The final component of the framework reflects the short-term and long-term *outcomes* of smartServPPINs, which can be conceptualized through a multi-dimensional and multi-level categorization. Specifically, we can identify innovation outcomes at four interrelated levels: 1) the innovative solution realized through the project; 2) the network; 3) the city; 4) the intercity level. As to the first level, the type of innovation (technological, non-technological), its degree of novelty and replicability are the most significant elements to consider. Developing new technological solutions, such as electronic management systems, digital platforms and e-service applications is a key objective for many smart city initiatives. However, the development of new technological applications in smart city projects is often the enabling condition for other (central) innovation outputs: *service innovations* in different smartness fields, i.e. the development of new or improved services for city users, such as new energy-efficient services (smart environment), e-car sharing and e-bike services (smart mobility); *social innovations*, i.e. the behavioural change of citizens (e.g. the reduction of their energy consumption) or the community involvement in public decision-making; *network-based innovations*, when the main goal of the project is the establishment of a new collaborative arrangement between private and public organizations. The replicability of the innovative solution is linked to the possibility of increasing the size of the related project by involving more stakeholders (also from different cities), funding and services (scaling of the project), or extending the geographical area of application/adoption of the solution within the same city or, more ambitiously, in other smart cities (European Parliament, 2014). At the network level, the main innovation outcomes can be primarily measured in terms of acquisition of new skills and competences by participants in the innovation network (learning) and increased social capital, especially in the form of accrued mutual trust. Acquiring new knowledge is key for both private and public organizations, since it increases their innovation capability and fosters knowledge transfer across different innovation projects (i.e. a specific partner would operate as a knowledge gatekeeper from one project to another). In a similar way, if trust building is a matched goal of project-based collaboration, this will reveal a crucial intangible asset for starting new innovation projects with the trusted partners. At the city level, the overall goal of any smart city strategy would always be to realize significant economic (e.g. new job opportunities, new businesses), social (e.g. better health, timesaving, democratic governance) and environmental (e.g. energy saving and lower Co2 emissions) outcomes through a portfolio of relevant initiatives and innovation projects. Finally, at the intercity level, the main outcomes derive from the possibility of benefiting from the practice transfer and learning from new and different environments. This can yield, among others, opportunities for a better assessment of the suitability of innovations for different circumstances and for improving their replicability and dissemination.

5 A comparative analysis of European smartServPINNs

Against the background of this conceptual framework, an exploratory empirical analysis was conducted based on two European case studies. Specifically, two smart city projects and the innovation networks associated with them have been analysed and compared in order to confront our framework with empirical evidences and add new insights on the nature and role of ServPPINs in the emerging and complex smart city landscape.

5.1 Method

The empirical investigation has been conducted through an explorative multiple case study analysis (Eisenhardt, 1989; Yin, 2003). This method allows in-depth insights into emerging fields and is particularly suitable for addressing ‘why’ and ‘how’ questions of the phenomenon under investigation (Yin, 2003). Therefore, it has been selected as the most appropriate method for addressing our research goals. In more detail, the first objective is to validate our framework for exploring the characteristics and role of ServPPINs in the implementation of smart city innovation projects. In this respect, in-depth case study analysis is aimed at showing how the complexity of these organizational arrangements can be disentangled by focusing on a set of nested components that encompass: 1) the structural features of these innovation

networks as well as their dynamics; 2) the innovation outcomes produced at various levels; 3) the broader smart city innovation context, which creates the general environment within which specific ServPPINs unfold over time and provides external drivers for their formation and up-take; 4) the networking regime, which creates the set of conditions of collaboration at project level and provides the internal drivers of smartServPPINs. The second objective is to provide an empirical contribution to advance existing knowledge on the characteristics of smartServPPINs, their set up and governance, and the relative importance of different drivers for the successful development of innovations for the smart transformation of cities. The case study analysis allows us to gain new knowledge about the functioning ('how' and 'why') of public-private service innovation networks through a deeper analysis in the smart city context.

The analysis is based on two case studies conducted by the authors within a broader research project that considers a number of European smart cities and focuses on several innovation projects within each of them. The selection of the cases was carried out at two different levels: the smart city level and the project level to which service innovation networks are associated. As to the first level, two cities being strongly committed and engaged in a *smarticization* process have been identified among a list of European best practices, which was compiled on the basis of available rankings, indexes, awards (including Ranking of European Medium-Sized Cities; Between Smart City Index; IDC Smart City Index; IESE Cities in Motion Index; World Smart City Awards). The fact that the two cities have both a formal 'smart strategy' plan and that innovation projects are part of a broader public mission towards the smart development of the city allows us for comparison. However, the two cities present differences in terms of focus, number and integration of initiatives and projects carried out under the smart city 'umbrella'. This allows us to examine the influence of the specific smart city innovation context on the development and operation of the two smartServPPINs under examination. With regard to the second level, this study adopted the selection criteria developed within the European FP7 Project ServPPIN - *The Contribution of Public and Private Services to European Growth and Welfare, and the Role of Public-Private Innovation Networks* (Gallouj *et al.*, 2013a): (1) the cases have a concrete innovation aiming at the improvement in service characteristics; (2) there is a constellation of public-private organizations that is central to the realization of the innovation in focus. Consistently with these criteria, we selected two cases: the Climate Street (*Klimaatstraat*) project in Amsterdam (The Netherlands) and the Love City Index project in Siracusa (Italy).

Climate Street (CS) represents a flagship innovation project among the official pilots of the Amsterdam Smart City Program, whose primary goal was the reduction of CO₂ emissions and energy consumption in a popular shopping street (the *Utrechtsestraat*) so as to improve its sustainability and its attractiveness for city visitors. The pilot was conceived as a small scale city demonstration and a testing pilot for a portfolio of sustainable innovations and advanced energy saving technologies (sensor monitoring systems for efficient energy management, smart solutions for public spaces, sustainable waste logistics innovations). The pilot was launched in 2009 by the Amsterdam Smart City (ASC), which is a public-private partnership set up to stimulate and advance local innovation projects aimed at testing and developing smart technology solutions focused on energy transition and open connectivity. Initiated in 2009 by the Amsterdam Economic Board (a not-profit public organization), the City of Amsterdam and two private companies, ASC has grown over two years to include more than 70 partners among businesses, authorities, research institutions and the citizens and more than 20 pilots. Among these formal projects, CS has been established as an international best practice of smart initiatives oriented at maximum energy efficiency and minimum environmental impact in the city and it is widely considered as a blueprint for other European cities (Amsterdam Smart City, 2011). The success of the project and its replication potential is also proved by the subsequent development of the smart device "Quby", an energy management system awarded with the 'Smart Grid Innovation Awards 2011' and implemented by 30 entrepreneurs in the Climate Street. Indeed, through the testing phase and end users' involvement, not only the Quby Owner (Home Automation Europe) further developed the device and scaled up its product abroad, but also one of the big energy companies in the Netherlands (Eneco) currently offers the Quby device free to its customers. The *Love City Index Siracusa* (LCIS) project was developed after that in 2012 the city of Siracusa was selected as the only Italian one for 'Smarter Cities Challenge', IBM's global competitive grants program that funds the deployment of IBM's top experts to cities' worldwide to help them address critical challenges and become smarter. During three weeks in June 2012, a team of six IBM experts worked in the city to deliver recommendations on the key challenges identified by the municipality, after analysing all relevant data and reports and meeting several representatives of local stakeholders (public actors, private firms, non-profit organisations, associations, citizens). Based on IBM team's findings, six fundamental 'pillar' recommendations were developed together with various projects that lay out how each recommendation could be achieved. In particular, one of them is directed to improve the tourist infrastructure and services, concentrating on understanding tourism needs and behaviours (IBM, 2012). In line with this goal, in September 2013 the LCIS project started with the purpose of developing a new mobile application, which is meant to be not only a digital guide for city visitors, but also a tool to engage them in the preservation of Siracusa's outstanding cultural heritage, which is part of the UNESCO World Heritage List. Through the three functionalities of the app (*Know-Feel-Act*), the user can get information about the selected point of interest (e.g. history, visiting hours, contact references, best next places around); communicate and share his/her feelings ('love') in front of the visited place; and, give his/her own opinions, suggestions and comments as an 'expert evaluator' to preserve Siracusa and its heritage. The 'buzz' and suggestions generated through the app are evaluated through social analytics in order to detect the Love Index of the city and give the public decision makers valuable information on the actions to be taken to preserve the sense of love people feel and improve the local tourist/cultural services. The first release of the Love City Index app (LCISiracusa) includes more than 60 points of interest in three different categories (Products, Landscapes, Buildings and Places) and received in 2014 the

Smart City Award at the most important Italian event dedicated to ICT (Smau). Siracusa municipality is actually engaged in the up grading of the app to extend the service to 1000 points of interest all over the surrounding territory.

Data about these cases were collected through a combination of sources, including secondary sources (reports, press articles, projects material, websites) and a series of semi-structured interviews with key actors, i.e. projects' leads and members of organisations involved in the projects. The interviews were conducted in the period May-July 2014, based on a semi-structured interview guide aimed at gathering information on the role of different actors in the network, the relationships among them, the governance and information mechanisms, the drivers and barriers to collaboration in the smartServPPINs, the short-term and long-term outcomes. Collected data were then compiled along the components of the framework in order to compare the information from the cases.

5.2 Results and discussion

In this section the selected smartServPPINs are analyzed and compared according to the framework's components. Looking first at their structures and processes, the two cases differ significantly in terms of composition, modes of inducement, governance structures and dynamics. In more detail, the network associated to the CS project was quite broad and diversified, including 19 partners from both the public and private sector. Private companies were mostly technology providers operating in different sectors (e.g. utilities and infrastructures, telecommunications, logistics) and included local providers and techno startups next to international players, such as Vodafone and Philips. However, the smartServPPIN was initiated by a small core team of partners: Amsterdam Smart City; Van Gansewinkel, a local waste collecting private company; Club of 30, a project organization specialized in the implementation of sustainable operational process solutions that was formally given the role of project management by ASC; the young Utrechtsestraat Business Association, involving all the 120 entrepreneurs of the street and represented by the shopping street manager. The formation of the innovation network was driven, through a bottom-up approach, by the decisive action of Van Gansewinkel that proposed the idea for the project to ASC, the shopping street manager and the association of local entrepreneurs. Involving the end-users (the entrepreneurs) in the innovation network as formal partners was the main goal of the initiators, since a number of technological innovations (including smart grids, energy scanners and smart meters) needed to be tested through real-life, daily use at the entrepreneurs' workplace, i.e. bars, restaurants and local shops in the street. At the same time, their involvement was necessary to achieve the long-term goal of the CS project, namely the change of end users' behavior and patterns of energy consumption. Beside the local entrepreneurs, the choice of the cooperation was predetermined (path dependent) only for Van Gansewinkel that previously collaborated with the municipality of Amsterdam and for Club of 30, which was directed by the prior commercial director of Van Gansenwinkel when the project was formally launched. For the vast majority of private companies that joined the project as development partners, the forms of partner selection corresponded rather to the supply chain type of the network (Schartinger, 2013). Specifically, the contributions of most partners did depend much upon their specific resources, i.e. finance, market knowledge as well as technology-based services to showcase in the street. Other network partners, such as utilities and infrastructure providers were selected by a call for tender based on their technical know-how and resources. As for entrepreneurs, only a small group of 40 inspired and motivated entrepreneurs was initially involved in the pilot and was formally given the role of "frontrunners" for individually testing new technologies and working together in the co-development of the CS concept. In the LCIS case, the project was associated to an innovation-oriented PPP, which can be considered a specific case of ServPPIN (Gallouj *et al.*, 2013b). The partnership was composed of the Siracusa municipality and the IBM Foundation Italy, a non-profit organization instituted by IBM for promoting technological innovation projects on the themes of culture, education, labor and social problems and providing financial as well as operational support to organizations and institutions working in these fields. This partnership was created in continuity with Siracusa participation to IBM's Smarter Cities Challenge by the joint initiative of the municipality and the IBM Foundation. Therefore, its initiation was essentially driven by public action (top-down approach) and based on a previous, positive relationship between the partners. The partnership operation was characterized by the distributed nature of responsibilities that well reflected actors' competences. In more detail, IBM Foundation Italy funded the project and involved the IBM Human Centric Solution Center for the R&D supervision and the technical development of the app's architecture. The municipality coordinated the project jointly with IBM Foundation Italy and participated to the development phase for the creation of the app's contents. In the project's final stage, the municipality involved the local Impact Hub¹⁷⁷ for collaborating with the partners (IBM Foundation Italy and IBM Human Centric Solution Center) in the presentation and promotion of the app. Impact Hub Siracusa was created in 2010 by a public-private initiative (a.o. Siracusa municipality, Catania University, Association of Cooperative Companies) within the European project Euro-South Hub. Since then, the Hub participated to several projects, contributing with its network of relationships and experiences of collaboration facilitation. Thus, in both cases the core network was formed by PPPs based on previous relationships that developed with the aim of leveraging the complementarity of competences and the possible synergies among the partners. Moreover, they are commonly characterized by the key role of multinational technological players (IBM, Philips, Vodafone) in the

¹⁷⁷ Impact Hub is a shared work and event space for a global community of entrepreneurs, activists, artists, and professionals using the power of business to drive positive social and environmental change. The first Impact Hub was founded in London in 2005 and has evolved into a rapidly expanding global network of over 7,000 professional members in 60 cities.

technological development of innovative solutions. This is not surprising in consideration of the smart nature of these networks and the related technological and market opportunities for these big firms. In the CS case, for example, it is difficult to assume that these technology providers would have joined the project without a strong belief in the high potential offered by ICT-based solutions to improve energy efficiency and reduce CO₂ emissions. Another common feature across the cases is the relative stability in the networks' composition and actors' roles along all the life cycle of the projects though they have different durations - two years for CS and three months for LCIS, respectively. This is particularly relevant in the CS case, where the network stability significantly mattered to drive the ServPPIN forward and to ensure its success in achieving the expected goals. Such a structural strength of the network is likely to be connected also to the well-structured approach adopted by the core team in the pre-initial phase of the project, which relied on the mapping of all the relevant stakeholders, the rigorous assessment of the potential environmental impact of the project and, finally, a dedicated effort to communicate to different stakeholders the relevance of the project's goals so as to ensure their partnering and collective commitment to the project. As highlighted by the project leader, *"Different groups have different targets.... You have to make sure that everyone is aware that you can reach your own target only with cooperation with each other... it takes a lot of time and effort to keep everyone committed, especially the entrepreneurs"*. Moreover, another relevant feature of CS smartServPPIN potentially contributing to its stability and performance was the adoption of a formal governance structure based on the creation of a dedicated entity - a steering committee representing all the partners - that centrally coordinated key decisions and activities. By contrast, the governance of the LCIS case was characterized by a shared but informal structure, with the two partners working jointly without an *ad hoc* administrative entity. This difference in the structure can be due also to the diverse scope of the two smartServPPINs, with the former posing greater governance challenges for the high number and variety of members.

With regard to the outcomes of the networks, in both cases the development of new technological applications was the enabling condition for other (central) innovation outputs. Specifically, CS can be considered as a complex 'architectural innovation' (Gallouj; Weinstein, 1997), where the change effort of a multi-agent interacting system is oriented at the co-production of different forms of technology-mediated and non-technological service innovations. The first types of innovations are closely connected to new technology products, solutions or devices (e.g. the Quby energy display) and offer new or improved services to city users (e.g. energy consumption information services, logistics services, LED-based lightening services). Non-technological innovations are social in nature, since the project also aimed at producing a change in the awareness and patterns of energy consumption of end users' (e.g. entrepreneurs and citizens). Also in the LCIS case, the technological output (the LCI Siracusa App) can be associated to a social innovation, being aimed at stimulating a behavioural change of users (awareness and responsibility towards the protection of the city and its cultural heritage) and their involvement in public decision-making. Indeed, describing the innovation concept, an IBM Manager stressed its social and participatory value: *"For the first time we addressed an important aspect that concerns what we call the 'rate of love' towards our artistic and cultural heritage. The way we feel in front of a work of art can now be measured and used by those who have the responsibility to make decisions for its protection and enhancement. This is very important, since smart cities are made of emotions beyond the technological aspects that support their development"*. At the same time, this app is also the vehicle for an innovation of practices within the public institution for decision-making processes related to cultural and tourism development, since these can be based on bottom-up information reflecting real users' needs. The social nature of innovations in both projects is also reflected at the broader city level, where they pursued to produce an environmental and cultural impact respectively, which in both cases is ultimately aimed at fostering cities' sustainable development. At the network level, the main innovation outcomes are related to the learning opportunities created by collective work and knowledge transfer among the partners. In the CS network, these mainly concern the adoption of the Living Lab methodology that relies on a real-life laboratory with end users acting as 'testers' of specific technologies or their combinations through their daily use at the workplace. For the other case, significant learning opportunities were reported with regard to the structured approach brought by IBM for communications management. As highlighted by Giuseppe Di Guardo, head of Siracusa municipality's Europe Office (Ufficio Programmi Complessi e Politiche Comunitarie): *"This partnership allowed us to learn much about such a valuable approach to managing interactions"*. Moreover, the collaboration with IBM was perceived as an opportunity for pushing an internal change process that was felt necessary for boosting urban innovation.

In the achievement of these outcomes, a number of external and internal drivers appear to be influential for the initiation, development and operation of the examined networks. With regard to those stemming from the broader smart city innovation context, the two cases present some common factors, namely the high importance of the public mission, i.e. the intention to improve the quality and efficiency of city services, accompanied by concrete actions from institutions in the form of innovation supporting initiatives; funding opportunities; institutional/political support to the network. Indeed, in the CS case increased environmental concerns produced strong pressure on public agents to improve the efficiency of city services and reduce the levels of pollution and CO₂ emissions through the development and adoption of energy-saving technologies by city users. In this respect, although the initial impulse to the project was given by a private waste collecting company, the decision of ASC to formally launch the project relied on the convincing nature of the proposed concept and the high energy-efficiency potential of the envisaged technologies. ASC's central role as initiator, coordinator and promoter shows the key function of the public actor for signaling the importance of the project and accelerating the network formation. Since the public-private partnership has acted from the beginning without any 'personal and financial interests' to bring interested parties together and foster collaboration,

it has built a solid public trustworthiness, thus providing an important impulse to network building. Public support was also given in the form of funding, with financial resources provided by both the non-profit public organization Amsterdam Economic Board, co-founder of ASC, and the Amsterdam Centrum District Administration. According to Ger Baron, cluster manager of ASC, Amsterdam is one of the few example of urban innovation that has showed to be sustainable through the balanced mix of the private and public actors: *“The Public administration support is essential: produces ‘trust’, open data, long-term commitment, policies and leadership”*. In a similar way, the LCIS project was itself the concrete result of the strong municipality’s commitment and efforts to smart urban innovation and to the definition of a holistic plan for balancing the competing economic imperatives of tourism and industry with its environment, transport, culture and the preservation of its great heritage. This commitment was reflected in the support to the project’s activation, development and promotion from the local public authority. At the same time, an important driver for the PPP’s set up was the support provided by IBM Foundation Italy, which financed the project, contributed to its coordination and made available highly specialized human resources, technological know-how and service solutions. Another significant external driver shared by the two cases was the orientation of institutional actors towards an inclusive approach to urban innovation, balancing top-down and bottom-up initiatives. The CS project perfectly reflects the approach deliberately adopted at higher level by ASC to stimulate collaboration and innovation through the development of smart city projects (Zygiaris, 2013). As reported by Ger Baron (2013), *“ASC does not just believe in a top-down approach; there is a strong belief at ASC that bottom-up ideas can contribute greatly to our city, especially when it comes to the development of new products and services”*. According to the cluster manager, an inclusive bottom-up approach enables end users (i.e. the Amsterdam’s citizens) to collaborate in the development and experimentation of products and services that are mainly directed at them and at the same time it is the most effective strategy for increasing citizens’ awareness to deal with environmental and sustainability challenges of the cities. Also the municipality of Siracusa has put into practice a number of inclusive initiatives to foster the collaboration among local stakeholders and the direct participation of the community in the implementation of the urban development plan. In particular, it organized several technical tables involving a high variety of local stakeholders to discuss key decisions and actions for planning the city’s future and pursued social empowerment, considered as a pillar for city’s development and branding. This result is in line with previous evidence on smart cities, highlighting the importance of an inclusive and participative bottom-up approach for the success of smart strategies (Achaerandio *et al.*, 2012; Komninos *et al.*, 2013; European Parliament, 2014).

With regard to internal drivers (i.e. stemming from the networking regime), the comparative analysis shows some common key factors in the two smartServPPINs. First, the adoption of a joint public-private leadership, which in the CS case was exerted by ASC (strategic leadership) and Club van 30 (operative leadership) and in the LCIS one was played by the Siracusa municipality and IBM Foundation Italy. In this regard, it is important to highlight that in both cases the collective nature of the leadership had its roots in previous collaboration and personal relations among involved parties. In the LCIS case, in particular, the positive regime between the partners also derived by the fact that the project was conceived in close continuity with past collaboration (i.e. Siracusa’s participation to IBM’s Smarter Cities Challenge). Moreover, inter-organisational relationships were characterized by a balance in actors’ influence and power in the network and win-win situations were guaranteed from the outset, when it was clear that collaborative innovation was beneficial for all the partners and the network dynamics was not influenced by opportunistic behavior and interests’ conflicts. In the case of CS, the presence of key innovative individuals provided a further important internal driver for the success of the innovation network. In this respect, the action taken by the shopping street manager was particularly crucial. Indeed, he served as local visionary pioneer and innovation champion for the project and together with ASC and the project manager *“had to work to connect and translate the Climate street concept to entrepreneurs”* convincing them to join the pilot. Actually, this was not an easy process since *“most entrepreneurs did not have the time to think about the environment”* (Sauer, 2012). His role, however, was essential not only in the initial stage of the network formation, but throughout the development process when it was necessary to ensure their involvement: *“the processes must be explained to the entrepreneur in a clear manner. It is important for the entrepreneur to be able to understand clearly what the benefits are for the business....the shopping street manager is the main point of contact and hereby can communicate with one voice to the entrepreneurs about all the developments in the street”* (Amsterdam Smart City, 2011). Indeed, the champion role of the street manager proved to be vital for the set-up of an effective communication system, which was direct, transparent, based on face-to-face information exchange, to promote their strong commitment to the project’s sustainability goals. Finally, the choice to initially involve in the pilot only a small number of more motivated and innovative entrepreneurs revealed itself as an important success factor (European Parliament, 2014), since through their convinced action they served as ‘ambassadors’ of the project, promoting its benefits to other entrepreneurs in the street and locally producing positive spillovers.

In sum, the two smartServPPINs share a number of common factors that are likely to contribute to their success, against a different maturity stage of cities’ *smarticization* and complexity of the innovative solution realized by the selected innovation projects. Table 1 provides an overview of the main common and different factors emerged from the comparative analysis. This, in particular, shows the applicability of the framework in different arenas, networking conditions and various level of complexity of innovation processes and outcomes.

Table 1. Summary of the comparative case analysis.

6 Conclusions and further research

The purpose of this paper is to provide a contribution to the increasingly relevant issue of innovation within the smart city context by leveraging the interpretive potential of the service innovation perspective, namely the concept of ServPPINs, drawing on the research stream disclosed by Gallouj and colleagues in recent years. These public-private innovation networks in services enrich the traditional concepts of innovation networks and PPPs and are a new means of approaching, from a network-based perspective, a field of innovation that is still largely underexplored, namely innovation in public services (Gallouj *et al.*, 2013a). Thus, it is believed that ServPPINs can provide a useful lens to advance the understanding of networked innovation within the complex and fast-changing landscape of smart cities, by better addressing the complexity of interactions between public, private, third-sector organizations and users/citizens communities in the development of innovative city services. Based on this concept, the paper proposes a conceptual framework for exploring the role of smartServPPINs in realizing opportunities for technological as well as non-

technological innovations in the smart city context and the factors influencing their effective operation. The proposed framework is then applied to the analysis of two European case studies of smart projects and the service innovation networks associated with them. The comparative analysis supports the interpretive capability of the ServPINN concept in the context of smart city innovation, thus providing a conceptual contribution to this emerging field. It is shown how the proposed framework can contribute to disentangling the complexity of these inter-organizational arrangements through its components and how this can apply in different arenas, conditions of networking and various level of complexity of innovation processes and outcomes. With regard to the second objective of the paper, the comparative analysis provides empirical evidence for advancing existing (but still scanty) knowledge about the characteristics of smart innovation networks, their set up and governance, and the relative importance of different drivers for the successful development of innovations for the smart transformation of cities. In particular, the comparison between two quite different cases allowed us to identify some common key factors for smartServPPINs success, notwithstanding their inherent differences with regard to the smart city innovation context and the level of complexity of the innovative solutions realized within the two projects. These common factors should be taken into account for the effective set up, management and diffusion of networked innovation models for the smart transformation of cities. From an operational point of view, this implies the need to develop an understanding of the role and the functioning of smartServPPINs and, based on this, to create/ensure the proper conditions that are functional to the activation and maintenance of both the external and internal key drivers of collaborative innovation, coherently with the specific smart city situation. In this direction, public actors have a key role and responsibility, since they are in the position to exert concrete actions at different levels to influence the effectiveness of collaborative innovation in the smart city context. Further research will be oriented to overcome the limits of the present study, by extending the number of cases to further validate and strengthen the applicability of the proposed framework. In this regard, it could be useful to perform cross-case analysis of different smartServPPINs within the same city as well as of similar networks in terms of goals and innovation types in different cities. Another future research direction to improve the contribution of the proposed framework is represented by a deeper analysis of network dynamics, which does not form the focus of the present paper, although it is essential to better explain the role and success as well as the potential barriers of smartServPPINs in realising innovations.

Citizen Generated Social Innovation Creating Institutional Change: Case Study of Restaurant Day

Outi Martikainen

Aalto University

This paper discusses social innovation as a phenomenon generated by citizens for citizens that is rooted in the growing citizen activity in innovation, concentrating on how it creates institutional change. The empirical data for the study was collected through semi-structured interviews and observation focusing on one case of citizen generated social innovation, Restaurant Day, a phenomenon initiated in Finland as a result of citizen activism. The findings of this paper indicate that institutional change can be created by a social innovation as a result of interplay between action and mental change when successful framing, illusion of legitimacy and ability to mobilize citizens initiate collective action.

1 Introduction

Innovation has become increasingly distributed across a variety of stakeholders (Bogers; West, 2012), an activity that includes users (von Hippel, 2005) and can be initiated from the grassroots level (Seyfang; Smith, 2007) as a citizen initiative. Social aspects of innovation (Hargadon, 2003, ix; Hellström, 2004) have received attention in scientific research as participation and collaboration have been acknowledged to have an important role in many parts of innovation process (Hellström, 2004). Social interactions are also a crucial component in social innovation; ‘social’ does not solely refer to the outcome of the innovation but also the actions and involvement of people in the process of creating the innovation (Moulaert, 2013, 2).

Social innovations answer a social need or bring social benefits to communities (Moulaert, 2013, 1). Besides a goal that supports enhancing social well-being, the means to reach that goal are social (Dawson; Daniel, 2010), with the realization of the innovation consisting of social interactions (Hellström, 2004). The social goal does not have to focus on solving global issues, but can involve smaller-scale community enhancement. Scientific research on social innovation is not well established yet (Chalmers, 2013; Maclean; Harvey; Gordon, 2013; Neumeier, 2012), but social innovation has raised increasing academic (Maclean et al., 2013) and societal (OKFN LOCAL: Finland, 2013) interest.

In this paper I explore social innovation as a phenomenon generated as a community effort, a grassroots phenomenon generated by ordinary citizens rather than a company. The focus is on how such social innovation can create institutional change, concentrating on the mechanisms initiating and establishing change and creating legitimacy around the social innovation. Social innovations often initiate change given that they are created to make a difference, solve a social issue (Moulaert, 2013, 16) or improve well-being (Dawson; Daniel, 2010). This creates a fruitful basis to consider institutional change as essentially related to social innovation. As social innovations tend to change practices, they prompt changes in different institutionalized systems. Studying social innovation and its ability to create change can help in understanding how they could be used more efficiently as vehicles of change. Collective action (Seo; Creed, 2002) has been crucial in creating change in the case of Restaurant Day. This resulted from the successful framing of the cause and the ability to mobilize citizens when facing a contradiction (Seo; Creed, 2002). Further study of the topic can clarify how ordinary citizens can be mobilized to support a social purpose.

Social innovation and institutional change have been connected previously (Cajaiba-Santana, 2014; Hämäläinen; Heiskala, 2007), but the approach in this paper is different. Previous research has examined the effects of institutions and institutional change on social innovation whereas my perspective is based on how social innovation can create institutional change.

This paper covers one specific case of social innovation, Restaurant Day, initiated as an attempt to make it easier for ordinary people to start their own restaurant in the face of complicated Finnish regulations. Restaurant Day was initiated in 2011 by a few active citizens who wanted to rebel against the regulations and at the same time create a food-based festival to bring people together. As the event has grown more popular, the focus has shifted away from rebelling and towards an empowering event that gives people an opportunity to express themselves. Restaurant Day has become an international phenomenon, raising interest abroad. It has been arranged in 56 countries, involving an estimated 38,500 restaurateurs and 1,060,000 customers during its existence of three years (Restaurant Day Homepage, Info). Through engaging a large number of citizens in contributing and visiting, Restaurant Day has initiated a mental change and prompted changes in the institutional order and citizens’ attitudes.

The findings of this paper imply that social innovation can initiate change through social innovation that acts as contradiction. If active citizens succeed in mobilizing collective action, the changes can spread to cover a wider audience, eventually having an effect at institutional level.

This introduction is followed by the theoretical background regarding social innovation and institutional change. After the theoretical background, the empirical basis of this paper is introduced covering the case description of Restaurant Day and the methods that were used for data collection and analysis. Then the empirical findings of this

paper are introduced and discussed in the light of existing research. Finally, concluding remarks summarize the main findings and implications of this paper.

2 Social Innovation and Institutional Change

Social innovation has not yet reached a normative state as a scholarly field and the dominant logic of social innovation is still being shaped (Chalmers, 2013). This can be seen in the variety of situations and approaches in which social innovation is referred to in scientific literature. Scientific literature on social innovation is scattered not only throughout different fields of research, it is also dispersed in the approach of defining social innovation varyingly as an effort, method, result or collaboratively initiated change (Neumeier, 2012). Inspired by Neumeier’s (2012) division I have collected in Table 1 a variety of social innovation definitions to provide an overview of the variance of the definitions. Table 1 does not fully follow Neumeier’s (2012) division; it is merely inspired by it, and is also based on my own findings from studies of social innovation and my interpretation of the definitions.

Table 1. Categorization of different definitions of social innovation.

Approach	Author	Definition
RESULT	Mulgan; Tucker; Ali; Sanders, 2007, 9	"Social innovation refers to new ideas that work in meeting social goals."
	Pol; Ville, 2009, 881	"an innovation is termed a <i>social innovation</i> if the implied new idea has the potential to improve either the quality or the quantity of life"
EFFORT	Mumford, 2002, 253	"The term social innovation, as used here, refers to the generation and implementation of new ideas about how people should organize interpersonal activities or social interactions, to meet one or more common goals."
	Dawson; Daniel, 2010, 10	"For us, social innovation can be broadly described as the development of new concepts, strategies and tools that support groups in achieving the objective of improved well-being"
CHANGE PROCESS	Neumeier, 2012, 55	"--we define social innovations as changes of attitudes, behaviour or perceptions of a group of people joined in a network of aligned interests that in relation to the group's horizon of experiences lead to new and improved ways of collaborative action within the group and beyond"
ALL-EMCOMPASSING	Cajaiba-Santana, 2014, 44	"--social innovations are new social practices created from collective, intentional, and goal-oriented actions aimed at prompting social change through the reconfiguration of how social goals are accomplished"

In this paper social innovation is defined as an innovation that answers a social need or brings social benefits to communities (Moulaert, 2013, 1) combined with social means to achieve these goals (Dawson; Daniel 2010). The need that is met by the social innovation can be any kind of social need ranging from a severe social problem to opportunities to improve the well-being of a community, and it can be a product, service, activity or change in institutional structures that brings improvement to how things have traditionally been done (Moulaert, 2013, 1).

