, 39, 40, 42, 43, 48, 49, 54, 56, 57, 60, 65, 71, 74, 78, 79, 87-89, 92, 97, 99, 100, 101-104, 107, 108, 113, 115, 116, 118, 124, 125, 129, 132, 134, 138, 143, 149, 153-157, 160, 162, 166-169, 173, 176, 178, 182, 184, 185, 187, 190, 192-194, 210 and 211. These totaled 73 variables of limited applicability to specific contexts, the equivalent of 34% of the variables studied.

We perceived, by this analysis, that one third of the variables are adherent to specific determined research locus. Some of the discarded variables in this analysis include Attitude Toward Outsourcing (16), Avoidance of Personal Interaction (17), Communication Effectiveness (27), Content Quality (39), Desire for Online Interpersonal Awareness (49), Level in the Hierarchy (113), Online Product Recommendation (132), Provider Recommendation (160) and Strategic Orientation (185).

The eliminated variables in this analysis are specific to one technology, culture or organization where the research was carried out. Thus, they become useful to study this specific context, but lose power of generalization to studies of any technology, culture or organization, and are, therefore, uninteresting for the present paper.

4.3 Overlap of variables caused by semantic proximity

This section eliminates duplicities that might be caused by the overlap of variables that have semantically close definitions, for example, Complexity of a Technology (Sarker; Valacich, 2010), defined as the degree of difficulty anticipated in using and adapting to a technology, overlapped to Effort Expectancy (Venkatesh *et al.*, 2003), defined as the degree in which use of a technology is expected to be free of effort. This analysis was performed to the variables that were not discarded on previous sections, that is, 124 variables were analyzed for semantic proximity overlap. The codes presented with the variables are the same used on Table 2.

As a first basis of comparison, we used the constituent variables from the approaches considered of reference on the present paper and presented on Table 1. Venkatesh *et al.* (2003), in proposing UTAUT, conducted an analysis of semantic overlap of variables related to various models of acceptance, and the task already performed is valid and applicable to this paper. The categories derived from the work of Venkatesh *et al.* (2003) will be called Categories' Set A. The following variables were identified as overlapping by semantic proximity to Performance Expectancy: Perceived Usefulness, Job Relevance, Relative Advantage and Outcome Expectations. We added the following variables to the categorization of Venkatesh *et al.* (2003): Observability, Output Quality and Results Demonstrability.

In the category Effort Expectancy, Venkatesh *et al.* (2003) identified the following variables: Perceived Ease of Use, Complexity, Ease of Use, Self-Efficacy and Trialability. In the category Social Influence, Venkatesh *et al.* (2003) classified Subjective Norms and Image. Visibility is a variable that possibly could, because of its definition, be seen as belonging to this category. However, when analyzing the evaluation items for this variable as proposed by Moore and Benbasat (1991), we perceived that Visibility does not comprise a social pressure to accept and adopt a technology, as seen in the other variables categorized in Social Influence, thus not allowing to list it in this category.

The last category on Venkatesh *et al.* (2003) is Facilitating Conditions, where Behavioral Control and Compatibility were classified. Four variables were analyzed as non-overlapping to any of the previous categories, forming independent categories: Habit, Hedonic Motivation, Price Value and Voluntariness of Use.

The other variables not belonging to the reference approaches were then rearranged according to the categories resulting from the previous step of overlap by semantic proximity analysis. The results are presented on Table 3 below. The numbering placed next to each variable corresponds to the codes used on Table 2.

Table 3. Set of variables overlapped by semantic proximity.

<i>Categories' Set A</i> (Venkatesh <i>et al.</i> , 2003; Venkatesh <i>et al.</i> , 2012)	<i>Component Variables</i>
Performance Expectancy (148)	Achievement Emotions (03), Behavioral Beliefs (19), Challenge Emotions (22), Compliance (32), Evaluative Beliefs (62), Extrinsic Motivation (69), Flexibility (73), Initial Beliefs (98), Job Relevance (109), Observability (130), Outcome Expectations (135 and 136), Output Quality (137), Perceived Performance (142), Perceived Usefulness (146), Perceived Benefits (147), Relative Advantage (163), Results Demonstrability (170), Strategic Usefulness (186) and Technical Quality (187)
Effort Expectancy (59)	Assistance (14), Complexity (30), Complexity of a Technology (31), Computer Self-Efficacy (33), Convenience (45), Ease of Use (55), Frustration (75), Learning Externalities (111), Learning Goal Orientation (112), Perceived Ease of Use (139), Self-Efficacy (174), Task-Technology Fit (196) and Trialability (202)
Social Influence (180)	Adjusted Beliefs (06), Agreeableness (10), Coercive Pressure (23), Competitive Pressure (29), Consumer Review (38), Discounting Own Information (52), External Influence (66), External Pressure (67), Herd Behavior (83), Identification (84), Image (85), Imitating Others (86), Informational Cascades (96), Interpersonal Influence (105), Mimetic Pressures (119), Network Externality (126), Normative Pressures (128), Observation of other's actions (131), Perceived Network Externalities (141), Relational Network (161), Social Image (179), Social Usefulness (181) and Subjective Norms (189)
Facilitating Conditions (70)	Access Facilitation (02), Behavioral Control (20), Compatibility (28) and Structural Assurances (188)
Habit (80)	Experience (63) and Technology Experience (199)
Hedonic Motivation (81)	Affect (7), Affective Quality (8), Coping Motivation (44), Intrinsic Motivation (106), Joy (110) and Perceived Enjoyment (140)
Price Value (158)	Perceived Service Cost (144), Relative Benefits (164), Sunk Costs (191) and Transition Costs (201)
Voluntariness of Use (213)	Environment-Based Voluntariness (61)

Continuing the work of cataloging, classifying and discussing the variables influencing the acceptance and adoption of technologies, 34 variables that did not fit the Categories' Set A listed on Table 3 remained. Thus, a second group of categories was created to include them, forming the Categories' Set B that can be visualized on Table 4. The categories of the Set B and their definitions are as follows:

- Perceived Risk: the risk perceived by the user as result from uncertainties and potential unwanted outcomes related to the use of the technology (Taylor, 1974);
- Awareness: the degree of knowledge the user has about the technologies available for use (Chan et al., 2010);
- Trust: the belief that the trustee will act cooperatively to fulfill the trustor's expectations without exploiting its vulnerabilities (Pavlou; Fygenson, 2006);
- Personal Innovativeness: Rogers (1983) had already defined Innovativeness as the degree to which the individual is relatively earlier in adopting new ideas than others. We will use a broader definition, considering Personal Innovativeness as the propensity of an individual to use new technologies;
- User's Characteristics (Moderators): the use of moderators has been widely discussed by Venkatesh *et al.* (2003) and Venkatesh *et al.* (2012). Here we consider the User's Characteristics as moderating factors, i.e. affecting the degree of direct influence of variables influencing the acceptance and adoption of technologies.

Table 4 presents the results of this categorization. The codes presented to the variables are the same used on Table 2.

Table 4. Distribution of variables of Categories' Set B considering overlaps by semantic proximity.

Categories' Set B	Component Variables
Perceived Risk	Anxiety (11), Concern For Information Privacy (21), Deterrence Emotions (50), Information Privacy (95), Loss Emotions (114), Need for Privacy (121), Privacy Concern (159), Risk Propensity (171), Threat Appraisal (200), Uncertainty Avoidance (206) and Uncertainty of Technology Adoption (207)
Awareness	Awareness (18), Curiosity (47), Distraction (53), Information Disparity (94) and Technological Opportunism (198)
Trust	Perceived Trustworthiness (145), Trust (203), Trust Propensity (204), Trusting Beliefs (205)
Personal Innovativeness	Comfort with Change (26), Contextual IT Needs (41), Culture of Innovativeness (46), Extraversion (68), Global IT Needs (77), Individual IT Culture (91), Inertia (93), Need for Uniqueness (122), Openness (133), Personal Innovativeness (150), Personal Self (151), Personal Innovativeness with IT (152), Self-Identity (175) and Situational IT Needs (177)
User's Characteristics (Moderators)	Age (09), Education Level (58), Gender (76), Income (90); and, Masculinity (117), Conscientiousness (36) and Neuroticism (127)

In the Perceived Risk category, we inserted variables related to concerns about privacy and personal information, which is understandable when it comes to the adoption of technologies that use the Internet or other mechanisms of information sharing, and possibly is the largest type of perceived risk.

In the Awareness category, we represented the factors that determine the knowledge, by the individual, of the opportunities for technologies available for use. Visibility is a variable that could possibly be categorized in Awareness. However, even though it wasn't classified in Social Influence, it still has points of convergence with other variables in the Social Influence category, and cannot be categorized in Awareness.

The Trust category groups variables based on the reliability perceived by the user in relation to the provider of the technology, and have little semantic variability among its component variables, as shown on Table 4.

Personal Innovativeness gathers variables related to behaviors already presented by the individual regarding the acceptance and adoption of technologies, especially innovative technologies, as a response to the necessities that the individual perceives as demands of technological natures. Therefore, it is a category whose variables show previous behavioral patterns. On variables such as Inertia (Polites; Karahanna, 2012), defined as an attachment to, and persistence of, existing behavioral patterns, we see this pattern as a negative influence to the acceptance and adoption of new technologies by the individual. At the group or organizational level, there are variables such as Culture of Innovativeness (Messerschmidt; Hinz, 2013), defined as existing IT capabilities that influence whether new technologies can be implemented in the existing IT architecture.

Finally, we categorized the User's Characteristics that, adopting the perspective of Venkatesh *et al.* (2003) and Venkatesh *et al.* (2012), may moderate the variables that establish direct influence relations on intention to use and actual use of technologies. Two subdivisions are noticeable in this category, wherein the first one is composed of demographic and social-economic variables (Age, Education Level, Gender and Income), and the second is related to the individual endogenous characteristics, corresponding to the subject's personality and psychological aspects (Conscientiousness, Masculinity and Neuroticism).

4.4 Proposing a research agenda

It is possible to consider that 124 variables analyzed in this paper have strong application potential in the creation of conceptual models to study the acceptance and adoption of technologies. These variables have been rearranged and regrouped into 13 construct categories, after the demonstration of duplicity and derivation in the variables examined in the articles analyzed.

Of the 13 major categories organized in the paper, eight were established from the analysis of five reference theoretical approaches, those previous to the 2009-2014 period. Of the 124 variables whose constitutive definition seems to be more adherent to the application in the composition of conceptual models to study the acceptance and adoption of technologies, 76 (69%) were grouped into the eight reference categories (Categories' Set A). That is, we noticed that a small degree of novelty with respect to the key variables used in more recent studies on acceptance and adoption of technologies, conducted between 2009 and 2014. Considering that two of the five categories that we refer to as the Categories' Set B – User's Characteristics and Personal Innovativeness – may also be partly framed in Categories' Set A (i.e., the five reference approaches), the novelty can be considered even lower.

Considering the categories Perceived Risk, Awareness and Trust, only 17 variables were classified as yet underexplored, which equates to 15% of the 124 variables. This index confirms, again, the small degree of novelty associated to the variables explored in recent studies on the acceptance and adoption of technologies.

From these results, we present some recommendations or issues that can collaborate with future research ideas about acceptance and adoption of technologies. The first suggestion is about the possible need to give more focus to the variables related to Perceived Risk, Awareness and Trust when composing new conceptual models for the development of researches.

A second recommendation would be to conduct empirical efforts aimed at identifying the nature (direct influence, indirect influence, etc.) and the strength of the existing relationships between the many variables available to the researcher, namely: a) Would it be appropriate to seek verification of negative correlation between the variables Perceived Risk and Trust upon adoption of technologies by the user? b) These two variables can influence the relationship between Performance Expectancy and the acceptance and adoption of technologies? c) How is the relationship between the variables Personal Innovativeness, User's Characteristics and Awareness? d) Can Facilitating Conditions be related to Awareness?

Furthermore, it is suggested to evaluate the existence and the type or nature of the relationship between the Visibility variable and other variables such as Awareness and Social Influence to define in which of these two categories the Visibility variable best fit to design future research hypothesis about technology adoption.

In addition to the suggestions of the questions presented above, the small degree of novelty of the variables presented in studies from the 2009-2014 period points to the lack of new constructs on acceptance and adoption of technologies studies. Our epistemological concern is to agree with Serva (2013) that is necessary to stimulate the *knowledge-process* and not the *knowledge-state*. To Ramos (1981, 118 as cited in Serva, 2013, 56): "The contemporary organizational discipline did not develop the analytical skills necessary to criticize their theoretical foundations [...] it sentenced itself to remain pre-analytical".

Other knowledge areas may point the contribution of different constructs. In Marketing, Ratchford and Barnhart (2012) and Parasuraman and Colby (2001), among others, have been already, for some time, studying readiness and propensity to consume technology.

It is also recommended to evaluate the different degrees of influence of variables influencing directly or indirectly the acceptance and adoption of technologies, considering the subjects positioned at different points in the innovation adopters categorization curve presented by Rogers (1983), as shown in Figure .

Figure 1. Adopters categorization based on the time in which the individual adopts one or more innovations.
Source: adapted from Rogers (1983, p. 247).

Different groups of individuals in different positions on the curve are, possibly, influenced at different levels and variables, depending on the segment to which they belong. It is pertinent to ask, for example, does Personal Innovativeness have a bigger influence on Innovators than on the Late Majority? Is Price Value more influential to Laggards than it is to Early Adopters?

5 Final considerations

This paper provided an assessment of the constructs adopted in the formulation of models applied to studies on the acceptance and adoption of technologies, considering articles published between 2009 and 2014. A small degree of novelty in the set of variables influencing adoption was noticed, and also that proposed elements in five approaches considered of reference in this paper are still intensively employed in most current studies, configuring multiple conceptual models under different labels or negligible changes in its constituent definitions.

This paper has also showed that some categories can still be considered as more recent variables, with potential to expand their application in future empirical studies aimed at their validation or consolidation. To this end, we provided initial inputs under the form of questions that may serve research agendas that can be developed on the theme in different contexts and technology users segments involving acceptance and adoption.

This paper has a limitation related to the set of journals consulted to survey articles, seen that they are restricted to the information systems area. It is recommended, in future reviews, the use of journal from other areas on the field of Business, such as Marketing, Consumer Behavior, etc., or other fields (Sociology, Economics, Consumer Psychology, etc.) that show interest in studies on acceptance and adoption of technologies, in order to get a clear and comprehensive assessment of the state of the art on this theme.

6 Acknowledgements

The authors of this paper acknowledge the Foundation for Research Support of the Federal District (FAPDF – Fundação de Apoio a Pesquisa do Distrito Federal), an agency of the State Secretariat of Science and Technology of the Federal District, Brazil, for the financial support given to the presentation of this work.

Expanding awareness of employees' competences: the holistic perspective

Riitta Forsten-Astikainen, Pia Heilmann, Terhi Tuominen

Lappeenranta University of Technology

The phenomenon of employees' competences has received increasing scholarly attention during the last years. However, scholars have not fully identified what individual and organizational-level outcomes there is when identifying the competences from holistic perspective. In our study, we aim to get a deeper understanding of 1) how the construct of competence is defined by employees in case organization and 2) what are the outcomes of identifying these competences at the individual and organizational-level? The study is based on qualitative research data gathered with storytelling and focus group interviews and the data was analyzed by using content analysis method. Based on our study, we argue that a comprehensive competence base enabled the evaluation of their own strengths and weaknesses in their jobs and the evaluation of new development possibilities in workplace. Finally, by applying the holistic competence model, employees had a possibility to obtain more equal work place.

Introduction

The research on employees' competences has received increasing scholarly attention during the last years (e.g., Lai, 2011; Sandberg, 2000; Rychen & Salkaniz, 2003; Cheetham & Chivers, 1998). The need for this research has emerged both from the science and from the practitioners/managers who aim to find new tools and strategies to capture employees' competences into practice. It should be also noted that the ability to successfully implement employees' competences into practice can also operate as a source of competitive advantages for organizations. Thus, the need for this kind of research is evident.

Employees' competences represent dynamic and multifaceted potential for organizational performance but this potential can be adequately mobilized through relevant opportunities, tasks and challenges (e.g., Lai, 2011). Especially employees' "hidden" latent competences should be realized as they can represent a valuable asset to the individual and the firm. These unconscious, "latent" competences can and should be investigated especially from the holistic perspective (Delamare Le Deist & Winterton, 2005; Cheetham & Chivers, 1998) as it goes into "deeper roots" of competence than the traditional competence view (Spencer & Spencer, 1993).

Even though the phenomenon of competence (from the holistic perspective) has received some scholarly attention, scholars have seen it's identification and measurement as difficult. That is, how can scholars identify the real and latent competence capacity, what kind of competences employee's experience and what are the outcomes of identifying these competences (at the individual and organizational level)? It is these research gaps this study aims to fulfill. In more detail, as the measurement of competence from the holistic perspective is still at the early stages of theory development, we employed qualitative research methods (by using storytelling and focused interview as research methods) in order to answer our research questions: 1) *How the construct of competence is defined and understood by employees in our case organization and 2) what are the outcomes of identifying these competences at the individual and organizational-level?*

2 Theoretical framework – different levels and views of competence

The phenomenon of employees' competences has been the focus of various studies during the last decades (e.g. Sandberg, 2000; Rychen & Salkaniz, 2003). The concept of competence (see e.g., Delamare Le deist & Winterton, 2005) is very multi-dimensional and difficult to define, identify or impute a coherent theory. One reason is various schools different schools, which define the concept of competence in different way. In more detail, the US focus is clearly on the "inputs", the abilities, aptitudes and talents that a person brings to a job, which enables them to perform satisfactorily or exceptionally. The USA School of competence e emphasizes much more potential rather than demonstrated proficiency. Another fundamental difference between the US and UK approaches in the 1980s and early 1990s was the US search for "excellence" and the exceptional compared to the British systematic identification of the skills needed to perform a role, which can be observed and assessed and therefore trained and developed. This has been described as "the difference between drivers of performance and standards of work. (Roberts 1997, 70). In this study our approach is the school of UK and the term competence. The Table 1. below clarifies some common definitions of competences.

Table 1. Some common definitions of competence found in the literature (Adapted from Woodall & Winstanley 1998 and Horton 2000 in Garavan & McGuire 2001, 150).

<p>Worker-oriented definitions</p> <p>1) The behavioral characteristics of an individual that are causally related to effective and/or superior performance in a job. This means that there is evidence that indicates that possession of the characteristic precedes and leads to effective and/or superior performance on the job (Boyatzis 1982)</p> <p>2) An underlying characteristic of an individual that is casually related to criterion referenced effective and/or superior performance in a job or situation (Spencer & Spencer 1993)</p> <p>3) A High performance or H-competency is relatively stable set of behaviors which produces superior workgroup performance in more complex organizational environments (Schroder 1989)</p>
<p>Work-oriented definitions</p> <p>4) Occupational competence (is) ... the ability to perform the activities within an occupation or function to the level of performance expected in employment (Management Charter Initiative 1990)</p> <p>5) The ability to perform the activities within an occupation (Nordhaug & Grønhaug 1994)</p> <p>6) An action, behavior or outcome which the person should be able to demonstrate (Training Standards Agency 2000)</p>
<p>Multidimensional definitions</p> <p>7) The ability to apply knowledge, understanding, practical and thinking skills to achieve effective performance to the standards required in employment. This includes solving problems and being sufficiently flexible to meet changing demands (NCVQ 1997)</p> <p>8) The skills, knowledge and understanding qualities and attributes, sets of values, beliefs and attitudes which lead to effective managerial performance in a given context, situation or role (Woodall & Winstanley 1998)</p>

Some authors suggest that competencies refer to the collective learning, the diverse production skills and the integration of multiple streams of technologies that exist inside the organization (Pralhad & Hamel 1990). Others refer to firm competencies as the skills of employees that comprise the competency (King & Zeithaml 2001), and that employees must engage in behavior that executes the competency (Leonard-Barton 1992). Competence has been defined as underlying characteristics of people, which are causally related to superior or effective performance in a job (Boyatzis 1982), and as the ability to perform activities within an occupation (Nordhaug & Grønhaug 1994).

In addition, there are separate terminology and approaches between several schools because each of them uses concepts of competence and competency, which have different definitions and the view depends on schools. For example, according to Snyder and Ebeling (1992), competence is a functional sense. Similarly, Gilbert (1996) argues that human competence is a function of worthy performance, which depends on the ratio of valuable accomplishments to costly behavior: Competent people are those who can create valuable results without excessively costly behavior. Competences have been traditionally defined through functional tasks. That is, competences can be seen as the ability to perform tasks so that the end results meet the requirements of a specific task (White, 1994; Robotham & Jubb, 1996; Ramitru & Barnard, 2001). This implies that competences are targeted at specific functions and the specific goals of (the part of) the organization (McDermott, 1998). Some authors have also used the term ‘competency’ when referring to occupational competence (Boam and Sparrow, 1992; Mitrani et al., 1992; Smith, 1993). Hartle argues that competency as ‘a characteristic of an individual that has been shown to drive superior job performance’ (1995).

The problematic of using competence as an overarching term is demonstrated by the apparently tautological definition provided by Dooley et al.: ‘Competency-based behavioural anchors are defined as performance capabilities needed to demonstrate knowledge, skill and ability (competency) acquisition’ (2004: 317). According to this view, competency is a sub-set of itself.

There are few attempts to get the common sense between the terminologies (Tate, 1995; Winterton and Winterton, 1999; Woodruffe, 1991). According to Boak (1991) ‘competency’ in the American sense complements ‘competence’ as used in the UK occupational standards. Burgoyne (1988) argues that ‘being competent’ (meeting the job demands) differs from ‘having the competencies’ (possessing the necessary attributes to perform competently). Woodruffe (1991) offers the clearest statement, contrasting areas of competence, defined as aspects of the job which an individual can perform, with competency, referring to a person’s behaviour underpinning competent performance (Delamare Le Deist & Winterton, 2005.)

Competences have been also investigated from the traditional and holistic competence perspectives. In more detail, traditional view of competence (e.g. Spencer & Spencer, 1993) has viewed it as a construct that is based on individual’s knowledge, skills and experience. However, the so called “holistic perspective of competence” (e.g. Delamare Le Deist & Winterton, 2005) views the construct of competence as more dynamic and multidimensional, which includes also employees’ personal behavior and ethical values. Overall, the concept of holism refers that “a view that an account of all the parts of a whole and of their interrelations is inadequate as an account of whole” (Mauntner, 1997; in Kelly & Horder, 2001). In addition, the holistic perspective entails also knowledge/cognitive competence (e.g., technical /

theoretical specialist and tacit-practical knowledge) and functional competence (e.g. occupation-specific) which form individual's professional competence (Cheetham & Chivers, 1998). Further, holistic model includes also meta-competencies such as communication, creativity and problem solving (Cheetham & Chivers, 1998). Finally, professional competence (in holistic model) is also shaped by the context of work, work environment and employee's personality and motivation (Cheetham & Chivers, 1998).

Regardless of the researches on holistic competence model, the majority of competence research has offered a relatively rational and positivist perspective which sees that competences are based solely on individuals' characteristics (Arnold & Davey, 1992; Sandberg, 2000; Garavan & McGuire, 2001). Noteworthy, this "rational and positivist perspective" (Sandberg, 2000; Garavan & McGuire, 2001) has ignored the contextual aspects of competences and sees them more as mechanistic and bureaucratic (compared to dynamic and holistic perspective).

Several scholars have also recognized that identifying the real and latent competences have several positive outcomes for individuals and organizations. Overall, employees' competencies are often well understood and implemented in organizations which have adopted the principles of "learning organizations" that support firms constantly to adopt new knowledge and insights through individuals and teams (see Sundberg, 2001). According to Arnold and Mackenzie Davey (1992), people's perceptions of their work-related competencies have great importance in occupational settings. Most importantly, employee work competences are likely to have effect on work performance and perception of training needs (e.g., Arnold & Mackenzie & Davey, 1992), career planning and development (e.g., London & Stumpf, 1982) and communication between the person and other people in the workplace (Carrole & Schneider, 1982).

Lai (2011) has also investigated the role of perceived competence mobilization (=the degree to which employees perceive that they have adequate opportunities to utilize their competences in their current jobs) and its attitudinal outcomes inside organizations. In more detail, Lai (2011) argue that employees' perceived competence mobilization is associated with a number of favorable employee attitudes, including intrinsic motivation, organizational commitment and intention to stay with the organization. Noteworthy, her study included only perceived competence mobilization but did not include "the latent competences" which the individual has.

Morrison et al. (2005) and Parker (2003) have also found that a high level of perceived skill utilization is linked to positive outcomes such as higher job-related affective well-being, higher job satisfaction, lower job-related depression, higher organizational commitment, higher job-related perceived competence and higher job-related feelings of worth. Perceived underemployment, in contrast, reflects a situation in which employees do not feel that they fully utilize their competence based on education and experience (Lai, 2011). Perceived underemployment is related to negative outcomes such as lower psychological well-being, increased job dissatisfaction, lower effective commitment to the organization and higher turnover intention (Erdogan & Bauer, 2009; Feldman, 1996; Feldman & Bolino, 2000; Feldman et al. 2002; Maynard et al., 2006).

It should be noted that employees' perceptions of their work-related competences have great importance in occupational settings as they have implications for career planning and development, analysis of training needs, communication between the person and other people in the workplace and self-ratings of competences are likely to influence a person's work performance (Arnold & Davey, 1992).

3 Context, data and methods

In qualitative studies, it is vital to justify why the researcher has selected a specific context and case and also justify her/his context from a sampling perspective (see Pratt, 2009). The case organization in this study is a development company (Ltd.) operating in social sector in Finland and thus, the social sector in Finland forms also the context of this study. The operation of regional competence centers are based on municipality co-operation. The central focus of the operation is creating co-operation with different actors (municipalities, service producers) relating to social work, research and education. Competence centers in social work area are open networks with light organization model. The operation is based on areal co-operative needs. This ensures flexibility and innovativeness.

The selected case represents a critical case and is an information-oriented selection (not random selection, see Flyvberg, 2006). In more detail, "a critical case can be defined as having strategic importance in relation to general problem" (p. 229) so that "if this is (not) valid for this case, then it applies to all (no) cases" (Flyvberg, 2006, p.229).