The emergence and diffusion of social innovation are crucial knowledge when examining social innovation. The emergence of Restaurant Day originates from the effort of ordinary citizens setting up an event with a social goal and social means to achieve it (Dawson; Daniel, 2010). In the case of Restaurant Day the emergence and diffusion have so far created institutional change on a small scale, changing practices and ways of doing things in regions where it has gained a strong support. Social innovation functions as the starting point for the change – the social issue causing contradiction (Seo; Creed, 2002) is framed (McAdam; McCarthy; Zald, 1996 cited in Hargrave; Van de Ven, 2006) in the form of a social innovation. After the initial contradiction the change gains foothold through individual actors and the collective action they succeed in mobilizing.

Diffusion of social innovation is linked to the emergence of institutional change, as change starts emerging when the innovation gains support. Diffusion is identified as the last stage of institutional change process preceding re-institutionalisation (Greenwood; Suddaby; Hinings, 2002). There is also a link to the other direction; institutional change can open opportunities for social innovations. Institutional change in this paper refers to a process where institutions change; it can be both organizational operation models (Scott 1995, p. xiii), or citizens’ shared beliefs and assumptions (Scott 2007, p. ix) that change.

Institutional change is usually initiated by a contradiction (Seo; Creed, 2002) or a jolt (Meyer; Brooks; Goes, 1990) that starts the change process, embodied for example in an idea of a social innovation. Change agents, for example social innovators, decide to challenge the prevailing system and mobilize collective action to their support (Seo; Creed,

2002). Contradiction can occur not only between opposing parties but also between people of the same constituent group (Swan; Bresnen; Robertson; Newell; Dopson, 2010).

Social movement scholars identify mobilizing structures and framing processes in explaining how change is achieved (McAdam et al., 1996 cited in Hargrave; Van de Ven, 2006). Mobilizing structures refer to the networks of actors and other resources that are available to be mobilized and engaged in collective action. Framing processes refer to the processes that social movement actors use in formulating the cause they are promoting. (McAdam et al., 1996, cited in Hargrave; Van de Ven, 2006)

Mobilizing resources and collective action as part of these resources is crucial in pushing through innovations to create change (Rao; Giorgi, 2006). Rao and Giorgi (2006) point out especially the importance of “social networks, formal and informal organizations, and conduits of contagion” based on their study of different extreme institutional change cases. Building a network of friends and potential allies or elite allies support mobilization (Rao; Giorgi, 2006). Hargrave and Van de Ven (2006) also acknowledge the construction of networks in mobilizing collective action. Dorado (2005) identifies leveraging as a means to mobilize resources. Leveraging consists of first defining a project, then gaining support for this project from supporting actors or backers, and then together with the backers trying to gain the support of external constituencies (DiMaggio, 1988 cited in Dorado, 2005). In leveraging the role of the actor who drives the project forward is important (Dorado, 2005). Skilful framing allows the actor to set the context and gives the actor power (Rao, 1998), and convincing others that there is a need for change and that the actor’s approach is the right one gives the actors the possibility to define and solve the problem in their own way (Fligstein, 1996).

Seo and Creed (2002) also identify collective action as an important part of the institutional change process emphasizing framing and mobilizing actions in their work. In the creation of new social structures the agents need to firstly develop alternative models of social arrangement (e.g. schemas, scripts, logics of action) and secondly to mobilize resources for political action to challenge the existing structures. These two, creating alternative frames and mobilizing resources, intertwine as the agents need to justify their attempt with the alternative models, and only if they succeed in creating credible schemas and scripts can they mobilize resources to political action. Seo and Creed (2002) argue that not all frames have equal potential to mobilize change efforts.

Activists frame the purpose and limits of the change movement. Successful framing (Seo; Creed, 2002) and utilizing social networks (Hargrave; Van de Ven, 2006; Rao; Giorgi, 2006) can also help in mobilizing resources through leveraging (Dorado, 2005) leading to collective action. Collective action precedes institutional change; when a critical mass (Neumeier, 2012) joins in pushing forward a change, changes are likely to occur at least to some extent. In this process legitimation is also important; collective action can be seen to legitimize a movement as legitimation occurs when people adopt ideas that exemplary others have first adopted (Mizruchi; Fein, 1999) through mimicry (Neumeier, 2012). Legitimation in itself also creates institutional change as a phenomenon becomes commonly accepted and legitimate (Suchman, 1995).

The actors who drive the change and mobilize resources are themselves also important in the change process and its legitimation. Den Hond and de Bakker’s (2007) reformative activist groups and radical activist groups have different approach to legitimizing their actions. In deinstitutionalization reformative activists justify their actions based on what they *do* using consequential arguments; radical activists justify their actions based on both what they *do* and what they *are* using both consequential and structural arguments accordingly. In re-institutionalization radical activist groups argue their cause with moral legitimacy, whereas reformative activist groups appeal to both moral and pragmatic reasoning. Another big difference between reformative and radical activist groups is whether they concentrate on de-institutionalization or re-institutionalization. Radicals put more time and effort in deinstitutionalization, and reformists put more time and effort in re-institutionalization.

Hensmans (2003) presents two archetypes of challengers similar to those of den Hond and de Bakker (2007). His modern reformers are similar to den Hond and de Bakker’s (2007) reformative activist groups, and his revolutionaries are like the radical activist groups of den Hond and de Bakker (2007). Revolutionaries are disruptive challengers; modern reformers are moderate challengers. Both position themselves in terms of justice, but revolutionaries are more antagonizing towards incumbents. (Hensmans, 2003) Hensmans (2003) also presents two archetypes of incumbents – resisters and classic reformers. Resisters resist challengers’ attempts for change, whereas classic reformers are renewing incumbents who are more open for change (Hensmans, 2003).

Rao and Giorgi (2006) talk about institutional entrepreneurs and suggest that they can be insiders or outsiders to a certain social system and that they can exploit the pre-existing logic within that social system or optionally import a new logic to that system from a different domain. Rao and Giorgi’s (2006) argument is that instead of explaining institutional change by external shocks it can be explained by people from within or outside the institution employing new or existing cultural logics in pushing forward their own institutional projects. (Rao; Giorgi, 2006) Institutional change can thus be initiated and led by agents who want to change the existing system.

Challengers can also collaborate with the incumbents. Independent activists and field incumbents can start working collaboratively and this collaboration changes the field in question (Van Wijk; Stam; Elfring; Zietsma; Den Hond, 2013). In order for the collaboration to work between the challenger movements and field incumbents there must be intensive interaction and communication between the parties, and recognition that they both are involved in an institutional change project. They also need to “develop shared norms, beliefs and frames of reference” to facilitate their interactions. A movement that is moderately structured can produce threats and market opportunities that the field incumbents will notice, at the same time being permeable to the incumbents’ influence. (van Wijk et al., 2013) Also

Castel and Friedberg (2010) agree that for a reform to succeed it owes as much to the incumbents and to challengers as it is a product of their interaction.

Rao, Monin and Durand (2003) identify two different movements with different motivations in creating institutional change: instrumental movements and identity movements. Instrumental movements aim at correcting injustices and challenging existing political and economic structures, and striving to change laws and governance structures. Identity movements on the other hand consist of actors who categorize themselves as group members and identify with this group. In identity movements the focus is on the defects that occur on the proximal level of identities of the existing institution. (Rao et al., 2003)

The loop of institutional change goes on forever; in the dialectical perspective to change no institution is seen to be permanent as new contradictions will always arise to challenge the existing systems (Seo; Creed, 2002; Hargrave; Van de Ven, 2006).

3 Context and Methodology

This section covers the empirical background of this paper. First, the phenomenon studied in this paper, Restaurant Day, is introduced. Second, the approach of this paper together with the data collection and analysis methods are presented.

3.1 Case Description of Restaurant Day

Restaurant Day is a one-day event that takes place every three months (Restaurant Day Homepage, Info) where anyone can set up their own restaurant, café or street food stand for one day. It was founded in Finland and took place for the first time in May 2011 (Restaurant Day Homepage). It has become very popular during the three years it has existed so far; Restaurant Day has been arranged in 56 countries, involving an estimated 38,500 restaurateurs and 1,060,000 customers during its existence of three years (Restaurant Day Homepage, Info).

Restaurant Day was originally initiated by a few active citizens, who wanted on one hand to rebel against regulations regarding selling and serving food that they found too strict and complicated (Aamulehti, 2014) and on the other hand to create a festival that brings people together around food (Nurmijärven Uutiset, 2012). As the event has grown more popular the focus has shifted further from rebelling and more towards supporting the well-being of the community and spicing up urban environment.

Restaurant Day functions as a joint effort of all the people taking part in it. It is an open event that anyone can take part in as a restaurateur or as a customer. It is based on voluntary citizens setting up restaurants and customers eating in these restaurants. (Maaseudun Tulevaisuus, 2014) The event itself is free; it costs nothing to register as a restaurateur. Restaurant Day is facilitated by a registered association Ravintolapäivä ry. It is a non-profit organization that runs on sponsorships and the money from different prizes. The people involved in the Restaurant Day organization are not paid but work for the event on a voluntary basis.

3.2 Data Collection and Analysis

This study was conducted as a case study (Laine; Bamberg; Jokinen, 2007, 9). The empirical data regarding the case of this paper, Restaurant Day, was collected by conducting observation and semi-structured interviews. Observation was conducted twice to gain access to possible interviewees and to observe the event in general. Majority of the data was collected through semi-structured interviews with Restaurant Day restaurateurs and with founders of the event.

The analysis of the data was done as thematic analysis, both with the observation data by coding and memoing (Emerson; Fretz; Shaw, 1995, 142-168) and with the interview data as a combination of data-driven coding and concept-driven coding (Gibbs, 2007, 44-46). Originally the analysis concentrated on finding themes related to the emergence of a citizen generated social innovation. During the analysis, however, other themes emerged that concentrated on the changes caused by the diffusion of the phenomenon. Also themes relating to how Restaurant Day has become legitimate emerged from the data. This led to concentrating on the changes social innovation can create and how as the focus of the paper.

4 Findings

This section concentrates on introducing the findings on how a citizen generated social innovation creates institutional change. In the case of Restaurant Day it has been the emergence and diffusion of the innovation that has created institutional change, and this change has occurred on two levels. First, there have been changes in citizens' perceptions on what can be acceptable behaviour that has initiated a feeling of empowerment in regards to their surroundings and what can be done there. Second, Restaurant Day has created institutional change in the structures and attitudes of cities where it has been strongly established, for example the City of Helsinki and the Finnish Government were mentioned in the interviews. Changes in citizens' shared beliefs and assumptions (Scott, 2007, ix) and changes in organizational operation models (Scott, 1995, xiii) have also been identified by Scott (2007, ix; 1995, xiii) as features of an institutional change process. The main changes that came up in the interviews were changes in citizens' attitudes; changes in urban culture as people use their urban environment more and in more creative ways; changes in food culture in the form of food events, street food, and ethnic food; and changes in permissions as Restaurant Day is for

example encouraged by the City of Helsinki, and has been approved by the Finnish Food Safety Authority Evira. In the words of one interviewee, restaurateur 7:

– – be a part of some kind of change that it has turned out to be, that things have changed after Restaurant Day was initiated. And now that you can see it, for example in Helsinki festival, that Restaurant Day has made a difference in the development – – it wasn't just fooling around and some kind of crazy one-off restaurant thing; in the long run it has actually led to development of street food, a new atmosphere in the street scene and a new attitude of the authorities towards legislation and other things. And that people in Helsinki and elsewhere in the world, they have understood and learned to utilize the city independently in a new way – –

In initiating Restaurant Day there was an issue the founders wanted to solve that caused contradiction, and they decided to act to show that the regulation causing the contradiction does not make sense thus challenging the current institutional order. This issue can be seen as a jolt (Meyer et al., 1990) or a contradiction (Seo; Creed, 2002) that causes institutional structures to start deinstitutionalizing (Greenwood et al., 2002) thus acting as the source of institutional change. In addition to the issue, there were people who wanted to challenge the prevailing way of doing things becoming the active agents in furthering institutional change.

An important part of actually achieving institutional change were the good mobilizing structures (McAdam et al., 1996 cited in Hargrave; Van de Ven, 2006); it came up in the interviews that the founders have wide networks of friends and acquaintances whose importance in mobilizing collective action is also recognized by Rao and Giorgi (2006) and Hargrave and Van de Ven (2006). In the beginning the founders were able to spread knowledge of Restaurant Day through these extensive networks. In addition, more networks could be built by spreading the word through the networks of the founders' networks in social media. The founders applied leveraging to mobilize resources (Dorado, 2005) as they first got a small number of people to join them in backing their cause, and from there on the movement spread to cover a wide audience and to affect institutions. As part of mobilizing collective action Restaurant Day also succeeded in framing (McAdam et al., 1996 cited in Hargrave; Van de Ven, 2006) their cause in a simple and appealing way which enabled collective action (Seo; Creed, 2002). They succeeded in framing their cause legitimate despite its possible illegality as their story was easy and compelling for media to talk about.

In the case of Restaurant Day the significance of networks in spreading knowledge became obvious throughout the interviews also with the Restaurant Day restaurateurs; all the interviewees had first heard of Restaurant Day through their friends, colleagues or school mates. So after the founders had started spreading word about Restaurant Day, the knowledge later continued spreading through the networks of people who knew about Restaurant Day, citizens who had participated in Restaurant Day and also through media.

In the spreading and diffusion of Restaurant Day preceding wider adoption many of the interviewees talked about general visibility and how the phenomenon became a hot topic in traditional media. It was mentioned how many of the interviewees had observed Restaurant Day in different media and how media got excited about Restaurant Day. One of the interviewees discussed how media visibility probably got the mass to participate in Restaurant Day. An interesting aspect of the media attention was that the different media were the proactive ones to approach Restaurant Day starting to tell the story of Restaurant Day and individual Restaurant Day restaurateurs to wider audiences. This kind of spreading of the knowledge of Restaurant Day through various networks and in legitimate channels was important in the diffusion and adoption of Restaurant Day. The event raised interest among citizens, and the knowledge of the event and participation rate expanded quickly resulting in collective action.

Figure 1. Change in attitudes leading to action, which again re-enforces changes in attitudes.

An important step in actually making a change in people's attitudes is how Restaurant Day succeeded in becoming legitimized. This happened as a result of the interplay between action and mental change (Figure 1), with the aid of visibility in social and traditional media. Media played a big role in spreading word about Restaurant Day to wider audiences as they made stories of Restaurant Day in TV and in different papers: "On Restaurant Day - - all the big main

news agencies - - went strolling around and did a story, and during that summer you could say that a snowball effect got started, people started looking forward to the next Restaurant Day“ (Founder 1).

This kind of spreading of the knowledge of Restaurant Day through various networks and in legitimate channels was in itself creating legitimacy and advancing the diffusion of Restaurant Day. The diffusion on its part also increased the legitimation of Restaurant Day as more people participated in Restaurant Day. The legitimacy can thus be seen to originate also from mimicry which Neumeier (2012) identifies in the context of social innovation adoption and acceptance.

Citizens accepted and adopted Restaurant Day which initiated a mental change, as has been acknowledged by founder 2: “I myself consider the change in attitudes, the mental click in people’s heads, realizing like wow these kinds of things can be done – - is the coolest thing we have accomplished.” Especially in the early days of Restaurant Day it was unclear to people whether this kind of action was acceptable and legal. Some people were worried about needing permissions for doing something like this, like restaurateur 6 mentioned: “Many people ask, even if they know about Restaurant Day, that where do you make a notification about this. Nowhere, just do it.” So the hop from being sympathetic towards Restaurant Day to actually becoming one of the contributors required a change in how this kind of citizen activism was regarded, perceived and accepted.

There has been a long period of time when the city and the urban space has been considered as something outside of us, people have regarded that there is an official institution called the city, and the city does everything that happens in the city and gives permissions to everything that happens in the city – - it has been a challenge to get people to believe that there is no barrier to sell buns out there, there are no laws or regulations that prohibit it directly – - it is still one of the biggest challenges when Restaurant Day expand to new places. (Founder 1)

The original philosophy of Restaurant Day was not to care about whether permissions are needed or not, and just setting up pop-up restaurants without asking permissions like founder 2 expressed it: “We didn’t ask anyone if this was a problem, we didn’t really give a chance for problems.” The example the first participants set showed other citizens too that no problems followed from doing this without permissions. The second time Restaurant Day took place the participation increased a lot: “- - maybe not during the first time but already the second time Restaurant Day had grown so big that there was no chance to stop it anymore” (Founder 2). This kind of cycle of attitudes changing and leading to citizens activating and participating (Figure) gave Restaurant Day a critical mass of supporters (Neumeier, 2012), so the phenomenon could no longer be stopped.

Once you reach the critical mass and there are enough people thinking this is a good idea, and especially when it comes to Restaurant Day people are quite passionately thinking this is a good idea, there is such an asset that we can inevitably go through all problems. (Founder 2)

The institutional change created by Restaurant Day started from affecting the attitudes and behaviour of individual citizens. After this structural and attitude changes in strong Finnish institutes like the state and the city of Helsinki have also occurred.

I think you can see the change very concretely in Helsinki at least. Firstly during the past three years the atmosphere in here has become much more empowered, we can act, we can take over the urban spaces, this city belongs to us, overall we can try out different communal things – - It is not owing to Restaurant Day, but Restaurant Day has been strongly involved in creating such atmosphere and ambiance that things are possible and that we can do things together and that there are alternative ways. And like urban culture and urban culture events have started thriving after it. (Founder 2)

Founder 2 talked in the interview about how “legislation and instructions concretely, and how the city as an organization or different bureaus respond to this activism, it has changed a lot”. The attitude of the City of Helsinki has been very positive although Restaurant Day was initiated as something that broke some of its rules: “If the mayor talks how the city as an organization should learn how to involve people and including them in participatory development from Restaurant Day, it sure has given more weight to citizen democracy and such. It sends a really strong message.” (Founder 2) Other official parties like Finnish Food Safety Authority Evira have given statements about how Restaurant Day is acceptable and this kind of event can run without it being a problem regarding e.g. hygiene regulations which was mentioned by both founder members interviewed for this study. This indicates that structural enabling from official side has occurred which allows easier execution and expansion of Restaurant Day and other similar phenomena using the urban space for the purposes of citizens.

5 Discussion

Restaurant Day as a citizen generated social innovation has created institutional change through collective action that was initiated by contradiction. Contradiction is identified as the source of institutional change in research that approaches institutional change from a dialectical perspective (Seo; Creed, 2002). The starting point that caused Restaurant Day to initiate the process of institutional change is rooted in contradiction – the founders felt that the

regulations set by the Finnish Government regarding setting up a restaurant were too complicated. The founders thus acted as 'change agents' as the then existing institutional logic did not suit them (Seo; Creed, 2002). Swan et al. (2010) have stated that it is possible for the contradiction that initiates institutional change to occur also between people in the same constituent group, not only between opposing groups, but in the case of Restaurant Day the contradiction occurred between citizens and an institution.

Citizen generated social innovation can be seen as a statement of contradiction in itself, too, as it is a vehicle of solving a social issue. In addition to the founders initiating this social innovation as an act resulting from a contradiction, also the act itself can be seen as a contradiction because it is a social movement contradicting the prevailing system.

Restaurant Day is citizen generated and relatively open, and it is under constant evolution. A dialectical change process is a cyclical process where the new thesis eventually becomes the antithesis (Hargrave; Van de Ven, 2006), so institutional change never seems to be fully complete. Lately, as the event has established a relatively stable position, the on-going evolution is starting a new cycle of institutional change, this time changing Restaurant Day itself. The original goal and purpose that have driven the change in the beginning can turn into different purposes as the change diffuses and gains support. Therefore, in addition to the change that a social innovation creates in the surrounding mental and structural institutions, the innovation itself can change on an institutional level. So when the founders originally strived to make a change they were able to have a little bit differing goals, some being more interested in developing the food culture in Helsinki and some being more interested in developing urban culture and urban spaces, as the general change enabled all those goals. Now that the event has become established, the more specific wishes are raising their heads and the future directions of Restaurant Day are under institutional change.

Agency and the role of the challengers is another central feature to look at when discussing how institutional change happens. The contradiction that set the institutional change in motion was noticed by the Restaurant Day founders who I previously referred to as 'change agents'. The founders of Restaurant Day can be seen more as reformative activists than as radical activists (den Hond; de Bakker, 2007) – although they were ready to break rules and disregard the existing system, they justified their actions based on the institution's ways of working instead of its mere existence, and found legitimacy in both moral and pragmatic reasoning (de Hond; de Bakker, 2007) as they argued that setting up a restaurant should not be made so complicated for the citizens.

The founders of Restaurant Day were not insiders (Rao; Giorgi, 2006) in regards to the structural institution that it changed, but they can be seen as insiders (Rao; Giorgi, 2006) to the less structural changes, citizens' perceptions of what is allowed in an urban environment. They were themselves citizens who were not sure what is permitted and what is not on behalf of e.g. Finnish Government when selling food in public, so in that sense they represented all ordinary citizens, except that they took action and started setting up pop-up restaurants despite not knowing whether it was allowed. As one significant institutional change here is the attitude change in citizens, the founders can be seen to have initiated the change from within the institution (Rao; Giorgi, 2006).

In regards to the more structural institutional change that Restaurant Day initiated in at least the City of Helsinki and Finnish Government, there has not occurred collaboration between the challengers and incumbents per se as has been observed to happen in some cases during institutional change (van Wijk et al., 2013) but the incumbents have not resisted the change either. These institutions could thus be defined as classic reformers according to Hensmans's (2003) study. The interaction that a successful institutional change requires between the challenger and incumbents (Castel; Friedberg, 2010) exists in a way that for example Helsinki allows Restaurant Day to take place and even utilizes it in its own marketing actions, but no reciprocal collaboration has been established between these two parties, although Restaurant Day has tried to initiate collaboration.

It is pointed out by Seo and Creed (2002) that creating alternative frames is a requisite to mobilizing collective action. In the case of Restaurant Day this seems to have happened in a bit of a cumulative way, starting with the initial framing that led to small-scale mobilization, and then this mobilization and the example these people showed led to a more massive mobilization. Political opportunity structures (McAdam et al., 1996 cited in Hargrave; Van de Ven, 2006) eventually turned out to be favourable to Restaurant Day. The founders took roles of outlaws, only to end up noticing that the prevailing institutions, both the mental institutions of acceptable behaviour in the minds of the citizens as well as the more structural institutions setting official rules, accepted and welcomed the change without much opposition.

The dialectical approach to collective action by Hargrave and Van de Ven (2006) that identifies conflict, power and politics as important building blocks of the change process can be found in the creation and diffusion of Restaurant Day too. A conflict started the change process. It is hard to say whether the founders had much power as such; it seems like the power they had came from the idea and their skills in selling that idea to other people resulting in a small movement that was the source of power. They chose their approach in how to engage in the conflict, just going ahead and doing what they wanted to do without asking for permission, and importantly engaging other people from the very beginning thus gaining more force.

Restaurant Day started out as resembling an instrumental movement but it has evolved more to the direction of an identity movement (Rao et al., 2003). In the beginning there was a clear inclination to making a difference and fixing an injustice and striving for policy changes as is suggested to be typical of an instrumental movement (Rao et al., 2003). As the larger masses joined in arranging Restaurant Day the movement has shifted more towards an identity movement that focuses on the defects in the institution related to identities (Rao et al., 2003). However, there did not seem to be much interaction between separate contributors of Restaurant Day. Interactions took place on micro level, participants

interacting within the little hub their own restaurant created consisting of their own social group, their customers and their existing friends. No interactions seemed to exist between different restaurants. So there seems to be features of both movement types which is perhaps partly explained by the evolution Restaurant Day has gone through, going from a bit of a rebellious act to a national favourite, and partly by the fact that a very heterogeneous collection of people with very heterogeneous incentives contribute to Restaurant Day.

It is difficult to say for sure whether the institutional change in institutional structures in Finland and Helsinki are exclusively due to the fact that so many people were supportive of Restaurant Day, or if the institutions themselves found this action supportable. Perhaps it is a mixture of both, or again an interplay where gradual change in the attitudes of the institutions occurred as more people joined to support Restaurant Day.

6 Conclusions

The findings of this paper help understanding the mechanisms that create institutional change as a result of a social innovation. Social innovations occur in contradicting situations when new social solutions are created to solve social problems. Institutional change is created as the social innovation spreads through networks and becomes visible by earning attention in legitimate media, resulting in people slowly changing their attitudes. As more people take action due to this change in attitudes, the cycle of changing attitudes that lead to action spreads creating collective action and legitimacy around the citizen generated social innovation.

The empirical findings on institutional changes and mechanisms leading to it covered in this paper concentrate mainly on changes in Helsinki where Restaurant Day was initiated and where it has established itself most strongly. I believe concentrating on citizens in Helsinki provides an understanding of a citizen generated social innovation in a context where it thrives, and provides a rather ideal situation for studying how social innovation can create institutional change. The findings of this study are limited to one specific case, Restaurant Day, and might therefore not be applicable to all citizen generated social innovations.

The number of interviews and the amount of observation conducted for this paper are limited due to the restricted time and resources that could be used for this paper. The data gives a good general picture of the phenomenon at hand, but more data could strengthen the reliability of the findings.

In future it would be interesting to widen this study to cover several similar cases of citizen generated social innovation to see how well the findings of this study apply to the phenomenon in general. Also an evolutionary perspective would be worth studying, examining the lifecycles of citizen generated social innovations, how they evolve over time and how different stages of the innovation create change. Extending the data to cover more evidence on the realized changes Restaurant Day and similar social innovations have caused in institutions would be a very interesting extension of this study. Additional data to study the changes could be interviews with city officials, or a study of the changes in different regulations since Restaurant Day – or other citizen generated social innovation events – was initiated. Concentrating on the citizen-to-citizen phenomenon could also give interesting insights into how this kind of activity could be utilized more in the society.

The environmental impact of economic activity on the planet: the role of service activities

José Aureliano Martín Segura, José Luis Navarro Espigares

University of Granada (Spain)

Climate change is considered one of the most complex challenges of this century, from which no country is immune, nor can, by itself, address the interconnected challenges, nor the impressive technological change needed. We have reviewed proposals and lines of action that are being suggested by international organizations to combat climate change and promote sustainable development, as well as the mechanisms that have been put in place to help with this task.

All econometric estimates in the panel data indicate that indeed the said index not only contributes to increased mortality, but also to increased investment in R & D. In addition, higher fixed effects are located in developed countries, including Russia and China, in the first case, and Brazil in the second. The periods that the model detects as having the greatest time effects range from 1989-2010 in the first case and from 1996 to 2011 in the second.

1 Introduction and objectives

The 2010 World Bank report on Development and Climate Change indicates that the projected temperature increase during the next 100 years due to the growth in emissions of greenhouse gases could represent a global warming of 5° C with respect to the pre-industrial period. According to the report, such a warming has never before been registered in humanity and the resulting physical effects will severely limit development. If ambitious reduction efforts are carried out, such heating would reach 2° C, a level that is already considered dangerous.

Climate change is considered one of the most complex challenges of this century, from which no country is immune, nor can, by itself, address the interconnected challenges, nor the impressive technological change needed. Also, international agencies make it clear that it is developing countries that will bear the brunt— countries which must simultaneously cope with efforts to overcome poverty and promote economic growth. Therefore, a high degree of creativity and cooperation, a "climate-smart approach", is needed.

This is not new. In 1995 the Intergovernmental Panel on Climate Change (IPCC) warned that climate change would involve hazards to human health, as this could double or triple the number of deaths due to heat, disrupt food supplies, displace millions of people, and the extension of hotter tropical climates could bring malaria, encephalitis, and other diseases. It could also cause other infectious diseases due to flooding of sewer and coastal sanitation systems.

However, the results still do not seem to be very promising. Thus, from the study group Platform 2015, we see that with one year left in the period marked by the international community to accomplish the reduction of poverty, not only have the goals not been reached, but instead inequality has soared in most countries. Therefore, the Millennium Development Goals (MDGs) will not meet this goal, but indeed is each day also further from the solutions to climate change and environmental degradation. An example of this is that the Kyoto Protocol has still not been signed by some of those governments most responsible for harmful emissions, more than twenty years after its appearance. In this context, many people are waiting to see what the scope of the new post-2015 development agenda will be.

In this task, in addition to the important and controversial political decisions to be taken, companies will play a leading role. Their investment decisions, their systems of responsible and sustainable management, the varying degrees of collaboration with governments and international agencies— all of these issues, which are strategic decisions, in addition to their market positioning, will contribute greatly to whether the planet is sustainable or not. Our main objective is to estimate the impact of economic activity on environment by means of the calculation of an environmental impact index. Then some specific objectives will be developed. First we will study the association between environmental impact and mortality, as a variable representative of the health effects. Secondly, we will analyse the relationship between environmental impact and R&D investments. Finally, we will explore and estimate the possibilities of a specific service sector contribution in the fighting against climate change.

2 Methods and expected results

We have performed a literature review to try to analyse corporate behaviour in the present time of economic crisis with regard to sustainable and responsible management. We will try to discover the solutions that are being contemplated in economic and environmental science. We have also reviewed proposals and lines of action that are being suggested by international organisations to combat climate change and promote sustainable development, as well as the mechanisms that have been put in place to help with this task.

Then, a first estimate was made to test what is really happening in the world with regard to the economic and social impact that climate change is causing. One way to measure the environmental impact that our economic activity has on

the planet was discovered in the 1970s by biologist Paul Ehrlich and physicist John Holdren. This method utilises an index based on total population, wealth per capita, and environmental degradation.

The theoretical base of this index is founded on the analysis of what they call primary causes of environmental problems, which according to environmental experts are the following:

- Rapid population growth.
- Quick and wasteful consumption of resources.
- Simplification and degradation of parts of the life support systems of the earth.
- Poverty, which can lead to unsustainable use of non-renewable resources.
- Failure of the economic and political systems in promoting sustainable development.
- The drive to dominate and manage nature for our own uses without a thorough knowledge of its functioning

A way to connect environmental problems and their root causes, according to the aforementioned authors, would be through the above scheme to make environmental degradation dependent on the number of people, the average of resources used by each person (measured by the GDP per capita) and the amount of environmental pollution per unit of resource (which could be measured by the number of tons of CO2 per unit of GDP released into the atmosphere). Thus, in developing countries, the size of the population and the resulting degradation are often the most decisive factors. However, in developed countries, the main components are the high level of resource utilisation and the pollution generated.

In our research, with data provided by the World Bank, we have calculated the Ehrlich and Holdren index for all countries in the world (1961-2012). Then we compared the results, country by country, with mortality rates and R&D investments. Mortality rates, according to Amartya Sen (Sen, A. and Kliksberg, B, 2007:112), give the best picture of health and disease levels in a population. We have also employed R&D investments in our comparison to reflect the efforts made by economic agents to improve the situation, by putting technological innovations in the service of sustainability. Other variables that measure this phenomenon in more detail will be sought in further investigations. The panel data technique was employed to obtain the econometric estimations.

2.1 Bibliographic review

Sometimes, the Economy has been utilised as one of the classic solutions to lessen the impact of our activity on the planet and improve environmental quality. However, the debate is heated. For example, not all experts agree about accepting that prices of the products should be based on total cost (external plus internal in the short and long term). Nor do they agree when it comes to relying more on the regulations than on market forces, or to putting more emphasis on the control and prevention of pollution. A list of possible economic solutions to pollution and waste of resources is provided in Miller (2002:404) (Table 1).

Table1. Economic Solutions to pollution and waste of resources.

<u>Solution</u>	<u>Internalise external costs</u>	<u>Innovation</u>	<u>International competitiveness</u>	<u>Administrative costs</u>	<u>Increase government income</u>
<u>Regulation</u>	partially	<u>Can stimulate</u>	<u>Decrease *</u>	<u>High</u>	<u>No</u>
<u>Subsidies</u>	<u>No</u>	<u>Can stimulate</u>	<u>Increase</u>	<u>Low</u>	<u>No</u>
<u>Removal of harmful subsidies</u>	<u>No</u>	<u>Can stimulate</u>	<u>Decrease *</u>	<u>Low</u>	<u>Yes</u>
<u>Marketable rights</u>	<u>Yes</u>	<u>Stimulate</u>	<u>Decrease *</u>	<u>Low</u>	<u>Yes</u>
<u>Green taxes</u>	<u>Yes</u>	<u>Stimulate</u>	<u>Decrease *</u>	<u>Low</u>	<u>Yes</u>
<u>User fees</u>	<u>Yes</u>	<u>Can stimulate</u>	<u>Decrease *</u>	<u>Low</u>	<u>Yes</u>
<u>Pollution prevention bonus</u>	<u>Yes</u>	<u>Stimulate</u>	<u>Decrease *</u>	<u>Low</u>	<u>No</u>
* Unless more productive and cost effective technologies are developed.					

Source: Miller, T.G.(2002)

Regarding the relationship between taxation and the environment, Puig Ventosa (2010) found that in Spain, 2000-2005, allowances of tax deductions for expenditure on R & D and technological innovation induced companies to increase environmental investments in the years following their application. Nevertheless, he did not find sufficient evidence of a positive impact caused by fiscal allowances on innovation and development.

Another interesting approach is based on knowledge of the opinion of companies regarding the implementation of sustainable management strategies in times of crisis like the present. As a result of the financial circumstances, many companies, have been forced to curtail their spending, including that related to Corporate Social Responsibility (CSR), since it generates more costs (Orlitzky et al.,2003;. Fernandez-Feijoo, 2009). Others firms think that some CSR initiatives could be delayed or cancelled due to the financial crisis (Njoroge, 2009). However, at the same time, the

global financial crisis also provides wide opportunities for responsible companies in terms of brand reputation, employee satisfaction, economic efficiency and improved productivity.

Although social initiatives represent an additional financial cost, in times of crisis, we recommend the implementation of CSR in seven areas of consensus: innovation, workplace environment, the role of stakeholders, business strategy, market orientation, investor confidence and internal revision (Porter and Kramer, 2002; Fernandez-Feijoo, 2009).

Karaibrahimoglu (2010) investigated the performance of CSR in the period 2007 (before the financial crisis) and 2008 (beginning of the crisis in the American market) from the perspective of stakeholders. The study used a sample of 100 firms randomly selected from the "Fortune 500" ranking. The performance analysis was done by means of a content analysis of non-financial annual reports. The results show a decrease in CSR projects due to the financial crisis. This decrease is greater in the U.S. than in Europe.

However, Giannarakis and Theotokas (2011) using a transformation in the levels of implementation of the GRI (Global Reporting Guidelines) for evaluating the responsible performance of 112 companies in 2007-2010, obtained an increase in the performance of the responsible companies before and during the financial crisis, except for the period 2009-2010.

The results of the work of Jacob (2012) show that the financial crisis of 2008 had a clear impact on CSR initiatives in many companies, due to the exceptional pressure that companies had to face to survive; with massive layoffs and cuts in spending on community involvement programs. However, not all the impacts of the crisis were negative. Some areas related to CSR were boosted and were reinforced after the crisis, such as corporate governance, environmental policies and compensation policies. The companies gave more importance to issues related to interest groups that they perceived as the most influential. Therefore, a subject such as environmental policies constituted a risk if the "green investors" were to decide to withdraw their support. Jacob shows that social risks affecting the business reputation are explicitly presented in the annual reports with direct reference to environmental and human rights issues. The supply chain management and the risks associated with compliance with codes of business conduct are also highlighted in these reports. The importance of social risks and their impact on the reputation of companies is usually made explicit in internal reports but not in published annual reports on CSR practices.

From the consideration of CSR practices in a context of strategic positioning of companies, Fernandez-Feijoo (2009) combines the concepts of CSR and crisis, concluding that, in times of crisis, CSR can go from being considered a threat to becoming an opportunity. The idea is that the economic crisis accentuates certain business needs that can be solved by the implementation process of CSR. Such needs include innovation, the work environment, the role of stakeholders, business strategy, market orientation, investor confidence and a deep inner revision.

The implementation of responsible practices requires an innovation process that is the key to achieving long-term survival of the company, which is perfectly compatible in periods of crisis. At the same time, CSR provides a desirable work environment where motivation and corporate culture permit facing periods of crisis. CSR creates an alliance with stakeholders that reorients the perceived risk of these crisis periods to the company. From the point of view of business strategy, CSR is reinforcement for the process. CSR strengthens transparency and communication of the company, allowing it to fortify its market position. Transparency and communication prevent distrust of investors, something critical in times of crisis. In short, the development of CSR implementation processes in businesses compel an internal revision of identity, modes of operation and attitude towards totally compatible responsible values in times of crisis, with the guarantee of its survival. However, we can find various business reactions; some opt to strengthen responsible practices as a strategy to combat the crisis and others, on the contrary, seek to reduce the costs associated with CSR in the short-term to meet the challenges imposed by the crisis (Yelkikalan & Köse, 2012).

What this crisis has clearly shown is that CSR is a phenomenon that is here to stay. This is not a fad or a temporary phenomenon. CSR is increasingly linked to the business strategy of strengthening businesses in the long run. The partnership strategy with stakeholders provides a clearer character to traditional competitive strategies. We cannot expect CSR to be the only solution for crisis; neither can the adjustment processes on employment or wages be avoided. However, it is important to evaluate its cumulative positive effects on relationships with other social and economic agents, as well as in relation to the protection and preservation of the environment.

Finally, we have analysed some of the most important recommendations made by some international organisations to promote sustainable development and help curb climate change.

Thus, the World Bank, in its 2010 report, reached the following fundamental conclusions:

1. The reduction of poverty and sustainable development remain key priorities at the international level.
2. Despite the above, climate change must be addressed urgently. It is estimated that developing countries will bear between 75% and 80% of the cost of the damage caused. In Africa and Southern Asia alone, it would cause a permanent reduction in GDP of between 4% and 5%.
3. It is unlikely that economic growth by itself would be sufficiently fast or equitable to counter threats from climate change.
4. So what is needed is an immediate revolution in the energy sector to spread already available technologies, with low carbon emission levels, accompanied by substantial investment in the next generation of technologies. This is one of strategic sectors for entrepreneurship.

5. It must begin with the high-income countries. They should take steps to reduce their own emissions. This would free some "pollution space" for developing countries. Furthermore, it should have international support to promote the exchange of knowledge, technology and information. This would be another important strategic direction for the business sector.
6. It is estimated that in the coming decades energy systems should be transformed worldwide to reduce global emissions by between 50% and 80%. This will require that new infrastructure projects be built to withstand extreme conditions. Likewise, it is necessary to increase agricultural productivity and efficiency in water use to feed 3,000 million people without subjecting ecosystems to greater dangers— another new strategic direction for the business investment sector.
7. Finally, it calls for a global climate deal that is fair and effective that would involve new forms of financial and technical assistance, both for adaptation and to achieve growth with low carbon emission levels in developing countries. This is another business opportunity for high-tech companies in developed countries.

Meanwhile, the UNDP 2013 Human Development Report affects virtually the same issues as those highlighted by the World Bank. That is, it highlights the rise of the South, and what they call the "drivers" for more effective development: a developmental dynamic state, the ability to connect with global markets and the promotion of social inclusion and human development of large amplitude. That is to say, trade relations between Southern countries are increasing, although the need for international cooperation to carry out all the policies is still needed, mainly in areas such as education, health and the environment, not to mention the great infrastructure investments. All of this represents a wealth of opportunities for innovative companies and for generating clean and sustainable technologies.

Regarding the service sector, we believe that their contribution to climate change must be analyzed through the transport subsector, because the growth of economic activity and the transport models (Alcántara and Padilla, 2010: 25) are two main factors behind the increase in CO₂ emissions worldwide. Some studies estimates his contribution between 13 and 25% of total CO₂ emissions in the world (Transportation Commission, 2010: 27). These figures can be corroborated with the series offered by the World Bank¹⁷⁸, which reports that emissions in 2010 reached 33.615 million Metric Tons of CO₂, of which 5,811 were generated by the transport sector (including domestic aviation, road and rail transportation of people and products). These modes represented in 2010 over 17% of total emissions, excluding marine bunkers and international aviation.

2.2 Econometric estimates

We have made a first econometric estimation through panel data techniques. For this we have used the data provided by the World Bank, from 1961 until 2012, such as GDP per capita, total tons of greenhouse gases that are released into the atmosphere per unit of consumption and total population, for each of the 214 countries registered. With these three variables, an index of environmental impact was built, following the design from the 1960s of biologist Paul Ehrlich and physicist John Holdren, referred to above. Once this index was developed, we first built a model that attempts to analyse the relationship between the same two key variables. One is the level of R + D + i investment in countries in which some funds are being devoted to the improvement and implementation of new technologies to help combat climate change, among others the annual mortality rate was included. Mortality rates, according to Amartya Sen, give the best picture of health and disease levels in a population.

Results and some graphs are shown in the relevant section. Thus, with regard to the comparison between the impact index built and the CO₂ emissions (Graph 1 and 2), we see that the evolution is different in all cases, independently the comparison was made using the CO₂ emissions per unit of consumption (CO₂_GDP) or per population unit (CO₂_PC). Comparing index and poverty (Graph 3), we see that growth is sustained and almost parallel. However, in relation with the mortality variable (Graph 4), we see that both intersect around the 90s, following a growing trend rate impact compared to a downward mortality. Finally, the comparison of investments in R + D + i (Graph 5) shows an upward trend in both.

Graph 1

Graph 2

Graph 3

Graph 4

Graph 5

We made two fixed effects econometric estimates, into sections and years. In the first case (Table 2), we try to estimate the effect that is caused by the environmental impact index calculated on the mortality rate, which, as was said, would be the variable that gives us the best view of health and disease levels in a population, as indicators of human development. In the second estimate (Table 3), we analyse the effect such an impact has on global investments in R + D + i (without detailing, for the moment, what percentage of them is dedicated to investment in renewable energy or other technologies to help curb climate change).

Table 2. Effect of environmental impact index on mortality.

Dependent Variable: MORTALITY

F-statistic	22.58170	Durbin-Watson stat	0.453008
Prob(F-statistic)	0.000000		

In the first case, a positive and significant relationship between index environmental impact and the mortality rate is observed, indicating that the damage that climate change is causing the planet, is having its effects in increased mortality, globally speaking. If you look at the table of fixed effects coefficients by countries (Table 4), it can be seen that the largest effects are surprisingly in some developed countries (Germany, Belgium, Japan, United Kingdom...), plus China, Russia and North Korea. If we analyse the fixed effects coefficients by years (Table 5), in the period of 1983-2010 they become negative.

Table 4. Cross-section fixed mortality.

Regarding the second estimate, a positive and significant effect on the index of investments in R + D + i, is also observed, many of them being aimed at new technologies and renewable energy, which may be helping that the effects of the said impact would not be even greater. Analysing the fixed effects of countries for this case (Table 6) shows that other countries like Brazil or Russia are also added to the list of developed countries. With respect to the fixed effects for years (Table 7), the period of greatest effect in this case is between 1996 and 2011.

2.3 Transport's contribution to climate change.

Using data from the World Bank, we have built several graphs. In Graph 6, the evolution of the total CO2 emissions compared to transport emissions (in metric tons) is shown. In Graph 7 we compare the impact index we have built with total CO2 emissions per GDP, both global and due to transport. It is noted that the trend of both are similar.

Graph 6

Graph 7

To study the link between CO2 emissions resulting from the transport and the environmental impact index a specific econometric estimation was carried out. The results can be seen in Table 8, and indicates that the influence of transport emissions in the overall impact index is statistically significant but negative, which could be an evidence of the positive results from the previous international efforts described above, at least in developed countries. In fact, when calculating the country fixed effects (Table 9) we can see that in developed countries fixed effects coefficients are higher.

3 Conclusions

All econometric estimates in the panel data indicate that indeed the said index not only contributes to increased mortality, but also to increased investment in R & D. In addition, higher fixed effects are located in developed countries, including Russia and China, in the first case, and Brazil in the second. Periods in which the model detects changes in the temporal effects range from 1983 to 2010 in the first case, and from 1996 to 2011 in the second.

The literature supports that there are great investment opportunities for businesses in areas such as infrastructure, education, health and new technologies related to renewable energy.

The fact that this is giving important development in the Southern countries, and that trade relations between them is increasing, does not mean that there are not still opportunities for companies in developed countries, because their greater knowledge and technological development operates as an important factor to generate a positive collaboration with these countries for sustainable development.

With regard to the transport sector, although some studies estimate that the percentage of emissions represents 25% of the total, when we analyzed the correlation with the impact index, we obtained a statistically significant relationship, but negative, with fixed effects coefficients higher in most developed countries. This could be the evidence of the environmental positive effects derived from international changes in transport models.

Utilizing strategic business networks in the field of SME's in Finnish wood product sector - A case study based on two companies

Osmo Mattila, Kaisa Hämäläinen, Liina Häyrinen, Sami Berghäll, Anne Toppinen

University of Helsinki, Department of Forest Sciences

In Finnish wood product industry, optimizing production has traditionally been in the main focus of the companies. Recently, domestic wood product markets have faced the tightening global competition and new players focusing customer value creation processes. In order to be able to serve customers comprehensively, business networks are needed. Despite the challenges, only a few of the wood product companies have started to re-think their business models and to challenge the dominant market structures. Therefore, the objective of this study is to understand different business models in the market through two case companies that have adopted new types of network business models

1 Introduction

Wood product industry is a market in a flux. Traditional production orientation does not seem to fulfil the requirements of a modern customer. Recently, domestic wood product markets have faced the tightening global competition and new players focusing customer value creation processes. The majority of the wood industry enterprises are small or medium (SME) and they struggle with lack of resources. Dynamic capabilities are needed to address rapidly changing environments (Teece et al., 1997). Jarillo (1993) argues that compared to vertically integrated companies, business networks are a more capable form of organization in order to react to rapid changes in market environment. By increasing the level of networking it might be possible to create more adaptable business models.

Services sector is growing everywhere in the world accounting more than 70 percent of the gross domestic product in regions such as USA, and European Union (CIA, 2012). In recent service marketing literature, discussion about services has been one of the main topics event to the degree that it may even be artificial to make a division between services and products. As Vargo and Morgan (2005) argue, also product-centric firms have always provided services. Ravald and Grönroos (1996) use term 'value carrier' to describe the mechanism how a firm can offer a value proposition to a customer.

Construction sector and wood products are good examples of markets where the physical part of service plays an important role by not only enabling the basic level of service (e.g. living in a house) but also has potentially other levels of customer value. As one of the rare renewable raw-materials, forest-based products may have a bright future in the product-intensive service markets by having potential to substitute materials like plastic and concrete. Anyhow, customers still buy something beyond physical product (Vargo; Lusch, 2004) and companies should be more focused on customer value rather than their own production limitations.

Thus, while the tradition in forest product industry is very product oriented, networking might be one way to widen a company's resource pool to better be able to serve customers. Majority of the Finnish wood product companies are small or medium sized family-owned businesses. According to Ali-Yrkkö et al. (2007), this kind of companies usually have low incentives to become international. From the viewpoint of networking, Varamäki and Vesalainen (2003) argue participating to be one of the major challenges of SMEs. Despite the potential advantages of networking (Varamäki; Vesalainen, 2003; Pätäri, 2010; Toppinen et al., 2011) networks are dominantly not seen as strategic resources (Toppinen et al., 2011). According to Arhio (2007), networking carpentry enterprises are better able to innovate and to develop their business than the ones doing all in-house. Thus, while the benefits seem to be clear, there is lack of research in wood products industry considering networking.

2 Objectives and implementation

The objective of the study is to analyse and understand the networks of two case companies. Qualitative data were collected among the companies and their network partners by face-to-face themed interviews. Data were analysed by classifying them into themes. The companies were chosen on the basis of their activity using networks in their business.

Both companies operate in wood product business but are not actual competitors because of differing products and core competences. Company A is a relative new actor in wood construction sector. The business of it is built around wood panel construction including the whole building value chain from planning to installation and maintenance. The business model of company A is built on the idea of networking. Company B has a more traditional business model producing wooden claddings and other wooden construction materials. It sells a complete service package and has built a network to support installation and maintenance. The selected companies were interesting because of their wish to operate via a network-based business model.

The representatives of company A and B were given the same interview framework including the following themes: 1) current networks and members, 2) core competences and resources, 3) benefits and opportunities of networking, 4) obstacles and problems of networking, 5) potential future networks, 6) innovativeness, 7) trust, openness and

commitment. The expert of wood product industry was given an interview framework which was slightly more general in details but included the same themes. Many of the interviewees of the company networks also commented the whole wood product sector. The themes of the interviews are based on the theoretical framework. Interviews were implemented in the end of 2013. All the interviews were recorded and transcribed. This paper is based on the Master's thesis by Hämäläinen (2014).

3 Theoretical framework

Thorell (1986) defines network as a long-term relationship between two or more organisations. They can be loose or tight depending on the number of members, commitment and interaction (Williamson, 1975; Thorelli, 1986). Networks can be borderless, self-organizing systems that emerge from interaction or more intentionally created 'strategic networks' (Jarillo, 1993). Different types of networks require different types of management, and value creation logic has a fundamental role in influencing effective mechanisms for governance (Möller; Rajala, 2007). Ireland et al. (2002) name the selecting of network partners to be a starting point for efficient and profitable network. According to Morgan and Hunt (1994), trust and commitment are important elements for the relationship.

Möller and Rajala (2007) identify and place value nets on a value-system continuum (Figure 1). *Current business nets* in the left end have achieved relative stability and high level of resources. Vertical demand-supply nets and part of horizontal market nets are postulated to belong to this domain. *Business renewal nets* aim at increasing the efficiency of the existing nets by improving their offerings or specific parts of the business processes either continuously or as project-based, like customer solution nets. *Emerging business nets* concern radical, discontinuous and system-wide changes where new technologies, business concepts or even business fields are being created. Application nets are formed to support the race for achieving commercially viable business applications out of the evolving technology and they generally have a hub company. Dominant design nets generally consist of diagonal coalitions of partially competing and partially complementing companies that proactively try to create coalitions. Innovation networks are generally loose science and technology-based research networks. (Möller; Rajala, 2007).

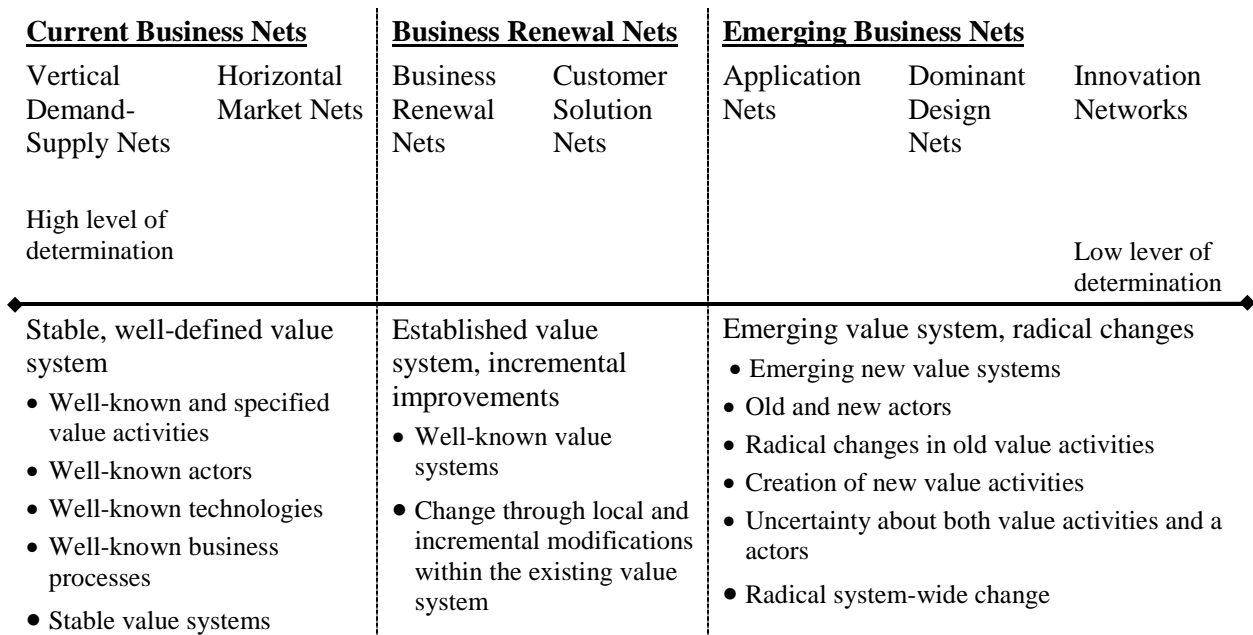

Figure 1. Business net classification framework (Möller; Rajala, 2007).

4 Results

4.1 Company A network structure

Company A is a company producing wood elements. Even though it is not a proper hub company of the network, it has a central role in the network that offers substitutions for concrete elements in the construction sector. Company A has created a strong network around the main product to enable offering a tailored full building service package. Network consists of either companies or specialists of architectural planning, construction planning, building services, HVAC and ICT, material procurement and subcontracting, logistics and installation (Figure 2).

Figure 2. Company A network structure.

The main idea of the network is to work together in close connection to reach the shared goal together as balanced partners. To customers, the network offers complete and competitive building services. The members of the network thought that shared goals are crucial for success. This kind of a network was also said to be something unusual in the sector: “This may be the first one in Finland but were are not any kinds of pilots. This is a common way to build in Sweden, Norway, Austria, Switzerland and from Frankfurt onwards in German states”. Finnish construction culture was mentioned to be a subcontracting network lead by a hub company with relations more like trading than networking. Another success factor has been the choosing of network partners. In this network they have been selected on the basis of positive experiences of collaboration in previous projects, track record in wood construction sector, capabilities to commit to the shared goals, and ability to learn from one's past.

As benefits from networking the members mentioned increased capacity to offer larger entities and efficiency in marketing even though marketing is still done independently from the other network members. However, the respondents saw this last comment was given changing in the future. Thus, combining resources it is possible to offers services to a larger customer group and network offers prospects to get to the international markets. Potential innovativeness originating from the structure combining different kinds of specialists is also seen as benefit: “It is clear that this kind of network has potential to innovate and come up with new ideas and solutions. This alliance structure is innovative by its nature”. However, innovativeness in the wood product sector was criticized by one of the interviewees as chasing too much revolutionary ideas and forgetting the reality of everyday business.

4.2 Company B network structure

Company B manufactures wooden claddings and other construction materials and sells installation services for the products. It does not have own labour for installation but it uses a large network of installing companies (Fixure 3). Towards customers this seems like subcontracting but towards installation companies the collaboration is deeper. All the areas of responsibilities are clearly described between the network partners.

Figure 3. Company B network structure.

Networking started from customer needs of a large entity which helped the partners to concentrate to their own core competencies. Deep collaboration increases the total quality of the process in this kind of service: “You ruin the whole process if the quality of the installation is not desirable”. Choosing of network partners depends on their track records and reputation: “If we don’t accept some partner, the reason may be because of their poor management of finances”.

Interviewees were conscious of growth potential the network enables. By being able to offer large services it is possible to have customers outside their normal customer segments. For installation companies this means more work. Growth may set some challenges in the future because communication has until now been based on close geographic locations of the partners: “It is a real advantage to be so close to company B that we meet almost every day”.

Resources of the network of company B are currently sufficient but scalability of the network is questionable. For the present, installation companies are spatial and after a certain point they do not get more out of the potential growth if company B just seeks for more partners. There are also challenges about openness when company B is the only one of the network to negotiate with customers: “If we only could reach the level of openness when I was involved in negotiations”.

4.3 General comments concerning networks in the wood product sector

Among the interviewees, potential of networking was identified. According to the interviewees, especially concentrating on own core competencies: “If you have to offer variety of products, solutions, have a good marketing system, sales and visibility, the only way the SMEs can do it is to create a network or alliance with a coherent strategy”.

Despite experiences and positive attitude towards networking, lack of courage, ear of change and negative attitudes towards competitors as potential partners were mentioned to hinder the development: “I think it is a Finno-Ugric genetic error that we are handicapped as team-players. It is usually a want to dominate because of belief of knowing better than the partner. Envy is an obstacle.” Small players can only have a very limited assortment of products and services which was recognized to be a problem in marketing.

4.4 Key findings

As a summary of results (Table 1), the network of company A is close to intentionally created strategic value network that has members with clear roles and responsibilities (see: Möller et al 2005). Network of company A also had a shared goal of creating a substitute to concrete elements in multi-storage house construction. The network of company B instead, is closer to subcontracting network than strategic network. The partners have a wider variety of goals including offering complete installation process of wooden claddings, finding reliable and high-quality partners and increasing the size of the business. Track record and reputation were mentioned to be the most important partner selection criteria. Reasons for failures in networking were related to not obeying the shared rules (network A) and low quality (network B).

Table 1. Summary of the results.

	Network A	Network B	General industry practices now
Structure and business idea	A hub company and balanced network partners with a shared goal	A hub company with partners concentrating on their own core competencies	Networking at low level, opportunities identified
Objective of the network	Offer substitutes to concrete elements in the multi-story building market	Slightly differing objectives among partners, high quality wooden claddings with full services, economic value	Promoting export, becoming international, offering larger entities to customers
Network partners and selection criteria	Track record in wood construction sector, networking skills, members selected by benchmarking	Relationships and earlier experiences in collaboration, proper management of finances	Image, track record, quality of work; proper management of finances increasing
Benefits and opportunities	Innovativeness opportunity in a specialist network	Scalability if new partners are found	Improve profitability, larger entities for to customers
Resources	Lacking in installation and operative management of the industrial plant	Lack of salesforce and difficulties in finding good partners	Increasing role of customers requires resource integration for small companies
Openness, trust and commitment	Open atmosphere, dialogic and trustful culture that allows challenging	Commitment based on contracts, more openness needed, employing the installation companies increases trust	Openness and trust as starting point, technical documentations
Problems and threats	Current poor economic situation in the sector, copying the building system as a threat, internetwork resource allocation problems	Current poor economic situation in the sector, difficulties in finding new partners	Current poor economic situation as threat; suspicious attitude

Generally in the wood product sector, networks were seen to have potential especially for SMEs by offering them resources to be able to increase the current potential customer groups. Potential for improving cost efficiency was also identified. However, the culture in the industry is different. Short-term profits and subcontracting define usually collaboration. Suspicious attitude towards other players in the market was seen as an obstacle for cooperation and development. In addition, customers and end-users are rarely embedded in business models or decision making.

5 Discussion

The companies studied in this research have very different network business models. Even though company A has a central role, the network consists of balanced partners with a shared goal of creating a substitute for concrete building elements. All the partners have their own areas of responsibilities. The network of company B has a clearer role as a hub company. The collaboration has features of network business model but also of subcontracting. The members of the network of company B have not a clearly shared goal.

When considering the business net classification framework by Möller and Rajala (2007), the network of company A can be placed more on the right on the continuum compared to the network of company B (Figure 4). Network A consists mostly of old actors who have created a new-in-the-market value creation system. The network of company B is more stable and has an established value system reaching for incremental improvements. This network was found to offer a solution to a customer rather than created intentionally. However, company B does not have an own substitute to their services and in this context can therefore be defined to be network-oriented.

<u>Current Business Nets</u>		<u>Business Renewal Nets</u>		<u>Emerging Business Nets</u>		
		<i>Company B</i>		<i>Company A</i>		
Vertical Demand-Supply Nets	Horizontal Market Nets	Business Renewal Nets	Customer Solution Nets	Application Nets	Dominant Design Nets	Innovation Networks
High level of determination				Low level of determination		
Stable, well-defined value system <ul style="list-style-type: none"> • Well-known and specified value activities • Well-known actors • Well-known technologies • Well-known business processes • Stable value systems 		Established value system, incremental improvements <ul style="list-style-type: none"> • Well-known value systems • Change through local and incremental modifications within the existing value system 		Emerging value system, radical changes <ul style="list-style-type: none"> • Emerging new value systems • Old and new actors • Radical changes in old value activities • Creation of new value activities • Uncertainty about both value activities and a actors • Radical system-wide change 		

Figure 4. Networks of companies A and B on the business net classification network by Möller and Rajala (2007).

Reputation and resources were mentioned as important selection criteria for network partners. Both of the networks lack of some resources and some difficulties in finding proper partners. One reason may be the limited size of the market when operating in Finland but also the dominating suspicious attitude towards competitors as potential partners may be a reason. Both of the case companies also mentioned bad experiences of networking.

6 Limitations and themes future research

Qualitative case research was a proper method for the research and the objectives of understanding the networking of the selected companies was fulfilled despite the rather small numbers of interviews. However, the selected companies are not representing the companies in the field well but are rather special cases. This lowers the level of generalization of the research.

The companies in the market are small and mostly operating in the domestic market. This makes their scale small and other actors in the markets are seen more like threats than potential partners. One interesting topic for future research would be, why there are so few network-based business models in Finnish wood product industry even though their potential is recognized.

Practices of social-business innovation

Mele Cristina, Russo-Spena Tiziana

University of Naples "Federico II"

This study focuses on social-business innovation as a new integrated approach to address the complexity of the social issue social as well as the business endeavour. The authors set up the following research questions that led empirical study and theoretical contribution: 1) how can we frame social-business innovation? Social-business innovation is not simply a new solution (goods or services) but a service provision of multiple benefits for several actors. It is an enabler of value, well-being and viability. In this perspective the study provides evidence of a different way of thinking and acting about problems or opportunities: a process involving reflections with various stakeholders not only on what to do but on how to do.

Three practices of doing social-business innovation are addressed: 1) engaging, 2) promoting, and 3) institutionalizing.

1 Introduction

The Europe 2020 strategy is about delivering growth that is: [smart](#), through more effective investments in education, research and innovation; [sustainable](#), thanks to a decisive move towards a low-carbon economy; and [inclusive](#), with a strong emphasis on job creation and poverty reduction (Europe 2020).

The Europe 2020 Strategy makes clear that the future wealth and wellbeing of citizens depends on smart, sustainable and inclusive economy. Societal challenges are of particular interest to companies, not as a charitable favour to society, but because they also provide a tremendous business as well as social potential (Moss-Kanter, 1999; Porter and Kramer 2011). The range of innovative opportunities opens up to companies able to ride the social trend. For example Unilever has launched the project of social open innovation (Sustainable Living Plan) within the corporate vision "to double the size of the business, whilst reducing our environmental footprint and increasing our positive social impact" (www.unilever.com/sustainable-living-2014 www.). Also IDEO launched OpenIdeo, an open innovation platform to engage the global community to solve "big challenges for social good" (<https://openideo.com/challenge>).

Moss-Kanter (1999) revealed that traditionally business viewed the social sector "as a dumping ground for spare cash, obsolete equipment, and tired executives" (p.123). However some companies have begun to approach social context as a learning laboratory to move beyond corporate social responsibility to corporate social innovation. These companies see social problems are economic problems: *they have learned that applying their energies to solving the chronic problems of the social sector powerfully stimulates their own business development. ...Not spare change, but real change-sustainable, replicable, institutionalized change that transforms schools, prospects, and neighbourhoods. And that means getting business deeply involved in non-traditional ways. Tackling social sector problems forces companies to stretch their capabilities to produce innovations that have business as well as community payoffs. ... This is not charity; it is R&D-a strategic business investment (p. 124).*

The slogan 'Doing well by doing good' reflects the changes in attitudes in many companies (Roper and Parker, 2013) whereas "the goal of business is not profit maximization alone, but also societal acceptability" (Lähdesmäki and Siltaoja, 2010, p. 214). A new kind of organizations joining a social or environmental mission with a business performance has appeared. These companies are not for-profit or nonprofit, but they are a sort of blend of the two; they are "for-benefit enterprises" (Sabeti, 2011), forming what has been called the fourth sector of economy (with a change in legislation in several Nations).