As the purpose of this study is to generate new knowledge on this topic, theoretical sampling (see Eisenhardt & Graebner, 2007) was appropriate. Theoretical sampling refers to when "cases are selected because they are particularly suitable for illuminating and extending relationships and logic among constructs" (Eisenhardt & Graebner, 2007: 27).

The research group included 16 participants who worked in the development company in social sector. Table 2. Illustrates the backgrounds of participants of the study.

Table 2. The backgrounds of participants.

Participant no	Age	Male/female	Task
1	40	Male	Development planner
2	33	Male	Development planner
3	51	Female	Development planner
4	34	Female	Development planner
5	40	Female	Network coordinator
6	52	Female	Development planner
7	49	Female	Development manager
8	60	Female	Assistant
9	27	Female	Patient advisor
10	34	Female	Development planner
11	42	Female	Development planner
12	46	Female	Project coordinator
13	45	Female	Development planner
14	46	Female	Financial secretary
15	52	Female	CEO
16	46	Female	Development planner

14 out of 16 interviewees were female whereas only two interviewees were men (see table 2). Interviewees were between the ages of 27 and 60 (most of them being in their 40ties) and nine of out 16 were development planner in their occupation. As most the interviewees’ work-related tasks were focused on development planning, it was for these employees to identify their real and latent competence base. When conducting the interviews, each participant wrote the answer to the question “Describe what competencies you have?” and then we used group interviews and presented the holistic competence map (Cheetham & Chivers, 1998).

One form of meaning construction frequently identified in qualitative interview data is story (Mishler 1986). The underlying premise of story inquiry is the belief that individuals make sense of their world most effectively by telling stories (Ricoeur 1981, Smith 1981, White 1981, Connelly & Clandinin 1986, 1990, Sacks 1986, 1992, Riessman 1990, 1991, 1993, Bruner 1991, Clandinin & Connelly 1994, Wiltshire 1995). It is important to note that, for the interpretive researcher, the historical truth of an individuals account (story) of an event is not the primary issue’ (Riessman 1993, p. 6

A focus group is a group of individuals selected and assembled by researchers to discuss and utilize their personal experience to comment research topic. As a research technique, the focus group employs guided, interactional discussion as a means of generating “the rich details of complex experiences and the reasoning behind an individual's actions, beliefs, perceptions and attitudes” (Carey, 1995). This information can be used to identify potential areas of inquiry or to clarify subject matter that, by its nature, eludes other research instruments. The “focus” underpinning the discussions is anything that engages the focus group in a collective activity, “such as viewing a film, examining a single health education message or simply debating a particular set of questions” (Kitzinger, 1994). According to Powell and Single (1996), a focus group is especially useful when 1) existing knowledge of a subject is inadequate and elaboration of pertinent issues or the generation of new hypotheses is necessary before a relevant and valid questionnaire can be constructed or an existing one enhanced, 2) the subject under investigation is complex and concurrent use of additional data collection methods is required to ensure validity or 3) the subject under investigation is complex and comprises a number of variables. A focus group enables the researcher to concentrate time and resources on the study’s most pertinent variables.

In analyzing the story telling papers and focus group interviews, we used content analysis, which is both the analysis method and thematic method. We studied the storytelling papers and transcribed interviews mainly inductively (Pratt, 2009) without guiding theory structure or a structure of pre-selected rating (Silverman, 1989) and identified. Spencer, Ritchie, and O’Connor (2003) have described the iterative process throughout analysis. The first level (data management) generates themes and concepts and the purpose is to label or tag data. According to Braun & Clarke (2005), what counts as a theme is not (usually) dependent on quantifiable measures but instead, it depends on whether the potential theme captures something relevant to the investigated research question (Braun and Clarke, 2006). Researchers classified and sorted the data at the second level (descriptive accounts) in order to ascertain their meaning. The third level (explanatory accounts) addresses how and why questions and establishes the typologies.

The current study followed the above mentioned iterative process. First, we coded and identified themes and concepts before classifying and sorting themes and issues, and then establishing head typologies. Finally, we addressed the research questions on the basis of the research data gathered.

4 Findings

The findings from the first part of the study (16 employee stories) revealed that each participant experienced their competence individually and differently. In general, the participants understood the concept of competence much narrower than what the Cheetham & Chivers (1998) have presented. For example, one interviewee stated following: *“it helps to perform all tasks when you understand the diversity of your competences. And the workplace as well.”*

When comparing the answers with the category of competences by Cheetham & Chivers (1998), we identified that some of the participants experienced that their competences have only two aspects: cognitive and personal competence (see Spencer & Spencer, 1998). For example, one interviewee suggested that *“I have good ADP skills and then I’m a good listener and I have good interpersonal skills.”* However, only a view used the whole scale of competence model when evaluating their competences (see table 2 for quotes).

Noteworthy, no one mentioned professional behavior, obeying the law or the work-related ethics when evaluating their competences. For example, no one mentioned the concealment of confidential information in their story – even though it is closely related to the field of operation in the study. However, several participants described only substance competence (“hard competence”) or competences that relate to their own behavior or their values (“soft competences”) (see Woodall and Winstanley, 1998). Following quotes describe well this: *“I have a good substance competence”; “I get along with all kinds of people and I can encourage people.”*

Several participants described their competences only as meta competences, like communication skills and social interaction, creativity, innovativeness, problem-solving skills and the ability to perceive big entities. For example, one participant described following: *“I’m good to create the networks, I’m very flexibility and I can tolerate the stress.”*

Some of the participants described their cognitive and functional competence in that way that meta competence was intertwined with the evaluation of their competences. For example, describing competences could be that they manage their every-day-life routines well and they can apply problem-solving skills and flexibility (see table 2 for quotes).

Further, their presumption was that their so called “substance competence” is automatic, built-in operation which they cannot even think in every-day-life operation (see also Sandberg, 2000). Employees experienced that their comprehensive competence base manifested in that their sub-conscious directs their operation and uses different ways to operate in different situations – without the employee even realizes it (Lai, 2011). In addition, employees constructed different meanings of competences; they were considered as “real” as they matched the individual’s perceptions of the operation related to the context (Wierdsma, 2007).

So called “super meta competence” which manifests as the “ability to reflect” manifested in several stories: employees identified critically and analytically their own deficiencies but also the talents and gifts and they could evaluate their own operation from the perspective of others (see table 2 for quotes.)

Interviewees also suggested that change and the tolerance of change demanded skills such as the ability to change their thinking and operation methods, flexibility and open mind. All of the employees experienced change as positive which operates as a precondition and a “driver” of operation and development. In addition, change made it possible for them to use their creativity, because through change, they were able to recognize aspects that require changes, alternative operation methods and models in their work. High tolerance of change strengthened also the tolerance of insecurity and complexity (Lai, 2011). In addition, high tolerance of change also helped them to adjust to their presence (see table 2 for quotes).

Change also enabled the development of their work to various different directions (within the strategy of their company). Through change, participants experienced that they could grab to new tasks and when the opportunity arises, they could move from their “comfortable zone” voluntarily. Change enabled watching new situations and it created a feeling that things proceed and development is happening, and then they could ignore their “old and safe ways/habits” (Lai, 2011).

Employees also highlighted their networking-related competences in that it helped them develop new innovations and service entities and it also enabled to take into account the customer’s perspective. For example, one interviewee stated that: *“I’m a director of many networks and I feel, that I’m conversational and give space to others. Such action requires that I have to be good for summarizing all discussions and conclusions.”*

Networking was seen as a precondition for own learning when the job description was unique and when they did not have colleagues with whom they could discuss with their work-related issues and problems and development areas related to their work. In this way, network offered a natural support and a route to development (see Morrison et al., 2005). In addition, operating in a network brought up their own competence and especially their ability to reflex their own operation. Networks were also seen as a possibility to learn how to create networks, how to manage them and they experienced networks as a good way of “making things clear” and an arena of managing their competences (see table 2 for quotes.)

Ability to network was seen as a living condition and as something that maintains their job satisfaction. For example, many of the employees have stated their jobs by building networks (Parker, 2003)

Several participants started description of their competences by describing their families and hobbies. This was also related to value- and ethical competences which told much about the personal values of the employee. In more detail, these were the most valued factors that came before their work: *“Outside of work I’m an older sister, mother for three children (one of them is hearing-impaired) and I live in such a “new family”. So I have my own family and in addition my husband’s children and family.”*

For example, employees identified competences related to their hobbies (for example in the sport association) or their tasks in similar associations (for example, as a trainer). Personal hobbies such as playing instruments, singing, gardening, out-door activities, moving in the nature, boating, diving, skiing and taking care of their pets were mentioned in the employees' stories. Family-life was also seen closely related to their competences and especially women described it through their role as a mother: what it required and demanded, what kind of results they were able to achieve by being mothers and how they could implement their role as a mother to their work. Following quote describes this theme: *"I'm a wife. I have received a good present – the gift to love. I'm a mother to two children. I have had possibility to learn to be mother with my children."*

Employees roles as a mother and a partner was strongly seen as a nurse, ability to control their emotions, ability to understand different generations, taking care of the daily routines and for challenges which single mums experienced. In addition, employees also highlighted their competences related to their relationship with their spouses and interaction with their relatives and friends (Dooley et al., 2004). Age and life experience from work life was seen as a huge strength which enabled them to receive also demanding job-related tasks and to constantly develop their skills and competences.

In several employee stories, competence was seen as a synonym for "being good in something" or they needed improvement in some other aspect – or they had succeeded in something.

The Table 3 illustrates the example of arranged themes based on the findings.

Table 3. Example of arranged themes.

Example from the text	Code	Theme
<p>"Also have good organizing skills."</p> <p>"Addition, I have good ADP skills."</p> <p>"I can do several things with the computer: memorandums, power point presentations, reports, tables, diagrams.."</p>	<p>Formal knowledge base of profession, basic routines -how, what, who, when etc., range of profession specific functions and tasks, planning, monitoring, implementing, IT skills</p>	<p>Substance based approach</p>
<p>"I can think big entities and analyze and combine my experience, operational environment, information from outside etc. And to combine people and things.."</p> <p>"I have noticed that my strength is the ability to picture large entities and to combine things together, the way things are related to each other.."</p>	<p>Creativity, problem solving, learning/self-development, mental agility, analysis, reflection</p>	<p>Meta competences oriented</p>
<p>"In the working life I like changes, when they are justified in a somehow reasonable way.."</p> <p>"In my own work, changes keep me cheerful and they challenge me in a nice way to develop own professional competence."</p>	<p>Tolerance of chance, network capability</p>	<p>Chance and network capability as competence drivers</p>
<p>"I am actively involved in the operation of two sport associations"</p> <p>"I am a single mum of two teen age boys, in which I have succeeded in quite well.."</p>	<p>Family, hobbies, leisure activities</p>	<p>Private life oriented and competence perspective</p>
<p>"In the inter-personal relationships I am the conciliator and the listener."</p> <p>" As a manager of the networks I am discussing and I give room for others."</p>	<p><i>Self confidence, control of emotions and stress, listening skills, task centeredness', empathy, values, ethical competences</i></p>	<p><i>Unknown personal/behavioral competences</i></p>

In the second phase of the study, we presented the holistic competence model by Cheetham & Chivers (1998) and each part of the model was discussed carefully with the participants. Based on this holistic competence model, the employees realized their competence base much more comprehensively as what they had previously thought of themselves: *"I think this is good in that it somehow this domination of cognitive competence becomes more equal with other aspects of the competence."*

Realizing this produced an explanation for why the work atmosphere in the organization was perceived as positive and something that supported everyone. In addition, learning was enabled through colleagues. Several employees also understood the meaning of their attitude that relates to their personal competence; even though the substance competence would be fine, it would anyway disappear if the attitude was not right. Identifying employees' competences

comprehensively was perceived as something that unites and encourages in change and in the inner organizational dynamics (see Erdogan & Bauer, 2009; Feldman, 1996, Maynard, 2006).

"It eases at least the coping when you understand the complexity of competences and in a way it kind of helps to understand work place, I mean like the way employees have focused their competences differently."... "then the attitude, if you take an attitude like I can"..."I think this is like a richness that everyone sees it differently and we don't label employees as better or worse.."

"If you identify the different competence levels, then if we organize teams then we can put right assembling"

In summary of the participants had not identified and recognized their own competences according to the holistic competence model by Cheetham & Chivers (1998).

"These are things which I have taken as granted, these are something which are always present...I had insights when you see these things written down"

In addition, several participants experienced that it made them "easier to work" as they had identified their whole comprehensive base, because then they realized that if they would fail, they would still have several other competence aspects where they would be strong. Comprehensive competence base enabled the evaluation of their own strengths and weaknesses and it enabled them to evaluate new development possibilities. In addition, participants felt it was richness to recognize that every employee in the company looks at things differently, depending on their level of competence (development level). By recognizing this, the focus group expressed that by using the holistic competence model, they are able to achieve more equal working place. This finding also pushes the previous knowledge of the outcomes of using holistic competence model in the workplace to the edges of new scientific knowledge. That is, to our knowledge, this finding has not been highlighted in the previous studies of holistic competence model (see Cheetham & Chivers, 1998).

In addition, the holistic competence model gave tools for self-management, which reflected also to the inner dynamics inside their organization:

"I somehow thought of the recruiting situation, that in that situation we could actually apply this model and on the other hand, the development discussions and then to apply for self-management and for evaluating own core competences."

We also notified that the participants highlighted competences related to their personality and to their ethical operation: attitude towards the work, customers, colleagues, empathy, personal behavior, giving feedback to colleagues and behaving ethically. The identification of holistic competence model helped them to tolerate more differences, being helpful, equal, creating "we-spirit" and understanding the meaning of inter-personal skills (see Cheetham & Chivers, 1998; Sundberg, 2001).

5 Discussion and conclusions

The object of this study was to get a deeper understanding of what individual and organizational-level outcomes there is when identifying the competences from holistic perspective. It is shown in various scientific research that scholars have seen the identification of competences as difficult. In addition there exists also a research gap concerning how the holistic perspective can and should be best applied in order to harness employees' real and latent competences into practice. The study answered to the research questions: "how the construct of competence is defined and understood by employees' in case organization and 2) what are the outcomes of identifying these competences at the individual and organizational level?"

Based on our study, we argue that the employees in our case company defined and understood the competence mainly as the traditional competence view focused on cognitive and functional competences (e.g., Spencer & Spencer, 1993). However, the holistic competence approach (e.g., Cheetham & Chivers, 1998) provided a significant insight to employees understanding of their very broad competences and an in-depth understanding of their own work. The findings of our study has several theoretical insights (see Corley & Gioia, 2011) that push forward the current knowledge on how holistic competence approach can be applied in order to harness employees' competences into practice. In addition, we found that utilizing holistic competence approach in order to map out employees' competences has several individual and organizational-level outcomes this has.

That is we found that identifying these competences had several positive outcomes both to the individuals (employees) and to the case organization and can lead to effective and/or superior performance on the job (Boyatzis, 1982). At the individual level, understanding the holistic competence view made it easier to own reflection and understanding behavior and actions of other employees, the importance of empathy and capability to control of own emotions. Training Standard Agency (2000) mention, that identifying individuals own competences it leads to an action, behavior or outcome which the person should be able to demonstrate.

In summary, the holistic perspective increased employee's well-being in organization. As Woodall and Winstanley (1998) has argued multidimensional approach includes the skills, knowledge and understanding qualities and attributes, sets of values, beliefs and attitudes which lead to effective managerial performance in a given context, situation or role. Secondly, employees experienced a new kind of job satisfaction as they found that they own a lot more competences and that part of these competences are "latent" as they had been hidden and unconscious. At the organizational level, identifying employees' competences was also important and had positive outcomes. employees' competencies are often well understood and implemented in organizations which have adopted the principles of "learning organizations" that

support firms constantly to adopt new knowledge and insights through individuals and teams (see Sundberg, 2001). Finally, we argue that the concept of holistic competence view helped in self-assessment, reflection and attitude editing both to the individual and organizational level.

The first contribution of this study is to emphasize the value of understanding the holistic competence approach. For example it is useful in recruiting process and development discussion when identifying employees' features and hidden talents. The topic has been less studied, and its thematic has not experienced significant or even fitted the business related decision making. From managerial aspect one benefit is the new way of understanding the tacit dimension in work place atmosphere and group dynamics. Secondly, the research enables the development of recruiting and development discussion processes, if it is possible to create, for example, the question tools which help to evaluate the intangible and abstract issues from holistic competence perspective. Thirdly, the study underlines the importance of creating an assessment tool for recruitment process targeting to evaluation of holistic competence approach and intangible and abstract issues.

Limitations

This study is a qualitative case study and only one case organization was examined. Therefore, the results cannot be generalized in a larger extend. However, information was gathered from 16 employees and there were two methods: storytelling and focus group interviews. In the future it might be interesting to repeat the study with personnel in different context.

Les nouvelles pratiques dans le commerce de détail alimentaire peuvent-elles permettre des économies d'énergie?

Charlotte Fourcroy

¹Chercheur au laboratoire Clersé, Université Lille 1

Dans le contexte actuel de la transition énergétique et notamment d'un renforcement des réglementations énergétiques, le secteur du commerce de détail alimentaire s'intéresse de plus en plus à la question de la maîtrise de ses consommations d'énergie. Un certain nombre d'innovations technologiques sont mises en œuvre (adoptées), par exemple la mise en place de systèmes de ventilation innovants ou la fermeture des meubles réfrigérés. Mais d'autres changements en cours dans le secteur sont également susceptibles d'influencer fortement le montant des consommations d'énergie. Ces innovations de services ou organisationnelles sont plus rarement prises en compte dans les réflexions quant à l'évolution des consommations d'énergie. Ce sont ces innovations et leurs répercussions énergétiques que nous cherchons à identifier dans le cadre de ce papier.

1 Introduction

La question de la maîtrise de la demande d'énergie dans le secteur du commerce de détail alimentaire se limite souvent à l'analyse des innovations technologiques capables de réduire les consommations d'énergie. Ce biais *technologiste* n'est pas spécifique au secteur du commerce et concerne plus largement l'ensemble des activités de services.

Un parallèle peut-être fait entre cette vision de la maîtrise de la demande d'énergie et celle de la question des innovations, en général, dans les services : longtemps, l'étude des innovations dans les services s'est limitée à l'adoption par les services d'innovations technologiques produites dans le secteur industriel (Barras, 1986 ; Miozzo et Soette, 2001). C'est la perspective *technologiste*, selon la terminologie introduite par Gallouj et Savona (2009). Par la suite, un certain nombre de travaux ont porté sur les innovations purement non technologiques, notamment dans les services intensifs en connaissance (Desai et Low, 1987 ; Gallouj, 1991 ; Miles, 2007). Ils relèvent de l'approche *servicielle*, selon la terminologie introduite par Gallouj et Savona (2009). Plus récemment, constatant que la frontière entre les biens et les services est de plus en plus floue (de nombreux services ont une composante matérielle importante et de nombreux biens ont une composante servicielle importante), il est apparu des travaux dits d'une approche *intégratrice* (Gallouj et Weinstein, 1997 ; DeVries, 2006 ; Windrum et Garcia-Goni, 2008).

Notre hypothèse est la suivante : dans le domaine de la maîtrise de la demande d'énergie, il est important d'élargir l'analyse des innovations capables d'influencer les consommations d'énergie aux innovations non technologiques. D'autres formes d'innovation (des innovations de services) sont susceptibles d'influencer fortement la demande d'énergie dans le secteur du commerce. Dans cet article, nous étudions donc l'articulation entre les problématiques de l'innovation et de l'énergie dans le secteur du commerce de détail alimentaire. Nous ne nous limitons pas aux innovations mises en œuvre dans le but de réduire les consommations d'énergie. Nous souhaitons aller au delà, en déterminant les répercussions énergétiques des innovations mises en œuvre pour répondre aux grands enjeux du secteur.

Pour répondre à ces questions, nous proposons un modèle d'analyse théorique, pour l'ensemble des services. Ce dernier repose sur une adaptation de la représentation du produit (biens ou services) en termes de caractéristiques, dans le prolongement des travaux de Gallouj et Weinstein (1997), qui met en évidence les relations entre l'innovation dans les services et l'évolution des consommations d'énergie. Sur cette base, nous identifions différents axes d'innovation dans les services, du point de vue de leurs répercussions sur les consommations d'énergie. Nous appliquons ensuite ce modèle théorique à l'analyse du secteur du commerce de détail alimentaire. Nous avons mené une série d'entretiens semi-directifs auprès de dirigeants des principaux groupes du commerce de détail en France et des associations et fédérations qui les soutiennent. Nous avons également rencontré des directeurs de magasin, et recueilli auprès d'eux des informations précises sur les consommations d'énergie, au niveau d'un établissement et sur mesures d'économie d'énergie mise en œuvre. Notre troisième groupe d'interlocuteurs est constitué de professionnels de la logistique du commerce alimentaire, la logistique étant une composante essentielle de l'activité de commerce, très active sur les questions d'énergie. Le contenu des grilles d'entretien a été adapté à chaque type d'interlocuteurs, mais, d'une façon générale, les questions ont porté sur les consommations d'énergie de l'activité commerciale (les principaux postes, les enjeux énergétiques, etc.), sur les dynamiques du secteur et sur leurs répercussions énergétiques. Au total, nous avons rencontré 13 personnes. Pour rendre compte du contenu des entretiens (tous enregistrés et retranscrits), nous avons utilisé la méthode d'analyse thématique¹²⁴.

Dans une première section, nous présentons donc notre modèle théorique pour l'analyse des dynamiques d'innovation dans les services et de leurs répercussions énergétiques. Ce modèle rend compte de la diversité des dynamiques d'innovation pouvant influencer les consommations d'énergie, au delà des mesures de maîtrise de la

¹²⁴ La liste des personnes rencontrées, la grille d'entretien, ainsi que la grille d'analyse thématique sont présentées en détail dans Fourcroy (2013).

demande d'énergie. Dans une seconde section, nous appliquons ce cadre d'analyse au secteur du commerce de détail alimentaire pour identifier les dynamiques d'innovation à l'œuvre qui ont des répercussions importantes sur les consommations d'énergie, à la hausse ou à la baisse.

2 Un modèle d'analyse des dynamiques d'innovation dans les services et de leurs répercussions énergétiques

2.1 Une représentation des services, adaptée à l'analyse de leur demande d'énergie

Gallouj et Weinstein (1997) s'appuient sur les travaux de Lancaster (1966) et de Saviotti et Metcalfe (1984) pour proposer une définition du produit (un bien ou un service) en termes de caractéristiques (figure 1). Un produit peut être représenté par la combinaison de différents vecteurs de caractéristiques : un vecteur des caractéristiques de service, un vecteur des caractéristiques techniques et deux vecteurs des compétences, des prestataires et des clients. Le vecteur des caractéristiques de service est composé de caractéristiques qui justifient le recours au service, mais aussi de caractéristiques complémentaires qui améliorent les performances des précédentes et d'externalités. Les compétences sont incorporées à l'individu, à un groupe d'individus ou encore à une organisation. Elles sont le fruit de sa formation, de son expérience, de ses interactions, etc. Elles sont, le plus souvent tacites, et difficilement transmissibles. D'ordre scientifique, technique, opérationnel ou relationnel, elles sont mobilisées pour utiliser les techniques ou directement pour réaliser le service. La prestation de services nécessite non seulement la mobilisation de compétences de la part du prestataire, mais également de la part du client, qui coproduit généralement le service. La coproduction qui est une caractéristique importante du service peut, ainsi, être représentée par l'articulation de ces deux vecteurs de compétences. Le vecteur des caractéristiques techniques est défini comme l'ensemble des techniques utilisées pour réaliser le produit. Ces techniques peuvent être tangibles (du matériel informatique, de logistique, ou de coiffure, par exemple) ou intangibles (un instrument mathématique, une méthode de travail, etc.). Elles sont codifiées, transmissibles et indépendantes des individus. Dans le modèle initial, seules les techniques du prestataire sont prises en compte. Par la suite, les techniques du client ont été ajoutées (DeVries, 2006 ; Gallouj et Savona, 2010) : avec le développement des technologies de l'information et de la communication, l'interface client/prestataire fait de plus en plus souvent intervenir les technologies du client.

Figure 4. La représentation générale des biens et services selon Gallouj et Weinstein (1997).

Ce modèle est utile et adapté (sous réserve de quelques amendements) à l'étude des consommations d'énergie des services. Le mécanisme de formation de la demande d'énergie est récapitulée dans la figure 2. La réalisation du service (du *besoin de services*) suscite un *besoin de services de l'énergie* (c'est-à-dire d'énergie utile) : un travail, un mouvement, un élévation de température, etc. Ce dernier dépend d'un certain nombre de facteurs exogènes, comme le

climat extérieur ou les apports internes et gratuits de chaleur¹²⁵. Les consommations d'énergie réelles, nécessaires pour satisfaire ce besoin d'*énergie utile* sont, ensuite, fonction des caractéristiques techniques des équipements utilisés, ainsi que de la façon dont ces équipements sont utilisés. Ainsi, les éléments à l'origine de la demande d'énergie apparaissent de façon plus ou moins explicite dans le modèle : les équipements, les comportements d'utilisation, le niveau de service demandé, etc. Les consommations d'énergie peuvent, elles-mêmes, être formulées en termes de caractéristiques de services (caractéristiques complémentaires ou externalités).

Figure 5. Le mécanisme général de formation de la demande d'énergie.

Nous proposons également plusieurs amendements à la représentation initiale, pour l'adapter à notre étude. Ces modifications concernent les techniques, les compétences et le périmètre du service.

2.1.1 Modifications des vecteurs des caractéristiques techniques

Dans la représentation du produit en termes de caractéristiques, le vecteur des caractéristiques techniques est parfois appelé le vecteur des techniques, ce qui traduit une ambiguïté entre les artefacts techniques individuels (les techniques) et leurs composants internes (les caractéristiques techniques). Or, les services ne sont pas incorporés dans des composants techniques dont ils seraient indissociables. En revanche, ils peuvent mobiliser des outillages techniques. Il faudrait donc envisager un vecteur des techniques à deux dimensions : celles des techniques mobilisées (c'est-à-dire les outils techniques non incorporés) et celle des caractéristiques techniques internes (c'est-à-dire les composants techniques internes) de chacune de ces techniques. Pour simplifier cependant, dans la suite de ce chapitre, nous ne faisons généralement mention que d'une seule dimension. On définira ainsi le vecteur des techniques comme l'ensemble des *outils techniques* mis en œuvre pour fournir le service.