Management scholars have recently highlighted the need to integrate social and business perspectives in order to identify and prioritise the role of companies in pursuing social challenges at a higher level (Rubalcaba et al., 2013). Despite some progress, there is still a paucity of theoretical debate and empirical evidence on the link between the social and business innovation. Business innovations aim to satisfy market needs improving companies' economic performance (Trott 2008). Social innovations are defined instead as innovative activities and services that are motivated by the goal of meeting social needs (Pol and Ville, 2009) and improve the quality of life (Rubalcaba et al., 2012). There are no studies on a joint definition of what is a social-business innovation.

Furthermore while the existing literature on social innovation addresses the questions of what, where and who makes social innovation happen, by focusing on the role and the actions of non-profit and public organizations, some scholars (Llie and During 2012) propose an alternative perspective that deals less with the accountability of the social innovation process and more with acknowledging the practices of social innovation starting with individuals and groups in the communities. Also in business studies there is a growing interest in understanding the practices of innovation (Mele and Russo-Spena, 2015a, 2015b) to depict the role of actors, resources, activities and institutions.

The objective of paper is how to frame social business innovation. To address this aim we open up both the dimension of "what" social-service innovation is and the "practice" that is how social-business innovation is developed.

The paper is articulated as follows. First we present a literature review on business innovation and social innovation. Second, the methodology is illustrated. Then, the findings focus on innovative value proposition and practices of social business innovation. The work ends with discussion and some implications.

2 Literature review

Business innovation refers to a wide literature in business studies, while social innovation has roots in different domains such as sociology, economics and more recently management and marketing. We offer brief reviews to frame business innovation and social innovation.

2.1 Business Innovation

Business innovation concerns translating ideas into goods and services for which customers will pay. It must be replicable at economic cost for the company and it must satisfy a specific need in the market (Tidd, Pavitt and Bessant, 2001; Trott, 2008).

According to Drucker (2002) innovation is the means by which the entrepreneur creates new wealth by producing resources or using existing resources. The sources of innovation are multiple ranging from changes, opportunities and needs within the company, the industry and the market. Companies view markets' needs as opportunities to generate and develop new ideas, serve new markets and improve business performance. Innovation comes out from the effort to create purposeful changes in the company's economic potential. Innovation is driven thus by business motivations.

Within the business domain, innovation allows the company to feed its revenues pattern, increase market share and drive sustainable competitive advantage. Traditionally the value creation process behind innovation process looks at the customer as the recipient of the new output while the main beneficiary is the company.

Innovation debate in business studies has focused on three main topics among others: 1) the degree of newness of the innovation output; 2) the main sources of innovation patterns and 3) the process of innovation.

New ideas can be applied in product innovation or in process and organization innovation (Clark and Wheelwright, 1993; Nonaka and Takeuchi, 1995; Trott, 1998). The newness refers to small changes to and variations of existing products (incremental innovation) or to completely new products (radical innovation) related to a new technological paradigm or to a new market creation (Henderson and Clark, 1990; Garcia and Calantone, 2002). Technology and market are seen indeed as main drivers of innovation patterns: the technology-driven model (Henderson and Clark, 1990; Li and Calantone, 1998) sees the market as a recipient of research and development (R&D) breakthroughs while the market-driven model (von Hippel, 1988; Baker and Sinkula, 2005) regard market orientation as the main source of the R&D efforts. In both cases the development of new product and new service development follows a closed linear process well depicted in the stage gate model which proceeds with phases separated by gates (Cooper, 1988). This traditional model of innovation has been challenged by the open innovation model (Chesbrough, 2003) whereas the flow of innovation activities opens to external actors with whom the company can collaborate to increase its knowledge and resources assets. The cooperation enriches the creativity and the potential to develop innovations.

Studies within service-dominant logic (Vargo and Lusch 2004, 2008) have recently offered a fresh contribution to innovation debate. First of all, the conceptualization of innovation in terms of S-D logic is primarily based on the different meaning of service. Rather than being seen as an outcome (i.e., not as new goods or new services), innovation is perceived as a process wherein provider and user together seek out ways that enable them to successfully collaborate in resource integration, by fostering thus value creation. In this perspective the focus moves to innovative value proposition.

Second, the newness of an innovation seen from the perspective of S-D logic does not have to be technological; it can also refer to a product being used in new ways, as in a different context, place or time. The divide market/technology is overcome with the view that it is beneficiary, the person who determines the value of an innovation brought about by the integration of resources, context and experience (Vargo, Akaka, Weiland, forthcoming).

Third, S-D logic stresses that successful innovation relies on all participants collaboratively co-creating value within an open and democratized process because single companies do not have enough knowledge and resources to develop innovations (Lusch et al., 2010). Innovation is framed thus as the process by which stakeholders variously contribute, collaborate, cooperate, i.e the process is one of co-innovation (Russo-Spena and Mele, 2012). Such contributions occur in an integrated many-to-many way through A2A interactions (Gummesson and Polese 2009; Gummesson and Mele, 2010; Vargo and Lusch, 2011) in the open network and in the larger service ecosystem (Vargo and Lusch, 2011; Mele, Russo Spena and Colurcio, 2014). This view overcomes the traditional way of seeing the customer as the recipient of the newness and the company as the main beneficiary in terms of economic performance: all the company's stakeholders can benefit from innovation processes.

Recently, the process view has been stressed also by some studies adopting the practice-based approach to innovation (Hildreth and Kimble, 2004; Duguid, 2005). By advocating a contextual and process-oriented view of co-creation and innovation Russo-Spena and Mele (2012) and Mele and Russo Spena (2015a; 2015 b) address innovation

as a set of co-creation practices that involve an array of factors, including actors, actions and resources, in addition to the mere innovation output itself: innovators are seen as carriers of practices who perform actions through the use and integration of resources (symbolic, linguistic and material). The practice-based approach offers a broader view to frame innovation, Focusing on practices enables indeed scholars to see and analyze the social connections among individuals, collectives, organizations, institutions, and the social contexts in which these connections are formed.

2.2 Social innovation

Although the concept of social innovation is not new (Drucker, 1987), the boundaries of social innovation research stream have not yet been completely defined. The debate has boosted during the last decades, spurred notably by the growing interest in fields related to economics (public finance), entrepreneurship and management, technology, sociology and policy (Hans-Werner et al., 2012). Notwithstanding, some common features could be framed, the disagreement about what social innovation is and what is not is still strong

The attention of scholars has been concentrated differently (Hubert et al. 2010). In some studies the focus is strictly narrowed to the social instances addressing innovative efforts of organizations whose primary purposes are social. Other scholars claim for a broader concept of social innovation by referring to innovative activities exploiting social issues as opportunity to identify unmet needs and develop solutions that create new markets (Porter and Kramer, 2011).

2.2.1 Social innovation: social demand perspective

The social innovation debate has its roots in the social instances that respond to pressing social needs traditionally not addressed by the market. In the social demand perspective social innovation concerns complex issues in various areas of society - employment, poverty, housing, health care - and is directed towards vulnerable groups in society (Mulgan 2006). The most heralded approach to definition of social innovation is that of Stanford social innovation research team defining social innovation as a “novel solution to a social problem that is more effective, efficient, sustainable, or just than existing solutions and for which the value created accrues primarily to society as a whole rather than private individuals” (Phills et al., 2008: p. 39). The kind of value that innovation is expected to delivery is less tied to issues concerned with profit as Pol and Ville (2009) affirm: “*Social innovation involves new ideas improving quality or quantity of life, not necessarily linked with economic profits. The ultimate end of social innovation is to help create better futures*” (pag. 884).

In this sense social innovation rests on an integrated system of related products and services; it needs to provide benefits towards public or society instead of satisfying private issues (such as gains for entrepreneurs, investors and consumers) and to prove effects that are longer in the time. This has important implications not only in terms of goals and its beneficiaries, but also in terms of main actors as agent of innovation. Different scholars claim the social innovative activities as predominantly developed and diffused through organisations whose primary purposes are social (Mulgan 2006). They tend to limit social innovation domains to public and nonprofits organisations, implicitly or explicitly excluding firms and other for-profit organizations. Although scholars have made valiant efforts to broaden prevailing conceptions of social entrepreneurship and social enterprise (Hall et al. 2012), the trade-off between social and business innovation remains still preeminent in this perspective. While the business innovator is seen to place priority on improving firms’ competitive position by gaining short-term benefits (such as market share and profits), the responsibility to take care of society and prevent negative impacts in the long-term are the only challenges which a social-innovator deals with (Yunus et al., 2010). The managers and partners of social companies operate without seeking to add pecuniary or other materials gains to their assets and profits; when they occur they are in principle to be invested in the enterprise (Schoning, 2013).

Private companies have complementary roles as agent of social innovation and in some cases they use social issues as a business opportunity while also addressing economics concerns. In particular, the base-of-the-pyramid (BOP) and subsistence marketplace literatures have recently affirmed in the social debated as an attempt to merge social and business perspectives. These literatures suggest that companies can create profitable markets while also helping the poor in addressing their urgent needs (Anderson and Markides, 2007). Strategic social issues occur when companies accept social responsibility and integrate it into their core business strategy. The creation of new markets for BoP communities are seen as an opportunity that firm can grasp mainly through a re-design of product and delivery platform without changing their basic technology (Prahalad and Hammond, 2002). Two important and related aspects characterize innovation at the BOP: 1) the role of large firms in the market economy as innovators also penetrating the BoP markets; 2) the need of combining social and economic goals also through a new form of partners to be involved. By looking at the process of innovating with non-traditional partners, such as NGO, local communities and others, some scholars (Hall et al. 2014) argue that BOP innovations are in their nature collaborative involving both profit and no-profit businesses.

2.2.2 Social innovation: the integrated perspective

Hints towards the elaboration of advancement in the social innovation debate can be found in more recent contributions calling for a multidimensional and systemic approach (Roome, 2013) (see Table 1).

According to Schmidpeter (2012) addressing the societal challenges necessary postulate new approaches to their solution with new roles and interactions of various actors resulting in social innovation. In the integrated perspective social innovation works towards a systemic social change including changes in values, power, beliefs, practices and it focuses on the “collective” aspect of the process of innovation which cannot simply be reduced to the contribution of single actor no matter how extraordinary or grand it may be (Neumeier, 2012; Osburg and Schmidpeter, 2013; Rubalcaba, et al. 2013).

Social innovation is seen not only as a way to respond to new social problems that cannot be fixed with traditional business or policy instruments but as solution to more global challenges (including environmental challenges) ensuring e economic performance too under a new integrated social-economic paradigm. As Viñals (2013) outlines it consists of putting innovative new systems into the place to bring up social change.

This perspective provides new meaningful insights as the plurality of news concepts they conveyed. Firstly, social innovation rises necessarily through a collective and participative process as it runs through interactions between a wider spectrum of actors including individual, public, private and third sector organizations and any others who are interested in solving a social problem (Rubalcaba et al., 2013). It is a networking based phenomenon that extends beyond simple products or service relationships and relies on the simultaneous development of organization, technologies, services and multiple network relationships (Le Ber and Branzei, 2010).

This integrated view puts into the focus also the implementation and diffusion of new practices rather than just narrowing innovation to the development of new ideas. Some authors define social innovation in terms of creating new social practices or new way of combining them (Hochgerner, 2013; Cajaiba-Santana, 2013). According to Hochgerner (2013) social innovation cannot be built up on the basis of established practices and it necessarily involves a renewal of resources, practices and schemas with the power to transform society and its practices.

The changes regard not only the way the social agents act and interact with each other, but the social context in which these actions take place through the creation of new social systems (Caulier-Grice et al., 2012; Hochgerner, 2013). How to complement technological and economic innovation with changes in attitudes and values, strategies and policies, organisational structure and processes comes in to the matter as well as responsibilities and tasks of different institutions involved.

The process of collective creation for social innovation is complex because of its networking implications; moreover it includes the idea of multi empowering agents who act and think collectively in the development and implementation of new ideas to promote social change (Rubalcaba et al., 2012; Cajaiba-Santana, 2013). The empowerment of individuals based on the revitalization of social aspects as well as the interplay between the top down and bottom up of innovation process activities are important in social innovation (Neumeier, 2012). Top-down activities from the main institutions (including business policies and regulation issues) are necessary for the materialization of social innovation; anyhow the bottom-up activities are the engine of social innovation and are linked to social and people empowerment.

Table 1. Definitions of social innovation in a broader systemic perspective.

Wesley and Antadze (2010)	Social innovation is a complex process of introducing new products, processes or programs that profoundly change the basic routines, resource and authority flows, or beliefs of the social system in which the innovation occurs. Such successful social innovations have durability and broad impact.
Neumeier (2012: p. 55)	Social innovations are non-material: their material outcomes are solely a supplementary result and they focus not on needs but on asset building Social innovation is “changes of attitudes, behaviours or perceptions of a group of people joined in a network of aligned interests that in relation to the group’s horizon of experiences lead to new and improved ways of collaborative action within the group and beyond.”
Rubalcaba, Di Meglio, Gallego (2013: p. 202)	Social innovation is participative, implies the process of social interactions between individual citizens and organizations and involves a spectrum of actors and stakeholders who have a vested interest in solving a social problem. Accordingly the collective creation process for social innovation is complex and can involve multiple public, private and third sector organizations.
Caulier-Grice, Davies, Patrick, Norman. (2012: p. 18)	Social innovations are new solutions (products, services, models, markets, processes etc.) that simultaneously meet a social need (more effectively than existing solutions) and lead to new or improved capabilities and relationships and better use of assets and resources. In other words, social innovations are both good for society and enhance society’s capacity to act.
Viñals (2013: p. 4)	Social innovation refers to a design and implementation process as well as a process of disseminating new social practices and policies. It encompasses innovations that are directly related to the search for solutions to society’s problems and challenges. These solutions often involve new form of communication and cooperation.

Cajaiba-Santana (2013: p.3)	The path of social innovation is not a social problem to be solved, but the social change it brings about. From this standing point, one can better perceive the specificity of the process of social innovation creation as new ideas manifested in social actions leading to social change and proposing new alternatives and new social practices for social groups. Social innovation is a collective creation of new legitimated social practices aiming at social change.
Hochgerner (2013)	Social innovation is the new combination of social practices

3 AIM

The literature debate has gained a momentum to open up social innovation to business and management issues (Ellis, 2010; Rubalcaba et al., 2013). However, there are few studies that specifically relate business innovation with social innovation from an integrated perspective.

Social innovation looks at social and behavioural changes where the perspective is still public-agent focused and non-profit oriented (Rubalcaba et al., 2012). While institutions and public organizations lead social innovation process companies still are seen as actors that can participate to this process (Pol and Ville, 2009).

Recently it has becomes more salient to question whether firms have power in the way that institutions have power (Painter-Morland, 2013). The business world is stated to become often influential in many parts of society, including in public and political decisions. However when governments adopt new policies and strategies in response to popular or special interests to change society, businesses are much more often attentive to responding to market opportunities circumstances and their own competitive performance.

This paper starts from a view of the company as part of a broader system of economic, social, cultural and technological influences. The importance of the various influences depends on the firm’s ability to shape a new social-business innovation context. The issue concerns not simply the building up of a collaborative network of actors for the pursuit of the lead organization’s main innovation goals. The organizations take the lead of the social and business changes when they are more proficient in interactively shaping and collaboratively developing values, standards and rules by joining the interest of different social, economic and institutional actors (Hans-Werner et al., 2012).

The understanding of how the interplay between social and business systems enable context for social-business innovation is crucial at a time scholars are trying to understand how promoting social change by integrating governments, markets, and private initiatives.

The objective of paper is to provide a first answer to how frame business and social innovation by an integrated perspective. More specifically we deal with the following questions: 1) What is social-business innovation; 2) What are the practices of social-business innovation.

4 Method

We focused our analysis on the for-benefit enterprises, as a richer context to understand the interplay between the business and social issues. The double soul of this kind of companies makes them interesting to be analysed in order to get insights into the social-business innovation, without having one issue overwhelms the other (i.e a business-oriented social innovation vs. a social-oriented business innovation) but a more equilibrated situation.

We investigated the community of B-Corporations, a new type of company that uses the power of business to solve social and environmental problems. Such corporations are certified by the non-profit organisation, B Lab, and meet rigorous standards of social and environmental performance, accountability and transparency. This community is growing daily and includes organisations from all over the world. The B-Corporation community is increasing at an impressive rate, growing from 450 at the end of 2011 to 1000 as of August 2014.

The following quote well depict the vision of B-Corporations:

B Corps create higher quality jobs and improve the quality of life in our communities. And, as the movement grows, it has become an increasingly powerful agent of change. We are passing laws. We are driving capital. Government and the non profit sector are necessary but insufficient to address society's greatest challenges. Business, the most powerful man-made force on the planet, must create value for society, not just shareholders. Systemic challenges require systemic solutions and the B Corp movement offers a concrete, market-based and scalable solution.As a result of our collective success, individuals and communities will enjoy greater economic opportunity, society will address its most challenging environmental problems, and more people will find fulfilment by bringing their whole selves to work ([http: www.bcorporation.net](http://www.bcorporation.net) accessed 30 July 2014).

We selected a sample of 50 B-Corporations through a research based on key words (social innovation and business innovation) on the B-Corporations’ website. We investigated how companies frame social-business innovation and

develop innovative practices through multiple methods: netnography, interviews and seminars. The research adopted an emergent, flexible, abductive process, oscillating between theoretical insights and empirical work (Dubois and Gadde, 2002).

In accordance with netnography research, data include preliminary studies of the web-based context, naturalistic observations of the community and the activities of its members and direct interactions with the members of the innovating community (Kozinets, 2002).

The data were elaborated and analysed by setting up a two-phase investigation. First of all companies' documents and written interviews were analysed through a content analysis. As Weber notes (1990), content analysis classifies textual material reducing it to more relevant, manageable bits of data. The analysis began by identifying and quantifying certain words or *content* in documents to grasp their contextual use. Quantification was conducted to explore usage and not to infer meaning, as advised by Hsieh and Shannon (2005). However, the analysis was not only limited to measuring the frequency of specific words or content (i.e., manifest content), but it also included a summative approach (Hsieh and Shannon, 2005) to *discover* underlying meanings of the words or the content and used quotations to illustrate issues and phenomena revealed by the investigation (i.e. latent content).

In the second step, we wrote a case report for each company. We carried out an intra-case and cross-case analysis in order to understand similarities and differences in the companies' approaches to social-business innovation.

Finally we discuss final framework and the paper with some senior managers from one B-Corporation. This procedure is a good example of a "member check" procedure (Lincoln and Guba, 1985). Taking such steps increases the quality (i.e., the construct validity) of a study. Concerning the generalizability of the results, we followed the advices by Halinen and Törnroos (2005) and Järvensivu and Törnroos (2010), our research was not used to generate theories, but instead to obtain new insights and to generate a local and context-specific understanding of social-business innovation.

5 Findings

5.1 Social-business innovation and value propositions

For B-Corporations social innovation is more than a social issue related to the narrowed interest of poor people. The new value propositions emerge from the business strategies, practices and values that meet the social needs (the what) and improves the society (for What). Both of these aspects are identified according to the wider integrated perspective of business and social.

Regarding the "what" of their innovative strategy, the core of social innovations is how enabling users to change their behaviour and improve the quality of their lives by maintaining a healthier living environment. Coherently B-Corporations define innovative value propositions that articulate social, environmental, life quality, well being themes and that produce direct or indirect effects . In many cases the example of a direct improvement in the quality of life is an innovation that increases well-being immediately, such as through the provision of new healthy, educational or consultancy services. In other cases the improvement is provided to encourage users towards products or services with less environmental impact. These innovations contribute indirectly and in the longer term to people's quality of life by encouraging social and sustainability behaviours.

"The company conducts business on a Triple Bottom Line model, indeed it makes measuring success by the social, environmental, and economic impacts. We provide a compelling and self-powered experience e to users capable of improve quality of their life by maintaining healthier living environment. By delivering solar energy solutions to homes and businesses, its activities are slowing the destructive effects of climate change. And at the same time, its customers are gaining energy independence while supporting a local, green economy. This can be seen as a win-win-win, with the results being a cleaner, safer planet, increased energy independence, and a robust local economy" (B-Corp N.37).

"The company regards water as an essential, long-term environmental and community asset: their systems are designed to preserve the quality and quantity of available freshwater supplies and they manage water so that communities can reclaim its nutrients, biomass, heat, and non-potable supply as part of a complete sustainable systems approach to water, energy, and land management" (B-Corp N.22).

Regarding the "for what" the solutions the B corporations propose for societal challenge include new value propositions able to impact on people, society and organizations as well. The following quotes depict how all these aspects have to be considered at whole:

"Many businesses are interested in increasing brand value, improving employee satisfaction, and saving money, through "going responsibility." This initial interest, however, is often stymied by conflicting priorities, confusion about next steps, or the lack of a clear value proposition that directly links increased social and environmental responsibility with tangible business outcomes" (B-Corp N.3.)

“The reason why of social innovation is linked to the capacity to balance the search for a social justice with a healthy environment with a vibrant economy. Social innovations will only have an impact on society if they bring about changes of behaviour and create long-term value for all” (B-Corp N.6).

“Designing meaningful innovations that create value for users, organizations, and society requires a holistic view to integrate seemingly conflicting needs and requirements into compelling solutions” (B-Corp N.19.)

The “change we seek” framework (see Fig. 1) shows how B-Corporations articulate the meaningful innovations that combine “creating ‘something good for the users, ‘doing well’ for the organization, ‘doing good’ for the total community and creating an impact at societal level (source: B-Corporations’ document).

Figure 1. “The change we seek”.

Four main pillars structure the areas of influence that B-Corporations’ innovation strives to improve: Community, Workers, Environment and Governance.

Emerging value for the community is revealed in sentences that not only report the word “community” as the most cited but also includes phrases like “we”..., “for others”, “better for all”, “for our partners”. In addition to ensure that the change pursued goes beyond the immediacy of the market transactions, the opportunities for value creation are enhanced in visualizing tangible and intangible benefits across local, supply chain and organisational context.

Value and relationship development with community, workers and business partners are highly integrated. A wide dialogue with all these parts forms the basis of the B corps value proposition (see Table 2). They are crafted to include anything that is necessary to perform the intended social function. So an explicitly recall is devoted to all economic and social actors that are required to develop a coherent social-facing solution collaboratively.

Table 2. The four pillars of Social-Business Innovation.

Community	Provide local communities with great opportunities Make responsibility conditions for the entire business Assure equal and fair relationships to small local producers
Worker	Improve economic social and psychological conditions of employees Provide a vehicle for worker to develop and achieve their personal and professional aspirations
Environment	Changing how people view their role in creating a sustainable future
Governance	Pursue financial stability by providing sustainable value delivery for all Assure long-term financial health to invest in employees customer and community

B-Corporations measure the impact of their innovation on local communities to be provided with information, practices and other supports for their betterment. Similarly they work to create responsible conditions for the whole ecosystem including suppliers, distributors, small local firms and other partners. Also the employees are considered key actors in B-Corporations social innovation strategy. The changes in work conditions provide employees with opportunities that increase job satisfaction and guide them in their contributions to social value. And finally social innovations promote

the resource effectiveness both in the sense of greener and environmental results that in the financial aspects. Having invested in the new value propositions with the expectation that investment will grow in value not only is in the B-Corporations' legit object but it also assures the financial health to invest in the larger community.

"I saw many impressive no-profits doing good work, but they seemed challenged to reach scale," he recalled, noting the need, especially in the beginning, to invest "significant" amounts in his company's mission. "It was only when my company grew, and I began to reinvest my earnings in coffee communities abroad, that I saw I could really make a difference." I felt that a no-profit business model would have slowed down his progress. He wouldn't have been able to bring together growers (farmers overseas) and roasters (businesses usually based in the United States) without a profit motive for both" (B-Corp N.15).

In sum, the enrichment of value proposition across the four pillars enables the balancing of value across the different parties and ensures the creation of social-business value: it is the value created in better connecting social-environment and business issues and that overcomes the idea of simple 'economic welfare'.

5.2 Practices of social-business innovation

B-Corporations develop innovative value proposition through three practices that are peculiar ways of doing social-business innovation: 1) engaging, 2) promoting, and 3) institutionalizing.

5.2.1 The practice of engaging

B-Corporations recognize that pursuing social-business innovation is not a sole-actor endeavour, but it requires the engagement of multiple actors to whom the innovation can affect. The practice of engaging multiple actors, such as companies, consumers, users, institutions, public organizations and others, allows having access to a higher variety of resources enriching the resource integration process and increasing value co-creation. The following quotes illustrate this issue:

"The initiative of 'Green Your Challenges' is the idea that leverages the powerful concept of "gaming for good" to engage members online in a fun, educational environment while influencing eco-friendly behaviours offline" (B-Corp N.5)

"The Hub LA is the first membership club structured for impact professionals in Los Angeles. It looks to serve as a catalyst for members to further their positive impact in the world and reinforce their social entrepreneurial missions. The Hub LA is not just focused on startups nor does it refer to itself as a co-working space; what it offers is much more curated, thoughtful and mission-driven. The Hub LA hosts members, facilitates collaboration and introductions, and produces programs and formats in which members engage" (B-Corp N.5).

"M. Consulting develops innovative solutions to social problems through social entrepreneurship projects. FUTURE IS BRIGHTER is a social entrepreneurship project developed by the Mikado Team. The Future is Brighter is a development project that brings together those who need knowledge and those who have knowledge via innovative and interactive methods. The project creates synergy among educational institutions, private sector companies and NGOs and thus creates multi- dimensional social benefit. Making experience and knowledge sharing possible via innovative methods. The aims of the project are: • Creating synergy among educational institutions, private sector and NGOs ; • Being a personal and professional development channel ; • Founding a network of thousands of youngsters • Encouraging employee volunteering" (B-Corp N.25).

"As nonprofit organizations face lack of resources and an increasingly complex world today, many foundations need to work together in order to share their knowledge, their skills and to address their needs and issues in our communities. Company's expertise in planning and meeting facilitation can help ensure that foundations will work together and become a truly effective partner in a mutually beneficial relationship with each other and the community" " (B-Corp N.40).

The engaging practice emerges through the tuning of actors' values and behaviours toward collective efforts. B-Corporations develop initiatives of social networking to build their communities. The aim is to strengthen the actors' ties within the ecosystem by developing working communities, whereas the social-business innovation develops as a collective effort- .

"The RIA (Red de Innovación y Aprendizaje) or Learning and Innovation Network, is a network of 70 education and technology centers located in underserved communities in the State of Mexico, providing access to information technologies and quality educational opportunities.! The model is composed of four parts: Access to robust IT infrastructure; Selection and development of relevant educational content for all ages; A blended

learning model with skilled facilitators and educational software; and Analysis of each student's performance to revise and improve course content" (B-Corp N.1).

"By developing social innovation process the company's goal is to inspire smarter choices for a more sustainable future. We believe that individual actions, such as increasing recycling or learning about greener ways to purchase, consume or dispose of products, can add up to a big impact for our planet! So we realize a lot of social-networking and real-world actions" (B-Corp N.2).

"The company offers a facilitated approach to stakeholder meetings that gives all participant groups the opportunity to contribute to planning the meeting, assures relevant, engaging, and goal oriented agenda sessions, and leaves both the organization and participating stakeholders with memorable and recognizable results from the meeting" (B-Corp N.26).

5.2.2 The practice of promoting change

B-Corporations do not develop new goods and new services as the end outcome to increase profit and competitive positions. New goods are appliances to new service provision (i.e. the real innovation) able to enable value co-creation for the involved stakeholders. Benefits to community and the whole ecosystem guide the innovation process. In this perspective the core of social-business innovation is to promote a change in values and behaviours. 'The change we seek' slogan becomes a value shaping companies' way of thinking and doing. At the same time it is a value to be spread out to the communities.

"Through the Integrated Objectives Model (IOM) the industry is mobilized, attracting capital and investment and involving other parties in the pursuit of poverty relief, and at the same time, empowering its own corporate and industrial objectives (high economic return concurring with high environmental and social returns). We believe in a new way to conduct business in which social and economic profitability work together. We are more than a company; we aim to create a wave of technological innovation to overcome poverty.

The Change We Seek®: AIC has mobilized industry, attracting capital and investment and involving other parties in the pursuit of poverty relief, and at the same time, empowering its own corporate and industrial objectives (high economic return concurring with high environmental and social returns)" ((B-Corp N.48).

The practice of promoting change emerges through specific activities such as educating, teaching, supporting and empowering and planning. The common *leit motiv* is to make the challenges happen and modify the status quo. They serve to open up opportunities for a wide range of actors to become collaborative change agents in transformations for social.

In this sense B-Corporations work as the engine of the social-business ecosystem, as they symbolize the spark leading to the beginning of all other actors' efforts towards sustainability

"The digital divide in Mexico is significant with 69% of the population, or 86 million people, lacking access to computers or the Internet. Mexico's education system has the lowest performance in the Program for International Student Assessment (PISA) among OECD members despite the fact that 25% of public spending goes towards education. Company's innovation projects aim to create education technology solutions to drive down the digital and educational gap in low-income communities in Mexico" (B-Corp N.1).

"HUMAN is a one-of-a-kind nutritional distribution platform that develops healthy vending machines, healthy micro markets (unattended self-checkout convenience stores), and direct delivery services to bring convenient, healthier, and better-for-you foods and drinks to people". The company's name is an acronym standing for "Helping Unite Mankind And Nutrition". HUMAN has innovated a new model for "instant" nutrition placing its machines in over 1200 schools, hospitals and other locations across North America. The core of their business is to solve social and environmental problems expressed in their mission: "make healthy food more convenient than junk food". Along with its innovative offering HUMAN promotes improved nutrition and entrepreneurial education in underserved schools and to fight childhood obesity via their charity, HUMAN Everywhere (B-Corp N.10).

"Strategic Sustainability Consulting's innovation projects provide sustainability knowledge to under-resourced organizations that want to 'go green'. We believe that, before you spend significant time or money on specific "green" initiatives, it is important to understand how sustainability influences your business model, your value chain, and your products and services" (B-Corp N.6).

"ThinkImpact is a social enterprise with offices in Ghana, Kenya, Rwanda and South Africa. Through their global experiential education programs they help people start something meaningful. ThinkImpact offers offline and online programs, for students, universities and companies in order to power experiential education

programs that catalyze social innovation and entrepreneurship. Social Innovations are designed to leverage local resources – rather than offer traditional aid – building market opportunities, creating jobs, and connecting people through collaboration. By focusing on opportunities and empowering individuals to start something, they envision inspiring microenterprises that sell products and services that improve lives, creating critical new jobs along the way” (B-Corp N.30).

“Upcycling offers sustainable solutions that help people reduce their waste stream and environmental impact. We seek to help solve the problem of waste by teaching people how Upcycling or re-purposing will close the recycling loop and lessen dependence on virgin and non-replenish able resources” (B-Corp N.22).

5.2.3 The practice of institutionalizing

Although B-Corporations promote changes and challenge the status quo through continuous improvement, they also work to institutionalize social-business innovation or what can be defined as their ‘breaking free from traditional management’ both in terms of language, actions and performances. The practice of institutionalizing new values, norms and behaviours enable the emerging of a new social-business ecosystem (i.e. the one of B-Corporations).

“Ethics and integrity are at the core of our work at ThinkImpact; when we say we “Think Impact” we are expressing a worldview. We believe in the power of business to make positive impact in the world but only when the highest ethical standards are in the corporate DNA. We chose to become a B Corp because it provided a powerful tool to benchmark our work and to learn new ways to improve our company while adding transparency to our operation “(B-Corp N.30).