Le terme de *techniques* regroupe les techniques tangibles et les techniques intangibles. Les techniques tangibles correspondent notamment à l'ensemble des équipements du service. Certaines de ces techniques tangibles sont consommatrices d'énergie (T_e). D'autres ne consomment pas directement d'énergie, mais influencent le besoin d'*énergie utile*. Elles correspondent principalement à des techniques renvoyant aux bâtiments (T_b). Les techniques intangibles correspondent, pour leur part, aux routines et méthodes de travail. Certaines techniques intangibles ont une influence directe sur les consommations d'énergie : les méthodes d'utilisation des techniques (M_e).

2.1.2 Modifications des vecteurs des compétences

Nous proposons également d'élargir le sens des *compétences*. En effet, les caractéristiques de services ne sont pas simplement le résultat de la mobilisation conjointe des compétences et des techniques. Il existe une abondante littérature sur l'influence des comportements humains sur la demande d'énergie (Wilson et Dowlatabadi, 2007 ; Lutzenhiser, 1993 ; Van Raaij et Verhallen, 1983). Cette littérature converge vers l'idée que le comportement dépend non seulement des compétences au sens strict, mais aussi des compétences au sens large (c'est-à-dire des valeurs, des croyances, des normes, des habitudes) et des conditions extérieures.

Dans le vecteur *compétences*, nous proposons donc d'intégrer l'ensemble des *caractéristiques* des individus dont dépend leur comportement¹²⁶. Comme dans la représentation de Gallouj et Weinstein (1997), ces caractéristiques sont le résultat des expériences, formations et autres interactions des individus. Elles sont, le plus souvent, tacites et difficiles à transmettre.

¹²⁵ Les apports internes de chaleur correspondent à l'apport de chaleur par les occupants ou les équipements. Les apports gratuits correspondent à l'ensoleillement.

¹²⁶ Il est, bien sûr, entendu que le comportement ne dépend pas uniquement de ces caractéristiques, mais notamment aussi des méthodes ou routines dont dispose l'individu et qui sont, pour leur part, décrites dans le vecteur des techniques.

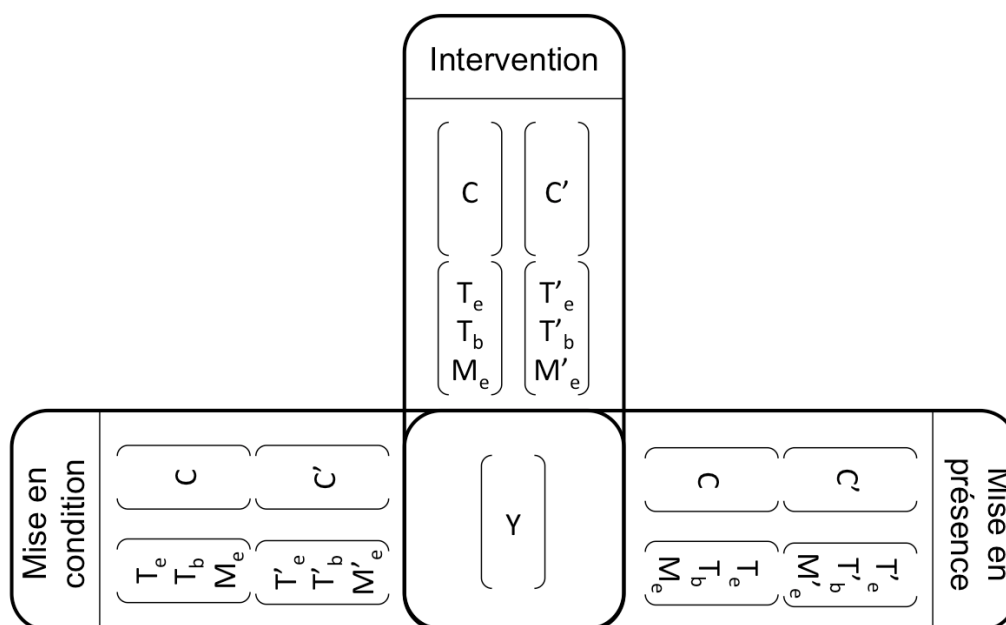

2.1.3 Evolution du périmètre des services

La plupart des travaux théoriques en sciences économiques, consacrés à la définition des activités de services, concernent, ce que nous appelons *l'intervention* de service (I), c'est-à-dire l'ensemble des activités de back-office et de front-office mobilisées pour rendre un service aux clients. C'est à la définition et à la conceptualisation de *l'intervention* de services que sont consacrés les travaux de Hill (1977, 1999), la métaphore du « triangle des services » (Gadrey, 2003), ou la décomposition fonctionnelle des services (Gadrey, 1991 ; Gallouj, 1999). Mais, notamment lorsque l'on s'intéresse aux consommations d'énergie, il est particulièrement important d'élargir la définition des services et leur périmètre¹²⁷.

L'intervention de service nécessite des interactions entre les prestataires, les clients et le support de la prestation de services, donc une certaine forme de *mise en présence* des différentes parties prenantes. Cette *mise en présence* (M_p) peut s'opérer par un déplacement en amont de l'intervention de service ou elle peut prendre la forme d'une mise en présence virtuelle sans déplacement par l'usage des TIC.

Par ailleurs, l'intervention de services se déroule dans un (ou plusieurs) lieu(x) qui sont *mis en condition* pour accueillir le service : aménagement, nettoyage, chauffage, éclairage, etc. Une partie de ces activités de *mise en condition* (M_c) nécessite des consommations d'énergie, principalement le chauffage, l'éclairage et la climatisation des lieux où se déroule le service.

Ainsi, pour adapter la représentation par les caractéristiques de Gallouj et Weinstein (1997) à l'analyse de l'évolution des consommations d'énergie, il est nécessaire d'y intégrer la *mise en présence* et la *mise en condition* des locaux (figure 3).

Avec C et C' respectivement les compétences des prestataires et des clients et T_e, T_b, M_e et T'_e, T'_b, M'_e respectivement les techniques et méthodes des prestataires et des clients (T_e les techniques énergétiques, T_b les techniques du bâti et M_e les méthodes d'utilisation des techniques énergétiques).

Figure 6. Une représentation du service adaptée à la question de la consommation énergétique.

Cette adaptation traduit un élargissement à la fois horizontal et vertical du périmètre traditionnel du service. L'intégration de la mise en présence traduit une extension horizontale du périmètre du service. Sa superficie est plus grande puisqu'elle prend en compte des activités jusque-là généralement exclues (la mobilité). L'intégration de la mise en condition des locaux traduit quant à elle une extension verticale : un niveau de détail plus fin sur les activités qui se situent dans le périmètre traditionnel du service. Il n'y a pas en théorie de difficulté à accepter ces trois catégories (I, M_p, M_c), mais, dans la pratique, les frontières entre elles peuvent être contingentes. Ainsi, dans le cas des services d'hébergement (hôtels, maisons de retraites, hôpitaux, établissements pénitentiaires), la frontière n'est pas claire entre

¹²⁷ Les travaux en sciences de gestion adoptent généralement aussi une définition élargie des services, et distinguent notamment les services de cœur de métier et les services de soutien (Shostack, 1977 ; Gronroos, 1990 ; Lovelock et al., 2004).

les activités de *mise en condition* comme le chauffage, l'éclairage ou le nettoyage et les activités d'*intervention de services*¹²⁸. Dans un service de transport, l'activité d'intervention est, pour l'essentiel, identique à l'activité de mobilité.

2.2 Un modèle d'analyse des répercussions énergétiques de l'innovation dans les services

La nouvelle représentation générale du produit fournit ainsi une heuristique intéressante pour identifier les relations entre l'innovation dans les services et l'évolution de la demande d'énergie par les services. À partir de cette heuristique nous voulons proposer un modèle d'analyse des dynamiques de l'innovation dans les services, adapté à l'étude des consommations d'énergie.

Nous mettons ainsi en évidence un certain nombre d'*axes d'innovation* à l'œuvre dans les services. Le premier axe d'innovation correspond à la recherche d'une baisse des consommations d'énergie finale, à service rendu identique. Les autres axes d'innovation n'ont pas, généralement, pour principal déterminant les consommations d'énergie, mais ils ont pourtant des répercussions directes sur leur niveau. Il s'agit, comme nous le verrons, des axes d'*enrichissement* du service, de *resserrement*, de *délégation* et de *mutualisation*.

2.2.1 L'axe d'efficacité énergétique

Le premier axe d'innovation correspond à la recherche d'efficacité énergétique, c'est-à-dire à la réduction des consommations d'énergie des services, à service rendu constant. À besoin de service constant, les consommations d'énergie dépendent des techniques tangibles consommatrices d'énergie (T_e , T'_e), des méthodes mises en œuvre (M_e , M'_e), des compétences des utilisateurs (C , C'), ainsi que des techniques du *bâti* (T_b , T'_b). Les innovations relevant de la logique d'efficacité énergétique se traduisent donc par une évolution d'un ou de plusieurs des vecteurs. Cette évolution peut prendre la forme de l'amélioration, l'ajout, la suppression, l'association ou encore la dissociation d'une ou de plusieurs caractéristique(s).

À besoin de services constant, une évolution du vecteur des techniques traduit, principalement, l'amélioration de la performance énergétique d'une technique existante, passant par l'évolution de ses caractéristiques techniques. Une évolution des compétences des utilisateurs peut, pour sa part, traduire l'aptitude des utilisateurs à réduire directement les consommations énergétiques ou leur capacité à mobiliser des techniques tangibles ou intangibles (méthodes, protocoles) qui réduisent les consommations énergétiques.

Différentes trajectoires d'innovation peuvent être envisagées, selon les différents éléments à l'origine de la demande d'énergie : le bâti, les techniques consommatrices d'énergie, les méthodes et compétences (c'est-à-dire le *comportement énergétique*). Les trajectoires d'innovation des techniques énergétiques et des techniques du bâti correspondent à l'amélioration de leurs performances énergétiques, généralement pour répondre aux exigences réglementaires ou pour obtenir une labellisation. Les trajectoires d'innovation des comportements énergétiques correspondent à la sensibilisation des individus et à la mise en œuvre de processus d'organisation moins consommateurs d'énergie.

Une autre innovation se développe depuis quelques années. Elle ne vise pas à réduire, directement, la demande d'énergie des services, mais à introduire un service élémentaire de production d'énergie (production décentralisée d'électricité à partir de panneaux solaires ou d'éoliennes, par exemple)¹²⁹. Il s'agit, ici, d'une modification des caractéristiques du service, plus spécifiquement de l'ajout d'un service élémentaire. On peut cependant considérer que cette innovation relève de l'axe d'*efficacité énergétique* car le service, dans ses caractéristiques de service *principales*, n'est pas modifié.

Ces innovations peuvent être intentionnelles, le fruit d'une stratégie raisonnée, ou involontaires, simples conséquences d'une évolution du contexte dans lequel s'inscrit le service. Par exemple, dans la mesure où les ampoules à incandescence classiques sont peu à peu éliminées du marché, la substitution par des lampes basse consommation ne sera pas nécessairement justifiée par un objectif explicite de l'utilisateur, mais plutôt par l'évolution de l'offre disponible. La réglementation thermique (RT 2005 et RT 2012) impose un certain niveau de performance énergétique pour les bâtiments neufs et, dans une moindre mesure, les bâtiments rénovés. De même l'adoption d'un comportement respectueux de l'environnement par les prestataires de service n'est pas nécessairement le résultat d'un effort volontaire de l'organisation de services, mais le simple résultat d'habitudes ou de normes sociales.

2.2.2 L'axe d'enrichissement du service

L'*enrichissement* du service correspond à une augmentation du besoin de services. Une augmentation du besoin de services correspond à une évolution du vecteur des caractéristiques de services qui se traduit, généralement, par une évolution des vecteurs des techniques et des compétences.

¹²⁸ Une distinction similaire existe pour la définition des normes de consommation d'énergie des bâtiments BBC. On distingue, en effet, les usages *process* (qui correspondent à ce que nous appelons l'intervention) et les usages *non process* (comparables à la mise en condition). La définition des usages *process* et *non process* est propre à chaque sous-branche du secteur tertiaire. Elle est discutable et fait d'ailleurs l'objet de négociations serrées entre les pouvoirs publics et les professionnels de la sous-branche.

¹²⁹ Généralement, l'énergie produite est revendue au fournisseur d'énergie à un tarif avantageux, ce qui permet de réduire, au total, le coût des consommations d'énergie. Cependant, les tarifs de rachat de l'électricité diminuent.

Il peut s'agir de l'adjonction de caractéristiques de services, voire de l'adjonction de services élémentaires¹³⁰. Ainsi, la dynamique de diversification des services (Gadrey, 1994 ; Djellal et Gallouj, 2007) relève de l'*enrichissement* du service. Dans le secteur de la santé, des cliniques privées haut de gamme proposent un service d'hébergement luxueux et un grand nombre de services périphériques, comme des services de balnéothérapie et d'équipements de remise en forme de qualité.

Il peut, également, s'agir de l'amélioration des caractéristiques de services existantes¹³¹. À titre d'exemple, le passage d'un service hospitalier traditionnel à un service *enrichi* peut se traduire par la mise à disposition de chambres et de lieux communs plus spacieux aux patients. Ces améliorations des caractéristiques de services entraînent une augmentation des besoins de *services de l'énergie* et donc, toutes choses égales par ailleurs, une augmentation des consommations d'énergie. L'amélioration des caractéristiques de services peut également prendre d'autres formes, comme l'amélioration de la performance *métier* d'une technologie (c'est-à-dire l'efficacité dans la réalisation de la fonction principale qui lui est assignée), qui se fait généralement au prix d'une dégradation des rendements énergétiques.

Il peut, finalement, s'agir d'une évolution dans la façon de *réaliser* certaines caractéristiques de services, principalement par la mise en place d'équipements ou de logiciels¹³². La tendance à la technicisation des activités, qui entraîne une hausse de la demande d'énergie, relève de la logique d'innovation d'enrichissement du service.

Les innovations relevant de cet axe ne visent pas à modifier les consommations d'énergie, mais à faire évoluer le service rendu aux clients. Pourtant, indirectement, elles influencent, à la hausse, le volume des consommations d'énergie. À moyen termes, le renforcement des contraintes énergétiques ou l'augmentation du coût de l'énergie pourraient accroître le poids des consommations d'énergie comme déterminants de l'innovation et éventuellement freiner le développement de ces innovations.

2.2.3 L'axe de resserrement du service

Le *resserrement* du service correspond à une réduction du besoin de services. Les besoins de services étant à l'origine de la demande d'énergie, les innovations relevant de cet axe induisent une baisse des consommations d'énergie. La réduction du besoin de services se traduit de diverses façons, en termes d'évolution des caractéristiques.

Il peut s'agir, tout d'abord, de la suppression d'une (ou de plusieurs) caractéristique(s) de services, voire de la suppression de services élémentaires. La réduction du besoin de services peut également se traduire par une réduction qualitative de certaines caractéristiques de services, ou encore par la formalisation et la standardisation des caractéristiques existantes, notamment par la mise en place de routines¹³³.

Le développement de services simplifiés avec les formules *low-cost* relève de cet axe. Le développement des services à distance, en tant qu'ils permettent de réduire ou de supprimer certains services de déplacement, relève également de cet axe.

Comme l'axe d'efficacité énergétique, le *resserrement* du service permet généralement des économies d'énergie. La distinction entre ces deux axes repose sur le déterminant de l'innovation. Pour les innovations relevant de l'axe de resserrement, le principal déterminant de l'innovation n'est pas la recherche d'économie d'énergie, mais la volonté de proposer un nouveau service. Cela étant dit, ces innovations permettent des économies d'énergie et, en cas d'augmentation du coût de l'énergie ou de renforcement des contraintes énergétiques, leur développement serait favorisé.

2.2.4 L'axe de délégation

La *délégation* correspond à une évolution dans l'attribution des tâches entre les parties prenantes au service, et donc dans la répartition des consommations d'énergie entre le client et le prestataire. Ces innovations ont, également, des répercussions sur les techniques ou les compétences mobilisées et donc sur le volume global des consommations.

La répartition des consommations d'énergie entre les parties prenantes au service dépend principalement du lieu où se déroule l'interaction (chez le prestataire, chez le client, à distance, etc.), de la nature de la mise en présence (déplacement physique ou mise en présence virtuelle) et de l'entité qui se déplace (le client ou le prestataire), tous ces éléments étant fortement liés. Ainsi, le développement de services à domicile relève de cet axe. Dans le cas d'un service à domicile, la mise en condition est réalisée par les techniques et les compétences du client du service, et non par les techniques et les compétences du prestataire. À l'inverse, une partie des déplacements des clients font place aux déplacements des prestataires. Le développement des services à distance relève également, en partie, de cet axe, quand il s'agit de substituer des livraisons aux déplacements des clients.

La *délégation* peut également s'exprimer dans le sens de la délégation de certaines tâches, traditionnellement réalisées par d'autres acteurs de la société, aux entreprises de services. Ainsi, les tendances au développement des services aux entreprises et des services aux ménages relèvent de cet axe. La *marchéisation* des services domestiques

¹³⁰ Une innovation incrémentielle ou architecturale, selon la terminologie de Gallouj et Weinstein (1997).

¹³¹ Une innovation d'amélioration, selon la terminologie de Gallouj et Weinstein (1997).

¹³² Une innovation de formalisation, selon la terminologie de Gallouj et Weinstein (1997).

¹³³ Respectivement des innovations incrémentielles, d'amélioration et des innovations de formalisation, selon la terminologie de Gallouj et Weinstein (1997).

correspond à la délégation des tâches, précédemment réalisée par les ménages, à des entreprises de services. Du point de vue des consommations d'énergie du secteur des services, cela se traduit, toutes choses égales par ailleurs, par une hausse des consommations d'énergie.

La *délégation* est une logique qui s'exprime lorsque l'on étudie un système. Si l'on adopte le point de vue d'un établissement de services, cette logique correspond soit à un *enrichissement*, soit à un *resserrement* du service. Ainsi, par exemple, le développement d'un service de livraison dans le commerce de détail, correspond, en soi, à une délégation, par laquelle un service traditionnellement rendu par le client (le service de déplacement du client) est délégué aux prestataires du service de commerce. Du point de vue du service rendu par l'établissement de commerce de détail, il s'agit d'un enrichissement du service.

2.2.5 L'axe de mutualisation

La *mutualisation* correspond à la combinaison de plusieurs services similaires, initialement réalisés par différents prestataires. Il s'agit, par exemple, de regrouper les activités de plusieurs organismes au sein d'une même entité. Les innovations relevant de cet axe visent la rationalisation des services, c'est-à-dire la réduction globale des coûts et des équipements utilisés. Elles peuvent alors se traduire par une réduction des consommations d'énergie, bien que les économies d'énergie soient rarement à l'origine de la décision d'innovation.

Il s'agit ici de combiner des services identiques, afin d'augmenter le poids ou la valeur de certaines caractéristiques de services. Au niveau inter-organisationnel, les innovations relevant de la *mutualisation* n'entraînent pas une augmentation du service rendu (contrairement à celles relevant de l'*enrichissement*). Mais l'augmentation du poids et de la valeur de certaines caractéristiques de services peut permettre une évolution des vecteurs des techniques (des économies d'échelle) : une diminution du nombre d'équipements et de consommables nécessaires.

Cet axe d'innovation s'exprime dans les activités pour lesquelles des économies d'échelle sont possibles et dans les activités que les organisations acceptent d'*externaliser*, c'est-à-dire principalement les activités périphériques ou de soutien au cœur de métier de l'activité. Ces innovations concernent, d'une part, les activités de services qui externalisent une partie de leurs services périphériques (la restauration dans l'enseignement ou la santé, par exemple) et, d'autre part, les activités industrielles qui externalisent une partie de leurs fonctions de services (la facturation, les ressources humaines, la restauration, etc.). L'économie de la fonctionnalité ou le développement des *produits-services*¹³⁴ relève également, en partie, de cette logique. Il s'agit alors de mutualiser les services rendus par différents équipements. Toutes choses égales par ailleurs, la mutualisation des équipements permet de réduire le nombre d'équipements nécessaires et donc les consommations d'énergie pour les produire.

2.2.6 La combinaison de plusieurs axes

Dans la réalité, les innovations relèvent généralement de plusieurs de ces axes. Ainsi, le développement du commerce en ligne relève à la fois de l'axe d'*enrichissement*, de l'axe de *resserrement* et de l'axe de *délégation*. Le *resserrement* du service correspond à la suppression du service de *mise en condition* de la zone de vente et des consommations d'énergie associées. L'*enrichissement* du service s'exprime par l'ajout des services tels que la *mise en présence virtuelle* ou le *conditionnement des produits* et donc une hausse des consommations d'énergie. Finalement, la *délégation* se traduit par une évolution des déplacements : le client ne se rend plus sur le lieu de vente pour retirer son colis, mais c'est souvent le prestataire qui lui livre.

3 Les dynamiques d'innovation dans le secteur du commerce de détail alimentaire et leurs répercussions énergétiques

L'innovation dans les services de commerce a fait l'objet d'une littérature abondante (McNair, 1958 ; Hollander, 1960 ; Levy *et al.*, 2005 ; Gallouj et Toivonen, 2009). Il existe également une littérature, certes moins abondante, consacrée aux répercussions énergétiques des innovations organisationnelles dans le commerce. Cette littérature met l'accent sur une tendance spécifique de l'innovation, à savoir le développement du e-commerce non-alimentaire (Abukhader et Jönson, 2003 ; Williams et Tagami, 2003 ; Edwards *et al.*, 2010).

Notre objectif est, ici, d'élargir cette réflexion pour rendre compte des principales dynamiques d'innovation et de changement dans le commerce de détail alimentaire et de leurs impacts énergétiques. Nous nous appuyons sur les entretiens que nous avons réalisés, ainsi que sur le modèle d'analyse développé dans la section précédente.

¹³⁴ Un nouveau modèle économique qui substitue la vente de l'usage d'un bien à la vente du bien lui-même. Ce modèle économique a plusieurs intitulés, pour plusieurs angles d'analyse et plusieurs écoles de pensée. C'est ce modèle qui est au cœur de l'économie de la fonctionnalité (Giarini et Stahel, 1990 ; Stahel, 1998 ; Bourg et Buclet, 2005 ; Du Tertre, 2007), de l'économie quaternaire (Debonneuil, 2010), de l'économie de l'expérience (Pine et Gilmore, 1998) ou de la *service dominant logic* (Lusch, 2006), mais aussi des concepts d'Eco-Efficient Services (Meijkamp, 1998, 2000 ; Bartolomeo *et al.*, 2003).

3.1 Le développement d'offres de commerce simplifiées

Deux formats de commerce se développent particulièrement, ces dernières années : les commerces de proximité (dont les commerces de type *hard-discount*) et les formules de type *drive*. Ces formats correspondent à des offres simplifiées (une logique de resserrement du service), comparativement aux hypermarchés traditionnels, en ce qu'ils proposent un assortiment de produits moins large, moins de services périphériques et, dans le cas du *drive*, aucun accueil du client sur la zone de vente.

Actuellement, en France, le nombre d'hypermarchés ne progresse presque plus¹³⁵ et les nouvelles implantations, dans le commerce de détail alimentaire, correspondent principalement à des commerces de proximité de type supermarché ou supérette de centre-ville (Pompougnac, 2009 ; Jaffredo, 2009 ; Parabellum et Bossman Consultants, 2012). Ainsi, le nombre de commerces de proximité a cru, en moyenne, de 0,6% par an en France entre 2002 et 2008 (Solard, 2010). En termes de parts de marché, ce format de commerce a atteint plus de 6% du marché de l'alimentaire en 2011, soit une augmentation de 0,2 points par rapport à l'année précédente (enquête Kantar Worldpanel pour 2011). Les commerces de proximité sont constitués à la fois des commerces d'alimentation spécialisés, et non spécialisés (dont les petits supermarchés, les supérettes, etc.). Ce sont ces derniers qui connaissent une croissance particulièrement dynamique (Désaunay, 2012).

Dans la catégorie des commerces de proximité, on compte les commerces de type *hard-discount* (HD) qui sont, généralement, des magasins de petite taille. Leur expansion a été particulièrement importante dans les années 2000. Aujourd'hui, elle semble fléchir en France (Michel, 2010 ; Puget, 2012).

Les *drives*, pour leur part, ont fait leur apparition il y a quelques années. Ils ne représentent encore qu'une faible part de marché des produits de grande consommation (moins de 2% en 2012, d'après des données de LSA), mais ils sont l'un des principaux vecteurs de croissance actuellement, représentant 80% de la croissance de Auchan et 33% de celle de Leclerc (sur les produits de grande consommation, en 2011, données LSA). Actuellement, toutes les grandes enseignes sont présentes sur ce segment d'activité. Il existe deux formes principales de *drive* : le *drive* accolé au magasin et le *drive* indépendant. Auchan est le premier à avoir ouvert des *drives* indépendants avec les *Chrono Drive*. System U, au contraire, ouvre principalement des *drives* accolés à des magasins de l'enseigne. Dans ce cas, le *drive* n'a pas ou peu d'entrepôts dédiés, son ouverture est plus simple et moins coûteuse, mais son organisation est plus compliquée.

3.1.1 Les moteurs du développement des formats de magasin simplifiés.

L'évolution de la demande des consommateurs est la principale explication du développement des formats de magasin simplifiés comme les commerces de proximité ou le e-commerce. Du fait de l'évolution des modes de vie, notamment de l'augmentation de la part des femmes qui travaillent et de la valorisation du temps libre, faire les courses alimentaires devient une activité pénible à laquelle on veut consacrer peu de temps. Dans ce contexte, le commerce de proximité et le commerce en ligne sont préférés aux grands hypermarchés de périphérie (Lemoine, 2010 ; Désaunay, 2012). Certains chercheurs évoquent également une évolution des valeurs des consommateurs, qui donnent de plus en plus d'importance à des critères comme la taille humaine des commerces, la proximité (relationnelle et géographique) avec les commerçants et l'origine locale des produits (Lemoine, 2010, Dujin *et al.*, 2011 ; Désaunay, 2012 ; Ifop, 2012).

L'urbanisation, le vieillissement de la population (et notamment la migration des ménages âgés dans les centres villes), ainsi que la réduction de la taille des foyers¹³⁶ favorisent également le développement des formats de commerce simplifiés et plus accessibles, comme les commerces de proximité (Lemoine, 2010 ; Désaunay, 2012).

Finalement, du fait de la hausse du coût des énergies, les Français cherchent, de plus en plus, à réduire leur budget pour les déplacements. Cet élément joue en défaveur des grands hypermarchés situés en périphérie des villes, pour lesquels les déplacements en voiture sont quasiment obligatoires et en faveur des commerces de proximité, de la livraison, ou des *drives* (dans lesquels on peut se rendre sur le chemin de retour du travail ou d'une autre activité).

Les petits commerces (commerces de proximité et *hard-discount*) bénéficient également d'une législation favorable, puisque un permis de construire suffit pour ouvrir un commerce de moins de 1000 m². Plus globalement, il existe une volonté des pouvoirs publics de redynamiser les centres villes, qui passe par le retour des commerces de périphérie dans les centres (Lemoine, 2010).

Cependant, dans les centres villes, les commerces de proximité sont confrontés aux contraintes de la logistique urbaine : la congestion de trafic, la pollution locale, les nuisances sonores, la sécurité routière, les règlementations spécifiques à la circulation en ville, etc. Les magasins cherchent donc des solutions pour faire face à ces difficultés. Des solutions innovantes émergent, comme la livraison de nuit, ou le développement de l'approvisionnement par voie fluviale ou ferroviaire. La multiplication des points de vente pose également des difficultés : les volumes à livrer sont moins importants, les points de livraisons plus nombreux et, par conséquent, l'approvisionnement est moins efficient. Le manque d'espace disponible en ville limite, par ailleurs, les nouvelles installations. Finalement, le comportement du

¹³⁵ Pour autant, cette évolution ne signifie pas la disparition des hypermarchés, dont presque aucune fermeture n'a été constatée, ni la diminution des surfaces des commerces existants (Ferrante, 2012).

¹³⁶ Pour un faible volume d'achat, il n'est pas nécessairement rentable de se rendre dans un hypermarché (Parabellum et Bossman Consultants, 2012).

consommateur est différent : il vient plus régulièrement, pour un panier moyen moindre. Le commerce de proximité doit s'adapter à cette demande particulière.

Le commerce en ligne, appliqué à l'alimentaire, est longtemps resté tout à fait marginal, du fait des difficultés logistiques qu'il pose. Dans les premiers temps, le commerce en ligne s'accompagnait d'une offre de livraison des clients. Or, celle-ci pose plusieurs difficultés. Certaines sont spécifiques aux produits frais alimentaires, qui sont difficiles à transporter et pour lesquels la chaîne du froid doit être respectée. Contrairement à la phase d'approvisionnement où chaque produit est livré, en grande quantité, au commerce ou à l'entrepôt, dans le cas de la livraison à domicile c'est un panier de course hétérogène contenant une grande diversité de produits, en petite quantité, qui doit être livré aux clients. Par ailleurs, en milieu rural, du fait des distances importantes à parcourir, la livraison représente un coût important que ni les commerçants ni les clients ne semblent prêts à prendre en charge. C'est en zone urbaine que la livraison se développe, mais sa croissance est limitée par des difficultés liées cette fois à des enjeux de logistique urbaine : congestion du trafic¹³⁷, pollution, etc. Finalement, la livraison pose une dernière difficulté, qui n'est pas spécifique aux produits alimentaires : le client doit être présent sur le lieu de livraison, pour réceptionner les colis. Cette nécessité entraîne de nombreux ratés et augmente la complication et le coût de la livraison (Bratt et Persson, 2001 ; Siikavirta *et al.*, 2003).

Si les difficultés de la livraison ont pu être un frein au développement du commerce alimentaire en ligne, les enseignes du commerce de détail proposent une nouvelle solution depuis quelques années : le drive. Celui-ci permet de proposer une solution de commerce sur Internet tout en s'affranchissant de la contrainte de la livraison. Pour les clients, cette solution présente de nombreux avantages par rapport au commerce traditionnel. Elle permet notamment de faire ses courses rapidement. Elle est également plus flexible que la livraison (pas de rendez-vous à prendre, le client se rend au drive quand il le souhaite) et moins coûteuse (gratuite, en général). Malgré sa part de marché encore faible, le drive est actuellement un moteur majeur de la croissance des enseignes.

3.1.2 Des services simplifiés, moins consommateurs d'énergie.

Pour étudier les éventuelles répercussions énergétiques du développement de ces services simplifiés, nous comparons la demande d'énergie des formats simplifiés (commerces de proximité et commerces en ligne avec drive) à celle des grands commerces de type hypermarchés et grands supermarchés, qui, actuellement, représentent le cœur de l'offre du commerce de détail alimentaire.

3.1.2.1 Comparaison des consommations d'énergie entre un petit commerce de type commerce de proximité ou hard-discount et un grand commerce de type hypermarché.

Le service d'intervention. La principale différence entre les caractéristiques de service d'un hypermarché et celles d'un commerce de proximité, du point de vue des consommations d'énergie, c'est la proportion de linéaires froids. Alors que, dans un hypermarché, les produits alimentaires frais représentent environ 35%, en moyenne, de la surface de vente, dans un supermarché leur proportion atteint les 45% (données ACNielsen 2007/ FCD). Nous n'avons pas trouvé de données aussi précises concernant les plus petits formats de commerce alimentaire (du fait de leur hétérogénéité, peu de données sont disponibles), mais il est communément admis que plus la surface de vente est petite et plus la part des produits alimentaires et frais est importante. Une proportion supérieure de linéaires froids signifie des consommations unitaires (par unité de surface) plus importantes (la production de froid étant le plus gros poste de consommation dans les commerces).

Les compétences disponibles dans un commerce de proximité ou un hypermarché ne sont pas identiques. Si les hypermarchés peuvent se permettre d'embaucher un technicien pour s'occuper quasi exclusivement des questions d'énergie, ce n'est pas le cas des plus petits formats de magasin. Par conséquent, les commerces de proximité auront plus de difficultés à suivre et maîtriser leurs consommations d'énergie. Ce constat concerne autant le service d'intervention que le service de *mise en condition*.

Le service de mise en condition. La principale différence entre les commerces de proximité et les hypermarchés concerne les techniques du bâti. Les commerces de proximité sont situés en centre-ville, où l'offre de bâtiments est limitée. L'ouverture d'un nouveau magasin correspond généralement à la reprise d'un bâtiment (et non à une construction neuve). Les choix du lieu d'implantation sont dictés par les disponibilités et le critère de la performance des locaux est peu pris en compte. Par ailleurs, les locaux sont loués, le plus souvent. La location constitue un frein à la mise en œuvre de travaux d'amélioration des performances énergétiques : le propriétaire ne souhaite pas effectuer des travaux dont il ne bénéficierait pas directement et le locataire ne souhaite pas effectuer des travaux dont il ne profiterait que pour un laps de temps donné et pour lesquels le temps de retour sur investissement serait supérieur à son bail. C'est une barrière à l'efficacité énergétique reconnue (le problème des incitations partagées), qui pourrait cependant être levée avec la généralisation du *bail vert*.

Le service de mise en présence. Les caractéristiques de service de l'approvisionnement et des déplacements des clients évoluent. Concernant l'approvisionnement, nous avons vu que les livraisons d'un hypermarché ou d'un magasin de proximité sont très différentes : celles d'un magasin de proximité sont plus petites en volume, moins fréquentes et

¹³⁷ La congestion du trafic, quand elle est associée à (ou accentuée par) des camions des enseignes du commerce de détail, véhicule une mauvaise image des enseignes.

moins régulières. Cette évolution a des répercussions sur les méthodes ou routines d'approvisionnement. Les méthodes d'optimisation de l'approvisionnement ont, jusqu'à présent, été surtout réfléchies pour le format hypermarché et ne sont pas adaptées aux commerces de proximité : quantités moindres, livraisons plus erratiques et livraisons urbaines. Actuellement, de nouvelles méthodes sont en cours d'expérimentation (la livraison de nuit, par exemple), mais l'approvisionnement des commerces de proximité reste moins efficient et donc plus consommateur d'énergie, que celui des hypermarchés. Par ailleurs, les horaires de livraison des commerces de proximité, situés en ville, sont plus contraints, du fait des réglementations de circulation. Les moyens de transport utilisés (une technique consommatrice d'énergie) doivent être adaptés : plus petits, moins bruyants, moins polluants, etc. Certains projets expérimentent le recours à des modes de transport nouveaux, comme la livraison par tramway.

Concernant les caractéristiques de services des déplacements des clients, les distances parcourues pour se rendre à un commerce de proximité sont plus courtes que pour un hypermarché. Les commerces de proximité sont localisés dans les centres villes, dans des lieux de passage. Un client qui se rend dans un commerce de proximité ne réalise pas un long trajet, le magasin qu'il choisit est proche de son lieu d'habitation ou sur un trajet qu'il effectue régulièrement pour un autre motif. Cette évolution des caractéristiques de service, couplée à la réduction du panier moyen acheté, a des répercussions sur le choix du mode de transport du client : ce dernier aura plus facilement recours à des modes de transport doux ou aux transports en commun pour faire ses courses. Moins longs et réalisés avec des modes de transport plus économes en énergie, les déplacements des clients sont moins consommateurs d'énergie dans le cas d'un achat dans un commerce de proximité que dans celui d'un achat dans un hypermarché. À l'échelle globale, même si l'on tient compte du fait que les clients se rendent de façon plus régulière dans les commerces de proximité, l'avantage en termes de dépense énergétique reste au commerce de proximité (Browne *et al.*, 2008 ; Rizet *et al.*, 2010).

3.1.2.2 Comparaison des consommations d'énergie entre un drive et un hypermarché

Le service d'intervention. Les innovations affectant les interventions concernent principalement l'accueil du client, la préparation et la mise à disposition des marchandises. Le service élémentaire d'accueil des clients sur le lieu de vente (et les consommations d'énergie associées) est en partie supprimé dans le cas du drive. Le service élémentaire de fabrication (comme les traiteurs ou bouchers, dans le commerce de détail) est également souvent supprimé. Celui du maintien des produits frais à température n'a plus lieu que dans les zones de réserves.

En revanche, un nouveau service élémentaire est introduit : le conditionnement des commandes. Il s'agit d'emballer les marchandises commandées par les clients. Les techniques requises sont principalement non énergétiques : cartons, emballages plastiques, éléments de calage, diables, etc. Lorsque le conditionnement est réalisé à très grande échelle et pour des produits homogènes, il peut être automatisé et réalisé par des machines. Dans le cas du drive, c'est rarement le cas, et ce service est peu consommateur d'énergie. Les caractéristiques de service du conditionnement sont notamment le poids du colis, sa taille, son contenu (et l'hétérogénéité de celui-ci), ses conditions de conservation (pour les aliments frais), sa fragilité, etc. Ces caractéristiques de services influencent le choix des techniques utilisées pour le service de mise en présence.

La mise en condition. Les services élémentaires de mise en condition des locaux destinés à recevoir les clients et des laboratoires de préparation de certaines commandes sont supprimés. Dans le cas du drive, les locaux à mettre en condition se limitent, pour l'essentiel, à des bureaux, des locaux techniques (informatiques, notamment) et des entrepôts. Les caractéristiques de service de la mise en condition dépendent fortement des locaux auxquels la mise en condition s'applique. Or, en comparaison d'une zone de vente, les locaux maintenus dans le cas du drive exigent des niveaux de température et d'éclairage plus faibles¹³⁸ et un volume moindre (le nombre de produits disposés par unité de volume est supérieur). Au total, pour la mise en condition, le bilan des consommations d'énergie est en faveur du drive.

La mise en présence. Dans le e-commerce, les clients ne se déplacent plus vers les locaux de commerce pour sélectionner leurs achats, le choix se fait à distance, par le biais d'un nouveau service élémentaire : la mise en présence virtuelle. Dans ce nouveau service élémentaire, les techniques consommatrices d'énergie du prestataire sont les serveurs, le site Internet, etc. Celles du client sont principalement l'ordinateur à partir duquel il se connecte. Les caractéristiques de ce service, comme la durée de connexion ou la quantité de données transmises, influencent les consommations d'énergie. La mise en œuvre de ce nouveau service entraîne des consommations d'énergie pour le client et le prestataire. À l'échelle de l'ensemble des transactions de commerce, ces consommations d'énergie, qui correspondent au fonctionnement des serveurs sont, généralement, considérées comme très importantes (Faucheux *et al.*, 2002). Cependant, elles ne sont qu'en faible partie attribuables aux achats en ligne¹³⁹ et, encore en plus faible partie, aux achats de biens alimentaires pour le drive. Par ailleurs, ces consommations existent aussi pour le commerce traditionnel, puisque les acheteurs se rendent, de plus en plus souvent, sur les sites Internet avant leurs achats pour comparer les prix et les produits.

¹³⁸ Même si, dans le cas du e-commerce alimentaire un certain nombre d'entrepôts doivent être maintenus à basse température pour la conservation des aliments, ces derniers peuvent être plus efficaces énergétiquement que les meubles froids des zones de vente, n'étant pas soumis aux mêmes contraintes d'accessibilité et de confort rendues nécessaires par la présence du client.

¹³⁹ Moins de 5% des visites de sites Internet de vente sont motivées par l'achat selon l'enquête de Carat Expert de 2005, enquête réalisée auprès de 500 internautes en mai 2005 et rapportée par le Journal du Net.

Les marchandises acquises sont des biens tangibles non échangeables virtuellement, d'où la nécessité pour les clients, suite à l'achat, de se déplacer pour retirer leurs paniers de produits. Il n'y a pas de raison de penser que les distances entre le domicile de l'acheteur et le point de retrait de la marchandise diminuent sensiblement (par rapport au commerce traditionnel), sauf à envisager un développement massif des drives et donc un maillage plus important sur le territoire. Bien que cette distance reste identique, de nombreux acteurs du secteur considèrent que la distance réellement parcourue pour se rendre au point de retrait est plus faible que celle parcourue pour se rendre dans un commerce traditionnel. La durée de l'intervention (l'une des caractéristiques de service de l'*intervention*) est très courte dans le cas de l'enlèvement des marchandises dans un drive, ce qui permet à l'acheteur de combiner le déplacement vers le drive avec un déplacement pour un autre motif : il peut se rendre au drive sur le chemin du retour du travail, par exemple.

Au total, la formule de l'enlèvement de la marchandise dans un drive permet, en théorie, de réduire les consommations d'énergie pour la *mise en présence*. À notre connaissance, il n'existe que très peu d'études portant sur l'estimation des gains énergétiques permis par le drive en comparaison du commerce traditionnel ou de la livraison. L'une d'entre elles nous a paru particulièrement intéressante puisqu'elle propose une estimation des gains en termes de km parcourus et d'occupation de l'espace par semaine, selon différents scénarios de développement du e-commerce, en termes de parts de marché, mais aussi de choix logistiques : livraisons ou enlèvement (Durand *et al.*, 2010). Les résultats de l'estimation indiquent que la formule de drive est la plus performante en termes de distance parcourue.

3.2 La diversification des canaux de distribution

Actuellement, l'une des stratégies des enseignes du commerce de détail alimentaire consiste à diversifier les canaux de distribution. Cette diversification s'exprime au niveau des magasins, par le développement de services périphériques tels que le drive, la livraison à domicile, l'offre de produits discount, etc. Elle s'exprime, également, à l'échelle des enseignes qui proposent aux consommateurs divers formats de magasins : des hypermarchés en périphérie, des commerces de proximité, des drives, etc. Ainsi, les services simplifiés, que nous avons examinés dans la section précédente, ne se substituent pas, dans la réalité, aux services traditionnels, mais ils s'ajoutent plutôt à eux. Cette dynamique d'innovation relève donc, à l'échelle des enseignes du commerce de détail, d'un *enrichissement* du service, selon la terminologie introduite dans la section 2.

Les dynamiques décrites dans les modèles d'innovation du type de la roue de la distribution ou de la théorie de l'accordéon (McNair, 1958 ; Hollander, 1960) ne sont pas validées, ici. Ces dynamiques traduisent la répétition du processus de simplification puis de diversification des formats de distribution : les nouveaux formats pénètrent le marché en proposant des prix bas et peu de services, ils ont des marges faibles, peu à peu ils se développent et se diversifient, jusqu'à devenir chers et vulnérables aux nouveaux entrants. Or, la dynamique que nous décrivons correspond plutôt au développement simultané des différents formats de commerce, au sein des enseignes : des formats simplifiés, comme les commerces de proximité, les commerces de type hard-discount ou le commerce en ligne et des formats diversifiés, comme des hypermarchés proposant un large assortiment et de nombreux services périphériques. Cette dynamique peut éventuellement être décrite selon le modèle du Big Middle (Levy *et al.*, 2005)¹⁴⁰. Le hard-discount, le drive, le commerce de proximité qui appartenaient respectivement aux segments *bon marché*, *innovant* et *en danger*, intègrent, peu à peu, le segment *Big Middle*.

3.2.1 Les moteurs de la diversification des canaux de distribution

Plusieurs phénomènes peuvent expliquer cette tendance à la diversification des canaux de distribution dans le commerce alimentaire de détail. Pour commencer, le modèle de l'hypermarché, qui représentait jusqu'à présent le Big Middle du commerce alimentaire, voit ses perspectives de croissance ralentir, du simple fait que le territoire soit déjà densément maillé. D'après des données de l'INSEE, il y aurait, en France, un hypermarché pour 46000 habitants, une densité supérieure à celle de beaucoup de pays européens. Les grandes enseignes de la distribution alimentaire cherchent, donc, de nouvelles opportunités de développement.

Par ailleurs, face à l'expansion du hard-discount depuis les années 2000 et au développement du commerce sur Internet (bien qu'encore limité dans le secteur alimentaire), les grands groupes de la distribution alimentaire doivent repenser leur offre. Certaines enseignes ont racheté ou développé des filiales spécialisées dans le hard-discount (Dia pour Carrefour, Leader Price pour Casino, etc.), mais globalement, la stratégie de la plupart d'entre elles a été de développer, en parallèle de leur offre traditionnelle, de nouvelles offres, comme des offres discount ou des offres de commerce en ligne.

La diversification des canaux de distribution permet aux enseignes d'acquérir un avantage concurrentiel et de conquérir une part plus importante du marché alimentaire (Rosenbloom, 2007 ; Bezes, 2012). En particulier, cette stratégie leur permet de toucher plus de clients, en communiquant plus largement sur leur offre, par le biais des différents canaux de distribution (Ansari *et al.*, 2008).

¹⁴⁰ Le modèle du Big Middle traduit une segmentation du secteur du commerce entre un segment Big Middle regroupant le(s) format(s) de commerce dominant(s), un segment *innovant* et un segment *bon marché* qui peuvent être rentables sur le court-terme, mais qui, pour se développer et augmenter leurs profits, doivent s'intégrer au segment Big Middle, et un segment *en danger* où peuvent tomber les commerces du Big Middle s'ils relâchent leurs efforts et proposent trop peu d'innovations ou des prix trop élevés.

3.2.2 Les répercussions énergétiques complexes de la diversification des canaux de distribution.

Cette dynamique d'innovation relève, à l'échelle des magasins ou des enseignes, d'un *enrichissement* du service, dans le sens où, les magasins et les enseignes se développent et proposent plus de services. Les services qui se développent le plus (le drive et le commerce de proximité) sont, individuellement, moins consommateurs d'énergie que les formats de commerce traditionnel. Cependant, comme nous venons de le voir, ces formats ne se substituent pas totalement aux grands commerces, mais s'y ajoutent en partie.

À l'échelle d'un établissement ou d'une enseigne, l'ajout de services supplémentaires se traduit, toutes choses égales par ailleurs, par une augmentation des consommations d'énergie, relatives à la réalisation du supplément de services (l'intervention supplémentaire, la mise en condition de l'extension éventuelle du bâtiment, les déplacements additionnels engendrés, etc.). Cependant, la mise en œuvre de ces services périphériques a des répercussions directes sur l'ensemble du service de commerce et de ses caractéristiques de services. En particulier, le chiffre d'affaires total de l'établissement ou de l'enseigne évolue (l'objectif de l'adjonction de ces services périphériques est de le faire croître). Le chiffre d'affaires attribuable au service de commerce traditionnel évolue également, plutôt à la baisse, pour sa part, les nouveaux formats s'y substituant en partie. À l'échelle du pays, les répercussions globales sur les consommations d'énergie dépendent, donc, du degré de substitution de ces formats simplifiés aux formats traditionnels.

3.3 La mise en œuvre d'une logistique mutualisée

La logique de *mutualisation* s'exprime, principalement, au sein de l'activité de logistique d'approvisionnement¹⁴¹. Elle se traduit par le regroupement de plusieurs partenaires de la chaîne logistique pour réaliser leurs activités logistiques au sein d'un même entrepôt et livrer ensemble leurs clients (les commerces).

L'une des premières expériences françaises de mutualisation a été mise en place en 2004 par les entreprises Sara Lee et Cadbury, des concurrents sur le marché de l'agro-alimentaire. À partir de plateformes en propre, elles livrent ensemble leurs distributeurs. Les industriels Reckitt-Benckiser, Henkel et Colgate, des concurrents sur le marché des produits DPH (Droguerie, Parfumerie, Hygiène), ont également choisi de mutualiser leur logistique, depuis 2006. Ils ont deux entrepôts en commun en France, à partir desquels ils livrent ensemble leurs clients (Le Moigne et Bouniol, 2008). Danone, ID Logistic et Carrefour se sont également organisés et ont mis en place un EMCA, dont nous expliquons le principe dans le paragraphe suivant.

Plusieurs types de schémas de logistique mutualisée voient le jour. Un premier exemple correspond à la consolidation, mise en place notamment par Carrefour. Historiquement, chaque usine livrait en direct les centres de distributions régionaux d'une enseigne. Ce type d'organisation est illustré par la figure 4.

Figure 7. Schéma logistique traditionnel et non optimal.

¹⁴¹ La logistique est exclue du périmètre traditionnel du commerce de détail, cependant, ici, nous avons élargi ce périmètre pour tenir compte de l'ensemble des sources de consommation d'énergie des services.

Actuellement, Carrefour met en place des Centre de Consolidation et de Collaboration (CCC). L'enseigne demande aux usines de livrer ces CCC, à partir desquels elle prend en charge toute la logistique. Puisque le CCC contient de nombreuses références, Carrefour peut livrer ses magasins avec des camions complets. Nous illustrons cette organisation dans la figure 5.

Figure 8. Exemple de logistique mutualisée : les Centres de Consolidation et de Collaboration (CCC).

Un autre modèle intitulé l'EMCA (Entrepôt Mutualisé de Consolidation Aval) est à l'œuvre. Les stocks sont repoussés en amont de la chaîne logistique, ce qui libère de la surface chez les distributeurs. Cette surface disponible peut servir de zone de stockage à un industriel. Ainsi, l'industriel peut livrer, en flux tendu, le distributeur en question, mais également d'autres distributeurs à proximité. Ce type d'organisation est illustré par la figure 6.

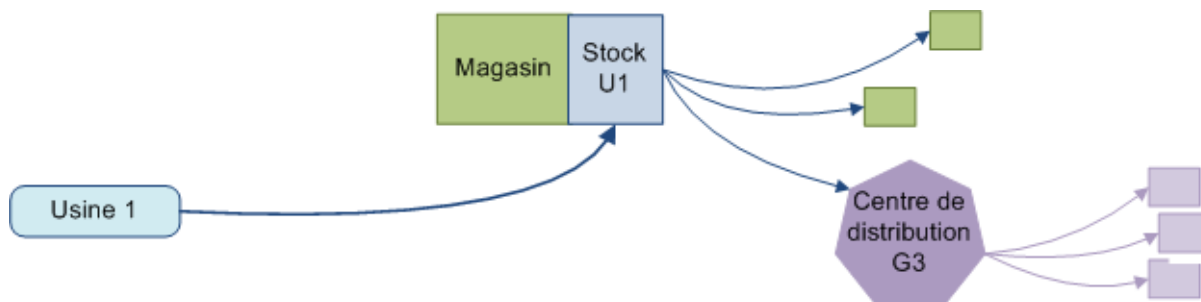

Figure 9. Exemple de logistique mutualisée : les Entrepôts Mutualisés de Consolidation Aval (EMCA)

3.3.1 Les moteurs de la mise en œuvre d'une logistique mutualisée

La mutualisation des moyens logistiques constitue, tout d'abord, une réponse à l'évolution du cadre réglementaire régissant les relations entre industriels et distributeurs (Livolsi et Camman, 2012). En particulier, la Loi de Modernisation de l'Économie durcit les contraintes de la logistique. Pour y faire face, industriels et distributeurs semblent s'orienter vers une réorganisation de leur logistique.

La mise en œuvre d'une logistique mutualisée répond, également, à une recherche de performance économique, ainsi qu'au renforcement des contraintes environnementales. La mutualisation des entrepôts et/ou des transports permet d'optimiser le nombre d'entrepôts et de camions nécessaires, d'organiser des tournées plus efficaces pour la livraison des commerces, et d'avoir recours à des modes de transport économes en énergie, comme le transport ferroviaire ou fluvial (ces modes de transport ne sont envisageables que pour transporter une quantité importante de marchandises). Danone, par exemple, a réduit ses émissions de carbone de 500 tonnes par an (Hénaff, 2011) grâce à l'initiative de mutualisation EMCA avec Carrefour et ID Logistics. Cette réduction s'explique par le recours au transport ferroviaire et par l'optimisation de la logistique (tant que Danone ne livrait que Carrefour, les quantités livrées ne permettaient pas le recours à ce type de transport).