The first keystone of institutionalization is the certification. The certificate helps the consumers to identify companies promoting the change as well as investors to have profits without sacrificing the welfare of society, even helping to make a difference.

“We became a B Corp because we fervently want to change the world. With our expertise in marketing and communication, we want to work with companies and organizations who are actively engaged in making the world a better place. Our B Corp certification not only tells the world what we believe but also provides opportunities to challenge other businesses to operate in a new way” (B-Corp N.9).

“The C-Level Management has been developing the ‘Socially Conscious DNA’ for a number of organizations. The mission is to teach organization how they can create a sustainable giving program within their organization that restructures the DNA of the culture through a complete brand infusion of their guiding principles. The company has also developed a strategic partner ecosystem able to offer a complete set of solutions for business problems. The fundamental goal of C-Level is to recruit social conscious employees, partners, and customers that are working together to significantly affect the way companies support their community” (B-Corp N.39).

The second keystone is the process of B Corporation Assessment. All B-Corporations measure indeed their impact and achieve at least 80 points on the B Impact Assessment to validate that they have achieved a significant threshold of impact. They also expand their corporate duties to include the consideration of the interests of all stakeholders, not just shareholders. B Corps are typically focused on improving and sustaining their impact over time and generating profit simultaneously.

“We envision that in a generation's time, all businesses will measure and manage their impact as readily as they do profitability. We manage what we measure. This is one of the most basic truths in business. It follows that we ought to measure what matters most: the ability of a business to not only generate returns, but also to create value for its customers, employees, community, and the environment”. (<http://bimpactassessment.net>. Accessed 30 June 2014).

The B-Lab provides standards, benchmarks and tools to enable the assessment by B Corporations. The process follows three steps:

- 1) assess how the company performs against a lot of best practices on employee, community, and environmental impact.
- 2) compare company’s impact and see how company stacks up against other businesses.
- 3) improve company’s impact by developing a plan to improve company’s practices, and help company’s staff to implement them easily with B Corps’ Best Practice Guides and Examples.

This process of assessment allows improving practices and focuses on higher impact projects of social-business innovation.

“The Assessment gave us a sense of what practices to prioritize over others. Before, we were doing a lot of offsets for our operations, and the Assessment forced us to ask harder questions about the carbon in our supply chain or about making our warehouse more energy efficient. So it helped our money go much further by just asking us the tough questions” (B-Corp N. 11).

“The B Impact Assessment incentivized us to take the time to quantitatively measure the performance of our programs. For example, we provide several opportunities for employees to participate in environmental or social activism. But we didn't know how many employees participated and to what degree. But this Assessment asked us those tough questions, and we took the time to measure and manage the participation and outcomes of these programs. This has given us a better understanding of which ones are most effective and which ones could be made more robust. Because the Assessment gathers all of this information in one place, it allowed us to really recognize our strengths as well as see where we have room for improvement” (B-Corp N.50).

In sum, this process of assessment allows to share values and practices shaping a new service ecosystem based on the joint creation of social-business value. It not only offers answers but it is a tool to rise up questions.

“We entered the Assessment with the notion that we had a tremendous impact as a corporate citizen. The Assessment revealed to us that we were engaged in many positive practices but that there was much room for improvement in almost every area we were being scored on. First, we needed to take a look at our suppliers. What were their practices and did their practices reflect our values?” (B-Corp N.21).

“As a company who thought they were a very socially-conscious business, however we found that our initial score was well below the threshold for a certified B-Corp. The Assessment process was very educational as it gave us strong inspiration and some concrete ideas to act upon. There are many practices we were unaware of that the Assessment opened our eyes to. We began to ask ourselves: how to implement our values into formal practices” (B-Corp N.16).

6 Discussion

This study focuses on social-business innovation as a new integrated approach to address the complexity of the social issue social as well as the business endeavour. By moving beyond the mainstream research of both social and business innovation, the authors questioned on how framing social-business innovation from an integrated perspective.

This main research question led empirical study and theoretical contribution under two main questions.

The first question was: What social-business innovation is?

The B-Corporations' innovation model provides a suitable evidence of how organisations accomplish social and business aims. B-Corporations overcome the traditional boundaries distinguishing among social and business companies by integrating societal, ecological and economic impacts into their innovation strategies. B-Corporations' social-business innovation deals with the challenge of trying to simultaneously manage social, environmental and business performances by offering an appealing value proposition behind that there is the idea of making money by doing better. Their role differently from social enterprise is not to serve as an enabler for the poor but they contribute to create the overall value for society from being part of and contributing to create something larger or more permanent. In doing so such companies provide evidence and arguments for a new perspective on social innovation that challenges the traditional weakness of social business (Westley and Antadze 2010). The concepts of success and the health of the innovation are intrinsically linked to an integrated perspective taking a multiple actors-centred focus of value creations. The four pillars (i.e. Community, Workers, Environment and Governance) of social-business innovation model of B-Corporations appears as an highly integrated approach based on concepts of socio-cultural impact as the starting point of innovation-solution, and involving all actors that are deemed relevant to accomplish social aim as well as business interest.

Social-business innovation deals mainly with providing tangible and intangible multiple benefits towards several actors (Figure 2). Value co-creation and relationship development with community, workers, business partners and society are highly integrated. A wide dialogue with all these parts forms the basis of the value proposition in terms of social-business innovation. The value co-creation emerges as an A2A and many to many patterns.

Figure 2. Social-business innovation: value, well-being and viability.

The phenomenon seems to be complex and multi-layered. By adopting a wider perspective on value, we address that social-business innovation enables the co-creation of well-being (Rosenbaum et al., 2011; Anderson et al., 2013). Well-being is a multi-dimensional construct (Stiglitz, Sen, & Fitoussi 2009) closely related to quality of life concept:

An individual's perception of their position in life in the context of the culture and value systems in which they live and in relation to their goals, expectations, standards and concerns. It is a broad ranging concept affected in a complex way by the person's physical health, psychological state, personal beliefs, social relationships and their relationship to salient features of their environment (World Health Organization, 1997).

The elements that are defined as “well-being outcomes” – happiness, health, decreasing disparity, access, literacy - represent value that B-Corporations aim to reach by considering not only individual but collective level of benefits. By addressing co-creation of value and well-being, the viability of the service ecosystem increases (Wieland, Polese, Vargo and Lusch, 2012).

Close to the first, the second question was: What are the practices of social-business innovation?

Social-business innovation is not simply a new solution (goods or services) but a service provision of multiple benefits for several actors. It is thus an enabler of value, well-being and viability (Rubalcaba et al 2013). In this perspective B-Corporations' social innovation model provides evidence of a different way of thinking and acting about problems or opportunities: a process involving reflections with various stakeholders not only on what to do but also on how to do.

B-Corporations develop innovative value propositions through three practices that are peculiar ways of doing social-business innovation (figure 3): 1) engaging, 2) promoting, and 3) institutionalizing. The practice of engaging emerges when B-Corporations involve multiple actors, such as companies, consumers, users, institutions, public organizations and others, to have the availability of a wider variety of resources as well as to enable social-business innovation not as a sole-actor endeavour but as a collective accomplishment. Social-business innovation initiatives start with an ill-defined problem. Through continuous knowledge exchange, insights are enhanced and new knowledge gaps are identified; this causes the need to invite new actors to contribute along the way. The engagement of multiple actors to whom the innovation can affect is necessary to stimulate a change in the way of thinking and behaving. The practice of promoting a change require several actions as educating, teaching, supporting and empowering and planning. All these actions challenge the status quo but at the same time support a practice of institutionalizing where new values, norms and behaviours are set. The institutionalization enables the emergence as well as supports the viability of service ecosystem

Social-business innovation requires a variety of actors, working in concert with the agent starting the innovative project. In line with Caulker-Grice et al (2012), Hochgerner (2013) and Rubalcaba et al. (2013) the study emphasises that social innovations more than the proposal of new product or new services can be seen as a proposal of changing practices.

All together the three practices depict the way of doing of B-Corporations social-business innovation whereas a simultaneously impact is created on consumer and business conduct, social norms, institutional structures laws and routines which govern and enable social innovation to flourish. The emphasis is more on the importance of coordinated goal-oriented multiple actions via emergence of practices that facilitate social sense-making and create a support to sustain and institutionalise social transformation.

Figure 3. Practices of social-business innovation.

7 Implications and further research

This work gives a framing of social-business innovation as an integrated concept and does not support the idea of social *and* business as two separated issues able to be joined according the contextual and occasional opportunities.

Specific implications for managers and scholars can be drawn.

Concerning the practitioner side, this study suggests that managers should frame innovation according a joint perspective between the social and business issues, without having one issue overwhelms the other (i.e. a business-oriented social innovation vs. a social-oriented business innovation) but adopting a more equilibrated approach. Second the process of deployment new value propositions should take into consideration the multiple benefits according to the several actors to whom the innovation can affect or be affected. Third a practice-based approach can be adopted to recognize the role of actors, actions, resources and institutions in enabling social-business innovation. This approach seems appropriate to understand social-business innovation, as it looks at how different actors face ill-defined problems and interact to integrate desirability, feasibility and viability in new ways of doing.

Some scholars argue for the need to improve understanding and implementation of social innovations by joining the business and social perspectives (Rubalcaba et al., 2012). Business innovations as well as social innovations show some point of contacts in their literature evolution: both are collaborative in nature and interactively processes: ventures whose success relies on the involvement of many stakeholders outside corporate boundaries. However joining the two perspectives requires studying the concurrent, interdependent and dynamic process going on: defining both new value propositions for customer and for network of stakeholders that combine their resources into a coherent solution aimed to respond to both business and social needs.

The results of this study suggest several avenues for further exploration. First, additional case studies investigating the study’s findings would help determine whether there is even stronger empirical evidence supporting the new perspective. Second, if social innovation increasingly evolves towards involving challenges at economic, social and institutional system more investigation is needed to unravel the mechanisms enabling firms to converge towards common social-economic aims and stabilized relationships with institutions and other public- private actors in a new social-business innovation context.

Additional questions could be formulated to provide more generalizable evidence on the new perspective and paradox resolution in the successful management of social, environmental and financial goals.

How do firm frame value proposition in a way that it must resonate with broader stakeholder’s issues? How do firms promote incentives in the different businesses to support behaviours’ changes? How do the new institutions (values, rules) that firms contribute to create could be harmonised with different policies and strategies?

Furthermore it is interesting to analyse the process of value co-creation as complex and multi-layered (Chandler and Vargo, 2011). Moving beyond the single dyad the A2A perspective within a service ecosystem view (Mele et al. 2014) seems to offer a useful approach to frame the social-business innovation.

Services system evolution in the EU: An agent based modeling approach

Liviu-Alexandru Micu¹, Ileana Ciutacu²

¹Bucharest Academy of Economic Studies, ²Romanian Academy

The objectives of this synergetic reasearch between Informatics and Economics are defining a holistic perspective of the EU system and creating an agent based model (ABM) for testing different policies. The paper comprises a short literature review, a presentation of the NetLogo ABM along with the real data database used, the simulated scenarios, their corresponding results and interpretation. Thus, even if a technical one, the model reveals different types of unexpected innovations that can offer solutions or may themselves be solutions to some societal challenges like ageing population, environmental problems, labor market issues et cetera.

Keywords: agent based models, service system, economic policies, EU evolution

1 Introduction

In today's economy, we speak mostly of regions than of countries, at least on the European Union's territory. Therefore, even if the territorial point of view is changing the economic expectations remain the same: how much will that country or region grow and develop over time. One of the problems here is the fact that when we measure the growth of a country, region or union like the EU, we tend to do that separately, but a recent research proves us tha we should not do it like this, but we should do the opposite (Ciutacu, I., Savulescu, I., Dumitrascu, LM., 2012).

As a draft concept, a system first appears in Greek philosophy. Stating that “a whole is more than the sum of its components”, Aristotle provides a first definition for the notion of system that will develop and evolve in time, only reaching its current form at the beginning of our century (Stoica, Maricica, 2001). Some hundrets of years later, in 1950, Ludwig von Bertalanffy founded the theory of systems. From his perspective, a system can be defined as a reunion of interacting/interdependent elements, acting for the achievement of a shared goal, by using a complex of material, energy, financial, informative and human resources (Bertalanffy, L, 1968).

The concept of system is frequently used in various fields of economy, technology, nature and society. Thus, we can find business, information, biology, education, production, social systems, etc. Their shared feature is the relatively high number of components that come to interact with the environment with a view to achieving an objective that may be a law of nature or a man-made objective, as happens with the services system of the EU, which is a complex system.

A good solution to studying the different types of systems mentioned above can be the use of ABMs, because these are computerised simulations of artificial worlds with structures as diverse and complete as needed, in which different types of agents interact by using predefined rules. Also, ABM allow their agents to behave according to learnings of past experiences and to their current situation, and in this way an ABM can handle the nonlinear behaviour of a complex system in a wider range that previous conventional models can. Like this, ABM allow policy makers to simulate and explore quantitative and qualitative consequences of different policy scenarios upon artificial economy models that can be built as a simplified model of a real one (Ciutacu, I, 2012).

2 Literature review

2.1 About systems theory

According to some authors, a system is any section of reality where a complex of phenomena, objects, processes, finite concepts or mutually interconnected groups can be identified, jointly and orderly operating with a view to achieving well defined, pre-established and planned objectives. This definition of a system includes three essential elements: a purpose (objective) motivating the conception and existence of a system; a certain organization (order) of its elements; the supply of information, energy and materials to components, for the proper achievement of goals.

The multitude of relations between the components of a system, as well as the relations between the components and the whole build the structure of the system, while the multitude of the system's features at a given moment determines its state.

Any system is an integrated whole of its components and only appears when a range of elements begin to mutually interact.

Any system's purpose is accomplished through the achievement of its goals. Ideal goals are the easiest to identify in system analysis. Generally, in complex economic systems, objectives are not clear, as happens with the services system in the EU.

When analyzing objectives, alternatives or unwanted consequences should also be taken into account. Usually, economic systems do not aim at a single objective, but at a wide range of objectives. Therefore, several issues arise regarding such objectives:

- their hierarchical structure;
- their aggregation or decomposition;
- how to achieve them;
- establishing any disturbing factors likely to affect objectives;
- ordering objectives based on certain criteria;
- establishing the performance measures assessing such criteria;
- assessing the consequences of objectives and re-assessing them, if applicable.

In the case of **complex economic systems** (such as the services system of the EU or the economies of certain countries) including a wide range of subsystems, objectives should be organized in a hierarchical structure, considering the priorities, the internal structure of the system and the environmental impact. When establishing the objectives of the subsystem, both the internal and external objectives of the system should be set. Decision makers are influenced by equivalent factors in the connected systems they cooperate with, that may result in changes to the objectives. All this makes sense and can be easily managed by means of the NetLogo software.

With a view to reflecting the complexity of this system, as well as having relevant results, we have used agent-based models in the NetLogo software, as you will see in the applied part of this article.

2.2 About ABMs and NetLogo

ABMs are already successfully used in simulating situations and helping policy-makers create and implement policies in different scientific and/or real domains like: Epidemiology, Demographics, Economics et cetera. In Economics, probably the biggest agent-based model is the EURACE project that models the European economy (Lengnick, M, 2011).

ABM can be designed and created by using various computer programs and can be run on computers on a range that goes from the simple PCs to the very powerful computers. Some of these programs are: Repast, R, NetLogo and various more. In this research we used NetLogo which was designed by Ury Wilensky in 1999 and developed ever since at The Center for Connected Learning and Computer-Based Modeling of the Northwestern University. This ABM developing program runs as a standalone application on the Java virtual machine of computers that use Mackintosh, Windows, Linux or various other platforms.

NetLogo allows its users to create an artificial 2D or 3D world and explore the connection between the micro-level behavior of individuals and the macro-level patterns that emerge from their interactions. By using a special programming language (derived from the Logo programming language) users can predefine rules and instructions for the four types of NetLogo entities: turtles, patches, links and the observer. Patches are immobile agents that give the artificial world its form (quadrilater, cylinder or torus), turtles are mobile agents that can change their position in the world, links connect two or more turtles and help the modeler to set different generations of turtles (a directed link creates a parent-child relationship), while the observer helps the designer see better the world he creates. The time in the NetLogo ABMs can be measured either in ticks (the time a turtle needs to go from a patch to one that is next to it) or in seconds.

3 The model

3.1 The NetLogo world (description):

- The shape of the NetLogo world is a rectangle of 30 per 30 patches, with 1 patch having 9 pixels.
- The time of this world is calculated in ticks (the time a turtle needs to move from one patch to one of those next to it) and we will consider that a tick is equal to a year in human time.
- The mobile agents in this world (turtles) are the following the EU (turtle 1), the 28 countries that the EU is made of, the populations of these countries, the products the EU citizens produce. The order of the numbering of the turtles is that from the table below.
- The currency of this world is “value”, each country’s currency is calculated by multiplying 1 value to its Implied PPP conversion rate in the table below. We chose this method that uses the exchange rate with the current international dollar, rather than using the euro, because in this way we have both an exchange rate and a value for the purchasing power in that country.
- The EU from our model has the same 28 countries (Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxemburg, Malta, Poland, Portugal, Romania, Slovenia, Slovakia, Spain, Sweden, The Netherlands, The United Kingdom) that the real EU has.
- Each country in the model has a population number equal to the one (without the millions) in the table below that has the data for the population and for the unemployment rate in each EU country.
- We suppose that the entire population of each EU country is employed in a random percentage either in farming, in industry or in the service sector. This percentages are the same in the entire EU.

Table 1. EU data.

No.	Country	Population (million persons)	Unemployment (% of total labor force)	Implied PPP conversion rate (national currency per current international dollar)
1	Austria	8.45	4.2	0.87
2	Belgium	11.02	7.23	0.90
3	Cyprus	0.83	7.78	0.76
4	Estonia	1.34	12.48	0.60
5	Finland	5.43	7.78	0.98
6	France	63.37	9.68	0.91
7	Germany	81.61	5.98	0.84
8	Greece	11.20	17.31	0.73
9	Ireland	4.57	14.39	0.86
10	Italy	60.90	8.37	0.86
11	Luxembourg	0.52	6.04	1.02
12	Malta	0.43	6.40	0.6
13	Netherlands	16.77	4.50	0.86
14	Portugal	10.68	12.74	0.69
15	Slovak Republic	5.42	13.40	0.55
16	Slovenia	2.02	8.08	0.61
17	Spain	46.36	21.64	0.76
18	Bulgaria	7.36	12.46	0.75
19	Croatia	4.42	13.25	4.45
20	Hungary	9.96	10.95	151.58
21	Latvia	2.22	15.63	0.41
22	Lithuania	3.25	15.50	1.81
23	Poland	37.64	9.65	2.04
24	Romania	21.38	7.21	2.31
25	Serbia	7.43	23.65	45.39
26	Denmark	5.58*	7.0*	1**
27	The United Kingdom	63.70*	7.9*	0.5**
28	Sweden	9.52*	8.0*	1**

3.2 EU country agents' characteristics in NetLogo:

- There are 28 agents, one for every country in the EU.
- Each country is shaped as a circle, has a size of 3 patches and a label with its name. The EU country agent is immobile in the NetLogo world and has a specific color calculated after its order in the table above. The EU agent's shape is a circle as well with the size 4 (patches) and with the color blue.
- Each country has incomes and expenditures. Its incomes are made of the sum of the values of the products its population produce and the incomes the EU distributes to it. Its expenditures are made of the sum of the money it sends to the EU and of the salaries it pays to its population for the goods they produce either in farming, in industry or in the service sector.
- All the countries have no differentiation between its farming, industry and services sectors.
- Each country is connected to its population and to the products that its population produces by links. Thus the EU country agent knows when a new product has been made, when a product was sold and when one of its citizens must be paid for its work.

- Each country is connected to the EU agent by links, thus each country contributes to the EU budget with a randomly chosen percentage of its incomes and receives as well, a random percentage of what the EU has gathered at the end of the time period (a tick).
- When a country receives a product from one of its citizens it pays it 1 unit of value. And it receives 1.1 units of value.

3.3 Population (EU citizens' agents):

- The population of each country can be recognized after the colors of the EU citizens that are the same of the country's they belong to.
- The number of the population is fixed during the run.
- These are the only agents in the model that can move, thus giving this world its dynamics.
- If the agent is employed in farming its shape is "person farmer", if it is employed in industry its shape is "person construction", if it is employed in services its shape is "person service" and if it is unemployed is "person".
- A part of each country's population is employed in agriculture, industry and services. The percentages for these distributions are chosen randomly.
- Each EU citizen can make its own product for which the country that employs it pays it a salary. Thus, regardless of the country, farmers produce "apples", workers produce "bottles" and the EU citizens that are employed in the service sector produce "boxes". For each product it produces the EU citizen receives 1 unit of value. The products are disposed randomly in the NetLogo world and the change to produce something is as well random and happens if "random 10 <= 5".
- For every step an EU citizen makes (these are the only turtle agents that can move) it loses 0.1 units of value and when it encounters a product, it consumes it and receives for it 0.9 units of value.
- When an EU citizen remains without any value units it remains immobile unless a product is produced where it stands and it can consume it.

3.4 Scenarios:

In this model our aim is to see what happens with the wealth (the number of value units) of the entire EU and with that of the EU members if:

- a) The incomes of the EU are distributed to the EU country members proportionally to each country's by the number of population it has.
- b) The incomes of the EU are distributed in a higher percentage to the countries that have a number of population employed in the services sector higher than the EU average.
- c) The incomes of the EU are distributed in a higher percentage to the countries that have a number of population employed in the farming sector higher than the EU average.
- d) The incomes of the EU are distributed in a higher percentage to the countries that have a number of population employed in the industry sector higher than the EU average.

All these scenarios will be run for 5, 25 and 50 ticks.

4 Results:

Scenario a) The incomes of the EU are distributed to the EU country members proportionally to each country's by the number of population it has.

After we ran the first scenario for **5 ticks** the results were the following: the wealth of the EU was similar to the one it had after the first tick and the same happened to the most of the EU countries.

After we ran the first scenario for **25 ticks** the results showed that the wealth of the EU was with 31% smaller and that the countries that had a smaller number of citizens were beginning to lose their wealth.

At the end of the **50 ticks** of the first scenario, the results implied that the wealth of the EU was with 40% smaller, while the countries that had a few or 1 citizen were almost bankrupt.

Scenario b) The incomes of the EU are distributed in a higher percentage to the countries that have a number of population employed in the services sector higher than the EU average.

After we ran the second scenario for **5 ticks** the results were the following: the wealth of the EU was, as well, similar to the one it had after the first tick and the same happened to the most of the EU countries.

After we ran the second scenario for **25 ticks** the results showed that the wealth of the EU was with 25% smaller and that the countries that had a smaller number of citizens employed in the services sector lost about 50% of their initial wealth.

At the end of the **50 ticks** of the second scenario, the results implied that the wealth of the EU was with 30% smaller, while the countries that had 1 or more citizens employed in the services sector had had a walth increase of 33%, while those with no such employes were almost bankrupt.

Scenario c) The incomes of the EU are distributed in a higher percentage to the countries that have a number of population employed in the farming sector higher than the EU average.

After we ran the third scenario for **5 ticks** the results were the following: the wealth of the EU was, as well, similar to the one it had after the first tick and the same happened to the the EU countries that had citizens employed in the farming sector, the other countries were losing wealth.

After we ran the third scenario for **25 ticks** the results showed that the wealth of the EU was with 22% smaller and that the countries that had a smaller number of citizens employed in the farming sector or none lost from 30 to 38% of their initial wealth.

At the end of the **50 ticks** of the third scenario, the results implied that the wealth of the EU was with 25% smaller, while the countries that had 1 or more citizens employed in the farming sector had had a wealth increase of 35%, while those with no such employees were as well as in the other scenarios, almost bankrupt.

Scenario d) The incomes of the EU are distributed in a higher percentage to the countries that have a number of population employed in the industry sector higher than the EU average.

After we ran the fourth scenario for **5 ticks** the results were the following: the wealth of the EU was as well similar to the one it had after the first tick and the same happened to the most of the EU countries.

After we ran the fourth scenario for **25 ticks** the results showed that the wealth of the EU was with 37% smaller and that the countries that had a small number of citizens employed in the industry sector were starting to lose their wealth.

At the end of the **50 ticks** of the first scenario, the results implied that the wealth of the EU was with 42% smaller, while the countries that had a a few or 1 citizen employed in the industry sector increased their wealth with 43%, while those with a few or no such citizens were almost bankrupt.

5 Conclusions:

5.1 Model conclusions

The conclusions of the run of our 4 scenarios in the ABM we constructed are the following: the effects of the policies can be seen, similar to what happens in the real world, several years. This can be observed here as well because for the 5 ticks run for all the scenarios the results are simmilar, while those for the 25 ticks run are completely different one from the other and most important, wery different from the situation the model left. Another interesting observation is the fact that when the EU agent distributes randomly its incomes according to the population in each country, the results are better than in the scenario where it distributes it to the countries that have the most citizens employed in the service sector or the industry one, but not as good as the scenario where the EU distributes its income to the countries that have more employees in the farming sector. Perhaps this, even if just an ABM scenario should make the policy makers of evrey EU countr calculate more the choices they make.

5.2 Improvements that can be brought to the model

Because this model is a pilot one for the EU agent based model various improvements can be brought to it. A part of these that will be implemented in the authors' further research, are the following:

- Writing a piece of code that sets a seed button (a random number that NetLogo uses to calculate its random numbers) and gives the NetLogo model the possibility to rerun each scenario that is run on it.
- Another of the improvements that can be done for this model is to include the real data for the people employed in agriculture, industry and services and to give the EU citizens agents the possibility to reproduce.
- Another improvement that can be brought to this model is related to its graphics, the NetLogo world could have not only "relations between the countries" layer, but also a geographical one, because the countries could be arranged on a map of the EU. The population of each country will appear with every NetLogo run on the territory of its country.
- Creating firms owned by the government and privately owned firms that employ the population in each country.
- Allowing the countries to borrow value units from other countries and to make investments in the sectors it has (agriculture, industry or services sector).

Productivity and Services: safety telephone services for the elderly

Sole Molander¹, Helinä Melkas²

¹SoleMCOy, ²Lappeenranta University of Technology

The purpose of this paper is twofold. First, it aims to contribute to the services literature by identifying key components of service productivity. There is a research gap in the conceptual understanding of productivity in services. Second, this paper examines the use of service productivity components to advance productivity improvement. The case is safety telephone services, a type of technologically enabled care. Safety telephone services provide physical help when their customers need it. The services are mainly used by elderly persons. This study contributes by investigating if we can find those cases in which increasing organizational efficiency goes hand-in-hand with increasing value for customers so that organizations' needs and service users' expectations are in line and productivity is improved. (This paper is based on the dissertation by Molander, 2013. Our discussions have further crystallized the thoughts.)

1 The context

The population becomes older, and more outpatient and non-institutional home care is necessary. The services of the elderly receive much attention in state and local decision making in numerous countries. Preparing for the growing public expenses caused by the ageing population, places great challenges on the economy of the public sector. (Luoma; Rätty; Moisio; Parkkinen; Vaarama; Mäkinen, 2003) There is pressure to increase budgets for social care and health care. Organizations are facing several challenges in their efforts to better resort to closer performance evaluation that provides guidance in an elderly care environment. With respect to this, increasing productivity of elderly care services has become necessary.

Finland is one of the most developed economies in the world according to many rankings (World Economic Forum, 2009, 479), and in the forefront of social and economic development. It is useful to make this type of a study in Finland as it provides relevant information also for other advanced economies.

Population is aging due to lower birth rates and longer lifespan. This is considered by some the most important long term fiscal question in the industrial world. (Gruber; Wise, 2001) Practically all developed countries will have the ratio of working age population to retired population rapidly decrease during the first half of this current century. There will be almost 80 million elderly people with their care needs in Europe by year 2050, according to forecasts. (Leikas, 2008) According to population forecasts, one in four Finns (26.1%) will be aged 65 years or over in 2030. (Statistics Finland, 2009) In Finland, the average life expectancy for a female child born in the 1990s was over 80 years, and for a male child 73 years, as compared to 75 and 65 years, respectively, for those born in the 1970s.

The number of retired people in Finland has grown significantly, especially after 2005, and continues growing. The ratio of working age population to retired population will decrease in every EU country in the coming years. In Finland the ratio is developing in an unfavourable direction more rapidly than in any other EU country. Finland's ratio of working age population to retired population will be the worst among the EU countries from 2020 to the end of that decade. (Statistics Finland, 2009)

In Finland the proportion of persons aged over 65 in the population was estimated in 2009 to rise from 17% to 27% by 2040, and to 29% by 2060. The proportion of people of working age in the population will diminish from the then 66% to 58% by 2040, and to 56% by 2060. The number of working age people started to fall in 2010 when the large, post-war baby boom generations started to reach retirement age. (Statistics Finland, 2009) The baby boom generation is a term used in Finland for the generations born during 1945–1950, when the post-war birth rates were higher than usual. (Karisto, 2007, 91–108) Table 1 shows this population development.

Table 1. The Finnish population by age and gender at the end of 1960 and 2006, the population by age at the end of 2009, and the forecasts for 2040 and 2060.

YEAR		age 0-14 (%)	15-64 (%)	65- (%)	Total (%)
1960	women	28.5	62.5	8.9	100
	men	31.9	62.3	5.7	100
	population	30.1	62.4	7.4	100
2006	women	16.3	64.4	19.3	100
	men	17.8	68.6	13.5	100
	population	17.1	66.5	16.5	100
2009	population	17	66	17	100
2040	population	15	58	27	100
2060	population	15	56	29	100

The demographic dependency ratio, that is, the number of children and pensioners per one hundred persons of working age will rise rapidly in the near future. At the end of 2008, the demographic dependency ratio in Finland was 50.3. According to the projection, the dependency ratio in Finland will be 60.4 in 2016 and rise to 70.5 by 2026. In 2060, the demographic dependency ratio in Finland will be 79.1 (Statistics Finland, 2009), as shown in Figure 1.

Figure 1. Demographic dependency ratio in Finland between 1865–2060.

The ageing population affects the social care and health care expenses. In 2006, the social care expenditure in Finland was 26% of gross national product. (Official Statistics of Finland, 2008). According to a forecast, the social care expenditure will increase to 30% of the gross national product in Finland by 2030. (Official Statistics of Finland, 2008) In 2006, the health care expenditure in Finland was 8% of gross national product. (Official Statistics of Finland, 2008)

2 The study

It has long been understood that the sustainability of any organization depends on well managed productivity. The objective for organizations should be to reach customer perspective objectives, in other words to create value for service users. The idea is to reach high value for customers while organizational efficiency is not neglected. Previous research results highlight the need for especially the public sector to take into consideration the issue of value for customers

when estimating productivity. (Kaplan; Norton, 2001) (Boyle, 2006) (Gummeson, 2008) (Simpson, 2009) Unlike a manufactured product, which can be readily assessed, in services, value is still an elusive and abstract construction.

Customers experience the value of services subjectively in many different ways. (Blois, 1985) If productivity is understood as it traditionally is in manufacturing and economics - as the relationship of output to input - any increase in productivity by this means would usually decrease customer satisfaction in service organizations. (Anderson; Fornell; Rust, 1997, 129–149) This does not create a sustainable increase in productivity. Minimising input is not always the right goal.

2.1 The objective of the study

The purpose of this paper is twofold. First, it aims to contribute to the services literature by identifying key components of service productivity. Second, this paper examines the use of service productivity components to advance productivity improvement to deal with safety telephone services for the elderly, which is technologically enabled elderly care. Various kinds of technologically enabled services are being developed with increasing speed.