3.2.2 Une logistique mutualisée, facteur d'économies d'énergie

La logistique mutualisée est une innovation qui concerne l'ensemble des services élémentaires d'approvisionnement. Au sein même de ce service, on peut distinguer un service d'intervention, un service de mise en présence et un service de mise en condition. Le service d'intervention, dans le cas présent, correspond au transport des marchandises et, éventuellement, aux opérations de chargement et déchargement de celles-ci. Le service de mise en condition se traduit

par la mise en condition des zones de stockage des marchandises (les entrepôts). Le service de mise en présence correspond, ici, uniquement aux déplacements des prestataires du service depuis leur domicile.

Le service d'intervention. La mutualisation des flux permet une augmentation des volumes transportés sur la phase de transport depuis l'usine ou sur la phase de transport vers les magasins (une caractéristique du service de transport). Pour ce service élémentaire, l'augmentation du volume transporté a des répercussions sur les modes de transport disponibles (une technique énergétique) : pour transporter des volumes importants il est envisageable d'avoir recours aux transports fluviaux ou ferroviaires, qui, rapportés à la tonne de marchandises transportée, sont des modes de transport moins consommateurs d'énergie que le transport routier. Si ces modes de transport ne sont pas envisageables et que le transport est réalisé par route, le volume de marchandises par camion peut aussi être optimisé (une méthode) pour réduire les consommations d'énergie par tonne de marchandises transportée. De la même façon, un plus gros volume de marchandises à distribuer offre une marge de manœuvre plus importante pour organiser des tournées (une méthode) et ainsi optimiser les distances à parcourir (une caractéristique de services) et les consommations d'énergie associées.

Le service de mise en condition. À l'exception de ceux qui accueillent les produits frais et surgelés, qui nécessitent du refroidissement, les entrepôts sont généralement faiblement consommateurs d'énergie car les services attendus sont limités (peu de besoin de chauffage ou d'éclairage, pas ou peu de process). La logistique mutualisée peut également permettre de réduire le nombre d'entrepôts et, donc, les consommations d'énergie globales associées. Cependant, l'augmentation du volume dans chaque entrepôt peut rendre intéressante l'automatisation de certaines manipulations, donc l'introduction de techniques consommatrices d'énergie.

Le service de mise en présence. Peu de changements sont à attendre pour le service de mise en présence, qui ne correspond, ici, qu'aux déplacements domicile-travail des prestataires de la logistique d'approvisionnement.

4 Conclusion

Maîtriser les consommations d'énergie se limite généralement à introduire des innovations technologiques, telles que des systèmes de chauffage, d'éclairage ou de ventilation innovants et énergétiquement performants. Mais d'autres formes d'innovations, non technologiques, peuvent aussi avoir des répercussions importantes sur les consommations d'énergie, à la baisse ou à la hausse. Cinq axes d'innovation peuvent être identifiés, du point de vue de leurs répercussions énergétiques : l'axe d'efficacité énergétique, l'axe d'enrichissement du service, l'axe de resserrement du service, l'axe de mutualisation et l'axe de délégation.

Dans le commerce de détail alimentaire, un certain nombre de dynamiques d'innovation et de changement ont des répercussions majeures sur les consommations d'énergie. Tout d'abord, les commerces mettent en œuvre un certain nombre de mesures pour maîtriser leur demande d'énergie. On peut citer, par exemple, l'amélioration de la performance des bâtiments (isolation, sas à l'entrée pour limiter les pertes thermiques, etc.) ou la fermeture progressive des meubles frigorifiques. D'autres dynamiques d'innovation, ensuite, ne visent pas la maîtrise de la demande d'énergie, tout en ayant des répercussions substantielles sur les consommations d'énergie. Ainsi, le développement d'offres de commerce simplifiées (le « drive » ou le commerce de proximité, par exemple), la diversification des canaux de distribution ou encore la mise en place d'une logistique d'approvisionnement mutualisée, modifient certains déterminants majeurs des consommations d'énergie des commerces, comme la surface de vente, la surface de stockage, les services périphériques proposés, la distance à parcourir pour l'approvisionnement des magasins et pour la collecte des produits par les clients, etc. Ces innovations relèvent, respectivement, du *resserrement*, de l'*enrichissement* et de la *mutualisation* des services, selon la terminologie que nous avons introduite.

Du fait de la hausse prévisible du coût des énergies dans les années à venir, la question de l'énergie ne peut plus être négligée lors de la mise en place d'un projet. Cependant, dans les bâtiments de commerce, elle n'est pas un facteur stratégique qui serait à l'origine d'innovations ou de changements majeurs. À organisation constante, des efforts sont consentis pour réduire les consommations d'énergie, mais la question des consommations d'énergie ne remet pas en cause un mode d'organisation choisi pour satisfaire la demande des clients. Le commerce ne se réinvente pas pour réduire ses consommations d'énergie, c'est avant tout la demande des clients qui guide l'innovation. Cependant, les questions énergétiques influencent la demande des clients et donc indirectement les tendances d'innovation dans le commerce de détail. En particulier, l'augmentation du coût des énergies fossiles peut inciter (voire contraindre) les clients à modifier leurs comportements d'achat, notamment les distances qu'ils parcourent pour faire leurs courses et la fréquence de celles-ci. Ainsi, par le biais de son influence sur la demande des clients, l'énergie peut indirectement devenir un enjeu stratégique pour l'évolution de l'activité commerciale. Par ailleurs, aujourd'hui, la demande des consommateurs favorise le développement de formes de commerce, comme le « drive » ou le commerce de proximité, permettant, globalement, des économies d'énergie.

Nous avons limité notre périmètre d'étude au commerce de détail alimentaire. Cependant, les dynamiques d'innovation et de changement de ce secteur peuvent avoir des répercussions directes, notamment sur le secteur du commerce non alimentaire. Aujourd'hui, si les consommateurs cherchent, par exemple, à consacrer le moins de temps possible à leurs achats alimentaires hebdomadaires, ils valorisent, au contraire, les achats non alimentaires, comme les loisirs ou les nouvelles technologies. La dynamique de développement d'offres simplifiées dans le commerce de détail alimentaire se traduit par un recentrage de l'offre sur les produits alimentaires, les produits non alimentaires étant, alors, vendus dans d'autres formats de magasins. Actuellement, l'activité des commerces non alimentaires est beaucoup plus

dynamique que celle des commerces alimentaires. Bien que les commerces non alimentaires soient moins consommateurs d'énergie, notamment par unité de surface, il serait intéressant, dans l'analyse des répercussions énergétiques des dynamiques d'innovation du commerce alimentaire, de prendre en compte ces effets secondaires.

Engagement in service innovation: A case study of innovation of a tourism service

Lars Fuglsang¹, Anne Nordli Jørgensen² (in alphabetic order)

¹Roskilde University, ²Lillehammer University College

FIRST DRAFT

Innovation theory, based in the ideas of Schumpeter, may tend to create a contradiction between innovation and stability. Yet, as it is well recognized, innovation is also about implementation, replication and realization of new elements. Furthermore, research in service innovation demonstrates that innovation can be ad hoc changes, rapid application of new ideas, a posteriori recognition of innovation and ‘bricolage’ (Galloway and Weinstein, 1997; Toivonen et al., 2007; Fuglsang, 2010). These concepts indicate, at least implicitly, that innovation is a problem-solving activity that creates continuity between the past, the present and the future. We argue, based on a case study, that there is a need in research about service innovation, rather than analysing change as such and contrasting change with stability, to look for concepts that can bridge innovation and stabilization as two sides of the same coin. This paper uses the concept of engagement (Thévenot, 2001; Thévenot, 2007) to show, in a case study of service and experience innovation, how the development of new services and experiences may take place through different forms of innovative engagement with the world characterized by different forms stabilization and valuation.

1 Background

Innovation theory in the Schumpeterian tradition tends mostly to treat innovation as a dynamic process of ‘creative destruction.’ Innovation happens when economic agents create something new with prospective for economic development and when they break free of old economic practices. Following this, the literature has emphasised how novelty is created, realized and managed in practice. While this may, in fact, be interpreted as stabilization processes where actors seek to cope with the environment and its demands, the literature nevertheless tends to create a contradiction between innovation and stability. We argue, however, that there is a need to bridge innovation and stabilization as two related processes. For example, innovations can be interpreted as processes where innovative agents seek to relate new ideas to the demands of the environment by using known formats. Understood in this way, innovation and stabilization are not opposites but intertwined processes. Innovation implies a continuous attempt to coordinate ones activities with the environment by using formats which are recognizable and acceptable.

For the purpose of this paper we draw heavily of the ideas of Thévenot and his theory of engagement. Hence, Thévenot, in his work on engagement, seeks to analyse how actors cope dynamically with their environment by using certain established cognitive formats that enable coordination. Thévenot also argues that these cognitive formats represent a search for certain guaranteed goods:

I chose ‘engagement’ rather than a vocabulary of action or practice, as these focus attention exclusively on the human agent. My reasons were twofold. First, ‘engagement’ emphasizes the person’s dependence on the environment she relies on while grasping it by means of a certain cognitive format. Second, the term refers to a quest for a guaranteed good (as in the engagements of marriage or a contract) that makes it possible to assess what is relevant to know (Thévenot, 2007: 415).

Thus, following the ideas of Thévenot, we argue that innovative agents must cope with the environment by using certain known cognitive formats of engagement. According to Thévenot (2001; 2007) three such cognitive formats or forms of engagement can be distinguished: familiar engagement, engagement into plan and engagement into justifiable action (see section 3).

The research question we more specifically address, based in the engagement theory of Thévenot, is how innovation becomes stabilized by such cognitive formats; we also explore whether higher levels of engagements are always needed for innovations to stabilize. For example, at the lower levels of engagement, innovations can be accepted within a familiar world that people are attached to through personal affinities and emotional ties. At the higher levels, there can be requirements of more explicit and codified plans in order for an emerging practice to be recognizable and acceptable.

The remainder of the paper is structured as follows. First we briefly review the literature on service innovation and its limitations in regards to a concept of stabilization. We argue that innovation and stabilization can be seen as intertwined processes by taking an engagement perspective on innovation. Then we present the analytical framework of Thévenot which we will use in a case study of innovation. Following this we present our method, case-study and findings. Finally, in the conclusion, we discuss the potential contribution to service innovation studies.

2 Innovation in services

There is no clear way to define innovation, but there is agreement that innovation involves the process of realizing an idea in practice. Sundbo defines innovation as "...the effort to develop an element that has already been invented, so that it has a practical-commercial use, and to gain the acceptance of this element" (Sundbo, 1998: 12). Hence, innovation is a process whereby an invention becomes adopted in a societal context. The invention does not need to be new to the world nor to the market, but can also be new in a given context.

Innovation in services can be interpreted in a rather broad way as behavioural developments as compared to technological developments (see for example Rubalcaba et al., 2012). Hence it concerns new behavioural forms of service that become accepted. Further, the literature on service innovation may be divided into at least two streams, which can be called 1) process and 2) systems views of innovation. The process views are mostly management oriented and the system views mostly policy oriented.

1. Process views of innovation: In the Schumpeterian tradition innovation is often seen as a process of 'creative destruction' (Schumpeter, 1947). Notions like radical/abrupt innovation, disruptive innovation or business model innovation (Chesbrough, 2010) stress forms of innovation that imply radical changes of economic behaviour with significant economic impacts at the firm level or at the societal economic level. However, it is also recognized in the literature that innovation is an evolutionary, cumulative activity (Pavitt, 1984), where history, experience and continuity matters. Varied evolutionary modes of innovation have been identified for example the 'science, technology and innovation' mode and the 'doing, using and interacting' mode (Jensen et al., 2007). Innovation has also been seen as an interactive process which is contextualized (Lundvall, 1992).

Research on innovation in services has identified several patterns of innovation relevant for different types of service companies, such as the stage gate model (Alam and Perry, 2002), which is a formalised phase model of innovation applicable mostly to large service companies. Less formalised incremental types of innovation have also been identified such as ad hoc innovation (Gallouj and Weinstein, 1997), rapid application innovation (Toivonen et al., 2007), a posteriori recognition of innovation (ibid.), or practice based approaches such as bricolage, i.e. solving problems on the spot by resources at hand (Fuglsang, 2010; Fuglsang and Sørensen, 2011; cf. also Baker and Nelson, 2005). Generally, service innovations are shown to be more incremental, less R&D-based and less formalised than innovation in manufacturing (Rubalcaba et al., 2012). The interaction of manager, employee and customer is shown to be important. The literature shows that innovation can be employee-driven but also management-guided (Fuglsang and Sundbo, 2005; Rubalcaba et al., 2012). Service innovation can be shown to be a problem-solving activity that creates continuity between the past, the present and the future. Even though service innovation research also stresses the role of the customer and customer-based innovation (Sundbo and Toivonen, 2011), it tends mostly to take a 'productionist' and managerial view on the customer and the service. Customer-orientation is based in the company/employees experience of, and capacity to deal with, customers.

Recent conceptualizations of innovation have, however, been developed by drawing on the conceptual framework of the Service-Dominant (S-D) Logic. This approach is inspired by the customer-oriented research stemming from the service marketing literature. This literature conceptualizes service as 'resource' developed for customers. Hence, in this view, a service innovation is a new resource made available for customers. This is different from the previous distinction between product and process innovation which otherwise dominates the innovation literature (Rubalcaba et al., 2012; Skålén et al., 2013). The value of a service is not seen as embedded in a service or product, but it is created through the customer's use of the resource. The provider's role as innovator is to make a new value proposition to the customer, yet it is the customer who creates the value by using the resource independent of, or in collaboration with, the provider. The literature focuses the firm, the customer and the interaction between them. Innovation becomes an intentional move towards creating a meaningful value proposition for a customer.

2. Systems views of innovation: The systems approach to innovation takes a macro-level, policy-oriented and functional approach to innovation. The purpose is to analyse and understand how varied policy measures and support structures at the societal level can influence innovation processes in companies (Edquist, 2005). Research identifies activities, functions or institutions at the societal level (national, regional, or sectorial) that influence innovation processes at the micro level. Innovation systems research has also understood innovation systems as interactive processes stressing that the relationships between government support activities and company level activities are interactive and emergent processes (Bergek et al., 2008; Hekkert et al., 2007). Furthermore, it has been argued that more historical, industrial specific and contextual models are needed (Asheim and Coenen, 2005; Cooke and Morgan, 1998; Miettinen, 2002; Sørensen, 2007). Hence the process and the systems approaches converge around a notion of innovation as a contextualized interactive process. Alternative approaches to innovation systems in service have suggested that they are loosely coupled systems (Sundbo and Gallouj, 2000) or problem-based systems (Tether and Metcalfe, 2004) emerging from practical problem solving around a particular challenge acting as a focal devise. Thus in the service-oriented literature, innovation system refers to the concrete interactions of actors at the micro-level forming a practice rather than to the wider societal support structure. An even stronger convergence of system and process views we find in the Service-Dominant (S-D) logic (the service marketing literature) where system is defined as interaction of resources: "A service system is an arrangement of resources (including people, technology, information, etc.) connected to other systems by value propositions" (Vargo et al., 2008: 149).

Overall, including both process and systems views, both the classical ‘productionist’ service innovation literature and the ‘customerist’ service marketing literature tend to neglect that the provider and the customer may at least in some cases be seen as embedded in a common context. The literature mostly stresses that providers and customers belong to different systems or different spheres (Grönroos and Voima, 2013). Thus, a main problem in the literature is perhaps the relatively sharp distinction which is often made between provider and customer sphere and the subsequent ‘interactionist’ view of them, at least if interaction here means an isolated and conscious relation between a provider and a customer (see also Heinonen et al., 2013).

Rather than focusing the value-in-exchange (the provider sphere) or the value-in-use (the customer sphere), and the interaction between them, an engagement-oriented view would shift attention towards the common cognitive formats through which the innovations are presented and actors are engaged. For example, in the case of downhill cycling (the example of this paper) users, producers, volunteers and others become engaged in a familiar environment with common maintenance gatherings and construction of trails. It is not possible to maintain a sharp distinction between provider-sphere and customer-sphere. Rather than merely having a relationship with one another as provider and customer, actors are also engaged in mutually affirming the value of the practice-world under formation by referring to certain forms of engagement. The advantage of such a view would be to better understand how innovation is stabilized by certain cognitive formats rather than it is disrupting a practice. We hold that producers and users are engaged in stabilizing the value of an innovation by means of certain engagement strategies.

3 Engagement

Thévenot understands engagement as a relation between a human agent and the environment (Thévenot, 2001; Thévenot, 2007) in which the agent moves between a personalized conception of the world and a more generalized conception of the world. For example, in a service context, a company or person can give customers access to a unique personalized environment. But the service provider can also try to depersonalise the service by organizing it in accordance with certain standardized themes and conventions thereby adapting the value proposition to more to established codes and standards. Furthermore, in some cases this can be done in an even more general way with reference to the societal values the service offer is supposed to create, such as contributing to local and regional development. At centre of interest is here the format of engagement rather than the content of the engagement, as well as the goods it produces for the actors.

Thévenot makes a distinction between three types of engagement, familiar engagement, engagement in plan and engagement in justifiable action. Familiar engagement is when people relate to their environment by organizing it in a personalized way. Such a personalized environment is a bricolage of all kinds of things that have been accumulated and accommodated over time in a way that people become comfortable and at ease with them. The objects are not carved out in a very precise way with a specific purpose in mind, and the relation to them is almost tacit and emotional. The relation to the environment is two-sided as it is characterised both by a kind comfort with routines and also inquietude and distrust when the comfort disappears. Further, things are not organized according to explicit principles but by trial-and-error processes where actors incrementally learn how to organize them in a comfortable way according to personal and bodily needs. Thévenot compares this regime of engagement to ‘inhabiting a home’. How we live at home is difficult to account for because everything is organized in a very personalized way.

Engagement in plan, or in regular action, is engagement in the environment according to a specific plan or project. The plan or project represents an individual person who projects herself into the future. The inherent good is construction of individual autonomy. This is also what Thévenot calls conventional utility, because the plan relies on certain conventions and represents an investment in form. Engagement in plan makes it possible to coordinate actions between actors that are not present at the same time (Duymedjian and Ruling, 2010). Functions, roles, actions, purposes become specified, the disadvantage being that details are lost. Thévenot compares this to someone who wants to rent her apartment to another person and has to reorder her home according to conventions to make it functional and recognizable for another person. Engagement in plan is a framework for ‘normal’ effective and intentional action.

Engagement in justifiable action is actors’ attempts to critique, argue for and justify certain actions and conventions in terms of the societal/collective values they are supposed to produce. This may be triggered by a dispute, for example over a rented house. The tenant of the house questions whether it is in a proper state. The landlord then needs to justify how things have been made. For example, the house that seems in a bad shape can be justified in terms of efficiency, safety, market price, of patrimony (Thévenot, 2001), or in terms of local conventions.

These different forms of engagement can be seen as different degrees of extension of the agents into the environment or different degrees of disengagement from what is most personalized. They are different cognitive frameworks, more or less generalisable or institutionalized, through which people can open themselves towards the environment, coordinate action and attach certain meanings and values to it. For the purpose of this paper, it is suggested that the engagement approach can be used to explain how the value of a service innovation becomes framed and stabilized by agents engagement in a practice.

4 Method

The method is a case study of Hafjell bike park in Norway. The bike park known for downhill cycling. The case study method is relevant when the researcher wants to collect contextual experience about a phenomenon (Flyvbjerg, 2001) and when the boundaries of the phenomenon are not very clear (Yin, 2003). The intertwining of innovation and stabilization is a phenomenon which is until now analytically not very clear. Further, we argue that downhill cycling in Hafjell is an extreme case. Extreme cases (Flyvbjerg, 2006) “often reveal more information because they activate more actors and more basic mechanisms in the situation studied” (p. 229). The development of Hafjell Bike park, can be seen as an extreme case for several reasons. First, the growth has been extreme: From starting on scratch 13 years ago, digging the first bike track with bare hands, to host the World Championships 2014 with 1900 participants and 40.000 expected spectators. Second, Hafjell bike park is a great success both nationally as internationally. It is unique, because it is the only ski destination in Norway which has been able to build a sustainable downhill product generating profit. Third, Hafjell has overcome great challenges in justifying its relevance vis-à-vis the municipality and local landowners. In addition, it is a case relying largely on personal engagement of the core actors. The case study was selected by a strategic choice method by the following criteria: It should be possible to define it as a practice, the practice should represent an innovation and it should also be possible to recognize struggles of stabilizing the innovation. Downhill cycling can be defined as a practice i.e. a coherent cooperative human activity (MacIntyre, 1985: 187) which is relatively stable in time and socially recognized (Gherardi, 2006: 24). It is an innovation because the case further develops downhill cycling in a unique way. This represents an innovation in itself which consists of many small ad hoc and bricolage innovations. Finally it has been possible to recognize struggles of value stabilization during the innovation process as it shall be further explained in the section on findings.

Downhill cycling is a fairly recent practice still under development. It is a sports activity which is carried out in the mountains using a special type of mountain bike, security equipment, bike trails, and turns and hops that are constructed in the mountains by using a spade or an excavator. The activity is carried out by highly trained cyclists as an elite sport, but also as an amateur family activity much like downhill skiing. As an elite sport, it has its special tournaments such as the Norwegian championship, the Nordic championship, European championship, the World championship and the European cup.

The method of data gathering and analysis used in the study, is a narrative of a single case study. The narrative is based on 1) in depth retrospective interviews with the key innovators of the experience services, 2) long term observations of one of the authors, and 3) documentary materials.

The retrospective interviews where with five informants who represents the key players in the development of Hafjell bike park. In addition, one of the authors has worked in close relations to Hafjell bike park in all the development years. Her observations and intimate understanding made it possible to write the full story narrative which has then been checked and revised against the taped interviews by the other author. The 5 key players are: Geir, Head manager of Hafjell and the man who started the initiative of cycling and summer operation at Hafjell. Snorre, a local bike enthusiast and also a former skeleton and bob driver on the Norwegian team. Snorre and some friends started digging bike tracks for fun secretly in Hafjell. Later Snorre became the department manager of summer and bike activities at Hafjell. Kjell Tore, a local restaurant owner in Hafjell who had an idea of bike arrangements generating more traffic to his restaurants during summertime. Knut, a Norwegian downhill biker on world cup level who lives and works at Hafjell. Ole, head manager of Hafjell after Geir.

The paper presents a condensed version of the full narrative. The version highlights and explains key events of the case shedding light on our perspective of understanding innovation and stabilization of its value in group practice. We have codified the data based in our interpretation of the data and our interpretation of the three types of engagement mentioned by Thévenot. In principle, other forms of engagement may be found as well. The interpretation of data draws on the Flanagan critical incident technique (Flanagan, 1954), yet by studying 'events, processes and issues' related to specific problems (Chell, 1998: 68) we work with a broader and more phenomenological approach to critical events of the narrative.

5 Findings

In the following we present our findings in the form of a brief narrative which has been codified by means of the three concepts of engagement : familiar engagement, engagement in plan and engagement in justifiable action. The critical events are listed and further explained. We outline the types of values around which the innovation becomes stabilized in each engagement type. In the case study, the development of the whole bike park is seen as an innovation in itself, but it entails a number of ad hoc innovations, incremental innovations and bricolage innovations that emerge throughout the different strategies of engagement. In this way, innovation and engagement are intertwined processes.

Familiar engagement

1. Geir, leader of Hafjell, is experimenting with downhill cycling.
2. One day he meets Snorre in Salt Lake City.
3. Snorre is also experimenting with downhill biking.
4. Well it turns out: he is digging cycling routes in Hafjell (in secrecy), where Geir is leader!

When downhill cycling was developed at Hafjell, it was initially based in a personalized and familiar engagement in developing the practice. It was carried out without much explicit plan and under the radar of the formal bodies of Hafjell.

Geir was head manager of Hafjell Alpine Centre AS during the years 2003-2009. He had a passion for snow, snow production, slope construction and preparation of slopes. He travelled with his core staff to get inspiration from the world's largest ski resorts. Geir had a fascination for the summer bike activities in the largest ski resorts. He started to believe that ski resorts had to develop summer activities if they wanted to survive and remain competitive.

Geir visits Salt Lake during the Olympics in 2002 and accidentally meets the Norwegian skeleton participant Snorre. Geir explains his fascination with the bike trails they have built in Salt Lake City. Snorre listens closely because he, on top of his skeleton career, is an active biker. Since he was a child he has built hops, turns, and runs in the woods for biking. Snorre tells Geir about his hometown in Norway, and how he and some friends are digging bike trails without permission in the local ski resort. It turns out, to the surprise of both, that Snorre is digging the bike trails in the very alpine centre where Geir is the head manager!

Geir eventually hires Snorre to develop trails in the mountain. Geir understands quickly that he does not have the support from the Board of Hafjell. This means that Geir, in the beginning, secretly allows Snorre to dig trails up in the woods. Geir convinces the Board that the chair lift can be a great summer attraction for tourists and the Board agrees to a limited number of summer day operation in 2003. Secretly, Snorre and Geir build unique custom racks mounted on the chairs to transport bikes to the mountain. This makes it possible to sell day passes to downhill bikers during the summer season.

The overall innovation of Hafjell Bike Park itself starts with both Snorre's and Geir's personal and familiar engagement. Their engagements become soon intertwined and are followed up by several smaller innovations (more ad hoc, incremental and bricolage innovations). Geir allowing Snorre in secrecy to build in the woods pushes the motivation of Snorre to a more innovative and experimental development of tracks. Their cooperative engagement also leads to the development of purpose-built racks for transporting bikes with chair lift. It appears clearly in the case how engagement and innovation are intertwined processes.

Value stabilization: At the initial stage of the innovation process, the value of the innovation is affirmed by mutual praise and enthusiasm of the two core persons when they express to each other their confidence, ease and fascination of downhill cycling. The internal value is sedimented around the joy and fun of biking, the bodily knowledge and skills of Snorre who can easily build tracks that he is confident with due to the skills he has developed since childhood, and the secret prospect of developing downhill cycling into a summer activity. However, this value appraisal has some limitations and sacrifices. Firstly, the two core persons, without the support of the Board, have very limited resources and limited autonomy to act. Further, they are in deep trouble vis-à-vis the Board and other stakeholders in the area to whom they have still not explained what they are up to.

Engagement in plan

1. Kjell Tore, a restaurant manager, seeks out Geir, he would like to arrange downhill cycling competition. He wants to have more summer tourists.
2. Geir says Snorre already has started digging trails in the mountain on his own initiative; maybe they should meet.
3. They form a project and a project group.
4. They start to formulate visions for the future.
5. They arrange the Norwegian Championships. With the help of friends and acquaintances.
6. They use social media and a new media agency for inexpensive marketing
7. They arrange World Cups and eventually the World Championship

As they proceed in developing the downhill cycling at Hafjell, Geir and Snorre become more future-oriented and more engaged in plans. Yet, to some extent they must still rely on a familiar engagement using available family members and friends who can easily be recruited as staff and with whom they are at ease.

The engagement in plan takes off when Kjell Tore, a local restaurant manager, contacts Geir for a meeting. Kjell Tore struggles to get people to the restaurants during the summer. He needs more action in the destination and more activities that encourage people to visit Hafjell in the summertime. He has an idea that he wants to discuss with Geir. Kjell Tore has done a brilliant preparation for the meeting, and he presents a total packet of a complete bike-arrangement appealing to both experienced bikers, families with children and tourists. Based on his experiences from arranging ski competitions and thorough research on what it requires to arrange bike events, he manages to convince Geir that his idea is workable, and Geir answers:

This is interesting! This I wants to go ahead with, but first you need to meet someone. His name is Snorre Pedersen, and he uses a little bit different tactic than you do! He is digging biking tracks up here without permission!

Geir arranges a meeting between Snorre, Kjell Tore and himself. The beginning of a strong triangle corporation is born. Geir has a dream of Hafjell as a year-round destination offering year-round working places to the core staff. Kjell Tore

has a dream of hosting major events that cause people flocking to Hafjell. Snorre has a dream of building some of the world's best downhill biking tracks and one day be able to host the world's best cyclists. Three visions fitting into an overall vision! The meeting turns out to be the beginning of an exciting collaboration that will result in Hafjell emerging as one of several leading down hill destinations in the world.

Snorre and Kjell Tore manages together to motivate a local bicycle environment to engage in voluntary work for Hafjell. In addition Kjell Tore creates a local downhill bicycle club. Geir also highlights that Hafjell has a crucial role in relation to the local community and points out that the reputation effects are at least as valuable as income. Hafjell has a responsibility in regional development. Despite this, it is still 3- 5 years before Geir gets the board on his side and a green light to further investment in summer operations.

Kjell Tore uses the first two years to test different bike competition concepts, and then he specializes into downhill competitions, beginning with Norway Cups. The first years they are only allowed to use one of the chair lifts and the upper part of the alpine centre due to landowners. After several successful Norway Cup events under this chairlift, Hafjell applies for and gets, in 2006, responsibility for arranging the Norwegian Championships. The following year they arrange the Nordic Championships. According to Kjell Tore this is possible because of the strong partnership between Geir, Snorre and himself. They have all the decision power in their hands. Kjell Tore continues to push on to new challenges, and after the Nordic Championship, he proposes: "Should we try to apply for European Championships?" All agrees to give it a try and Kjell Tore initiates an application process. To everyone's surprise, Hafjell assigns the European Championships to Hafjell in 2010.

Snorre is also committed to making Hafjell bike park a leader in web and social media. Therefore, he is working hard to make specific parts of the trails perfectly ideal for photo-shoots. They remove trees for better views and sore grass to promote lushness and colour on the pictures. Snorre emphasizes the importance of both photos and movies to tell how wonderful the trails in Hafjell are. Hafjell bike park also initiates a corporation with a newly founded company, Anti Media, working with both pictures and movies. One of the people in the Anti Media comes from the bike community and expertise combination leads to fantastic film material from Hafjell shared actively on Facebook. Photos and film show not only intense cycling at a high level, but also beginners, children and adults experiencing the bike park.

For several years during the event work, Kjell Tore builds the event staff with the help from friends, acquaintances and volunteers. It becomes more and more challenging along with the larger events, to recruit enough staff. The long road of preparation and hard work towards the European Championships commences. Kjell Tore applies for financial support from the municipality, the county council and other public bodies, but the applications are all turned down. This means that Kjell Tore is forced to build his event committee and official group of friends and volunteers. An extensive and arduous task meets everyone involved; they become very exhausted during the process. However, the European Championships is seen as a great success. 210 minutes of television coverage in 70 countries finally means that they have the attention of the municipality and the local public. Suddenly it becomes of major focus and interest to expose what has been achieved at Hafjell. However, Geir has now quit his job as head manager in Hafjell because of internal conflicts. This is a huge problem for Kjell Tore and Snorre. They evaluate whether or not they should proceed. Kjell Tore is not used to say stop, and he suggests "We can apply for a World Cup event and consider the situation if we get it." This is of course what they do, and then they get it. The World Cup Final 2012 has to be arranged by Hafjell:

Everything up to this point was built on pure will, interests and volunteering from those who participated. No one got paid anything. For so many years, everything was built on volunteerism and volunteer! It had to end eventually. Arrangements had become so large that it was not enough with my family, my friends, family of Snorre and friends of Snorre! We needed 100s of officials, so we should move on to get professionalized!

During the period in which they apply for financial support, the international cycling association (ICA) calls Kjell. He is confronted with the most unexpected question: "Will you take upon you to host the World Championships in 2014?" Kjell Tore does not believe what he hears. Normally there is an extensive process to apply for world Championships and many destinations are mutually fighting to get the event. The ICA argues. "Hafjell has absolutely ideal facility for our events. We get massive praise from all participants who have been to Hafjell. The compact arena is perfect and close to both the accommodation, bike repair, and all it takes. Hafjell is perfect for the athletes." They end up with a "yes" to both the World Cup finals in 2012/2013 and the World Championship in 2014. Since Geir has quit Hafjell, Kjell Tore is now very careful in putting in place all relevant contracts with Hafjell for the arrangements.

Three visions based on familiar engagement, or three innovative ideas, fitting into an overall vision, illustrates how engagement and innovation becomes intertwined. The case shows how the actors are forced to engage into plans to push the development further if they want to succeed with their visions. The engagement into plan then again leads to new smaller innovations such as the creation of a local bicycle environment, cooperation with anti-media, and the development of facebook as a marketing tool.

Value stabilization: Engagement in plans means a more visionary, open and future-oriented approach with specific events to be organized which are recognized by the Board and the local community. The advantage is more visibility, recognition and autonomy to act. The engagement in plan is affirmed also by the practitioners on Facebook, among others, which is at the same time an effective and inexpensive channel for marketing. These future-oriented engagement strategies for Hafjell include the following statements: "So sick, must visit next season." "Thanks for the awesome time

did we spent last summer. It was one of the amazing times of year.” “Best park in Europe!!!” “Full credit to the builders for such awesome tracks.” “Well deserved Snorre! You and the guys are doing some great work.” And Snorre responds: “Wow! Big words guys! Thank you so much! Hope to see you here soon Chris. Absolute honor to work with you!”. There is, however, still a limitation and sacrifice of this enthusiastic engagement into such visionary future-oriented plans, namely that they are badly coordinated with stakeholders in the local community; the plans are not very well justified in relation to some of the local stakeholders.

Engagement in justifiable action

1. They have problems with landowners.
2. They have problems with the hospital and the municipality.
3. They have problems with Hafjell.

Eventually, Hafjell downhill cycling must justify itself in relation at least three local stakeholders: the landowners, the local hospital and a new management at Hafjell.

The landowners: In Norway, there are no restrictions on trail construction in the nature, as long as landowners have approved the project. This is quite different from other countries such as New Zealand, where it is quite inconceivable to be allowed to build similar bike trails as in Hafjell. This means that Norwegian destinations have significantly better conditions for building downhill trails than destinations in other countries. The only barrier is the consent from landowners. Geir was not always putting in place contracts and agreements before he acted. This creates challenges in relation to landowners for Snorre during the years. Some owners became strongly opposed to trail building on their ground, mostly because they were not well enough informed and had not been allowed to consent to action. When Geir ends his career, Snorre has to make a thorough cleaning job of contracts. He must make good contacts and communications with all landowners. In particular, one landowner has over the years been difficult to work with for Hafjell. Precisely this landowner appreciate in particular the close follow-up after Snorre’s cleaning, and turns perfectly round to be the one offering Hafjell to borrow equipment for trail maintenance.

The hospital: Downhill biking is an action sport, which means that there is always a risk of bad injuries. Different from many ski/bike destinations Hafjell has only 17 km to the nearest hospital, Lillehammer hospital, managing acute care, ambulance and helicopter. When serious injuries occur, competent medical help is only 10 minutes away. In spite of the hospital close by, Hafjell has, as the only bike destination in Norway, chosen to have bicycle patrols as well, corresponding to ski patrolling in winter. Snorre says that they have been very careful recruiting employees to the bike patrol. They have employed many who also work in the ambulance in Lillehammer. This is to get maximum possible expertise in damages, but also to create a good working relationship with the hospital. Snorre tells that Lillehammer hospital is divided in its attitude to the bike park! Some of the staff at the hospital are very upset with the damage coming in because of Hafjell. Meanwhile, others who know the bike park or work there praise the safety. Snorre and the bike park have several times invited the ambulance service staff to cycling and guiding in Hafjell. The guidance has then included inspection of the security conditions and access paths to injuries in the bike trails.

The new management at Hafjell: A new era starts at Hafjell when Ole is employed as the general manager to replace Geir. Ole has previously been recruited to several former companies for just cleaning up the finance and accounting. Ole is a figures’ man and he communicates through Excel and his accounting system. He has expertise from manufacturing and the power industry, but no knowledge and competences from ski resort operation! He constructs accounts that can demonstrate whether or not the bike park is capable of being break-even.

It is a challenge for the bike park that other concerned actors, such as the landowners and the local hospital that are not part of their familiar entourage, are initially more or less ignored. The personal and familiar engagement into the design of trails, slopes and hops leaves little attention to the other concerned actors and their varied needs and engagements. This lack of consideration leads to conflicts about the bike park. A language of dialogue and justification is needed in order to restore the relations. When Snorre starts to show more interest in the landowners’ rights, as well as Ole’s reasons for using a spreadsheet, positive relations across varied familiar engagements are created through mutual respect and justification.

Value stabilization: Hafjell bike park is required to justify its activities to the relevant stakeholders in the community. It must be argued in a publically acceptable way how this activity can be relevant in a societal context. Value has to be stabilized in dialogue with landowners, the municipality and the Hafjell management around the issues of property right, security and breaking-even also in order to show respect towards other agents familiar and personal engagements.

6 Conclusion

The paper used the concept of engagement (Thévenot 2001; 2007) to show, in a case study of service and experience innovation, how the development of new services and experiences may take place through different forms of innovative engagement with the environment. Actors relate to their environment through different cognitive formats by means of which they dynamically seek to adjust and stabilize the innovations. Three forms of engagement were distinguished based on Thévenot: familiar engagement, engagement in plan and engagement in justification.

In the case study the innovators, at least in the first stages of innovation, tended to take a familiar and personalized approach to their environment; but the sacrifice of this was lack of autonomy. In order to stabilize the value of the innovation in a wider context they eventually became more involved in plans and justifiable actions. This also helped them to negotiate the innovation in relation to outsiders with whom they did not share familiarity. The case study shows how varied types of engagement support each other. It also shows the key role of familiar engagement for service innovation where actors grasp the environment by means of what is familiar and emotionally acceptable.

The contribution to research on service innovation lies in the attempt to see innovation as dependent on varied cognitive formats of engagement. Further, from the case-study it appears that lower levels of engagement are important in the beginning of the innovation process while more highly institutionalized cognitive formats can be important at later stages. To innovate, the actors appear to develop a familiar relation to the environment and the resources at hand; yet they must also be able to develop plans and argue for their cause using a language of dialogue and justification.

The engagement approach is different from the interactionist approach that tends to dominate innovation research. This approach often stresses the interaction between providers and customers as well as their different value-orientations (value-in-exchange and value-in-use). Instead we have suggested that actors are oriented towards varied cognitive formats of engagement. Innovations become dynamically stabilized by using these formats of engagement. Hence, in this approach, it is the relation between agents and their environments as mediated by cognitive formats which is the basic analytical model.

Focusing engagement rather than interaction should lead to questions of how varied cognitive formats impact innovation. Sometimes it is assumed that highly institutionalised and formalized formats are preferable to more familiar forms. However, actors also need to feel in control of the resources and need to be able to activate them in a more personalised way in order to solve problems. The advantage of this approach is firstly that it becomes clearer what the impact of various cognitive formats can be on innovation, hence it has consequences for innovation management research. Secondly, it makes it possible to explore some potential links between social institutions, in the shape of cognitive formats, and innovation.

Compared to the marketing theory of value-in-use, the engagement approach tends to re-introduce a 'productionist', employee- and management-oriented view on service innovation. The agents are those who create innovations. However, in the engagement approach, innovation is not viewed only as linked to service providers in a narrow sense. Rather, the context of innovation is one of engagement, where agency can be undertaken by many types of actors including providers, users, volunteers etc. Unlike the marketing literature, this approach does not focus the value-in-use, but how value is approached and negotiated in a wider social context of engagement.

Future research could make comparative studies of the impact of cognitive formats on innovation in different contexts. Different cognitive formats may dominate in different industry sectors for example. Future research can also explore how an engagement-oriented approach can be combined with quantitative studies of innovation in services. The impact of cognitive formats on innovation may be explored in a more statistical and quantitative way.

The Role of Small Towns for Surrounding Rural Development: The Case of Metema Town, North West Ethiopia

Kassahun Gashu

Addis Ababa University

There is a growing need to identify the most appropriate mechanisms through which to stimulate economic activity across a broad range of economic sectors in rural areas. One strategy is to use small towns as 'sub-poles' in rural economic development but the effectiveness of such a strategy depends not only on the size of the various multipliers but their spatial distribution. The potential value of a town as a 'sub-pole' in local economic development is shown to be dependent on structural differences in the local economy, such as the particular mix of firms within towns. An operational framework is described which aims to examine the sectoral and locational variations which may affect the success of any small town sub-pole strategy, using some developed empirical tools to measure economic linkages. It then goes on assessing the potential role of small and mediums-sized towns as sub-poles in rural development. The paper concludes with some suggestions for future research in this field

Keywords: Small Towns; Rural Development; Sub Pole; Regional Development, Metema

1 Introduction

Small towns are increasingly being perceived as a possible focus for initiatives that seek to maintain or enhance the rural economy. The ability of small towns to generate economic growth in rural areas depends on the nature and strength of the linkages between the town and its surrounding hinterland (and vice versa). These are determined by the extent to which: Hinterland households earn income in the towns; Town households spend income in the hinterlands; and Town businesses source inputs (labour and goods and services) in the hinterlands.

These linkages work in both directions. Small towns and their surrounding rural areas are part of the same functional economic system and, as a result, numerous different types of economic linkages exist between them. A farmer may rely on neighboring towns for agricultural inputs, shopping, schools, healthcare and farm labour. A resident in a small town may use the rural hinterland for recreation and as a source of local food while a town employee may choose to live in the surrounding rural area and commute to work.

As a result of these links, small towns form an important component of rural economy and society. Increasingly they are being perceived as a possible focus for initiatives that seek to maintain or enhance the well being of rural areas as a whole.

From a rural development perspective, the spatial distribution of linkages between a small town and its hinterland is just as important as their size. Tacoli C. (1998) has shown that the economic footprint of different types of firms and different types of households vary. For instance, small firms tend to be more locally integrated than larger firms; retirees tend to spend a higher proportion of their income locally than single adults with no dependants. At another level, the relationship between small towns within a region can influence development trajectories. Urban-Rural relations, emphasize the potential for reducing inequalities between areas by pursuing polycentric objectives. In other words by developing complementary roles for adjacent small towns, overall rural development can be enhanced. This is likely to be particularly important in more remote rural areas (MoFED 2006):

Spatially tracking the nature of linkages between town and countryside and considering the nature of economic relations between small towns adds considerably to current understanding of spatial development in rural areas.

1.2 Statement of the Problem

Small towns are potentially attractive as a focus for future rural development initiatives for a number of reasons. In the first place, they may provide the opportunity to foster beneficial economic development while conserving the environmental assets of the open countryside, confining new built development to existing urban settlements and reducing the need for the town's residents to commute to work elsewhere. Second, they may already contain the concentrations of community and institutional capacity necessary to manage local, regional or national initiatives in a reliable and accountable manner. Finally, the concentration of rural economic development initiatives in small towns may take advantage of economic advantages of population clusters while allowing the benefits (in terms of both employment and income) to spread out to the surrounding countryside.

In the Ethiopian context, questions that need responses are many. Plan for Accelerated Sustainable Development to End Poverty (PASDEP), in its fourth pillar which promotes small town development motivates rural-urban linkage (MoFED, 2002; 2006). However, there are no sufficient studies on small towns as sub-poles for rural development. Such study will provide a general perspective on the role of small towns in attaining over all development. Hence, this

study attempts to fill this gap focusing on small towns' role on surrounding rural areas development. Several lessons can be drawn from this study, such as, factors that affect rural-urban interaction between small towns and their rural hinterlands; the current forms and magnitudes of rural-urban interaction, and the services and facilities provided by small towns. The Answers to these questions and others will help to enhance rural-urban interactions and the role played by small towns for sustainable and mutual development of urban and rural areas.

1.3 Objectives of the Research

1.3.1 General objective

The General objective of this research is to analyze the role of small towns for the development surrounding rural areas.

1.3.2 Specific Objectives

The specific objectives of this research are to 1) Examine the different types of economic linkages that exist between Metema town and its surrounding rural areas. 2) Measure the strength of economic integration between Metema town and its hinterland. 3) Evaluate the potential value of Metema town as a 'sub-pole' in local economic development. 4) Identify of the social, cultural, and multiplier effects of investing in small towns and hinterlands. 5) Discuss the policy implications of the results.

1.4 Research Questions

In rural-urban interactions study, a range of physical, economic and service linkages have to be examined. As Rondenilli and Evans (1983) stated cited by Demeke (1998:5), some of these are transport links, production and marketing links, the delivery of social services (health, education), technological linkages related with energy and communication, and public administration linkages.

Based on these concepts and the objectives forwarded above for the study, the following research questions are formulated. 1) What are the factors that affect rural-urban interaction between small towns and surrounding rural areas? 2) What are the major non-farm activities undertaken by farm households in the hinterlands of small towns? And what roles do they play in promoting rural-urban linkage? 3) To what extent do rural households use agricultural inputs? From where do they obtain these inputs? 4) To what extent do small towns depend on their rural hinterlands for agricultural produce consumption, labor and trading activities?

1.5. Research Methodology

1.5.1. Data Sources and Sample Size

1.5.1.1 Data sources

In order to conduct this research and to identify the different types of linkages data was collected from both primary and secondary sources. In the collection of primary data, questionnaire and personal observations was conducted in sample rural and urban areas and interviews will also be conducted with responsible personnel's of corresponding woreda agricultural and rural development offices of Metema woreda and municipality of Metema town.

Three sets of questionnaire pertaining to rural households, urban households and traders was prepared. The questions included in the questionnaire are related to linkages of consumption, production, and service provision in addition to socio economic characteristics such as demography, land holding and others that helps for the explanation of the phenomena.

The secondary data were derived from relevant organizations such as CSA, Woreda agricultural office, Amhara Region Bureau of Agriculture (ARBoA), Zonal planning offices, Municipality of the sample Metema town and others.

1.5.1.2 Sample Plan and Size

A two stage sampling design was used in the data collection. For the rural households, two rural kebeles with in a 10 km radius from the town were selected randomly in the first stage. The roasters of peasant associations were used as sampling frame. Similarly from two kebeles of Metema town two kebeles of the town were selected purposively. The urban kebele administration was used as a sampling frame. Formulas often used in most social science researches for sample size determination when the target population is less than 10,000. Yamane (1967:886) provides a simplified formula to calculate sample sizes.

$$n = \frac{N}{1 + N(e)^2}$$

Where:

n- is the sample size and

N- is the population size.

e- is the level of precision (confidence)

Substituting the value of N in the above formula the actual sample household number are calculated for both urban (where N = 11,118) and rural (where N = 69,428). The method results a sample size of 347 and 56 urban and rural households respectively. However, out of 56 urban sample households, 40 valid samples (30 urban households and 10 traders) were entered in to the analysis. Likewise, out of 347 rural sample households, 315 valid samples were entered in to the analysis. The remaining samples (16 urban sample households and 32 rural sample households) are accounted to be unacceptable because enumerators missed pertinent variables at the time of data collection and it was not viable to make an interview for the second time due to time and money constraints.

Besides, the researcher believes that such insignificant number will not have any major effect on the results of the study. Number of sample households in each kebele was determined as per of the proportion to the population size and samples are drawn using systematic sampling method.

1.5.2 Method of Data Analysis.

In the analysis of the data, both quantitative and qualitative methods will be used to examine the existing rural-urban linkage and its implications in the role of small towns in rural development. Quantitatively simple statistical tools such as percentages, means, standard deviation, charts, chi-square and ANOVA were used. The qualitative part includes analysis of attitudes, opinions, and suggestion of informants.

2 Factors Affecting Rural-Urban Interaction for development

The factors that affect linkages between rural and urban areas are various. Among other things, some of them are Agriculture research and Development, Information and communication technologies, Infrastructure development and market institutions (VonBroun, 2007; UN/FIG, 2004; UNDP, 2000; Tegege, 2005; Ellis and Harris, 2004; Fan S. et al., 2005; Dauglass, 1998; Eshetu, 2007; Mohammed, 2005).

Science and technology are fundamental for rural-urban linkages and in this context Agriculture Research is fundamental. The Green Revolution experience which include high-yielding varieties complemented with irrigation and intensive fertilizer use especially in Asia has shown that research and development can result in technological breakthrough that enable considerable improvement in agricultural growth, which in turn can translate into substantial rural development and poverty reduction (VonBroun, 2007:11).

Information and communication technologies can lower transaction cost by reducing information bottlenecks that hinder rural-urban linkage and by increasing search, screening and bargaining costs. Information Communication Technologies opening-up market possibilities for rural inhabitants (VonBroun, 2007:12; UN/FIG, 2004:3).

Infrastructure works as a bridge between the rural and urban world, and between agricultural sector and other sectors of the economy. In addition to direct impact, infrastructure may indirectly affect rural and urban linkages (VonBroun, 2007:12; UN/FIG, 2004:3; Ellis and Harris, 2004:2).

In developing countries, particularly low income ones, market failures such as deficiencies in information and lack of regulation and legal enforcement mechanisms persist and restrict the level of trade between urban and rural areas. Local rural-urban linkages can vary according to the larger spatial networks of towns, cities, transformation and communication flows (Dauglass, 1998:15; VonBroun, 2007:15).

Rural-Urban interaction is affected by economic situation and budget cutbacks. One of the marked distinctions between rural and urban areas in developing countries is consumption expenditure (UNDP, 2000:17). Strengthening rural-urban interaction without a capacity of rural areas to capture the upstream (providing inputs) and downstream (processing and marketing) activities associated with natural resource extraction and flows will only perpetuate low incomes (Ellis F. and Biggs S.(2001);UNDP, 2000:28).

There are regional differences in rural-urban interaction. In Nigeria the linkages are stronger in the southwest and the eastern region than in the northern region (UNDP, 2000:16). Differentials in physical development can be partly traced to this unequal rural-urban linkage between parts of the north and the south. Regions that had stronger rural-urban interaction have lower poverty level as compared to the areas, which had weaker linkages.

Moreover, socio-economic relations, structure of the rural economy, natural environment, and resources, rural production regimes process and pattern of urbanization, lack of balance rural-urban policy, land tenure and size are also factors determining rural-urban linkage (Dauglass, 1998, 1999:15–16; Tegege, 2005:157–159; Demeke, 1998:24–25; Eshetu, 2007:22; Mohammed, 2005).

3 Background of the Study Area

3.1 Location

Metema woreda is one of the woredas in North Gondar administrative zone of Amhara National Regional State. It is the largest woreda in the zone. The woreda is divided in to twenty two administrative kebeles. Two of the kebeles are found in the woreda capital, while the rest are rural kebeles. The woreda is bounded by Tacharmachiho woreda in the North, Chilga woreda in the East, Quara woreda in the South and Sudan in the West (see map below).

The study was conducted in Metema woreda of the Amhara National Regional State (ANRS).

Metema is located at about 900 km Northwest of Addis Ababa and about 180 km West of Gondar town. Metema is one of the West most Woredas of the Amhara Regional State. The woreda has an international boundary of more than 60 km with Sudan.

Fig: Map of the study área.

3.2 Topography and Areal Coverage

The topography of Metema Woreda is characterized by plain land. This indicates that larger proportion of the woreda is characterized by more than 90 percent less than 1000 m above sea level. The elevation of the woreda ranges from 500 meters to 1666 meters above sea level. The total areal coverage of the woreda is about 440,085 hectares.

3.3 Climate

According to Woreda Agricultural and Rural Development Office, the woreda has kola agro-ecological zone with annual temperature range 28–43 degree centigrade. The daily maximum temperature becomes very high during the months of March to May, during which the temperature can reach as high as 43 °C. The mean annual temperature is about 31 °C (ILRI, 2005). Mean annual rainfall of Metema area ranges from about 850 to around 1100 mm, and it receives a uni-modal rainfall (ILRI, 2005). The rainy months extend from June to the end of September. However, most of the rainfall is received during the months of July and August, during which the rainfall is erratic.

3.4 Land use

According to the Woreda Agriculture and Rural Development Office, the land use of the woreda is classified in to 86,360 hectare for farmland; 4,400 hectare for grazing; 177,600 hectare for forest; 3,660 hectare for settlement from this 894 hectare is used for social services; 116.2 hectare for perennial crops; 89,943 hectare for bushes and shrubs; 3708 hectare water bodies; 17,471 hectare could be cultivated; 7,752.2 hectare unusable and the remaining 6,800 hectare is for miscellaneous activities. Forest and bush land are diminishing over time due to farm land expansion.

This depicts that, the land use type and pattern of Metema woreda is more diversified. The nature of land use in the woredas is that larger proportion of the land is used for forest land. The land area used for perennial crops (about 0.03 percent) is smaller than others followed by irrigable land and settlement area and land covered by water bodies respectively.