There is a research gap in the conceptual understanding of productivity in services. Official statistics, reminded Gummeson (2008, 315–330), are deprived of value for customers and as such are obsolete and misleading in many respects. There is also a research gap in what could be done to improve services both from the organization's and the customers' point of view. This paper addresses these gaps by asking two questions:

- To increase value for service users, what has to be introduced to meet customer expectations?
- To increase organizations' efficiency, what does not constitute real value for service users and thus could be eliminated?

This paper is based on customer relationship management (CRM) theories (Reichheld, 1996) and lean principles. (Kindler; Krishnakanthan; Tinaika, 2007, 99–101) The paper looks at the input side of service production (efficiency) and at the same time the output side (value as customers experience it) studying ways to improve both in order to improve productivity in cases where quantifying is not possible. Furthermore this paper claims that expert defined quality is needed because customers do not always know what kind of services they would benefit from. (Lillrank, 2008)

2.2 Quality management

This study builds on the ideas of quality management (Selden, 1997) although most of the existing research studies do not explicitly address the service sector and as such are not directly applicable to this study. Quality management's quality control, quality assurance, and quality improvement actions are there to make sure that the given outcomes are accomplished on all the following three levels: a) quality policy level, b) level of strategic outcomes, using for instance the Balanced Scorecard (Kaplan; Norton, 2004), and c) level of operational outcomes, i.e., the daily management level.

The widely used Balanced Scorecard method, which is a strategic part of quality management, states that the purpose of quality management is to set goals and monitor that the goals are achieved. The goals are set on four levels: (Kaplan; Norton, 1992, 71–79)

- 1) learning and innovation: intangible assets – people, systems, and culture
- 2) internal business processes: to satisfy customers and shareholders - operations for effectiveness and efficiency
- 3) customers: how to create value for customers
- 4) financial: shareholder expectations, productivity and growth

Each of these four levels is linked in a chain of cause and effect from level 1 to level 4:

- Learning and innovation includes training programmes with the goal to improve employee skills (level 1).
- This leads to improvements in customer service (level 2), which, in turn,
- leads to greater customer satisfaction and customer loyalty (level 3) and,
- eventually to increased revenues and margins (level 4). (Kaplan; Norton, 2006)

The learning and innovation perspective (level 1) identifies the intangible assets that are most important to the strategy. The objectives in this perspective identify which jobs, skills, talents, and knowhow are most important for the organization. This perspective identifies which information systems, networks, and infrastructure, such as CRM systems, are needed. Employee competencies, technology, and systems such as CRM play a major role in improving operations. In addition, it identifies what kind of organizational climate and abilities are needed to mobilise and sustain the changes required to support the next level (level 2), the value-creating internal business processes.

2.3 The case

2.3.1 Structure

This paper is a deductive case study. It looks at matters from the organizations' and from the customers' points of view simultaneously and adds an outside expert view. A qualitative approach is appropriate in areas where research is at an early stage.

The study flow chart, shown in Figure 2, portrays how this study was structured starting from the theoretical foundation of CRM theories and ending with a way to investigate service productivity in situations where traditional ways are not possible or are not sufficient. Mixed methods are used; there are many items of evidence from many sources.

Figure 2. The study flow chart.

2.3.2 Value for service users

To increase value for service users, the question was proposed: What has to be introduced to meet customer expectations? This question refers to the idea of CRM (Reinartz; Krafft; Hoyer, 2004, 293-305) as a method of increasing an organization's effectiveness. CRM is one part of total quality management.

According to CRM theories, which were introduced by Reichheld (1996), customer satisfaction is conducive to enhancing customer relations, and it is profitable for an organization to have good customer relationships. Reichheld noted that long term relationships with customers cannot be established in a sustainable way if management only focuses on decisions creating short term benefits. Long term customer relationships create value for customers. When customers are provided with the services they are looking for, profits for the organization should accumulate. It may take time before customer relationships are developed in an organization. In customer relationship management, wrote Winer (2001), the attention "has changed from customer acquisition to customer retention", although it is sometimes difficult to distinguish between these two activities.

Appelqvist (2005) concluded, when studying the efficiency of industrial companies, that greater theoretical insights could be achieved by interpreting the collected data through the eyes of marketing management, including CRM. Grönroos (2007) concluded that the main focus in obtaining results is the continuous management of services and CRM. He pointed out that CRM brings the need to appreciate customers' expectations to all levels of an organization.

There is abundant research in the area of CRM both in industry and in services. This paper defines CRM as encompassing a myriad of activities across an organization, and aimed at ensuring productivity.

2.3.3 Organizations' efficiency

To increase organizations' efficiency, the question was proposed: What does not constitute real value for service users and thus could be eliminated? This question refers to the idea of lean services as a method of increasing an organization's efficiency.

Some organizations use a continuous improvement approach known as Kaizen. (This method became famous due to the book by Imai (1986)). The core principle of Kaizen continuous improvement is feedback. The purpose is efficiency by the identification, reduction, and elimination of suboptimal processes.

Lean information technology (LIT) (Kindler; Krishnakanthan; Tinaika, 2007, 99-101) is an extension of continuous improvement principles into the development and management of information and communication technology services. The central concern of LIT is the elimination of waste, which is seen as work that adds no value to a service. LIT can be used in the development of information and communication services. This affects efficiency, which is the input side of productivity.

Although lean principles are generally well established and have broad applicability, their extension from manufacturing into services has only emerged in the 21st century. Whereas LIT initiatives can be limited in scope and deliver results quickly, implementing LIT is a continuing and long-term process that may take years before the lean principles become intrinsic to an organization's culture. LIT promises to identify waste that causes poor customer service, lost business, higher than necessary operation costs and lost employee productivity.

2.3.4 Relationship Management of the Elderly

In one definition of the productivity of service organizations there is the efficiency of the organization on the input side, and on the output side the customers' view of the value of the services. Services are often tailor-made, and as such, they differ considerably between different customers and at different times. This leads to the conclusion that it does not serve any purpose if the outputs of service organizations are only counted in terms of numbers. An important measurement of a service organization's output is the subjective experience of its customers. Along with this point of view this paper looks into value for customers. Value is created by customers in the use of services and products, in co-creation with producers. Value is personal and implies the customer's involvement.

To learn about value, many methods have been developed. For the empirical part of this paper, a business area was identified where traditional ways of measuring value are difficult or in some cases even not possible. The way to define value here was to assess how well the services offered met customer expectations. It is important to have knowledge of customer expectations in order to create good value for customers.

Furthermore, this study points out that to avoid harmful decrease in value, limitations to the aspiration of efficiency should be implemented – one of such is that the organization is required to meet certain quality standards defined by experts. Customers do not always know what they need and may not have skills in technology.

Technical quality is probably necessary for most customers, but not sufficient, however. Expert defined service quality forms a judgment about an organization's processes and not the customer's. An organization and its customers can mean different things when they talk about the quality of services. Both views are needed. In this study expert defined quality and value for customers together define service effectiveness. Productivity of a service organization in this paper integrates an organization's input concept of efficiency and the organization's output concept of effectiveness. This can be expressed by the function:

$$productivity = f(organization's\ efficiency, customer\ experienced\ value, expert\ defined\ quality)$$

This is called Relationship Management of the Elderly.

According to Liu (2010), quality of services has in many studies been determined only from the provider's perspective so that organizations are generally focused on providing services that are technologically accurate and fast. Effectiveness is an important part of service outcome and the organizations' productivity. It is crucial to define both quality from the provider's perspective and value from the service user's perspective so that organizations can use the information in identifying bottlenecks in their operations and target for development, when they strive for improvements.

Productivity improvement can focus on real goals and effects that productivity improvement tries to achieve. Then it would be possible to move from quantity to combined expert defined quality and value for customers. Information that develops in contact with the customers can be utilised in creative ways to increase value for customers. Klaus and Maklan (2007, 115–122) pointed out that concentrating on customer experience blurs traditional distinctions between products and services because of the focus on customers' experience, which arises from combinations of products and services.

2.3.5 Data collection

This study used mixed methods. Data were collected in Finland and partly in Sweden from interviews of customers and personnel, and the study also examines 2830 safety telephone alarm calls. Moreover, expert defined service quality criteria were constructed by Quality Function Deployment-method (Mizuno and Akao, 1994) (Serkkola; Rauma; Molander, 2005). To avoid harmful decrease in value for customers, limitations to the aspiration of efficiency should be implemented – one of such is that the organization is required to meet certain quality standards defined by experts.

Call center services are, like any other services, perishable and heterogeneous, and service production and consumption take place simultaneously. What all these features mean as implications to the services is shown in Table 2. It shows the safety telephone call center service features and corresponding implications. A service process is a series of service encounters, where employees and customers, supported by systems and technology, meet and interact. In the safety telephone service environment, this happens through call centers and the help services. Although the help service is the core service of the safety telephone services, call centers are the main contact points for customers. As call centers are spreading in all areas of business, their importance can be seen more widely, too. Call centers are deployed throughout the world as a cost effective way of enabling a very large number of customers to interact with an organization.

Personnel and customer interviews were conducted. The interviews began with a short introduction of the research. The personnel interviews were conducted as theme interviews and proceeded according to their respective themes. Theme interviews pay regard to different views of different interviewees and to different meanings and contents they give to the same matters. The conversations were about call centers, management, customer expectations, and information transfer within safety telephone service networks.

Table 2. Call center operation features and the corresponding implications (Adapted to safety telephone services from Zeithaml; Parasuraman; Berry, 1985, 33–46).

Service features	Implications to services
Perishable	<ul style="list-style-type: none"> • cannot be stored • difficult to coordinate supply and demand • cannot be returned • cannot be shown without use • it is difficult for the customer to evaluate beforehand
Production and consumption simultaneous	<ul style="list-style-type: none"> • customers participate in the production • customers affect the end result • multiple distribution channels are possible
Heterogeneous	<ul style="list-style-type: none"> • production and value-in-use depend on employee actions • difficult to control quality and value-in-use • cannot guarantee that the service is that which has been promised

The interviews gave basic information on value for customers, on customer services in safety telephone service call centers, roles of call center operators, and content of information being transferred between operators and users. The interviews showed clearly the necessity to collect information in also other ways.

There were elderly people who did not know their own needs. That is why ways of studying the expectations of the elderly, other than the usual customer satisfaction surveys in the form of questionnaires, must be found. Further data were collected from alarm calls coming into a large national call center. The interviews permitted the development of the instrument that was used in the call center data collection.

As an example of how value for service customers can be investigated in the present day environment, this study looked at help requests coming in at a safety telephone call center and compared them to the answers given by the call center operators. (Molander, 2003) The incoming help requests represented customer expectations, and the compared answers represent how these expectations were satisfied. Giving help or sending for help contributed to meeting customer expectations and produced value. Up-to-date customer data also increased value for customers.

Furthermore, a second set of data about safety telephone alarm calls and the customers who made them was collected from a call center log database to shed more light on value for customers. This data concentrated on those cases where it was suspected that customer expectations were not met. The most recent alarm call of the selected customers had been made for a non-physical reason.

Workshops were also held. In one workshop, an expert group gathered. The experts were invited from the public sector help services, safety telephone service organizations, elderly care homes, and other organizations and companies in closely related fields to ensure a wide selection of interests. In selecting the expert group, care was taken to ensure that major official players in the field of safety telephone services were present.

A provider perspective of service quality was studied using the Quality Function Deployment method (Mizuno; Akao, 1994) involving the expert group. The group raised all the customer expectations that they thought were important. The Quality Function Deployment method was used to transform user demands into design quality and to deploy methods for achieving the design quality into subsystems. For safety telephone services the experts weighted the received alarm calls and help services according to their understanding of the importance of each part in the whole service system.

This can be considered a good approach when the assessed quality is used to limit the efficiency of organizations, and real customer expectations and value are found in other ways. The acceptable expert quality level was defined. This is the Zone of Tolerance model (Yap; Sweeney, 2007, 137–148) type of threshold. Also to evaluate effectiveness, it helps to find expert defined quality criteria since there are those among customers who do not know their needs. Also other methods than Quality Function Deployment could be used to set expert standards for the services.

These quality criteria are meant to benefit both private and public sector suppliers of safety telephone services, as well as buyers of these services. These quality criteria are not adequate alone for service effectiveness and customer satisfaction. Value for customers requires, in addition, another approach.

According to Frei (2006, 92–101) customers introduce variability to service processes in no fewer than five ways, so it is critical to determine which are causing mischief for efficiency before designing interventions. One type of variability that creates challenges for service companies is the "arrival variability", meaning that customers need services at their time of convenience; not all customers want to have service at the same time or at times necessarily convenient for the organization.

"Request variability" implies that customers' desires do not emerge along the organization's standard lines. Film enthusiasts may recall the diner scene in the film *Five Easy Pieces*, in which actor Jack Nicholson asks for a side order of wheat toast. The waitress tells him that they "don't have any side orders of toast" although toast is included in several meals in the menu. This is one way to limit request variability. The fact that customers' desires do not emerge along standard lines poses challenges for virtually every kind of service.

"Capability variability" means that organizations must work with customers whose own capabilities differ. This may be because of greater knowledge, skill, physical abilities, or resources, but some customers perform tasks easily and others require hand-holding. In a safety telephone service setting, a user may be more or less able to describe his/her situation or use the service at all, and this will affect the quality of care the user receives.

The fourth type of variability that creates challenges for service companies is the "effort variability", meaning that it is up to the customers how much effort they apply to the service task. The fifth, the "subjective preference variability", means that customers vary in their opinions about what it means to be treated well in a service environment. These last two are personal preferences, but they introduce as much unpredictability as any other variable and make it somewhat more difficult to serve a broad base of customers.

2.3.6 Results

This study handles organizations' productivity, expert defined quality and value for customers in an organizational context which is practically untouched in previous research studies. The research showed that productivity could be improved without metrics. The constructs of productivity have received limited research attention in qualitative literature.

This study used mixed methods. Many items of evidence from many sources were used. They yielded the same line of findings. Interviews of customers supported interviews of personnel. Safety telephone alarm call data were supported by the interview findings. Moreover, expert defined service quality criteria were supported by earlier findings from other sources of knowledge. Using multiple sources of evidence in the data collection phase increases validity, (Flick, 1992, 175–198) (Silverman, 2001) (Riege, 2003, 75–86) as this study did by collecting documents, interview tapes, and data samples for protection against researcher bias.

Results on value

The first research question - to increase value for service users, what has to be introduced to meet customer expectations - was looked into by dividing the question into two other questions: what services are received and how are the services received? Grönroos defined technical quality as what is received and functional quality as how the services are received. (Grönroos, 1988, 10–13) In this paper, expert defined quality and value for customers answer these questions.

Organizations worked with customers whose capabilities differed. Some customers were able to express their views better than others. Therefore some of the customers could not be interviewed in addition to which interviews would be costly and time consuming. Other methods were developed to discover customer expectations. Actual behaviour was investigated here because people could not always express themselves. They did not necessarily even know what was best.

The way to define value here was to assess how well the services offered met customer expectations. Comparing the services customers asked for and the services provided to them indicated whether customer expectations were met. This study showed that customers had their ideas concerning the contents of the services but many times the services did not meet these expectations. Customer expectations were observed by means of wellness technology. With the help of modern technology, customer expectations could be followed quickly and easily. It is acknowledged that technology development and utilisation may play a major role in improvement of productivity. (Melkas, 2013)

The incoming help requests represented customer expectations and the compared answers represented how these expectations were satisfied. Giving help or sending for help contributed to meeting customer expectations and produced value. In 76% of the customer alarm calls, customers did not ask for physical help, and there is evidence that customer expectations were not met. The sample of safety telephone alarm calls shows that in 24% of customer safety alarm calls customers had a physical help request and service was provided to the customers. In those cases we could see that customer expectations for services were more or less met.

Organizations saw some problems in fulfilling customer expectations in some cases because the background data of helpers and their telephone numbers were not in order. This could cause delays in providing help. Call center services of even the same organization were different at different times because the production of the services was, as always,

based on individual employees and thus were heterogeneous. It was difficult to control the value of call center operations because it is people who provided the services.

A help service had no value for customers or had only reduced value if the call center answered calls too slowly. It is difficult to build a competitive advantage based only on the functioning core service of providing physical help for the customers. To be competitive, an organization has to offer customers something more in comparison to other organizations. (Ylikoski, 2000)

Results on efficiency

There was an urgent need to further investigate closer what the expectations of the customers in the 76% of the safety alarm calls were, when customers did not expect physical help. The 55 customers of the second sample of customer alarm calls repeatedly made non-physical alarm calls. When customers made alarm calls and did not ask for physical help, customer expectations were not met by safety telephone services.

There was an indication of user expectations as regards social contact. Call center operators seemed to identify these users who made “social calls” daily. There was little or no attempt to solve this problem, which caused inefficiencies in operations. These users repeated their “social calls” over and over again. Call center operators knew these particular customers and their habits of making frequent calls. The existing services were burdened with such lack of efficiency.

Information is increasingly available through advanced computer solutions making it possible, at least in theory, to serve customers individually with customised services. However, too much customising can ruin a service providers’ efficiency. The question for safety telephone service providers and other elderly services is how to tailor their supply according to the distinct needs and characteristics of their customers. The supply architecture must be robust in order to be applicable to different demands in different customer situations. The goal could be to separate out customers who are currently harming the organization. This should allow the organization to think of other ways of serving those customers for whom the organization’s services are of no value. How customers perceive the value of services should affect the service offering. (Zeithaml; Bitner, 2000) Customers’ value and service organization’s productivity could be increased at the same time by minimising disturbance to the service production. It does not help to have high technology if service processes left room for uncertainties about customer expectations. Uncertainties could create mistakes and delays in providing services.

Technology was a help to call centers in identifying customers. Therefore, up-to-date customer data was an integral part of giving and receiving physical help when expected. Up-to-date customer data increased value for customers. It also enhanced efficiency because, for instance, then employees did not need to make several phone calls to different numbers. Safety telephone service organizations needed to ensure that their customer database only included correct information. A concern about this was raised during this study.

Investigating incoming customer alarm calls, this study found a two-fold problem in that some customer expectations were not met and these same customers also burdened the organization with demands. The organization did not even try to meet these demands and this harmed the organization’s efficiency. With the help of technology, the organization collected a considerable amount of useful data from its customers. However, the data were not used. With the help of this rich data of customer behaviour, which could be interpreted as customer expectations, the organization could ease the situation by increasing value for customers in order to decrease the burden caused by the demands on non-existing services.

The second research question was: To increase organizations’ efficiency, what does not constitute real value for service users and thus could be eliminated? Customer activity data gave information on how to service customers so that value for them could be increased and that organizational efficiency also could improve. Better value for customers goes here hand-in-hand with organizational efficiency. The results of this study clearly showed that service providers can improve things for their customers and, at the same time, also increase their own efficiency. This means increased productivity, which is the aim of every organization.

Using the best available databases requires that personnel have access to the database, the development of best practice guidelines, and the development of implementation plans in response to new data. Using information is not always straightforward for personnel, given the pressures of time and other commitments. Using data in a creative way puts pressure on the efficient use of an organization’s resources. Training personnel consumes more resources and again puts pressure on the efficiency of the organization. These must be taken into consideration when increasing value, so that the resource increase does not increase production expenses but decreases them in the long run. By solving inadequate and non-effective parts of the services, organizations can be brave in taking favourable steps in improving customer value, which can create a win-win situation for both customers and organizations.

2.3.7 Discussion and conclusions

If we tried to apply quantitative methods in the productivity of elderly care services, we would run into difficulties in measuring effectiveness. To successfully apply Relationship Management of the Elderly means that the traditional metrics used by organizations to measure the success of their services have to be updated. Financial and market-based indicators are important (Lehmann; Winer, 2001) but not used in this case. The quality of services provided may have seemed good from the service provider’s internal point of view even though customers complained. The service provider may not understand why customers were complaining as the services and technology were according to agreed

standards, personnel were trained, and the service network adequate. However, there is more than this to value for customers, as can be seen in this paper. An organization and its customers can mean different things when they talk about the quality of services. Both views are needed.

It was shown in this study that call centers can play a major role in answering the problem of recognising customer expectations beyond physical help expectations. The approach was taken here to look at customer satisfaction through call center operations. Recognising customer expectations and assessing the help required represent key elements in the strategy of providing help for elderly customers. The recognition of expectations is typically sometimes complicated because the customers in services for the elderly can be physically, recursively, or mentally impaired.

Customers did not always understand who to turn to. The elderly cannot be expected to be trained to distinguish between service providers. Making a distinction between service providers is often difficult even for those with all their cognitive abilities functioning well. The elderly expected some kind of help and if they did not get it, they pushed the safety telephone device button over and over again. In 76% of customer alarm calls no physical help was requested by the customers. So, in most of the alarm calls made by users, their problems remained unsolved. As a result the effectiveness and efficiency of the safety telephone service organization suffered. It seems that safety telephone services did not serve the users as well as they could. Organizations also did not seem to run as efficiently as they could.

Organizational efficiency aspirations can decrease customer experienced value. This study found a solution in which increasing organizational efficiency would go hand-in-hand with increasing value for customers; the result being that the organizations' needs and the service users' expectations would be in line. Based on the results of this study it is reasonable to argue that services can be planned, implemented, assessed and continuously improved to meet the needs of the customers whenever the services are used. With such actions it is possible to increase both customers' value and the productivity of services. Efficiency and effectiveness could be improved thus increasing the productivity of the organization. It could clearly be shown how to increase efficiency and to increase value to customers at the same time by looking at customer behaviour and organization's responses to it.

Call center operators of safety telephone service organizations interact with customers and they have a direct impact on value for customers. They can be called relationship promoters. (Melkas, 2004) The idea behind Relationship Management of the Elderly is to increase customer contact points, to investigate customers' reactions to these contacts, and to develop immediate responses to possible negative experiences. One of the key features would be to manage multichannel interactions. Successful businesses influence people through experiences, and these experiences render personal value. (Pine; Gilmore, 1998, 97–105) It can be seen from this study that a service provider created an experience every time it interacted with a customer. Although everyone in the organization is responsible for offering good quality services and every employee affects directly or indirectly value for customers, it is the call center operators who are in a key position here.

The problem was the adjustability and flexibility of employees to the expectations of the customers. Safety telephone services were not built for social calls, although this study shows that customers most often asked from them. Social calls were repeatedly made by the same customers. For the services to function effectively and efficiently, those customer expectations should be answered by someone. Safety telephone service organizations would benefit from taking care that the social calls get answered by them or by someone in their network. Call center services could thus meet customer expectations much better than they do presently. Organizations could develop services individually and together with networks of other service providers in order to provide complete services.

Any contact that customers have with an organization is a customer service encounter. Dissatisfied customers seemingly hurt the organization. New tools are needed to service those customers who at present receive no service. The organization can develop the tools within its organization, create a new organization for the services or join other existing service organizations. A manageable number of alternative modular service offerings, which can be adapted to individual customer situations and requests, could be developed. The idea is to develop optimum operative efficiency for the organization within the constraints set by customer requests and by expert assessment of quality.

Developing technology changes service production and gives an opportunity to increase productivity. For this study, a business area was identified where customers had their own ideas of the contents of the services, but the services provided do not meet these customer expectations. This could reflect the wider problem that elderly care services face a gap between elderly people's expectations and services provided by organizations.

As this study showed, safety telephone call centers collected a considerable amount of information about their customers, but the data were not used within the organization - or more generally within social and health care services to gain a better understanding of customer expectations or to give better services for customers. Such customer information could also become part of systematic planning and evaluation of elderly care services in general. The role of call center operators could be taken to a novel level in that user needs through call centers would have a real impact on social and health care services produced. This would be a new approach to such social service related work.

It is vital that medical and other information is included in elderly care services such as safety telephone services. Laws should not prevent the rational operations and forming of networks for those elderly care services that provide essential help. Privacy issues need to be taken into consideration but they should not prevent customers from getting proper help in whatever area they expect it.

Public sector organizations are dependent on ministries, other administrative bodies, and politicians in decision making. To develop services requires co-operation among everyone in the field. If technology is used to help in

developing value and efficiency, those possibilities, if used, make people happier both on the production side and on the consumption side.

With the help of modern technology, customer expectations can be followed quickly and easily and customers could co-create with the organization. In this study, this is referred to as Relationship Management of the Elderly. This type of an approach could be useful even in the development of other services for other ages and in different contexts. The approach of this study may be generalised beyond safety telephone service organizations. The approach may be used in many other situations and is useful especially where customers do not know or cannot express their needs. Childcare, preschool education, the healthcare of mentally disabled persons and many other similar situations provide opportunities to use this approach.

Based on this study, it can be recommended that further research is needed in value for customers, effectiveness, and productivity in social and health care, and more generally in all services. A multi-party focus means that long-term relationships should be built, not only on customer expectations but also on the expectations of other stakeholders like employees, suppliers, intermediaries, public sectors, and more. Using general network theory (Melkas, 2004) (Gummesson, 2008, 315-330) in future research could bring more clarity to the difficulties of managing networks.

Human or Technological Resources in XXI Century Schools: An Empirical Analysis

Oscar Montes Pineda, Luis Rubalcaba

Alcala University

Service and service innovation theory provides a powerful framework to understand how education is provided by breaking down and representing education as a set of characteristics. Two of the world strong education performer's countries, Finland and Korea, have been able to effectively educate every child regardless their socioeconomic level. Each country has implemented different strategies, leading to very different forms of education provision raising the question of the role played by human resources and/or technology in education provision. Using each countries individual sample of the PISA-2012 database, we employ multilevel models to investigate this quandary. Results suggest that human resources (competences) and technology (technical characteristics) influence student outcomes in both cases. Nevertheless, for each case there is a set of core competences and technical characteristics influencing the overall set of outcomes considered.

1 Introduction

A way to understand how education services are provided is by analysing education from a service perspective. Service and service innovation theory (Gallouj and Weinstein, 1997; Gallouj 1994, 2002) provides a powerful framework to understand (and measure) how education is provided by breaking down and representing education as a set of (service and social) characteristics, and more important, it clearly grips with and reveals ways to improve its dynamics, by modelling innovation in education and education (service) innovations. Gallouj & Weinstein's (1997) theoretical construct bases its fundamentals on the work of Lancaster (1966, 1971) and Saviotti-Metcalf (1984), by linking the intrinsic characteristics of education to a set of underpinning technical characteristics and competencies. Improvements in the technical characteristics and/or (actor's) competencies can lead to enhance the quality of the associated education characteristics that are of interest to students. This theoretical construct suggest that education (intrinsic) service characteristics (outputs) may depend on a bundle of technical characteristics and/or competencies, but more important, it also suggest possible overlapping of a bundle of technical characteristics and competencies underpinning (a single or) a set of service characteristics.

This latter concern is prominent to the point that Gallouj and Weinstein (1997) suggest that depending how technical characteristics, competencies and final service characteristics change or recombine will lead to different modes of innovation, clearly emphasising a specific relationships between each sets of characteristics. In fact, this issue has been highlighted by Windrum's (Windrum et al., 2009) reading over the Saviotti and Metcalf (1984) model relating technical and service characteristics - clearly extensible to the enhanced Gallouj and Weinstein's (1997) model - emphasising the possible existence of multiple and complex relationships between clusters of technical and service characteristics, but more interesting, the fluidity of their relationships over time. These considerations imply that education can become a complex service¹⁷⁹ in the sense that the delivery of education can combine several interfacing possibilities between learners and education providers influencing education outcomes in different ways.

Recent results of the Program for International Student Assessment (PISA 2012 Results in Focus, 2013) of the OECD¹⁸⁰ conclude that two of the strong education performer's countries, Finland and Korea, have been able to effectively educate every child regardless their socioeconomic level (including their origin or ethnicity)¹⁸¹. To do so, each country has implemented different strategies, leading to very different forms of education provision. While Finnish emphasise on high trained and empowered teachers, student early intervention (special lessons and individual support) and weekly (multidisciplinary) team teacher (and other school staff¹⁸²) meetings, Koreans encourage student hard work (in and out of school) and active learning (participatory, creative and independent) by integrating ICTs in their daily learning (digital textbooks and cyber-home) which is complemented with parent interest. From the service and service innovation theory perspective, these two ways of providing education clearly raises the questions of the role played by human resources and/or technology in education provision, but also (at the same time), the validity if the same set of

¹⁷⁹ Given the complexity of education services, OECD/CERI has launched several projects aimed to better understand its dynamics. Projects developed are Education and Social Progress, Governing Complex Educational Systems (GCES), Innovative Learning Environments (ILE), Innovative Teaching for Effective Learning and the Innovation Strategy for Education and Training. <http://www.oecd.org/edu/ceri/innovationstrategyforeducationandtraining.htm>

¹⁸⁰ <http://www.pearsonfoundation.org/oecd/> and <http://www.oecd.org/pisa/keyfindings/pisa-2012-results.htm>

¹⁸¹ Recent results of the PISA 2012 conclude that both countries (Finland and Korea) combine high levels of performance with equity in education opportunities (PISA 2012 Results in Focus, 2013)

¹⁸² Which can include among others, pedagogues or school principals.

technical characteristics and competencies influence several (and different) education outcomes (e.g. math, science and reading)¹⁸³.

Considering these facts, our research hypothesis guiding our work will be:

Hypothesis 1: Service and service innovation theory suggests that education outcomes are underpinned by a bundle of technical characteristics and competencies, but at the same time, possible overlapping vectors of these characteristics can exist influencing several but different outcomes (Gallouj and Weinstein, 1997; Windrum et al., 2009). Our first hypothesis will be to contrast to what extent, the same set of technical characteristics and competencies influence several (but different) education outcomes (as measured by PISA 2012, namely 15 year old students math, science and reading test scores) for each of our cases analysed.

Hypothesis 2: Given the fact that different ways to provide education are equally effective (OECD/PISA 2014), our second hypothesis will be to contrast to what extent technical characteristics (technology) and/or competencies (human resources) influence several but different education outcomes (as measured by PISA2012, math, science and reading test scores).

To do so, we will use each countries individual sample of the PISA-2012 database at student and school levels, and given the nested nature of the data, we employ multilevel (or hierarchical linear) models. Estimations have been made from a comparative approach, in a case-to-case basis. In the best of our knowledge, there is little evidence in research covering these issues (assessing education from a service and service innovation perspective) from an empirical point of view¹⁸⁴.

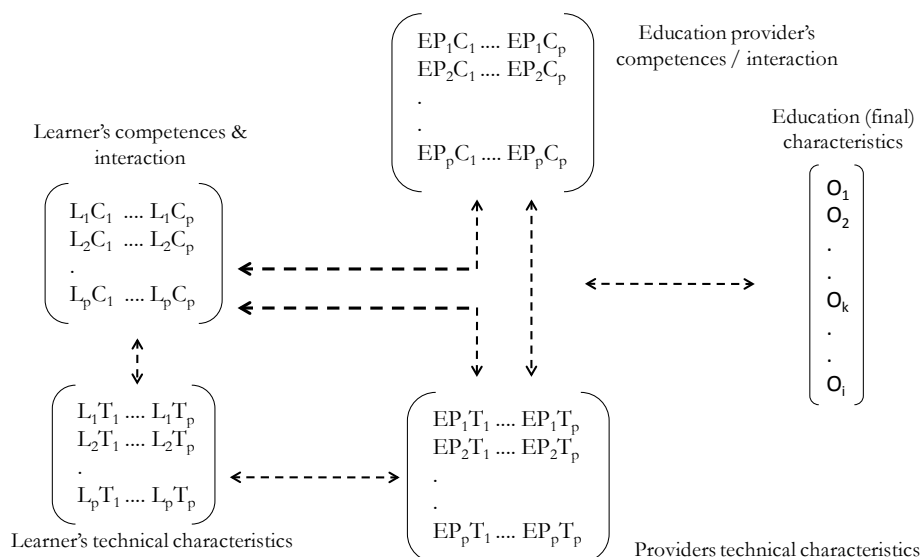

With this purpose, this paper is structured as follows. Section 2 presents the theoretical framework describing/representing education as a set of service (and social) characteristics, framing the link between the intrinsic characteristics of education to a set of underpinning technical characteristics and competencies. In the following sections, we present the data used, countries samples of the recently launched PISA2012 database, and describe the variables, namely those related to the technical characteristics, actors competencies and education (intrinsic) characteristics – 15 year student test scores in the domains of reading, math and science (Section 3), and the methodology used, two-level hierarchical models (students in schools) are described and justified, including specification steps followed for modeling each case that gives answer to each of our research hypothesis (in Section 4). Section 5 presents the results and discussion, including a brief robustness analysis. Section 6 presents the concluding remarks and the general conclusions.