3.5 Population

According to CSA (2007) the population of Metema Woreda was about 110,231. Of the total population 88,354 (80.15 percent) are rural inhabitants and 41,229 (46.66 percent) are female. This indicates that the numbers of rural inhabitants are more numerous than urban dwellers and the number of male and female population in the woreda are proportional. The inhabitants of the woreda are belonging to the Amahra ethnicity and Amharic and to some extent Arabic are media of communication. With regard to religion almost all inhabitants are followers of Orthodox Christians (90 percent), but there are few Muslims residing in the urban kebeles of the woreda. The population density of the woreda is about 25 persons per square kilometers.

The original residents of the area were Gumuz. Until recently, they have practiced slash and burning and hunting wild animals. They have also been engaged in making household furniture like chair, bed, pot and others. When the area became gradually populated, the natives were dominated by the new settlers. The original settlers (Gumuz) are now found only in three peasant associations, the Kumer Aftit, Tumet and Shinfa.

The total number of the indigenous people is around 500 (ILRI, 2005). Hence, much of the area is recently occupied by settlers from the highland part of the region. According to WoARD (2011), in the years of 2003, 2004 and 2005 during which new settlement programs occurred, 12,777, 4,124 and 16,258 new settlers were settled in the district, respectively. It shows that the population of the woreda capital, Metema and the Woreda as a whole increases rapidly from year to year.

3.6 Farming system

The major economic activity in the woreda in which the population engaged is mixed farming, which is a combination of crop production and livestock rearing and to some extent legal and illegal trade because of its proximity to the border. Due to erratic and torrential rainfall pattern farming operation is always at risk such as crop failure due to drought, shortage of livestock feed etc.

The agricultural production system in the study area is crop-livestock mixed. The crop-livestock mixed production system is the predominant system and exists in all over the district throughout the year. Crop production is the main agricultural activity for the livelihood of the smallholder farmer in the study area. The major crops grown include sorghum, rice, cotton, sesame, haricot bean, soybean and new emerging crops like teff, chickpeas and banana.

Livestock production is an integral part of the land use system. Production of cattle (as draught power, milk and meat), shoat (income and meat), donkey and camel (as Karoo and transport) and poultry was commonly practiced. WoARD (2009) report shows that the livestock population of the district is composed of 136,910 cattle, 32,024 goats, 1,686 sheep, 7,164 male donkeys, 7,127 poultry, 400 camels and 23,789 beehives. Cattle in the district are exported both legally and illegally, through smuggling to Sudan, while goats and other animals are mainly sold in local markets.

According to ILRI (2005), Metema district was categorized into cotton, sorghum and rice/ livestock based/ and sesame, cotton, and sorghum/ livestock based farming systems based on the type of crop production. The livestock production system is similar in both farming systems. Therefore, there are two types of farming systems used in the study district namely cotton based farming system and sesame based farming systems. Each has its own characteristic features regarding to the crop production nature.

According to ILRI (2005), 4 out of 18 peasant associations (PAs) belong to cotton farming system. They are Maka, Awlala, Genda Wuha and Kemechela. They are found in the Northeast parts of the district. The PAs are relatively colder in temperature, have higher altitude and rainfall. Farmers in the PAs practice slightly early planting of crops. The soil is black and water logging is a problem. The majority of the soils in this farming system have vertic property.

Many of the areas are also flat. The PAs in this farming system have different features in terms of suitability for crop production and amount of rainfall received. The majority of the soils are only suitable for growing cotton and rice. The PAs predominantly grow cotton and sesame in little amount. Cotton is grown in wide areas while sorghum and sesame are planted on very smaller areas.

Fourteen PAs belong to sesame based farming system. In order of importance, sesame, cotton and sorghum are the major crops produced in this farming system. A farmer could grow any one of these crops as the environmental conditions are equally suitable for these crops. The choice is set by the farmer upon observation of the season, high or low rainfall, and possible market prices. The altitude and rainfall in this farming system is less than the cotton based farming system. The altitude range for this farming system is between 550 and 700M asl (ILRI, 2005).

Farmers and agriculturists believe that the underground water table is high. In some places, sufficient amount of water could be obtained at less than 10m deep. Besides, three rivers are found in this farming system. These rivers make the area more potential for crop and livestock development. This farming system also has extensive grazing areas. There is also a place where the natural plantations for gum and incense are located.

3.7 Infrastructure

The availability of sufficient economic, social and physical infrastructure directly influences rural-urban linkages and the potential that small towns could play in balanced development process. Physical and social infrastructures with no doubt play a key role for rural and regional development.

A research on the rise of secondary cities also identifies ground transportation (roads and railways) as essential infrastructural investments. Road access within and between small towns and their hinterlands could faster rural-urban linkages in the form of production and consumption linkages. Social infrastructures like schools, health services, telecommunication, postal and banking services are also seen as necessary investments for development. The next section gives a general overview on physical and social infrastructure developments in the study areas.

3.7.1 Physical Infrastructure

The nature of land scope, resource endowment, policy environments of the government are among other things, some of the factors that resulted in unbalanced development of physical and social infrastructure.

3.7.1.1 Road Transport

The main asphalt road from Addis Ababa to Metema via Gondar about 800 km far from Addis Ababa could reach Metema woreda. The total length of the available road is about 483 km. It has 80 km asphalt road that is part of the main high way to Sudan, 55 km Gravel road and 348 km dry weather road joining kebeles each other in the woreda.

3.7.1.2 Water and Electricity

Efficient and effective production and consumption linkages could be promoted by the development and availability of such urban infrastructures like water and electric power supply.

Most of woreda capitals and even other minor towns in North Gondar zone receive electric power and are connected to the national grid. Surprisingly, the same is not true for Metema town. This town enjoys electric power supply during most of the days for about a maximum of 4 hours using private generators. However, in Metema woreda one rural kebele(Kokit), and three urban kebeles (two kebeles of Gendewuha, woreda capital and one kebele of Shenfa) have an access to 24 hours electric power.

With regard to water service at the woreda level, the woreda, has about 19 rural kebeles with shallow wells and about 2 rural kebeles with hand pump wells. This indicates that about 86.36 percent of the rural kebel in the woreda are users of water supply. At the woreda level it covers about 75.83 percent of the woreda's population.

3.7.2 Social Infrastructure

Similar to physical infrastructure social and institutional infrastructures such as education and health facilities, bank and/or credit services, and postal and telecommunication services are also important in promoting rural-urban linkages between hinterlands and towns for enhancing a more productive economy.

3.7.2.1 Education and Health Services

The comparison of distribution of social infrastructures such as education and health services at the woreda level, more or less there are proportional number of educational and health centers. The only difference is that there are one high school and preparatory school one vocational training which is administered by woreda education office.

3.7.2.2 Telecommunication and Banking Services

At the woreda level the study area Metema town in Metema woreda has no digital telephone service and there about no clients for fixed telephone. Recently from the rural kebeles found in the woreda almost all kebel are users of wireless telephone service. However, the service is intermittent and has no quality.

Moreover, Metema town has no postal service. As far as the banking service is concerned, at the woreda level, there are three banks in Metema town, two of them private and one government bank, commercial bank of Ethiopia.

3.8 Investment

Currently, there are investors who are engaging in agricultural sector in the woreda. These investors owned about 28,816 hectare of land. Of these majorly 94 are found in Delelo, 84 in Tumet and 386 minor investors in different parts of the woreda. These investors create employment opportunity for the local people and people from different corners of the country. They employed 4420 permanent employees and about 38,100 daily workers. All of them account about more than 129 million Birr fixed capital and more than 86 million Birr recurrent capital.

4 Patterns of Rural-Urban Linkage

4.1 Frequency of Visit to Small towns

Production, consumption and public service linkages are some of the basic forms of rural-urban linkages that may occur between urban centers and their surrounding hinterlands. The frequency of visit of farm households to the nearby towns

helps to detect the observed patterns of linkage. Towns are expected to provide markets for agricultural produce, serve as source of urban goods and services and off -farm employment to their hinterland people.

Since they are found at the lower level of urban hierarchy and are immediate destinations of rural people who live in the hinterlands, small towns are the most frequently visited centers by the rural people. In the same way, small towns in the study areas are the most frequently visited centers by almost all the sample households. The pattern of the frequency of visit varies from daily to once a month. As a result the observed frequencies of visit from different hinterlands are not the same (see Table 4.1).

Table 4.1. Frequency of Visit to the nearby small towns by KAs (Number and Percentage of households).

Frequency	Metema Woreda					
	Kumerafit		Kokit		Total	
	No	%	No	%	No	%
Daily	11	15.71	15	12.5	26	13.68
Once a week	10	14.28	37	30.83	47	24.74
Twice a week	37	52.86	43	35.83	80	42.1
Four times a week	1	1.43	3	2.5	4	2.1
Once a month	1	1.43	1	0.83	2	1.1
Twice a month	-	-	2	1.67	2	1.1
Total	60	85.71	101	84.73	161	84.73

Source: Own Survey (2011) Note: No- Number, % - percentage

Majority of the sample rural households in both kebeles visit the nearby small twice a week followed by once in a week and once a month. A χ^2 and ANOVA revealed that there is a significant difference in the frequency of visit between the two sample populations (see Table 4.2).

Table 4.2. χ^2 and R-value for frequency of visit by kebele.

Woreda	1	2	3	4	5	6	Sum
Kumerafit kebele	15(19.53)	107(85.95)	55(75.35)	2(3.35)	25(15.07)	22(13.39)	240
Kokit kebele	20(15.46)	47(68.05)	80(59.65)	4(2.65)	2(2.65)	2(10.6)	190
Sum	35	154	135	6	27	24	430

D.F(two tailed)=5
 Table value(two tailed)=11.07
 Level of significance(p)=0.05

Numbers in parenthesis are expected frequencies; D.F-Degree of Freedom

Note: 1= daily, 2= once a week, 3= Twice a week, 4= 4 times a week, 5= once a month, 6= twice a month

$$\chi^2 = 55.03$$

Standardized Residual (R- value) for frequency of visit

Woreda	1	2	3	4	5	6
Kumerafit Kebele	-1.03	2.27	-2.11	-0.74	2.56	2.35
kokit kebele	1.15	-2.55	2.63	0.83	-2.87	-2.64

$$R = \frac{(O-E)}{\sqrt{E}} \tag{1}$$

A variety of reasons are presented by sample households for visiting nearby small towns in the study areas. Among other things, market attendance to buy and sell items takes the largest share. Except this, all other purposes differ between the study sites in both kebeles, though there are multiple purposes (responses). In kumerafit kebele, farm households in the study sites reported that others (asking relatives, recreations, meeting etc), administration (court, police etc), social service (education, health) and lastly daily labour as their second to fifth reasons to visit nearby small town.

However, in kokit kebele sample farm households presented daily labour as their second most important reason followed by administration for visiting nearby small town (see Table 4.3).This falls in line with the expectation that farmers in food insecure area rely on the town for their livelihood.

Table 4.3. Reasons (purposes) for visiting small towns by KAs (number and percentage of households).

Reason/ Purpose	Metema woreda					
	Kumerafit kebele		Kokit kebele		Total	
	No	%	No	%	No	%
Buy and sell items	67	74.44	98	65.33	165	68.75
Social service	4	4.44	15	10.0	19	7.92
Administration	23	25.26	13	8.67	36	15.0
Daily labor	2	2.22	5	3.33	7	2.92
Other	21	23.33	26	17.33	47	19.58

Source: Own Survey (2011)

Regarding the mode of transportation to the small towns, sample farm households in the study sites reported that about 65 percent in kumerafit kebele and about 95 percent in kokit kebele visit small town on foot. However, about 33 percent in kumerafit kebele use either pack animals like cart, public transport or other means such as bicycle, while about 5 percents in kokit kebele use pack animals only (see Table 4.4).

Table 4.4. Mode of transport to Visit Small towns by kebele.

Mode of Transport	Kumerafit kebele		kokit-kebele	
	Number	Percent	Number	Percent
Pack animals	21	16.67	7	5.00
Public transport vehicles	10	7.93	-	-
On foot	82	65.00	143	95.00
Others	13	10.3	-	-

Source: Own Survey (2011)

Measuring in all these indicators and under the characteristics of farm economy like land holding size, livestock production and the volume of crop production between sample farm households in Metema woreda of North Gondar zone, the sample farm households in kumerafit kebele are in a better position than their counter parts. On the other hand, the need to supplement low agricultural production in kokit kebele lead to participate in low return non-farm activities. Therefore, we can generalize that the patterns of visit of small towns by hinterland people differ depending on the level of production of households.

4.2 Factors Affecting Rural-Urban Linkage in the Study Areas

As it is stated in the literature factors that affect rural- urban linkage can be categorized broadly as global, national and local factors. Largely it is the local factors that affect the linkage of small towns and their surrounding hinterlands. Several local factors are postulated to determine rural- urban linkages in the study areas.

These local factors can affect frequency of visit to the nearby small towns, pattern of input usage, the utilization of public service facilities, the consumption pattern of basic consumer and consumer durable goods, the participation in non- farm activities are supposed to have a significant influence. Some of these factors are income from agricultural activities and production status and resource endowment; distance from small towns; infrastructure development; non-availability of financial institutions and service provision capacity of towns.

It is very difficult to see these factors separately. Because one factor directly or indirectly influences the other and largely may lead to vicious circle.

4.2.1 Income and production status and resource endowment

For estimation of income volume of crop production and number of livestock owned are used as a proxy variable. Farm households who produce larger production together with large number of livestock ownership can have a possibility to visit the nearby small town frequently. And majority of the sample households in both sample sites forwarded that their purpose of visiting nearby small towns is market attendance. However, the volume of production and resource endowment varies considerably between the sites in the two kebeles; hence the purpose of market visitation may vary accordingly. Land holding size and its fertility can be used as indicator of resource endowment.

The purpose of visit to small towns and the participation of non-farm activities are directly or indirectly related with the volume of production and resource endowment. Farm households in sample kebeles apart from selling their production, they also frequently visit small towns either to sell products obtained from non-farm activities or seeking non-farm jobs. Participation in non-farm activities also varies with income level, since poor farmers are expected to be widely practiced in low return non-farm activities and relatively rich farmers in high return ones.

4.2.2 *Distance from small towns*

Distance is approximated between farm homesteads and nearby small towns in terms of travel time. Distance is highly significant for farmers in the hinterlands of small towns. It could have a negative influence on the frequency of visit to nearby towns.

Farm households whose homesteads are closer to the nearby small town have more chance to visit the nearby small town more frequently than those farm households whose homesteads are located at a distant place. As presented in the preceding section of this chapter, frequency of visit to nearby small towns by farm households in from four times to daily indicate that majority of their homesteads are located relatively closer to the nearby small town (between 3–4 km). On the other hand, in both sample kebeles some farm households who mentioned visiting the nearby small town once a month forwarded that their homesteads are located relatively within 7–9 km away from the nearby small towns. This indicated that, increased travel time to towns has negative effect on households visit to towns.

Therefore, we can conclude that impact of distance on the pattern of frequency of visit to nearby small towns agrees with variation in the levels of infrastructures development and the nature of landscape between the two sample kebeles. The frequency of visit in turn has influence on rural-urban linkages between towns and their hinterlands.

4.2.3 *Infrastructure development*

Infrastructure usually defines as underlying basic institutions and facilities or other essential elements that are necessary to sustain and enable economic growth. It represents a broad spectrum of activities and services without which no activity can undertake in the economy. It plays a key role in the society and constitutes the wheels, if not the engine of development. Infrastructure broadly classified in to physical, social and financial.

Improved infrastructure is a necessary condition for improving productivity in rural areas as well as for enhancing access of agricultural produce to both urban areas and export market. Therefore, in many ways developing countries, addressing rural-urban infrastructure gaps requires more government action. Infrastructure linkage to the economy is very multiple and complex, as it affects production and consumption directly, creates positive and negative spillover effects and involves large inflow of expenditure. It increases productivity; lowers production cost; improves quality of life; raises international competitiveness; attracts investment and helpful in urbanizing the economy.

In the study areas, infrastructure development is another local factor that may affects rural-urban linkages. There is some level of variation between the sample sites in the level of infrastructure development especially road transport. Rugged physical terrain, weak infrastructure based and inaccessibility are claimed to be some of the attributes of frequency of visit problems to nearby small towns.

4.2.4 *Availability of financial institutions*

The financial linkage of small towns to its hinterlands is based on the availability of financial institutions in the small towns, which will stimulate the rural people to use these institutions for loan and savings. In Metema town there are both governments and private formal financial institutions including branches of Amhara Credit and Saving Institutions.

The existence of financial institutions, especially banks in one area contribute a lot to positive rural-urban linkages and thereby play a significant role for livelihood diversification of rural households. Households who have access to credit can use it for a wide range of purposes such as for agriculture inputs purchase, for purchase of consumer durable and non-durable goods, for social services such as medical treatment and education.

In view of the fact that farmers in the study area have high access to formal credit service institutions, though some resort to informal credit sources, such as relatives and friends in urban areas.

There are thus very high financial flows from urban-based formal sources to rural households of the study kebeles. In the study sites, however, the main sources of financial capital for both rural and urban households may financial institutions.

The credit and saving scheme formed through the availability of financial institutions has helped to make rural-urban linkages sustainable and more effective towards initiating development activities. Credit and saving activities have cohesive effect between rural and urban areas and made rural-urban linkages stronger.

4.2.5 *Economic dynamism of towns*

The urban economies have potential for high growth if they can perform the role of producers of goods and services required by rural as well as urban economies and that of provider of markets and marketing services for rural outputs. Ample opportunities exist for strengthening and expanding the urban and rural economies for poverty alleviation. Thus strengthening local as well as regional level linkages to promote and expand economic activities is the major

operational strategies of rural-urban linkage for promoting economic development and sharing its benefits to help the people escape wide spread poverty.

4.2.6 Service utilization capacity

The other indicators of linkage which are associated with service provision capacity of towns are the utilization of public services such as education and health. The utilization of these services is also a function of income. Measured in terms of aforementioned indicators households in both sample kebeles have relatively proportional income. And households in Metema woreda have a capacity to use education and health services both in the nearby and distant places. However the utilization of these services is also related to the level of education of households head, family size and income and attitude towards the returns of education.

5 Conclusion and Recommendations

5.1 Conclusion

Improved rural-urban linkage is a vehicle for balanced socio-economic development of both rural and urban areas. The following are the major conclusions that could be drawn from the patterns and forms of rural-urban linkages in the study areas.

The study results indicated that, volume of production and resource endowments do not vary considerably between the sites. Hence, the purposes of market visit do not vary accordingly. Larger proportion of farmers' households in both sample sites visit the nearby small town (Metema) once a week.

The numbers of business activities located in Metema are larger. This has influence on the service provision capacity of towns to the hinterland people. Service provision capacity has in turn impact on rural-urban linkage.

The small towns and their corresponding hinterlands are located in the same geographical setting with proportional level of infrastructure development. The variation in the level of infrastructure has resulted in variation in rural-urban linkage. Hence, it implies that the availability of better infrastructure facilitates better rural-urban linkage.

6.2 Recommendations

Based on the observations made so far, the following are recommended to be in place to enhance rural-urban linkages and developmental role of the small towns in the study areas.

The small towns are similar to other small towns in the country and lack sufficient capacity to provide facilities and services to their dwellers and hinterland people. Hence, promoting the service provision capacity of small towns to provide sufficient services for its dwellers and hinterland people is necessary.

Road that connects rural and urban areas is very important to bring about all kinds of linkages. The low level of road network implies that the vast majority of areas is inaccessible to all weather roads reduces communication and mobility. It is important to prioritize road infrastructure development that links villages and local towns. This will enhance rural-urban linkages and facilitate mobility of people, flows of agricultural products and access to critical services.

It is important to facilitate the provision of credit/loan to farm households for input purchase from both formal financial institutions and credit and saving institutions. This will have an impact on the increment of production which in turn will have an impact on rural-urban linkage between towns and hinterlands.

Non-farm activities are underdeveloped. They can play a role in linking rural and urban areas. Therefore, promoting rural non-farm activities to create significant synergies between the rural and urban centers is needed in agriculturally rich and poor areas.

Occupational Health and Safety and its Interdependencies with Employee Satisfaction, Employee Motivation, and Productivity in Services – A Systematic Literature Review

Silvia Gliem, Janny Klabuhn

Brandenburg University of Technology Cottbus-Senftenberg

Service employees are exposed to risks threatening their health and safety in the workplace. Feeling to be at risk potentially influences motivation and satisfaction of employees and can also affect the performance of a firm. Detailed knowledge about the effects of occupational health and safety on productivity, employee motivation, and employee satisfaction will contribute to the understanding of these effects. Within this paper we perform a systematic literature review and uncover a lack of empirical studies that analyse the named relationships. Still, these relationships exist and reflect intuition, e.g., the better the occupational health and management system, the higher the employee motivation.

1 Relevance of Occupational Health and Safety in Services

As all other employees, service employees are exposed to risks threatening their health and safety in the workplace. For instance, in hospital laundrettes employees get in contact with contaminated laundry items that pose a serious risk to their health. However, within the variety of services, occupational health and safety risks differ as well. Think of banking services that involve other types of risks, e.g., bank hold-up, aggressive customers, burn-out, and different proportions of risks other than health or construction services, e.g., risk of infection, accident on site (O'Reilly, Olomolaiye, Tyler, Orr, 1994; Rozenfeld, Sacks, Rosenfeld, Baum, 2010). In conclusion, measures promoting occupational health and safety, defined as “*minimizing of hazardous effects and [...] the prevention of disease*” for employees (Luczak, Rötting, Brüggmann, 2000, 652), have to be in line with the safety needs of the service employees. In some cases, risky steps within the service process can be remodeled in such a way that employees are no longer exposed to certain risks. For instance, in hospital laundrettes robots can replace employees that normally process dirty and potentially contaminated laundry items (Gliem, Klabuhn, Litwin, 2014, 45). However, there are process steps in services, e.g., in health care services, that cannot be remodeled. If employees in such services are not properly protected in their work environment, there is a greater risk of accidents. Moreover, employees may refuse to go on with their job. Potential future employees might reconsider their occupational choice in order to avoid health and safety risks in the workplace and therefore induce staff shortages (Loeppke, 2008, 96-97). Motivation and satisfaction of employees facing safety threats in their workplace may decrease. As a consequence, productivity will drop. Bottlenecks in the supply of important services, e.g., health care, might be the result. For these services measures protecting the health and safety of employees are highly relevant. At the same time these measures need to be considered carefully for their connected costs and benefits. This is of particular interest when measures go beyond the minimum set of legal regulations. While costs can be analyzed quite easily, the benefits of occupational health and safety efforts for services are hard to evaluate.

In order to give evidence about the interdependencies between occupational health and safety and employee satisfaction, employee motivation, and productivity in services, we conducted a systematic literature review within this paper. The remainder is structured as follows: in Section 2 we identify the need for a systematic literature review on occupational health and safety within the area of service research as well as derive our research questions. Subsequently, in Section 3, we present the methodology for the systematic literature review. The results of our systematic literature review will be presented in Section 4. Results of the review, suggestions for future research, managerial implications, and limitations and conclusions of our research will be identified and discussed in Section 5, Section 6, Section 7, and Section 8.

2 The Need for a Systematic Literature Review on Occupational Health and Safety in Services

Systematic literature reviews serve as a method for the synthesis of knowledge within a specific area of research. They pinpoint key contributions and uncover gaps and weaknesses in past research. Results of systematic literature reviews guide future research (Cooper, 1998, 3). Furthermore, they narrow down the gap between research and practice by presenting the state of the art of research in a certain field of interest (Denyer & Tranfield, 2006, 214). The systematic fashion of the review process reduces biases that originate from the researchers conducting the review, e.g., using feedback loops, (Kitchenham, 2004; Tranfield, Denyer, & Smart, 2003). Therefore, reliable and reproducible evidence is generated (Cooper, 1998, 3). Within our research context, the systematic literature review is considered to be an

appropriate means to synthesize detailed knowledge about the interdependencies between occupational health and safety and employee satisfaction, employee motivation, and productivity.

Neither in the area of services nor in the field of occupational health and safety research systematic literature reviews have been conducted. However, our literature search revealed that several reviews (systematic and non-systematic) in the field of occupational health and safety research exist each targeting different key aspects. For instance, factors influencing occupational health and safety of young employees were elaborated from a literature review by Laberge and Ledoux (2011). Additionally, literature on particular service industries, e.g., construction industry (Laukkanen, 1999), or defined work spaces, e.g., robot workplaces (Helander, 1991), was reviewed. Literature reviews targeting at the evaluation of specific occupational health and safety measures were conducted in the attempt to unveil the potential influence of occupational health and safety measures on performance indicators of a firm (Olson, Winchester, 2008; Robson et al., 2007). Regardless, evidence was not sufficient in these days (Robson et al., 2007, 349) and newer results of research in this field have to be considered. One review that regards the interdependencies of employee satisfaction, employee motivation, and productivity with occupational health and safety is missing. Our paper aims at closing this knowledge gap by undertaking a systematic literature review and answering the following research question:

RQ: Which interdependencies between occupational health and safety and employee satisfaction, employee motivation, and productivity in services exist?

In order to answer this question, we will also discuss the changes of occupational health and safety needs of service employees over time that may have arisen from development and integration of technology in services and put into question the examination of the services industry in isolation from the manufacturing sector.¹⁴²

Results of this review are expected to facilitate the justification of occupational health and safety measures in general as well as encourage practitioners to invest in corresponding programs. Furthermore, the development of proper measures tailored to the specific needs of employees in different service areas will be forwarded.

3 Methodology

Within our systematic literature review we considered several approaches of different researchers from different fields of study (Cooper, 1998; Kitchenham, 2004; Tranfield, Denyer, & Smart, 2003). This enabled us to refine the stages of the review process and customize them to the needs of our specific research topic. Especially the proposed approach of Kitchenham (2004) enriched our review process with several feedback loops that contributed to the reduction of bias. As a result, we conducted the systematic literature review undergoing the stages presented in Figure 1.

Figure 1. Systematic Literature Review Process.

One of the first things within the systematic literature review which needs to be done is the definition of the search terms. In accordance with Kitchenham (2004, 7-8), we conducted a prior search in Google Scholar to refine search terms and increase the accuracy of results. Thereby, we focused on literature reviews (systematic and non-systematic) on the topic of occupational safety in general. The corresponding results helped us to find synonymous expressions for occupational safety that are “in use” in research. As well as this, we reduced the terms “employee motivation” and

¹⁴² Thanks to an anonymous reviewer who made this suggestion.

“employee satisfaction” to “motivation” and “satisfaction” to not exclude relevant articles from the review. For the same reason we did not include the term “service” or “services” in our search. In order to prevent the exclusion of articles that were carried out in a specific service branch, e.g. public administration. We conducted the search using search strings that were a combination of occupational safety or one of its synonyms and one of the terms “productivity”, “motivation”, or “satisfaction”. The list of search terms that were used is shown in Table 1.

Table 1. Search Terms for Electronic Databases.

Coding	Search Item
A	Occupational safety
B*	Workplace safety
C*	Safety at work
D*	Job safety
E	Productivity
F	Motivation
G	Satisfaction
*	Synonymous expressions for occupational safety

The search strings were employed in nine electronic databases. The complete list of electronic databases is shown in Table 2. We restricted our search to articles published in English. Additionally, they need to be published within January 1990 and December 2013. As another constraint, we only considered academic journals. Depending on the search mask of the electronic database, search terms or search strings were employed in the search fields “title of the publication”, “abstract”, or “full text”. We coded the different fields where search terms can be entered resulting in a three digit letter combination. Position one in this combination was assigned to the “title of the publication”, position two to the “abstract”, and position three to the “full text”. For instance, if the electronic database enabled the researcher to search for “occupational safety” in the title of publications and for “productivity” in the full text of the publication, this would result in the combination A.0.E with zero stating that none of the search terms were searched in the abstracts of publications. The results of the search in the electronic databases and the correspondent results are presented in Table 2.

Table 2. Number of Search Results per Electronic Database.

Database	1990-2013
Science Direct	608
Business Source Premier	396
Taylor & Francis	235
Wiley Online Library	118
Web of Science	101
Emerald Insight	88
Econ Biz	65
SpringerLink	58
SAGE Journals	38
	1707

Our database search for relevant literature resulted in 1,707 hits. The list of results underwent several steps of reduction, which included the removal of duplicates and of articles published in a language other than English. Due to the varying search masks offered by the databases, it was not possible to exclude publications from the research results that were not articles published in academic journals. Therefore, one selection step was to remove book reviews, books, or chapters of collected editions as well as non-article journal components, e.g., editorials, from the search results. Further inclusion and exclusion criteria are defined and described in Table 3.

Table 3. Inclusion and Exclusion Criteria for Articles.

Inclusion Criteria (IC)	Description
IC-1	The article’s subject is occupational health and safety management, the implementation and evaluation of occupational health and safety interventions, or the assessment of occupational health and safety risks.
IC-2	The article presents an empirical study carried out in the context of occupational health and safety.
IC-3	The empirical study presented in the article contains variables that can be interpreted as operationalization of occupational health and safety, productivity, employee motivation, or employee satisfaction.
IC-4	The empirical study presented in the article analyses the relationships between the variables occupational health and safety and productivity, employee motivation, and employee satisfaction.
Exclusion Criteria (EC)	Description
EC-1	The article’s full text was not accessible or available until the completion of this review article.
EC-2	The article presents an empirical study that is published again in a newer article.
EC-3	The article’s main focus is on reviewing literature on the topic of occupational health and safety.
EC-4	The article’s main focus is on proposing a model, framework, or research agenda on the topic of occupational health and safety.

To apply inclusion criterion 4 (see Table 3), we had to define *productivity*, *employee motivation*, and *employee satisfaction* first. Accordingly, *productivity* has to be an output-input-relationship with the outputs and the inputs not being further determined. *Employee motivation* is a process that fosters engagement, performance, and continuity within the occupational context (Luthans, 1998). *Employee satisfaction* can be described as a „(...) favorable attitude or pleasurable emotional state that result from a Person’s job experience or a fit between a person and an organization“ (Wanous, Lawler, 1972, 57).

Based on the above inclusion and exclusion criteria, the selection process was performed independently by the two authors. Subsequently to every selection step, the results were compared and discrepancies were discussed. The selection steps and the corresponding results of single selection steps are shown in Figure 2.

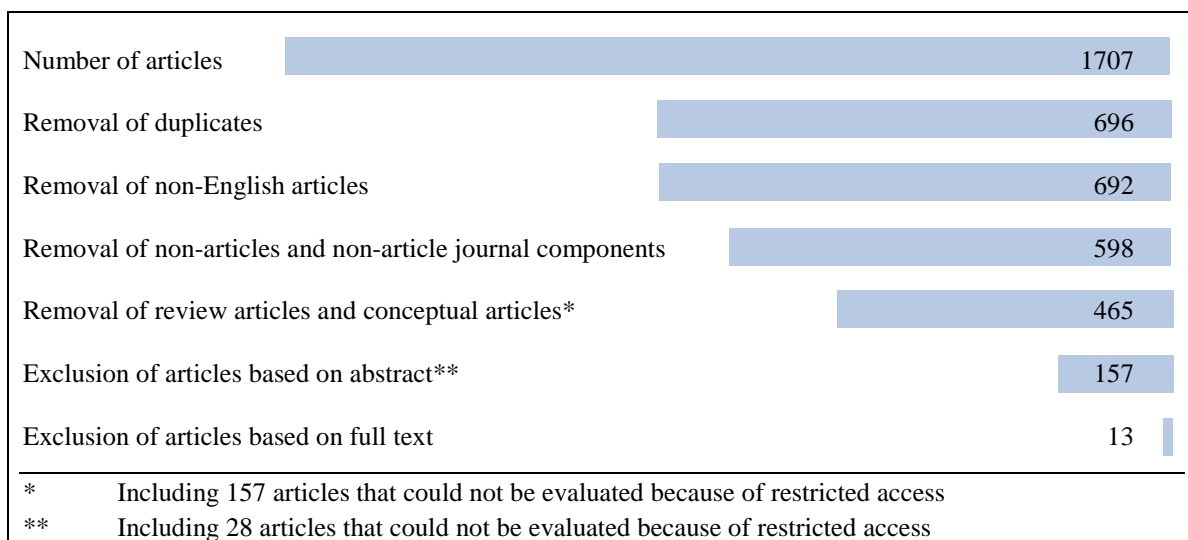

Figure 2. Selection Steps and Corresponding Results.

To answer the research question defined in Section 2, we needed to extract corresponding data based on the final selection of studies (Harden, Garcia, Oliver, Rees, Shepherd, Brunton, Oakley, 2004, 796). The first three data items

provide information about the year of publication (DI-1), the journal the article was published in (DI-2), and the country of origin of researchers who wrote the article (DI-3). It should be noted that this systematic literature review focuses on services. Therefore, data about the setting of the study has to be provided (DI-4a). If available, information about the concrete industry where the study was carried out was extracted also (DI-4b). Further, it was assessed whether data presented in the articles was collected predominantly through a quantitative or qualitative approach or a combination of both (DI-5a) and which concrete approach was employed (DI-5b). Decisive for this review were the interdependencies between the variables of occupational health and safety, productivity, employee motivation, and employee satisfaction. Hence, data items 6, 7, 8, and 9 present information about whether the variables were included and how they are coded in the article. Data about the interdependencies of these variables is given by data item 10. Both authors performed the data extraction independently and reviewed the results from the other when finished. Discrepancies were discussed and revised. The data items are presented in Table 4.

Table 4. Data Items and Description.

Data Item	Description
DI-1	Publication year
DI-2	Journal
DI-3	Researchers' country
DI-4a	Manufacturing (M) or Service Sector (S)
DI-4b	Specific industry or industries
DI-5a	Qualitative (1) or quantitative approach (2)
DI-5b	Method for data collection
DI-6	Operationalisation of occupational health and safety
DI-7	Operationalisation of productivity
DI-8	Operationalisation of employee motivation
DI-9	Operationalisation of employee satisfaction
DI-10	Relationship between variables analysed

In order to synthesise the resulting data we chose the narrative synthesis approach (Barnett-Page, Thomas, 2009; Denyer, Tranfield, 2006). This approach fits best to the structure and to the characteristics of our search results. It allows combining studies that used quantitative and qualitative approaches for data collection (Lukas, Baird, Arai, Law, Robert, 2007, 4) and incorporate the different embodiments of the concept of occupational health and safety that were found in the articles reviewed (Denyer, Tranfield, 2006, 219; see Section 4). Furthermore, the narrative synthesis approach aims at the provision of deep insights into a complicated research topic encouraging researchers and practitioners alike, and sharpening their view for future research and development of best practices (Rummrig, Fitzgerald, 2001). This corresponds with our research goals defined at the end of Section 2.

4 Results

According to the selection of studies as presented in Table 6 data from thirteen articles has been extracted. After we synthesised the data, the following results could be derived.

4.1 Geographical Distribution

Regarding the geographical distribution of articles, research from the USA was presented in five articles, two studies were carried out in Australia, and Asian and European countries were represented with one article each. Two articles were a joint work of researchers from two different countries (Taiwan and USA, Australia and the Netherlands). Research from African countries was not included.

4.2 Temporal Extent

Figure 3 presents the distribution of articles over time.

Figure 3. Distribution of Articles from 1990 to 2013.

Eleven articles were published after year 2000 and two articles were published before (1995 and 1999).

4.3 Sector

Six studies were carried out in services, three studies were settled in the manufacturing sector, and four studies were conducted in the service and the manufacturing sector. The particular branches covered by the studies are presented in Table 5. Three articles did not provide information about the particular branch in which the study was carried out.

Table 5. Manufacturing and Service Industries Presented by the Reviewed Studies.

Manufacturing Sector	Services Sector
Electronics	Construction
Metal	Health Care and Community Services
Plastic	Education
Food	Hoteling
Chemical	Insurance
Paper and Packaging	Public Administration
	Retail Trade
	Fire Service

4.4 Methodology

Only two articles employed a qualitative approach using a case study or case study like approach including interviews and observations for gathering data. Besides standardized (one study) and telephone assisted interviewing (one study), a questionnaire instrument was the predominant method to collect data in the studies using a quantitative approach (nine studies).

4.5 Operationalisation of Variables

The construct of occupational health and safety was presented heterogeneously in the included studies. There are researchers (Kilic, Selvi, 2009; Leoni, 2010) that measure occupational health and safety by a combination of items that assess and evaluate the actual occupational health and safety risks, the assessment of safety measures as well as the evaluation of the workplace. Thereby, general issues such as light, temperature, or aspects of working life that are not directly associated with the occupational health and safety measures employed by a firm are considered, e.g., employee awards or sufficiency of salaries (Kilic, Selvi, 2009, 913). Other studies put more emphasis on the “safety” aspect of occupational health and safety. Concrete safety measures, e.g., analysis of hazards, employee training (Shikdar, Sawaqed, 2003, 564), the use of special equipment (Mitropoulos, Cupido, 2009, 411), ergonomic interventions (Yeow, Nath Sen, 2003, 153), the safety management system implemented by the firm, e.g., planning for the case of emergency (Fernández-Muñiz, Montes-Peón, Vázquez-Ordás, 2009, 981), or a combination (Hadjimanolis, Boustras, 2013, 52-53) were measured. In contrast to the aforementioned studies, some studies dedicated focus on the assessment of actual and perceived risks. Liu and Hammitt (1999, 266-267) differentiate between perceived risks of “disabling injury” or “death”, McLain (1995, 1731-1732) assesses amongst others danger and the distribution of risk exposure for every employee, Huang, Chen, Rogers, and Krauss (2003, 253) used a one item scale to measure the employee’s estimation of the probability of getting injured on the job. Furthermore, two studies assessed the occupational health and safety using the construct of psychosocial safety climate (Dollard, Bakker, 2010; Law, Dollard, Tuckey, Dormann, 2011). One study measured job demands, e.g., risks and hazards, and job resources, e.g., safety climate (Nahrgang, Morgeson, Hofmann, 2011, 2). The operationalization of occupational health and safety as well as the variables productivity, employee motivation, and employee satisfaction are demonstrated in Table 6.

Table 6. Operationalisation of Occupational Health and Safety, Employee Motivation, and Employee Satisfaction.

Operationalization of	Occupational Health and Safety	Productivity	Employee motivation	Employee satisfaction
Authors				
Dollard, Bakker, 2010	Psychosocial safety climate (4 items)		Engagement (2 items)	
Fernández-Muñiz, Montes-Peón, Vázquez-Ordás, 2009	Safety policy (4 items), employees’ incentives (5 items), training in occupational hazards (9 items), communication in prevention matters (4 items), preventive planning (11 items)	Productivity (1 item)	Employee Motivation (1 item)	
Hadjimanolis, Boustras, 2013	Occupational health and safety policies and programs (5 items), safety climate (6 items), safety performance (4 items)			Employee satisfaction (3 items), organisational commitment (5 items)
Huang, Chen, Rogers, Krauss, 2003	Perceived injury risk (1 item)			Employee satisfaction (2 items)
Kilic, Selvi, 2009	Occupational health and security risk factors (25 items)			Employee satisfaction (20 items)
Law, Dollard, Tuckey, Dormann, 2011	Psychosocial safety climate (12 items)		Engagement (9 items)	
Leoni, 2010	Exposure to hazards (10 items); job characteristics (13 items)			Worker satisfaction
Liu, Hammitt, 1999	Perceived risk of disabling injury (20 items), perceived risk of death (20 items)			Rework intentions (1 item); quit intentions (1 item)
McLain, 1995	Danger (6 items), perceived risk (1 item), risk exposure distribution (4 items), economic value of health and safety (1 item)			Workplace satisfaction (6 items), overall employee satisfaction (3 items)
Mitropoulos, Cupido, 2009	Safety measures (10 items)	Work pace including time for reworking mistakes		

Operationalization of	Occupational Health and Safety	Productivity	Employee motivation	Employee satisfaction
Authors				
Nahrgang, Morgeson, Hofmann, 2011	Job demands (risks & hazards); burnout, job resource (safety climate)			Engagement (employee satisfaction, satisfaction with organisation, organisational commitment)
Shikdar, Sawaqed, 2003	Occupational health and safety compliance, hazard analysis, task analysis, ergonomic assessment	Productivity, absenteeism, lost work days, low work quality		Dissatisfaction
Yeow, Nath Sen, 2003	Ergonomic interventions	Cycle time, productivity		

None of the studies reviewed analyses occupational health and safety and its relationship to all three variables. Two studies analyzed the influences of occupational health and safety on productivity and employee motivation or on productivity and employee satisfaction, respectively. Three studies founded their proposed theoretical models on the job demands-job resources model; two of these expanded the job demands-job resources model with the construct of psychosocial safety climate.

With regards to the results of the studies, occupational health and safety has a positive influence on productivity (Fernández-Muñiz, Montes-Peón, Vázquez-Ordás, 2009; Yeow, Nath Sen, 2003) or can be seen as an indicator for productivity related problems (Mitropoulos, Cupido, 2009; Shikdar, Sawaqed, 2003). Employee motivation is also positively influenced by occupational health and safety. Although the effects of occupational health and safety measures on productivity are stronger (Fernández-Muñiz, Montes-Peón, Vázquez-Ordás, 2009). Furthermore, effects on employee motivation are the result of a particular mediator, e.g., skill discretion and decision authority (Dollard, Bakker, 2010), or job rewards (Law, Dollard, Tuckey, Dormann, 2011). Referring to employee satisfaction, the presence of risks to occupational health and safety does not automatically have significant influence (McLain, 1995; Nahrgang, Morgeson, Hofmann, 2011), whereas insufficient information about health and safety risks (Leoni, 2010) or inappropriate safety measures decreased employee satisfaction (Hadjimanolis, Boustras, 2013; Kilic, Selvi, 2009). Health and safety risks which are perceived as low resulted in high levels of employee satisfaction (McLain, 1995). The perception of safety risks as high resulted in an increase of employees’ intentions to quit the job and decreased intentions to continue with it (Liu, Hammitt, 1999).

5 Discussion

Despite of the little number of studies reviewed, research from the USA is presented by five articles and can therefore be considered as predominant. With regard to the distribution of articles over time it can be denoted that the majority of eleven articles were published after the year 2000. Only two articles were published before. This unequal distribution could be attributed to the development of information and communication technologies (ICT) in the late 1990s. The latter may have awoken awareness for occupational health and safety needs. At the same time, ICT facilitated the access to and the processing of data for researchers. Contrary to the focus of our paper on service firms, we included both manufacturing and service firms in our review. In fact, there were more studies carried out in services than in manufacturing. It could be assumed that the development and fit of regulatory frameworks on occupational health and safety in manufacturing is more advanced than in services. This in turn could be due to the industrialization that preceded the ongoing service revolution. Apart from that, the distinction between manufacturing and services when examining occupational health and safety from an employee’s perspective may be unnecessary. No matter in what kind of industry people are working, employees offer their manpower as a kind of a paid “service” to a firm. From this perspective, there is no occupational health and safety for manufacturing or service firms. Instead there is occupational health and safety tailored to the specific needs of employees on basis of the core activities they have to do at their work. This coincided with the findings of Shikdar and Sawaqed (2003, 569). The minor presence of qualitative approaches in the reviewed studies can be attributed to the higher acknowledgement of quantitative studies in research (Tashakkori, Teddlie, 1998, 3-13).

Further examination of the operationalization of occupational health and safety revealed that there are two theoretical approaches which appear to be influential. Both were represented within the articles reviewed. The first one is the job demands-job resources model (Bakker, Demerouti, 2007; Demerouti, Bakker, Nachreiner, Schaufeli, 2001; Schaufeli, Bakker, 2004) that assigns risk factors threatening occupational health and safety to either job demands or job resources. During earlier stages of this systematic literature review, we came across several researchers who used the job demands-job resources model as a foundation for their studies focusing on specific target groups, e.g., injured

union and non-union workers (Gillen, Baltz, Gassel, Kirsch, Vaccaro, 2002), workers on offshore installations (Nielsen, Mearns, Matthiesen, Eid, 2011), or cabin crews (Chen, Chen, 2014). However, latest research proved the job demands-job resources model as being a valuable tool for the analysis of factors influencing, e.g., the safety performance of employees taking into account participation and compliance to safety measures (Turner, Stride, Carter, McCaughey, Carroll, 2012) or employees' emotional exhaustion (Li, Jiang, Yao, Li, 2013).

The second theoretical approach expands the job demands-job resources model. The concept of "psychosocial safety climate" is introduced and seen as a preceding factor of job demands and job resources (Zohar, 1980; Zohar, 2003). The concept of "psychosocial safety climate" can be denoted as "*freedom from psychological and social risk or harm*" (Dollard, Bakker, 2010, 580). It constitutes a combination of aspects tackling the protection of the physical and psychological health of employees as well as their social well-being (Dollard, Bakker, 2010, 580). It was proved to be a predictor of psychological strain (Dollard; Opie; Lenthal; Wakerman; Knight; Dunn; Rickard; MacLeod, 2012), workgroup distress (Dollard, Tuckey, Dormann, 2012), and injuries occurring at particular work environments such as farming (Glasscock; Rasmussen; Carstensen; Hansen, 2006). The relationship between occupational health and safety and productivity appears to be manifold. It was stated that occupational health and safety measures unfold a positive influence on productivity. But it can be argued that pushing productivity increases the number of accidents and injuries and, that the work pace must fit the tasks that have to be accomplished (Filler, Golbe, 2003; Shikdar, Sawaqed, 2003). Mitropoulos and Cupido (2009) conducted a case study and confirmed this argument with their findings. They compared two framing crews and came to the conclusion that high productivity does not necessarily goes together with an elevated work pace. Instead, they found out that one framing crew took more time for specific tasks than the other but experienced no accidents and spent less time for the reworking of mistakes.

6 Implications for Future Research and Practitioners

This systematic literature review revealed that there is a substantial basis of research within the field of occupational health and safety. However, there were only few studies that analyse occupational health and safety together with productivity, employee motivation, and employee satisfaction. Therefore, future research should focus on these variables. Also quality issues may be of relevance and should be taken into account. Crucial for future research will be the definition of the concept of occupational health and safety. Our review showed that occupational health and safety comprises several dimensions of health and safety in the workplace ranging from perceived risks, actual risks, communication and training, and safety measures or combinations (see Section 5). When developing a definition for occupational health and safety, regulatory frameworks on occupational health and safety and the specific safety needs of employees that go beyond the minimum set of legal regulations have to be considered. A uniform definition of occupational health and safety would add value to studies conducted in the future. It would enable researchers to develop an appropriate scale for measuring occupational health and safety. Moreover, comparisons between firms and their occupational health and safety systems could be realised. Even the employment of meta-analytic approaches might be facilitated. While interdependencies between productivity, employee motivation, and employee satisfaction are a constant issue in service research, occupational safety and its interdependencies is poorly researched. In fact, the majority of articles that we came across during this review evolved from ergonomics, industrial science and safety science.

Contrary to our assumption, practitioners seem to have recognized the importance of protecting their employees against occupational health and safety risks. Still, occupational health and safety management systems are not a natural consequence, especially in developing countries (Shikdar, Sawaqed, 2003).

7 Limitation of the Systematic Literature Review

This systematic literature review involves several limitations. Regarding the search process our initial search resulted in 1,707 hits. In comparison to other systematic reviews carried out in the field of occupational health and safety (see Section 2), this number is rather small. Reasons for this can be twofold. First, this result can be attributed to our search strategy. Some search terms were exclusively employed for the search in the titles of publications and others exclusively in the search of full texts of publications. However, our initial search contained approximately 1,000 duplicates. The proportion of 60% of duplicates can be considered as an indicator pointing at the fact that fewer databases might have been sufficient. Second, when defining the search terms, we only considered synonymous expressions of occupational health and safety. Synonyms for the search terms *productivity*, *motivation*, and *satisfaction* were not defined and employed in the search. With regard to the articles finally included in the review, synonyms for productivity, e.g., performance, for motivation, e.g. engagement, and for satisfaction, e.g., rework or quit intentions, coexisted. Because of the high proportion of duplicates, we did not conduct a retrospective, e.g., by analysing the reference lists of included articles, nor a prospective search, e.g., using the "cited by" function in Google Scholar. Still, we spot-checked the reference lists of four of the finally included articles. More than three quarters of references containing occupational safety or one of its synonymous expressions in the title were already covered by our initial search which strengthens our point. The review is restricted on articles that were published in academic journals only. Academic journals publish the latest state of the art of particular research areas. Further, they can be regarded as reliable sources that maintain a relatively constant level of quality. By this constraint, we also excluded conference proceedings

from our review except they were published in an academic journal. Four non-English texts were excluded from the review. Making up only 0.2% of the initial search results, the language bias caused by the exclusion of these articles is rather small.

8 Conclusion

By this systematic literature review we aimed to find out which interdependencies exist between occupational health and safety and productivity, employee motivation, and employee satisfaction. We could confirm the existence of interdependent relationships between these variables. Further, these interdependencies could be observed in different industries. The substantial lack of a homogeneous definition of what it means for a firm to apply and perform occupational health and safety, complicates the generalisation of findings.

The role of quality certifications in exports of Chilean information technology services

Marcela Gómez¹, Nanno Mulder²

¹University of Chile, ²UN Economic Commission for Latin America and Caribbean

Information technology (IT) services have been a fast growing category of Chilean exports over the past decade. A parallel trend has been the spread of different types of quality certifications (QCs). This paper explores the hypothesis that the export performance is linked to the adoption of QCs to demonstrate capabilities to foreign clients. An alternative hypothesis is that QCs are mainly motivated by efficiency improvements. These hypotheses are explored using a semi-structured questionnaire which was sent to all 110 members of the Chilean Association of IT services firms. With a return rate of 38%, results suggest most firms adopted QCs to cut costs rather than improve their status before foreign buyers.

1 Introduction

Information technology (IT) services have been one of the fastest growing sectors of the Chilean economy over the past decade.¹⁴³ From 2001 to 2011, the value of its sales grew 14% per year on average. During the same period, the number of firms almost doubled from 580 to 1,032. Also, employment more than doubled from 16.7 thousand to 37.5 thousand persons engaged (National Statistical Institute, Encuesta Estructural de Servicios Anual). Exports grew at an average annual rate of 18.3% during this period, reaching US\$ 206 million in 2012.

Several factors may explain the rapid expansion of Chile's IT sector. First, there has been a high demand for IT services in the economy that aimed to increase its productivity and competitiveness. One expression of this was Chile's high investment rate in IT in 2012 (2.1% of GDP), which was among the highest in Latin America, according to the International Data Corporation. Second, the country has introduced several public-private initiatives (encompassing government institutions, business organizations and academia). These are aimed to modernize the public sector, reduce the productivity gap between small and large enterprises through the use of IT, and increase the attractiveness of Chile as a platform for IT offshore services for the rest of Latin America. A third factor has been the rapid spread of broadband in the country (Rivera von Hagen, Marinao and Mulder, 2014).

A parallel trend in Chile has been a fast adoption of different types of quality certifications (QCs). Within this sector, the most common QCs are Capability Maturity Model Integration (CMMI), ISO 9001 (a multisectoral standard) and IT Infrastructure Library Information (ITIL). Although there is a relatively abundant literature on the contribution of standards to goods trade, evidence on their role in IT services trade is limited to a few cases in India.

This paper explores the hypothesis that the rapid expansion of the Chilean IT sector's exports is linked to the adoption of international quality certifications (QCs) as a means to reduce information asymmetries between sellers and foreign buyers. This signal effect should directly boost exports. An alternative hypothesis is that firms adopt QCs to streamline procedures and cut costs, which does not directly impact on exports. Due to a lack of detailed data on Chilean IT firms, it is not possible to do econometric analyses to test both hypotheses. Instead a special survey was carried out. This study reports some exploratory results of a special survey conducted among the 110 members of the largest IT service producers association.

The survey's results provide some first answers on the use and motivations of QCs by Chilean IT producers. It turns out the majority of firms that answered the questionnaire have adopted some kind of certification to reduce costs and few have incorporated QCs to improve their status vis a vis foreign clients. The latter may result from the fact that most exports are to other Latin American countries, of which currently few require these QCs.