2 Theoretical framework: Education as a set of characteristics

Education as a service has some specific characteristics; it is intangible, interactive, requires certain simultaneity and can be defined in terms of co-production. Furthermore, this service traits, involve human relations, which lead to social (and community) interactions, suggesting that learners and educational providers interact (and co-produce) within educational communities (Rubalcaba, 2013).

¹⁸³ A third question would be how technical characteristics and competencies influence several (but different) final service characteristics over time. Given the data analyzed, this question becomes difficult to answer at this stage.

¹⁸⁴ Examples in this field addressed by the service and service innovation literature are Miles (1961) and Fuch (1965) or more recently Soette and Miozzo (1989) and Miozzo and Soette (2001) which aim to explain (uncover, classify or even theorize) the complexity of relation between "technical (or actors competencies) and service characteristics" of general services, including education.

Source: Own elaboration adapted to education building over Gallouj & Weinstein (1997) and De Vries (2006)

Figure 1. The characteristics-based representation of (education) services.

The framework. Considering these set of characteristics, education can be represented by the characteristics-based approach to goods and services (Gallouj and Weinstein, 1997; Gallouj 1994 and 2002)¹⁸⁵. This theoretical construct allow us to represents education as a system of interrelated vectors/matrixes (See Fig.1). We present an extended version¹⁸⁶, which includes five vectors/matrixes. Matrix $L_n C_p$ represents the competencies of the different users (knowledge and abilities), and their co-production abilities (student behaviours and student interactions)¹⁸⁷. Matrix $EP_m C_t$ represents the competencies (again, their knowledge and abilities) of the provider as well as their co-production abilities (highlighting again, provider's behaviours and providers interactions). The $L_n T_q$ matrix represents the technical characteristics of education associated to users and matrix $EP_m T_v$ represents the technical characteristics of the service (which normally are associated to providers). These later technical matrixes include tangible technical characteristics or intangible technical characteristics associated to the education service, in such a way that they can be used repeatedly for the provision (learning and teaching) of similar "ways" of education or different kinds of education (depending on whether they are more or less generic or specific). The final service outcome is represented by the vector O_i and is the result of the co-production capabilities of the user (matrix $L_n C_p$), the competencies of the provider (matrix $EP_m C_t$) and the technology of the users (matrix $L_n T_q$) and the providers (matrix $EP_m T_v$).

The model dynamics. Arrows in Figure1 draw attention on the co-production abilities of the users as being determinant of the service outcome. This means that student's play a relevant role in education provision including the use of a specific education service - the product (De Vries, 2006). Moreover, it also denotes the way service (education) is provided or deliver (high lightening the role of providers, its interactions and co-production with students), which could therefore be defined as the simultaneous employment of technical characteristics and competences ultimately used to produce the service (or final) characteristics (Gallouj, 2002; Gallouj and Savona, 2009), or what De Vries (2006) calls the co-production relationship, which can include several particular cases (Gallouj and Wesintein, 1997) such as: (1) a pure service (relating the users and providers competences and the service characteristics vector/matrixes), (2) a pure material good (linking the providers technical and service characteristics), as addressed by Saviotti and Metcalfe (1984) and Windrum et al (2009), or even (3) the link between users competences and providers technical and service characteristics, which can be considered the self-service characteristics (Gallouj and Wesintein, 1997; Gallouj, 2002 or De Vries, 2006).

¹⁸⁵We must emphasise that Gallouj and Wesintein's (1997) theoretical construct can be applicable to services but also goods (Gallouj and Savonna, 2009; Gallouj and Djellal, 2010). This means, they integrate tangible and intangible elements applicable to goods and services, following the idea initially proposed by Lancaster (1966 and 1971), to define or represent a product by its characteristics.

¹⁸⁶Based on Montes, Gallouj and Rubalcaba (2014)

¹⁸⁷This way of representing the "user vector" as a matrix of serveral users is supported by the importance of users' interrelations (possibility of interactions), underppined in the case of education on the so-called peer effect (Nechyba 1999; Burke and Sass, 2011; Duncan and Murnane, 2011 Sacerdote 2011; Borgonovi et al 2013), which exerts influence over education provision and outcomes directly (face-to-face) either in school or out of school, or indirectly (e.g. throughout social networks, email, etc..). Similarly to providers (See De Vries, 2006), the existence of multiple users and their interrelations (including the co-production with providers) opens the need to enhance the individual user competence and technical vector to an array of different competences and technical vectors associated with each user. In fact this ideas was partly considered by Von Hippel (1988).

These (special cases or) ways of provision or delivery of education (See Annex I presenting some specific examples), lead in fact to a better understanding of education characteristics, providing useful insights of the co-production abilities and technical characteristics. For example, one can think how traditional education is provided (See Annex I – Fig.5). Very briefly, education providers (normally "the" teacher) co-produce in class with a group of students where student also, interact between them and co-produce with the teacher. This co-production normally encompasses teachers explaining a group of students (or more individual explanation) the content of a topic (e.g. math). To do so, teachers use their competencies (e.g. math and pedagogical knowledge) and co-producing abilities (e.g. enthusiastic, organized and student sensible) and some specific "technical characteristics" of the service (e.g. explaining using a digital blackboard & based on a textbook). The outputs of the service can include a "better understanding of a difficult topic given teachers clear explanation", "student motivation given the teachers enthusiasm " and "higher test scores at the end of the year".

Applying this idea in modern education (See Figure 1), we can mention for example that in a school day, education service can include (1) a direct contact between the students (LC) and teachers (EPC) with certain competencies improving learning throughout the teacher-student relationship (e.g. teacher mentoring a student or a direct explaining of a topic/issue), further, (2) students can "co-produce" throughout provider's technology, relating the LC matrix and the EPT matrix, like in self-service (e.g. downloading material from the virtual web at school and reading it). Moreover, (3) a link between providers competencies (EPC) and their technology (EPT) can be implemented (e.g. working over class-presentations and uploading the material in the school on-line application) or even (4) link between student competencies (LC) and its technology (LT) can take place (e.g. a student using a personal computer/calculator to check math problems answers). This latter examples suggest that competencies of provider's or students can be codified and represented in the provider's technical vector (De Vries, 2006). Furthermore, co-production abilities can deal with interactions and behaviours between students, (5) linking the competencies ($L_n C_p$ vectors) of several students (e.g. attitude to help a peer to solve a math problem or provide school material - own notes or references- to some peers or even well-behaving - listening in class, paying attention, being quiet - during collective study/learning). This form of interaction and behaviours can also take place between providers, (6) relating providers ($EP_m C_i$) competencies (e.g. team teacher planning or preparing a workshop with parents or local actors, arriving sharply to class). Outputs in general (O_i vector) - following Gadrey's (1996) dissociation can include personal mentoring activities or a personalized curricula, easy access to a school subject content, or even achieving good grades in one or different subjects.

The evidence. Education research in the last decades (Sliwka, 2003, Instance and Sliwka, 2006; Beck and Kosnik, 2006; Vieluf et al., 2012; Van de Broek, 2012, OECD/ILE Project, 2012; Instance and Kool, 2013) suggest that education can be influenced by social and technical resources. This means that within an education service, groups of providers deliver several "educational services" to students, students also contribute to this delivery process throughout their co-production abilities and the "technical" link between students-providers opens new forms of co-production throughout more technological channels.

This implies that education can become a complex service in the sense that the delivery of education can combine several interfacing possibilities between several users and providers (competence and technical characteristics) and (final) service characteristics. In fact, this consideration has been highlighted before, as stated by Windrum's (Windrum et al., 2009) reading over Saviotti and Metcalfe (1984) model relating technical and service characteristics, emphasising the possible existence of complex relationships between clusters of technical and service characteristics as well as the fluidity of relationships over time. This fact is fully applicable in education.

3 Data and Variable Description

3.1 The Finnish and Korean PISA 2012 countries samples

The data used in this research come from the Program for International Student Assessment (PISA) 2012, and refer to the Finnish and Korean country samples. The selection criteria for choosing these countries (samples) has been on the one side, their excellent combination of high levels of performance with equity in education opportunities (PISA 2012 Results in Focus, OECD, 2013) and in the other, their markedly differences on their provision of education (OECD, 2011; Pearson/OECD video transcripts). PISA is an international assessment survey that measures students' abilities in the domains of reading, mathematics and science. According to the OECD (2012a), PISA focuses on young people's ability to use their knowledge and skills to face the challenges of real life and not to master a specific curriculum. Moreover, PISA takes place every three years, focusing on 15 year students, from OECD and partner countries. Five waves of PISA have taken place, namely 2000, 2003, 2006, 2009 and 2012. The PISA 2012 survey covers 65 countries and economies around the world. In addition, each wave has focused on a specific domain. In 2000 the focus was on reading, in 2003 its' focus was in mathematics and lastly, in 2006 it focused in science. The PISA-2009 and 2012 editions focused again in reading and mathematics literacy respectively. The Finnish and Korean countries samples contains 8.829 and 5.033 students from seventh to 11th grade ($M_F = 8,81^{188}$ and $M_K = 9,94$; $SD_F = 0.43$ and $SD_K = 0.24$) nested in 311 and 156 schools respectively.

¹⁸⁸ In the case of Finland compulsory education begins at the age of 7, covering 9 more years, thus, when taking PISA-2012 tests, students are normally in 8th grade on average.

3.2 Variable description

When choosing the variables we have followed our theoretical framework discussed in section 2, the enhanced characteristics-based approach to goods and services. Collecting (from PISA2012 database) data following this framework allow us to clearly identify a wide set of variables related to each characteristics vector/matrix considered in the service provision (actors competences and co-production abilities, and technical and service characteristics). Further and more important, assessing education from a service perspective allow us to investigate the existing statistical relationship between actor’s competence and technical vectors and service characteristics. The variables considered in our analysis are presented herein below.

Dependant variable. The dependant variable are the standardized test scores achieved by students in the domains of math, science and reading. The argument for choosing these variables has been considering a set of education outcomes (service characteristics) normally result of education provision

Table 1. Country Math, Science and Reading Test Scores Finland and Korea (Dep. Variable).

Variable	N	MIN	MAX	Mean (*)	SD (*)
FIN Math AVG	8.829	165,50	790,69	518,75	85,30
FIN Science AVG	8.829	128,44	852,87	545,44	92,96
FIN Read AVG	8.829	99,71	817,83	524,02	94,67
KOR Math AVG	5.033	161,11	888,82	553,77	99,09
KOR Science AVG	5.033	182,26	815,68	537,79	81,91
KOR Read AVG	5.033	109,42	784,34	535,79	86,54

Source: Own calculations using the Finnish and Korean countries samples of the Student PISA-2012 DB. (*) Countries average means and standard deviations have been computed as the average populations means and standard deviations of each plausible values (PV) for each domain. Further, each PV populations mean and standard deviation for each domain has been computed using Balanced Repeated Replication (BRR) (OECD, 2009).

For each literacy-domain (reading, mathematics and science), PISA2012 data reports for each student, five plausible values (see Adams and Wu, 2002). The general scale used¹⁸⁹, is transformed to reach an average of 500 (points) with a standard deviation of 100 (points) using a linear transformation. When a student's score is close to a point of the scale, it's more likely that students successfully respond to the items that are at that point or below it (score) and likewise, students are less likely to respond to items that are above that score. For our empirical analysis, in order to estimate the unbiased "population" estimates of our interest, we have followed the PISA Data Analysis Manual (OECD, 2009, 129–130).

Independent variables. Independent variables are presented herein below following our theoretical construct in section 2 and the aims (hypothesis) of our research. This means first, we describe the student/learners competencies (which include student general background variables, gender, origin and family composition), as control variables, general competencies associated to cumulative knowledge and abilities to the date, co-production abilities, namely related to behaviours and interactions and technical vector characteristics related to students, secondly, we describe the education providers vectors competence characteristics (namely those related to teachers, principals and parents), and lastly, we describe the technical vector characteristics of education, these latter variables are associated to the schooling process in broad sense, this means considering an ample set of characteristics that can be from particular school resources to more procedural and intangible know-how.

¹⁸⁹ This is estimated on standardized scores, which are based on mean zero and standard deviation 1. OECD-PISA (2012a)

Source: Own elaboration based on PISA2012 DATA. (*) T (type of variable), which can be continuous (C) or a dummy (D). Regarding the dummy variables, they taking the value 1 if characteristic holds and zero otherwise.

Variables describing students/learners competencies and technical characteristics are depicted in table 2. Regarding each learners background and general competencies (control variables), variables include gender, referred to boys (gender_M), the origin of students (native), if attending kindergarten for more than a year (kinder_more1), if students have not repeated any year in ISCED 1 (NOrepISCED_1) and ISCED 2 (NOrepISCED_2). All these variables are dummies, which take the value of 1 if the characteristic holds and 0 otherwise. One more variable has been included in this group, the student socioeconomic background index (SES), which is a continuous variable. This latter variable is an indicator that encompasses three components associated with the student's familiar and home environment, namely, (1) the level of parental occupation (job position), (2) the level of educational attainment of parents expressed in years of schooling and (3) the rate of student possessions at home. This last component in turn encompasses family welfare, cultural possessions and educational resources available in their homes, including the number of books.

The second and third group of learner's variables captures what we have called co-production abilities, which are related to student's behaviours and interactions between them. Regarding student behaviour, variables considered include those suggesting big effort of students at home, this is, working hard on math homework (wHRDhw_1) and studying hard for a math quiz (studhq_1). Moreover, variables considered relate students with in-class behaviour, such as paying attention (payatt_1) and active listening in math class (lstclass_1). Lastly, we have considered a variable related to student individual work in class which is deciding the method to solve math problems (empsp_1). As for the third group of variables capturing those abilities that involve student interactions, they include helping often their peers in math (peerhlp_2) and talking sometimes with peers about math (mpeertk_2).

As for learners' technical vector characteristics they include those technologies (in our case tangible) supporting students interactions out of school. Variables considered where if learners had a computer a home that can use for school work (comphm_1), if students had educational software installed (Edsfthm_1) and if they had a computer linked to internet (www_1).

Source: Own elaboration based on PISA2012 DATA. (*) T (type of variable), which can be continuous (C) or a dummy (D). Regarding the dummy variables, they taking the value 1 if characteristic holds and zero otherwise.

Our second group of variables described are those associated to education providers (Teachers and Principals on the one side and Parents in the other). See Table 3. Variables considered can be associated to provider’s competencies and co-production abilities (behaviours and interactions). Variables associated to teachers competencies and knowledge are the percentage of math teachers with a major in math (MT_majM) and the percentage of math teachers with an ISCED 5A in pedagogy (MT_5aPED). These first sets of variables are continuous. Regarding teachers co-production abilities (behaviour and interactions), variables include empowered teachers in the domains resource management (TEACHq5b and TEACHq6b, where teachers have the responsibility for planning and allocating resources) and organisation of instruction (TEACHq7b, TEACHq8b, TEACHq9b and TEACHq10b, where teachers have responsibility of disciplinary, assessment and admission policies including textbook choosing). Further, variables include enthusiastic teachers (TCHenth_1) and teachers interested in trying new methods and teaching practices (TCHnewMet_1). All variables considered in this second set are in general dummies, taking the value of one if the characteristic holds and zero otherwise.

Moreover, we have considered the index of teacher-related factors affecting school climate (tchSCHclim), which integrates a set of responses¹⁹⁰ from principal on how school climate can hinder student learning. It is a continuous variable where positive values reflect principals’ perceptions that these teacher-related issues hinder learning to a lesser extent, and negative values indicate that school principals believe that these teacher-related issues hinder learning to a greater extent, compared to the OECD average (OECD, 2013).

¹⁹⁰ The main concern of the index was to consider how important some school factors (Q.18 of the paper questionnaire and SC22q01 to q19 of the school PISA2012 data base) such as students not being encouraged to achieve their full potential; poor teacher-student relations; teachers having to teach students of heterogeneous ability levels within the same class; teachers having to teach students of diverse ethnic backgrounds within the same class; teachers’ low expectations of students; teachers not meeting individual students’ needs; teacher absenteeism; school staff resisting change; teachers being too strict with students; teacher being late for classes; and teachers not being well-prepared for classes have the potential to hinder student learning (OECD, 2013, Volume IV, 175).

Table 4. Providers Competencies External Actors (Parents).

Variables	Type	FIN (N = 311)		KOR (N=156)	
		m/f	sd/%	m/f	sd/%
Parents volunteer - extracurricular activities (PARextCV)	cont	6,16	13,64	6,77	14,18
Parents assisted teacher in school (PARassTCH)	cont	0,52	2,32	5,69	12,06
Parent participated in local school government (PARsgb)	cont	5,27	9,65	13,27	21,62
Parent discusses - child behaviour - own initiative (PARbehOWN)	cont	24,54	24,81	25,35	25,34
Parent discusses - child behaviour - Teacher initiative (PARbehTCH)	cont	44,62	33,50	45,95	38,90

Parent discusses - child progress - Teach initiative (PARprogTCH)	cont	55,69	33,81	47,68	38,02

Source: Own elaboration based on PISA2012 DATA. (*) T (type of variable), which in this case are continuous (C).

As for Principals, behaviours variables considered include empowered principals in the domains of human resources (prin3b and prin4b, having the responsibility over teacher's salaries) and resource management (prin5b and prin6b, having responsibility for planning and allocating resources). Regarding principals' interactions, variables considered namely targeted principals' abilities to joint work namely with faculty members and teachers, by empowering teachers-co-decision on decision making (PTdecMak_4) and for improving school culture (PTculture_4). Parents¹⁹¹ (as well as external actors) normally participate in education services (schooling) by supporting teachers (active participating on student activities by providing specialized knowledge, technical support, resources or assist teachers (and students) in their daily work) as well as becoming highly involved in the development of schools (becoming part of school advisory or governing board or Parent-Teacher Associations, or even supporting administrative or school maintenance tasks) in order to improve school services. Variables considered for parents (Table 4), deal with their interactions (with the rest of providers), namely with teachers. The set of variables include, the percentage of parents discussing with the teacher by own (PARbehOWN) or teacher initiative (PARbehTCH) child behaviour and child progress (PARprogOWN and PARprogTCH), the volunteering in extracurricular activities (PARextCV), assisting teachers teaching (PARassTCH) or participating in local government (PARsgb). Variables are depicted in table 4.

¹⁹¹ Given that parents play a relevant role at home and school, and given the empirical strategy we used (HLM), we considered that parents' specific characteristics – e.g. education level, job status (including time availability effect captured by parent working full or partially or not working status) or even parents' origin - must come associated at "student level" as they impact students outcomes by interacting with their children out of school. Further, those characteristics (namely interactions) of parents at school (e.g. parent participating in extracurricular classes or assisting teachers at school or even participating in Governing Boards), should be considered as school resources, as their impact have the potential to benefit the student (and school) bodies. The former individual parent characteristics (affecting student resources) have been included in the student SES indicator (which include as mentioned before, parents education attainment level and job position). The latter are those presented in Table 4, which include (and assumes) parental participation in school, suggesting potential effects over students. In any case, aggregated parental characteristics at school level of those parents actively participating in school activities (been these related to instruction or school development), can also be considered as school resources.

Table 5. Providers Technical Vector Characteristics School Actors (Principals and Teachers).

Source: Own elaboration based on PISA2012 DATA. (*) T (type of variable), which can be continuous (C) or a dummy (D). Regarding the dummy variables, they taking the value 1 if characteristic holds and zero otherwise.

Lastly, we present the technical characteristics of education service (Table 5). We refer to resources implemented at school level which normally allow "providers interact and are considered as interfaces": In this last group of variables we have those related to school content, considering if the school uses a standardize curriculum in math (StdMTHcv_1) and if implements similar content in different levels in some classes (simCNTdifLVL_2). Moreover, variables dealing with methods and organisation, includes no ability grouping and using adaptive pedagogy in some classes (NOabgADTped_2) and the index of ability grouping (ABG_1), this is, "no student grouping" either in class or within school. Two more variables are included in this subgroup, if schools offer extra math lessons (adMATles_1) and the purpose of these lessons, enrichment (PURadMATles_1) or remedial (PURadMATles_2). Regarding school resources we have considered those related to ICTs. For these group of variables we have consider not only the availability of specific devices at school but also their effective use by students, variables considered include a desktop computers (aDKtCOMP_1), laptops (aLapTOP_1), tablets or Ipads (aIPAD_1) and internet access (awwwSCH_1). Other variables considered where the ratio of computers liked to internet per student (compWEB) and as well as the index of quality of buildings and spaces (QUALphysST). This latter variable integrates variables related to school buildings and instructional spaces (Q.11 of the school questionnaire/SC14 of the school PISA2014data). Last, variables considered have been those labelled as traditional (or monetary controlled) by the mainstream literature, this is, class size (Csize), school type or structure (SHtype_3) and student-teacher ratio (STratio).

4 Methodology and Empirical Strategy.

The technique employed where two level hierarchical linear models (HLM¹⁹²). The consideration of this technique is based on the nested nature of the data used (PISA-2012 DB), where students are nested into schools, and schools in regions/countries, which properly accounts for the multilevel structure of the dataset and is useful to analyse the performances at different levels (e.g. student-level, school-level, etc.) while controlling for the variance across levels (Hox, 2002, Chapter 1). Furthermore, this technique has been considered in several studies in education (e.g. Bryk et al.,1993; Bryk and Raudenbush, 1988; Raudenbush, 1988; Calero and Escardíbul, 2007; Mancebón et al.,2010; Calero et al.,2009).

These grouping effects (nested data), suggest that the interaction between students of the same group are more similar than those of students in different groups, thus interaction between students in the same group cannot be considered statistically independent, violating the independent noise hypothesis. Hence, using traditional statistical

¹⁹² For building and running our modeling strategies we have used STATA V.13 software.

methods such as regressions or ANOVA¹⁹³ to analyze this type of data are not entirely applicable (Goldstein, 1995/1999; Raudenbush and Bryk, 2002; Hox, 2002). In fact, failure to recognize the hierarchical nature of data, could lead to unreliable estimates regarding the effectiveness of school characteristics and practices, which could lead to unfounded policies or practices (Raudenbush and Brick, 2002). Therefore, the use of hierarchical linear models appears to be the most appropriate statistical technique for treating nested data.

HLM displays different sub-models for each level of the data structure. These sub-models in turn capture the relationship between the variables at the same level, as well as the influence of higher-level variables on variables at lower levels.

In our case, following our theoretical construct¹⁹⁴, the general hierarchical linear model we implement in matrix notation is as follows:

$$(I) \quad Y = Z\gamma + X\beta + R\mu + \varepsilon$$

Where Y (the dependant variable) is the $n \times 1$ vector representing the education outcomes (student test scores), X is the $n \times p$ covariate matrix representing the learner (student level) characteristics and Z is the $n \times q$ covariate matrix of education providers (at school level) characteristics. Further, R is $n \times p$ covariate matrix for the random effects μ and ε represents the $n \times 1$ vector of individual errors, which we assume to be multivariate normal with mean zero and variance matrix $\sigma_\varepsilon^2 D$. γ , β and μ are the $n \times 1$ vectors of parameters to be estimated in the model.

Twelve models have been build (the null and the complete models for each literacy domain for each country sample) of which, the last six models address our research questions stated in section 1 of this paper. We followed a consolidated tradition in the applied statistics literature about student-level/school-level data, for which predictors have been included cumulatively (by level and set of variables), over the "null model" which has been considered our baseline specification (e.g. Lamb & Fullarton, 2001; Dronkers & Robert, 2008). The estimation approach (suitable for case analysis) has been made separately from a case-to-case approach.

The first six models are the null models for each literacy domain for each case (Finland and Korea), which considers only the dependent variable (math, science and reading student test scores, Y). This type of model is the indicator of the variability associated with the different levels involved in the analysis, and therefore serves as a reference for testing the goodness-of-fit of successive models.

The null model specification in levels (for each of the literacy domains of both countries analyzed) is as follows:

$$\text{Level 1:} \quad Y_{ij} = \beta_{0j} + \varepsilon_{ij} ; \text{ where } \varepsilon_{ij} \sim N(0, \sigma^2)$$

$$\text{Level 2:} \quad \beta_{0j} = \gamma_{00} + \mu_{0j} ; \text{ where } \mu_{0j} \sim N(0, \tau_{00})$$

In level 1, we observe how the test scores of student i in school j¹⁹⁵ is explained by the average achievement of school j (β_{0j}) and the individual error of student i in school j (ε_{ij}). In level 2, we observe how the average achievement of school j is explained by the overall mean of schools means (γ_{00}) and the school error term (μ_{0j}). In addition this first model also provides estimates for the variance of the student error (σ^2) and for the variance or the school level error (τ_{00}), which in turn can be used to determine how much of the total variance is accounted for by students and schools.

Our second group of models (the last six models), take into account learners (student level) and providers (school level) characteristics. The model is specified as a random intercept model considering multiple covariates from level 1 and level 2.

The variable intercept specification in levels is as follows:

$$\text{Level 1:} \quad Y_{ij} = \beta_{0j} + \beta_{1j} X_{ij} + \varepsilon_{ij} ; \text{ where } \varepsilon_{ij} \sim N(0, \sigma^2)$$

$$\text{Level 2:} \quad \beta_{0j} = \gamma_{00} + \gamma_{01} Z_j + \mu_{0j} ; \text{ where } \mu_{0j} \sim N(0, \tau_{00})$$

In Level 1 these group of models shows how the test score of student i in school j is explained by the average achievement of school j, the set of characteristics (competencies and technical characteristics) of student i in school j and the individual error term of student i in school j. Level two, shows how the average achievement of school j (the

¹⁹³ Analysis of Variance.

¹⁹⁴ We must emphasize that we have taken into consideration the production function approach (Hanushek, 1986, Levin, 1971, 1994) as well as its "particular" considerations when specifying this type of functions in education (Boardman and Murnane, 1979; Todd and Wolpin, 2003), when building-up our model (specifying the set of variables used between students/learners and providers at student level and those considered at school level).

¹⁹⁵ Formally, the first level shows that the performance of student i in school j is determined by the average student performance of school j and the individual error ε_{ij} , of student i in school j. We assume this error has mean zero and constant variance σ^2 , which is to be estimated. The second level shows that the average school performance of school j is determined by the overall performance of the schools (mean of school means) and school j random effect (or residual μ_{0j}). This residual μ_{0j} is assumed to be independent of the individual error term ε_{ij} . The subscripts i and j refer to each of the students (where $i = 1 \dots n$) and each of the schools (where $j = 1 \dots k$), respectively.

β_{0j} intercept) is explained by the (overall) mean of schools means, the school j (providers competencies and technical characteristics) general characteristics in school j and school j error term (μ_{0j}).

A more comprehensive reference for the statistical theory behind and a detailed methodological approach to hierarchical linear models (or multilevel models), can be check in Raudenbush and Bryk (2002) and Goldstein (1995 and 1999), including Hox, 2002.

5 Results and Discussion

Results achieved are presented in tables 6 to 9. For each country analysed we present three models, one for each education outcome (literacy domains in math, reading and science). Regarding the null models (Table 6), we observe that the overall average performance (γ_{00}) for each literacy domain in both countries/cases, are statistically different from zero and show positive values. Scores achieved are 507,5; 511,1 and 528,2 points and 551,1, 533,9 and 535,8 points for the math, reading and science domains of each case. Furthermore, for all models, statistically significant differences exist as first-level variance (σ^2) and second level random effect (τ_{0j}) clearly rejects the maximum likelihood contrast ($p < 0.01$) where the null hypothesis¹⁹⁶ assumes that both variations are (the same and equals) zero.

Table 6. NULL MODEL – Random Effects and Model's Fit Statistics.

BIC	103.880,56	105.841,88	105.725,02	58.557,43	57.451,52	56.881,32

P-values: *** $p < 0,01$; ** $p < 0,05$; $p < 0,1$

These facts supports that the intraclass correlation coefficient (ICC) is likewise significant, indicating the pertinence and need of multilevel modelling of our data. In the case-to-case analysis we can see how for each literacy domain, Finnish ICC's reaches the values of 11,7%, 12,2% and 12,4 respectively. Likewise for Korea, ICC's reach the values of 39,2, 36,6% and 36,2% respectively. This means that the 11,7%, 12,2% and 12,4% of Finland's and the 39,2%, 36,6% and 36,2% of Korean's variance of the average math, reading and science literacy domains performance of learners is due to differences between schools. When analyzing more in detail each of the countries ICC's, we observe that on average they vary considerably between countries, being higher in the case of Korea (for each literacy domain). Seen this situation from a different perspective¹⁹⁷, we can say that differences within schools (within any group) are higher in Finland (the highest) than in Korea.

Moreover, the deviances for each case are, 103.853,3 ; 105.814,64 and 105.697,77 for each literacy domain in Finland, and 58.540,76; 57.431,95 and 56.861,75 for Korea. If not needed at this stage of the analysis their value sets each model's baseline, which will help us test the goodness-of-fit of successive models when additional predictors are included which are supposed to reduce significantly this indicator. In summary, regarding the null model for each of the literacy domains in each country (six models), we can see the need for multilevel modelling given the data used.

Regarding the fixed effects, table 7 shows the results for the case of Finland and table 8 presents the results for the case of Korea. This distinction has been made to clearly identify the influence of actors' competencies and technical characteristics over different educational outcomes for each country. To prevent possible misspecification errors we have also included control variables related to student socioeconomic background, gender and geographic origin variables..

Therefore, regarding the Finnish case (Table 7), we observe that in general (except for the learners technical characteristics), learner's and provider's competencies and co-producing abilities and technical characteristics influence all three literacy domains, as some characteristics (for each literacy domain) are statistically different than zero and

¹⁹⁶ Statistically we consider a LR-type contrast, such that $H_0: \sigma^2 = \tau_{00} = 0$

¹⁹⁷ ICC for school level is computed as the ratio between level 2 variance (schools) and the sum of level 1 and level 2 variance (schools and students). This means in our model $ICC_{sch} = V(\tau_{00}) / [V(\sigma^2) + V(\tau_{00})]$

show positive and negative effects. This means that in general there is a set of competencies and technical characteristics that influence a set of education outcomes, measures as student test scores in the domains of math, reading and science.

By characteristics vectors, learner's competencies and co-producing abilities include knowledge and abilities (learnt) as a consequence of attending kinder for more than 1 year (Att_Kinder) and never repeating a grade (ISCED 1), being responsible with their own learning (studying hard for math quiz's - studhq - and paying attention in math class - payatt) and supportive with their peers (helping their peers with a subject - peerhlp). The rest of abilities analysed (highlighting empowered students in problem solving, talking with peer's about a subject, small group working or group working using a computer) influence differently or have not influence at all over each student outcomes (different literacy domains), as some of these variables are statistically different than zero and show positive or even negative effects over different literacy domains. Regarding the technical vector of learners, students having a computer (comphm_1) in their house for school purpose is statistical different than zero and show positive effects for the domains of reading and science but have no effect over the math domain.

Regarding the provider's competencies & coproducing abilities and technical characteristics, we must say that except for those co-producing abilities relating the joint-working of principals and teachers aimed at building a school culture (once a month) and the technical characteristic of specific class size, in general, the pattern observed is that of some variables being statistically different than zero and showing positive or negative effects over specific (but different) outcomes (one or two literacy domains) and other variables show no effects at all. Highlight the relevance of (math) teachers with an ISCED5A degree over reading and science test scores, the role of empowered teachers in budget allocation and principals in establishing teachers starting salaries over math test scores on the one hand, and the impact of the availability (and use) in schools of technology, desktops computers and laptops over math test scores and internet access availability over reading and science test scores on the other.

P-values: *** p<0,01; ** p< 0,05; p< 0,1

We focusing in the common (or core) competencies and technical characteristics influencing all outcomes (literacy domains), we observe that learner's competencies and co-producing abilities play key role in contrast to provider's competencies and technical characteristics. This consideration suggest that students co-producing abilities play a key

role over all set of outcomes (all domains), but individual provider's competencies/co-producing abilities and technical characteristics play specific roles over different (but individual) outcomes (literacy domains).

Shifting our analysis to the Korean case (table 8), general results achieved likewise show that student's and provider's competencies/co-production abilities and technical characteristics influence all set of outcomes (literacy domains). But more interesting and in contrast to the Finnish case, is that all vectors of all actors have common (or core) competencies and technical characteristics influencing all outcomes. These results suggest that Korean education provision is arranged in a way that more competencies and technical characteristics target a wider set of education outcomes.

More in detail analysing each vector, we observe for the learner's competencies and co-producing abilities some specificities. Abilities (and attitudes) include student engagement and responsibility with their own learning (paying attention in math class - *pyatt*) and with their peers (helping their peers with a subject - *peerhlp*) which are statistically different than zero and have positive effects over each literacy domains. Moreover, student's technical vector becomes relevant as having a computer at home (*comphm*), with an education software (*edsfthm*) and a link to the internet (*wwwhm*) for school purpose becomes statistically different of zero and shows positive values over all education outcomes (literacy domains).

Regarding the provider's competence and co-producing abilities mention the relevance of empowered principals when formulating school budget (*PRINq5a*) as well as parent's interest in their child's progress (*PARprogOWN*) becomes relevant over all outcomes. This variable captures parent's discussion with teachers of child progress by own initiative.

Last regarding the technical vector (associated to providers), we observe that not using the same (math) textbooks in every class (*SAMEtxbksM_2*), the non existence of ability grouping within (math) classes (*ABGwthCLASS_3*) and the

existence of extra classes of math for enrichment & remedial purpose (PURadMATles_3) show positive effects over all outcomes (literacy domains).

Table 9. COMPLETE MODEL - Random Effects and Model's Fit Statistics.

Students	31,85%	33,57%	30,40%	12,25%	13,92%	10,99%
Total (R2)	36,80%	36,37%	34,02%	32,01%	31,35%	28,41%

P-values: *** p<0,01; ** p< 0,05; p< 0,1

Finally, highlight that the random effects (see Table 9) in all cases - the Finnish and Korean samples - are statistically significant, as we reject the null hypothesis of the maximum likelihood contrast of variances being zero. Moreover, when analyzing the goodness of fit of each model, it's worth mentioning two issues. First, comparing the deviance in all cases (100.117,50 ; 101.975,16 and 102.237,49 for each domain in Finland, and 57.581,68, 56.383,97 and 56.017,40 for each domain in Korea), we see that all deviances¹⁹⁸ have been reduced in comparison with each case null models, as different predictors/covariates have been included. Second, we observe that the proportion of variance explained at schools level for the Finnish case is able to explain more than a 55% of all literacy domains and for Korea more than the 60% for each literacy domain.

To this end, following our research hypothesis we can conclude that in general all set of technical characteristics and actors competencies not always influence all education outcomes (test scores in the domains of math, reading and science), but there are some core (or common) technical characteristics and competencies that do influence all outcomes. Our results show that for Finland, core characteristics influencing all outcomes (for each domain) have to deal with student competences and co-production abilities. As for Korea, surprisingly, core (or common) characteristics influencing all outcomes belong to the students and provider's competencies/co-production abilities and technical characteristics of both student's and providers. In this context of common characteristics, we can mention a key role of competencies and co-production abilities of student's in the case of Finland. As for Korea, surprisingly, technical characteristics (including ICTs), and competence/co-producing abilities play a key role. In any case, we must emphasise that some specific technical characteristics or actor competences and co-producing abilities play a relevant role (given their effect size), over some specific outcomes. Highlight that in Finland, technical characteristics (including ICTs) play an important role in some education outcomes.

6 Final Remarks and General Conclusions

From an empirical point of view, we have analyse the extent to which the same set of technical characteristics and competences influence several education outcomes (as measured by the PISA2012 math, reading and science test scores) in two top performer countries, Finland and Korea. Further, given the fact that different ways to provide education are equally effective in terms of performance and equity, our research has address the role of technical characteristics and competences in the two cases analysed.

Results suggest that human resources (competencies) and technology (technical characteristics) influence all set of student outcomes in both cases analysed. Nevertheless, when focusing on core (common) actor competences and technical characteristics influencing the overall set of outcomes (math, reading and science test scores) in Finland student competences and technical characteristics (engagement and responsibility in their own and peer learning) play a

¹⁹⁸ It concerns the complete models, which are sensible lower than the null models for each case.

key role. As for Korea, surprisingly, learner's and provider's competences and technical characteristics of both, learner's and provider's become relevant.

More in detail - over these core characteristics – for the Finnish case, trained teachers and empowered principals, student engagement and responsible class attendance and the use of ICTs at school show positive effects over all outcomes. In the case of Korea student engagement with school, the use of ICTs' for school work, empowered principals and parental interest/support show positive effects over all outcomes domains. Hence, human and technology play a key role in education.

Having in mind that educational systems (and countries) are different given their social and cultural characteristics, our research suggest that by better understanding how education is provided, and more important, identifying for each case the core characteristics underpinning education outcomes, field for policy measures (and innovation) aiming to improve education outcomes is placed. In any case, further research must be encourage.

Service Innovation as a research theme: where 30 years of work have brought us?

Marina Moreira, Tomas Guimarães, Cristina Souza, Pedro Albuquerque

University of Brasilia, Brazil

This paper maps the evolution of the service innovation field of study over the last 30 years (1984-2014) by examining the content of 209 selected research papers and by constructing ten thematic categories later tested on a Multiple Correspondence Analysis - MCA. Frequencies for each category in temporal perspective show emerging and declining issues. We highlight top publishing journals and authors as well as top cited papers. Although recent, the service innovation field of study has issues of greatest expression (Performance, Sectorial analyses and Innovation efforts) and of lower expression (R&D, Public sector and Theoretical advances and modelling).

Introduction

This paper aims to map the evolution of the service innovation field of study over the last 30 years (1984-2014). To achieve such goal, this work carries on a large research by accessing open databases and directories in search of published papers related to the major theme of service innovation. The present work seeks to contribute to the understanding of the historical trajectory of the research theme as well as to point out future tendencies for the upcoming researches.

The service innovation theme has been highly described as recent and emerging over the last couple decades. Most of the literature around the theme states the works of Barras (1986; 1990) as the starting point for the study of service innovation. Since this first research effort, taken 28 years ago, many others contributions have been given to the major theme of service innovation. In the present moment, the innovation theory seems to have arrived to a point of no return at which we do recognize two postulates as true: services do constitute a major field of research in present times of “service economy” (Rubalcaba, 2007), from which we even derive service science themes; and service innovation is a consistent research field, having experienced advances in terms of theoretical propositions, modelling and testing. Therefore, after almost three decades of work, one major question emerges: where do we stand in terms of evolution concerning the service innovation research theme? We believe the answer to this particular question may be stated by splitting it into some minor research inquiries. Therefore, we state the two following inquiries: what are the majors research themes explored in service innovation and how do they relate to each other over time? And: which authors and journals have contributed more and which particular works have achieved higher degree of diffusion in the service innovation theme along the last 30 years?

The answer to these two minor questions requires methodological tools fitted well enough to support the mapping of a research theme along three decades. When searching for useful methods for such task, we came across many valuable literature reviews that showed a wide range of bibliometric procedures applied to different fields of research. One work in particular stood out in this search: the methodological work of Furrer, Thomas and Goussevskaia (2008). The authors have conducted a research in order to map the evolution of the strategic management field on 26 years of research by collecting published papers from the mentioned research field. After selecting the appropriate papers, the authors have built a database considering specific bibliometric data. They have performed a content analysis on the papers original keywords to constitute derived research themes therefore treated as variables in a statistical analysis called MCA – Multiple Correspondence Analysis. Such multivariate technique allowed the researchers to identify the correlations established among the constituted variables at a given time and, therefore, to map the evolution of the research themes within a period.

Although there are disparities between the original research field explored by Furrer et al. (2008) and the service innovation field, we assumed that the techniques deployed by late authors could represent a good starting point to map the trajectory of studies on the service innovation theme. Thus, this work traces its methodological lines from the mentioned work and adopts changes whenever necessary given the nature of the present research theme. Having the methods previously stated, the answer to the first minor inquiry - what are the majors research themes explored in service innovation and how do they relate to each other? – is given by examining the content of a large amount of selected research papers published on open source journals and constructing ten macro-themes later tested on an MCA analysis. Frequencies for each macro-theme are presented in temporal perspective, allowing us to identify emerging or declining issues. The second minor inquiry - which authors and journals publish more and which particular works have achieved higher degree of diffusion in the service innovation theme along the last 30 years? – is answered by showing the most popular journals publishing on the theme and the most cited authors and papers along the period. Additionally, this paper also shows the ten most widespread works and how they represent the major research themes.

The analyses presented in this paper are carried on a database constructed by authors by collecting bibliometric data from selected papers published from 1990 to July 2014. As we expected to assemble the largest possible amount of papers, we have mobilized the following multiple research directories: Annual Reviews, Oxford Journals, Science

(AAAS), Scielo, Cambridge Journals Online, SpringerLink, JSTOR Arts & Sciences III Collection (Social Sciences), Academic Search Premier - ASP (EBSCO), Directory of Open Access Journals – DOAJ, SAGE, ScienceDirect (Elsevier), Emerald Fulltext (Emerald) and Proquest – ABI Inform Global. The construction of this particular list of directories took into account some of our search options to be presented: a) rather than individual journals, only search directories were taken into account in order to prevent a journal from being privileged over another in selection procedures, so that all journals gathered in the directories had the same chance of appearance in this research; b) since this research intended to show the level of diffusion of individual papers according to their number of citations, we have chosen not to adopt selection criteria based on journals impact factor; c) only free access directories were considered on this basis.

Having the directories list set up, it was time to define which keywords would be used for research. Initially, two terms were chosen: "Innovation in services" and "service innovation". The first searches, however, showed that those key-words would not answer the inquiries we had previously established. The search for "innovation in services" brings as result a huge amount of papers that perform researches on service activities eventually citing the term innovation - which did not meet our expectations of selecting papers that discuss service innovation instead of casually mentioning an innovation in a service. Since this research aimed at selecting papers that discuss the phenomenon of innovation mobilizing theoretical argument related to the reality of services, the use of keywords combination "Innovation in services" showed itself to be unsuitable. Therefore, the research was carried on using "service innovation" as keyword.

The initial amount of papers on the selected directories consisted of 3045. A subsequent selection has been performed on such amount by adopting new discard criteria: a) every paper duplicity was eliminated; b) whenever possible, the search mechanisms were programmed to result in more specific searches, focusing on social sciences, but that was not always the case, so the use of the word "services" led us to find a multitude of papers from distant areas that had their own meanings for "services" - medicine, history, agronomy - and which subsequently had to be discarded, leaving us only social sciences papers; c) only papers that discuss, test or map service innovation were kept. Many papers that only mentioned the word innovation were discarded. Such procedure allowed the exclusion of papers that casually mentioned the word innovation - often as a synonym for change or novelty - but that did not discuss such phenomenon in the context of service activities. After applying the stated selection criteria's, we were finally able to build a database containing 209 papers published on the theme "service innovation" between 1990 and 2014.

Having such articles selection, we have built a database containing the following information about each article: directory of origin, periodical who published it, year of publication, title, authors, countries of origin for each author, original keywords and number of citations. This last item was added after obtaining each papers number of citations in Google Scholar. There have been some rare cases with no keywords originally assigned. In such circumstances, key words were attributed to those papers considering its title, content and methods.

To perform the proposed analyzes, this paper is structured as follows. First, we present a brief overview of the theoretical development for the service innovation theme. The methods description follows this section. Coding procedures are presented in details, showing our path to constitute ten explicative categories for the most frequent themes researched on service innovation. The paper then presents its analyses showing articles distribution on categories. Years of publication, top publishing journals and thematic proximity between themes are explored throughout several analyses. Top publishing countries, authors and top cited papers are also highlighted. In its very last session, we present a research agenda from thematic combination gaps.

1 Service Innovation: what do we know about the research field so far?

The task of mapping the studies on service innovation may consider this research topic within a broader context that encompasses innovation studies themselves. Since the initial studies of Schumpeter in 1912 (1934; 2013), a wide range of works have been published within a commonly called neo-Schumpeterian theoretical line, which gained notoriety from the 1950s.

This timeframe culminates on a paradigm shift in the economics studies. The industrial sector maintained its majority position in the composition of major world economies GDP during the first five decades of the last century (1900-1950). Therefore, the industrial sector became the focus of analysis for economic performance studies. In a parallel process, the service sector had been gaining notoriety in post-Fordist period (after 1940) which culminated with the decline of industrial activities.

Once industry was losing strength, the service sector drew a growing trend in terms of importance. This trajectory attracted attention of studies on economic performance, including studies on innovation topics, which have begun to recognize the urgency to apply sectorial perspective to their analysis (Pavitt, 1984). Thus arose the first studies on innovation in the service sector.

The works of Barras (1986; 1990) are commonly taken as the first to study innovation in services. In presenting its reverse product cycle, Barras (1986) infers that the innovation in services would not be endogenous, but result from the absorption of innovations originally generated in industry. By that point, the study of service innovation was restricted mainly to the analysis of technological innovations originating from manufacturing activities (Gallouj & Weinstein, 1997). This approach is commonly referred to as the technologist or assimilative one (Gallouj & Djellal, 2010).

In the decades of 1990 and 2000, many studies were published in order to advance this initial perspective. The debate on the services ability to generate genuine innovations became then a settled point and new debates emerged.

How do innovations happen in services and what are its characteristics were some of the notorious questions. A new wave of studies emerged with the purpose of understanding the specificities and peculiarities of innovation in services. Gallouj (2002) points that these studies share a common approach by carrying its analysis on peculiarities of services activities, what the author had previously names as the “service-oriented approach” (Gallouj & Weinstein, 1997) or the differentiation one (Gallouj & Djellal, 2010).

As the distinctions between services and manufacturing sector and activities become blurred (Coombs & Miles, 2000; Miles, 2000), one theoretical gap becomes clear: how could we understand innovation in a cross-sectoral perspective? Many relevant works (Sundbo, 1997; Sundbo & Gallouj, 2000) led to the construction of an approach to integrate services and goods into a single theoretical approach for the study of innovation. It is the integrative approach (Gallouj & Djellal, 2010).

In a recent state of the art traced by Gallouj and Savona (2009; 2010), some characteristics for the production on service innovation became clear. The authors report such production as “more fragmented and less empirically grounded than the literature on innovation in the manufacturing sector” (Gallouj & Savona, 2010, p. 27) and trace four axes along which the literature on the service innovation field could be analysed: assimilation vs demarcation; theoretical vs empirical; typological vs analytical; and demanded vs supply-oriented. The first axis contains works consistent with the technicist approach (assimilation) or the service-oriented (demarcation) one. The second one would split works into conceptual or empirical-based; as the third (typological vs analytical) will differentiate works that adopt a typology to systematize innovation in services of those who “aim to disassemble the evidence into components” (Gallouj & Savona, 2010, p. 29) for analytical purposes. The last axis divides works between those who focus on the role of demand and those who focus on the supply side on the innovation process.

The axes of analysis presented by Gallouj and Savona (2010) represent an effort to highlight - and possibly systematize - theoretical, methodological and approach choices adopted by late works. It is noteworthy, however, that their contribution differs from the purpose adopted in this particular work. The mentioned authors seek transversal axes for the analysis and they admit intersections between the axes themselves. Thus, one particular work could be analysed in the light of the four axes. We could analyse its assimilation or demarcation positioning; its theoretical or empirical options; its theoretical or analytical nature; and its placement by demand or supply oriented. The present paper, however, has its construction aimed at identifying recurring research themes in the 30 last year’s production on service innovation and we have as main goal to ensure that the issues outlined are mutually excluding each other. Thus, one research theme identified on the existing literature as “Performance”, for example, could not overlap other topics. Therefore, this work consists of an attempt to map the themes already mobilized in previous researches instead of constructing an analytic framework for the literature, as done by Gallouj & Savona (2010).

2 Method

Having the main purpose of this article - to map the evolution of the service innovation field of study over the last 30 years - as a target, the first step was to assemble the database formed by 209 articles analysed as early described in this paper's introduction section. The next step consisted on doing a content analysis on all selected articles. This analysis aimed to map the main themes and research options adopted by each of the papers in order to generate descriptive statistics able to show the more or less frequent options in the field of study. The construction of these statistics helped tracing the evolution of the main topics studied over the 30 years comprised in this research. This will elucidate the paths that researchers, editors and journals have chosen.

We extracted the following information from each of the selected articles: journal of origin, year of publication, title, authors, authors origin countries, original keywords and number of received citations. Statistical analyses were carried out on these data in order to achieve the desired outputs for this work. Thus, ten main outputs will be presented in the following sections: keywords after coding, top publishing journals, number of articles published by year from 1986-2014, number of published papers per keyword per year, Multiple Correspondence Analysis considering the whole production, Multiple Correspondence Analysis considering temporal cut-outs for comparison, top publishing countries, top publishing authors, top cited authors and works and the most influential papers positioned on our MCA analyses.

2.1 Coding

The coding performed in this study aimed to construct explanatory categories representing the main themes discussed in the analysed articles. The coding procedures considered the number of original keywords assigned by authors in their papers. This set of keywords was converted into one major list in order to identify the most frequent keywords used on service innovation. The total number of keywords obtained was 866. It is a high number and we believe it reflects the great variety of topics and low unification of keywords. The list made it clear that many keywords had absolute correspondence among themselves – such as “service science” and “service sciences” or “service” and “services” – and although initially different, they were manually merged. We came up with a list of 488 different unique keywords.

Most of the remaining keywords (372 of 488, 42.9%) had only one appearance on the list. These keywords were unhelpful for categorization, so they were discarded. 113 different keywords remained having at least two appearances in the database. These 113 keywords represented the starting point for coding. In the next step we eliminated terms representing pleonasms on the research topic itself, such as “services”, which appeared 28 times, or “innovation”, the

keyword with the highest incidence (77 appearances). Additional terms were also eliminated for the same reason, such as "service innovation" and "service industries".

Two extra discard procedures were carried out on terms representing countries of origin or research methods. Since our purpose was not to identify methodological approaches, but major themes worked in service innovation, we have excluded every keyword referred to as "methods", such as "content analysis" and "survey". After all discharges, the final items on the list dropped to 95, having 283 total appearances.

The 95 unique keywords suffered a content analysis and coding following the procedures presented by Bardin (1977), Bauer & Gaskell (2000) and Flick (2008a; 2008b). They generated nine thematic categories useful to explain the recurring themes in studies on service innovation. Only 20 out of 95 keywords did not match the nine categories. Considering the original amount of 283 appearances for the 95 keywords, 75 unique keywords covered 228 appearances, representing 80.5% of total appearances, a good balance. Such options allowed us to compose nine thematic categories with statistical power and meaningful representation in terms of their content. Table 1 shows every original keyword placed in the nine created categories.

Table 1. Original keywords and its placement into categories.

Categories	Original keywords
Customers	Customer service management; Customer involvement, Customer satisfaction, Co-creation, Consumer behavior, Customer co-creation, Customer orientation, Customer service, Customer interaction, Customer relations, Customers, Lead users, Service-Dominant Logic (SDL), Customization, Market orientation, Service encounters, Servitization.
ICT	ICT-based encounters, Communication Technologies, Information and Communications Technology (ICT), Information networks, Information Technology, Innovation network.
Innovation efforts	Strategy, Innovation orientation, Attitude, Innovativeness.
Knowledge	Knowledge-intensive business services (KIBS), Knowledge Sharing (KS), Knowledge, Knowledge management, Collaboration, Knowledge diffusion, Learning, Partner match.
NSD	New Service Development, Service development, Service design, New products.
Performance	Organizational performance, Service Innovation Performance (SIP), CIS, Critical success factors, Innovation Performance Indicator, New service performance, Organizational innovation, Service delivery, Service quality, Value creation.
Public sector	Innovation policy, Public sector, Public Service Innovation, Public services.
R&D	Open innovation, R&D services.
Sectorial analyses	Financial services, Service sectors, Manufacturing, Small firms, Emerging markets, Industrial services, Professional services, Telecommunications, Automotive industry, Banking services, Business-to-business services, Construction industry, Electronic commerce, Electronics industry, Gas industry, Health care, Health services, Hotel Industry, Oil industry, Small to medium-sized enterprises.

Once the categories were created, each paper was classified in order to fit into one or more categories. No limits were set about the number of categories per article, leading to articles that fit into one unique category, while others fit in two, three or even more. This fact explains why the total percent in Table 2 is not equal to 100%. In average numbers, each article fits into two categories, considering that we made 399 category placements for 209 articles. To set an article for a particular category, we have considered every one of the following: original keywords, title, abstract and performed research. Such procedure showed us the urgency to create an additional category to comprise articles who show theoretical advance for the field such as modelling or typologies propositions for service innovation. Since those articles usually had a broad approach focusing on theoretical contributions to the field itself – such as Gallouj & Weinstein (1997), who present a typology for service innovation –, they did not fit any minor theme in the field. Those papers have been placed in a new category created to encompass such items. The tenth category was named Theoretical advances and modeling. Table 2 shows the number of papers in each of the ten categories.

Table 2. Number of articles by category.

Categories	Number of articles	Valid Percent
Performance	68	32.54
Sectorial analyses	64	30.62
Innovation efforts	62	29.67
Customers	52	24.88
NSD	40	19.14
Knowledge	35	16.75

Categories	Number of articles	Valid Percent
ICT	28	13.40
Theoretical advances and modeling	20	9.57
Public sector	17	8.13
R&D	13	6.22
Total	399	190.91

3 Analysis

The 209 selected articles have been published from 1986 to 2014. Although the search for articles has considered 1984 as initial date, the first article actually selected was published in 1986. Table 3 shows the number of selected articles published per year. An interesting phenomenon may be observed about the year of publication. Although this research has considered 30 years in its pursuits and has obtained, effectively, a publication interval of 28 years (1986-2014 inclusive), the early years of this interval record very low incidence of articles published on the topic of service innovation. Until 2001, only 9.6% of selected articles had been published and only 20.6% until 2006. It means that 25,8% of the articles have been published along the first 21 years. The remaining 74.2% were published in the last seven years. These data underscore how recent the field of study is, achieving its publication peak only on the last decade. Although recent, the field's production has been stable, considering that the average number of publications in the years 2007-2010 remained constant, at around 14 per year. Between 2010 and 2011, there was a leap in annual publication numbers, which have increased from 16 to 28. This new level has showed itself to be stable from 2011 to 2013, with an average of 31 publications per year.

Table 3. Year of publication for selected articles.

	Frequency	Valid Percent	Cumulative Percent
1986	1	.5	.5
1988	1	.5	1.0
1989	3	1.4	2.4
1990	1	.5	2.9
1997	4	1.9	4.8
1998	3	1.4	6.2
1999	4	1.9	8.1
2000	2	1.0	9.1
2001	1	.5	9.6
2002	6	2.9	12.4
2003	5	2.4	14.8
2004	3	1.4	16.3
2005	3	1.4	17.7
2006	6	2.9	20.6
2007	11	5.3	25.8
2008	12	5.7	31.6
2009	16	7.7	39.2
2010	16	7.7	46.9
2011	28	13.4	60.3
2012	33	15.8	76.1
2013	33	15.8	91.9
2014	17	8.1	100.0
Total	209	100.0	

Another interesting analysis arose when considering the top publishing journals on the selected databases. 112 different journals appear in the list and 37.8% of the articles were published in journals who had one unique appearance on our

database. 50.2% of journals appear only once or twice in the database. Only 19 journals have achieved more than three papers published. Table 4 shows the 19 top journals.

Table 4. Top journals publishing selected articles.

Journals	Frequency	Percent	Cumulative Percent
Research Policy	16	7.7	7.7
Journal of Business & Industrial Marketing	11	5.3	12.9
Journal of Service Research	10	4.8	17.7
Journal of Services Marketing	10	4.8	22.5
Journal of Service Management	9	4.3	26.8
European Journal of Innovation Management	4	1.9	28.7
Industrial Management & Data Systems	4	1.9	30.6
International Journal of Operations & Production Management	4	1.9	32.5
Management Decision	4	1.9	34.4
Structural Change and Economic Dynamics	4	1.9	36.4
Innovation: management, policy & practice	3	1.4	37.8
Innovation: Management, policy & practice	3	1.4	39.2
International Business Research	3	1.4	40.7
International Journal of Academic Research in Business and S. Sciences	3	1.4	42.1
International Journal of Business and Social Science	3	1.4	43.5
International Journal of Production Economics	3	1.4	45.0
Journal of Evolutionary Economics	3	1.4	46.4
Managing Service Quality	3	1.4	47.8
The International Journal of Organizational Innovation	3	1.4	49.3

The construction of the ten categories reported in the previous section allowed us to evaluate the incidence of the main discussed themes (represented by our ten categories). Table 5 shows how many times a category has been mobilized considering 5 time cut-outs. We should remind our reader that such table does not express our number of articles, but the amount of existing categories mobilized on articles from our database. Data analysis for Table 5 shows increasing uses of categories over time. It is certainly coincident with the observed increase on the number of published papers along the years. On five temporal cutouts, the incidence of mobilized categories started on 10 and gradually raised to 25, 28, 121 and 215.

Table 5. Papers in categories over time.

Categories	1986-1990		1996-2000		2001-2005		2006-2010		2011-2014	
	Count	% for 1986-1990	Count	% for 1996-2000	Count	% for 2001-2005	Count	% for 2006-2010	Count	% for 2011-2014
Customers	2	20.0%	1	4.0%	4	14.3%	13	10.7%	32	14.9%

* There are no research records for 1991-1995.

We have calculated the proportional increase on the incidence of mobilized categories considering the total amount (399) as well as the individual amounts for each category. We adopted $PI_n = \frac{Count_n - Count_{n-1}}{Count_{n-1}}$, in which PI_n stands for Proportional Increase and $Count_n$ stands for the number of appearances for each category in a specific cut-out. The first column on Table 6 (PI_0) does not have established values, since we assumed the previous incidence was null. That logic also explains why we have set null value to the "Knowledge" category for 1996-2000 and 1986-1990, considering there were no previous non-null incidences. Thus, we calculate each of the proportional increases shown in Table 6 considering the second non-null incidence. Such proportional increase always accounts for the last non-null evidence on its previous time cutout. If a negative sign appears, it means its variation relative to previous time cutouts has actually decreased. In the absence of such signal, it has increased. Column OI on Table 6 stands for "Overall Increase". It summarizes the overall trajectory of increases in PI for each category considering the range between the maximum and minimum values of Counts for each category. At this point, we keep our option to consider only non-null PI and we apply $OI = \frac{Count_{max} - Count_{min}}{Count_{min}}$. This is why we forced our calculus for the minimum score on $Count_n$ instead of using $Count_0$. Therefore, OI shows how many times Counts have increased or decreased considering its maximum and minimum values from 1986-1990 until 2011-2014.

Table 6. Evolution of categories incidence over time.

Categories	1986-1990		1996-2000		2001-2005		2006-2010		2011-2014		OI
	Count ₀	PI ₀	Count ₁	PI ₁	Count ₂	PI ₂	Count ₃	PI ₃	Count ₄	PI ₄	
Customers	2	-	1	-0.5	4	3.00	13	2.25	32	1.46	31
ICT	1	-	2	1.00	3	0.50	11	2.67	11	0.00	10
Innovation Efforts	2	-	3	0.50	2	-0.33	22	10.00	33	0.50	16
Knowledge	0	-	3	-	6	1.00	12	1.00	14	0.17	4
NSD	2	-	0	-1.00	3	0.50	13	3.33	22	0.69	10
Performance	3	-	6	1.00	6	0.00	14	1.33	39	1.79	12
Public Sector	0	-	0	-	0	-	7	-	10	0.43	0.5
R&D	0	-	1	-	0	-1.00	4	-	8	1.00	7
Sectorial Analyses	0	-	7	-	2	-0.71	18	8.00	37	1.06	4
Theoretical Adv.	0	-	2	-	2	0.00	7	2.50	9	0.29	4
Values over 399	10	-	25	1.50	28	0.12	121	3.32	215	0.78	97

The results show us how every category evolved over time. While some subjects had a delayed appearance, such as Public Sector and R&D, other themes have had a more stable growth path from the very beginning, such as Customers, Innovation Efforts and Performance. The most often worked theme over the years is Performance, that scores for 17% of all Counts (considering the number of 399). Performance also reached 12 on its OI, experiencing a significant growth over time. Secondly in terms of appearance are the categories Sectorial Analyses and Innovation Efforts, both with 16% of appearance rate. Although they share the same appearance, their OI value is quite different. Sectorial Analyses OI is only four, showing the progressive growth has not been higher since the category has started later with a large number of works (7 in total) in the period 1996-2000. It happens to be a category that emerged in the second cut-out with plenty of frequency and that has succeeded to keep its force.

The Innovation Efforts category, on the other hand, reaches an elevated OI of 16, having begun with few appearances on the base and so remained for the first three cutouts. However, from fourth cut-out (2006–2010), it has suffered a very quick burst on its number of appearances, going from the previous average of 2 or 3 to 22 and, then, to 33.

By crossing OI, Counts and PI, we have mapped four similar trajectories performed by each of our 10 categories considering their OI and PI. We have therefore established four groups:

- Customers, Innovation Efforts and Performance issues are **Founders with high growth**, having received research attention since the emergence of the service innovation studies. They have grown in significant pace and became the most traditional themes within the studies on service innovation.
- ICT, NSD and Sectorial Analyses are **Non-founders with moderate growth**. Attention has been given to them from the beginning, but they have achieved small initial numbers. They represent an important share of all studies, with 7%, 10% and 16% of total appearances. They have intermediate Counts.
- R&D, Knowledge Modelling and Theoretical Advances are considered **Late appearance with moderate growth**. Those themes have not been explored from the beginning and have low Counts. They account for 3%, 9% and 5% of total appearances.
- Public Sector is considered **Late appearance and poor growth**, being a research theme with late adoption, having no appearance up to the third cut-out. It acquired some expression in the last two cutouts, assuming 4% of total appearances. However, it has the lowest Count of all: 0.5, showing weak growth.

Such groups appear in Figure 1 positioned in a double axis structure showing two dimensions: Adoption (with the initial adoption / Late adoption extremes) and Growth (with the Low growth / High growth extremes). The four groups and their positions are:

Figure 1. Groups position on Adoption X Dimension axis.

Having the thematic structure for the service innovation field in mind, some later questions have emerged. How do the ten categories relate to each other? Could we identify topics commonly seen together on service innovation studies? Could our data reveal gaps for thematic combinations rarely or never worked? The answers to those questions emerge from two Multiple Correspondence Analyses (MCA) we have performed.

MCA is a correspondence analysis that allows graphic display for multiple categorical variables. Therefore, it is a multivariate data analysis. In terms, it is similar to principal correspondence analysis, but it fits categorical data, such as

our 10 variables. Correspondence analyses use binary ratings "yes" and "no" to express the presence or the absence of an attribute. In our study, such ratings are set for each of our 209 papers considering if each one of them fits into a category or not (1 for "yes", 0 for "no"). In such technique, the chi-square value is transformed into an arithmetic measure of distance from a central point that represents the overall mean for the distribution (Hair, Black, Babin, Anderson & Tatham, 2006). An MCA is based on multi-way tables that show relationships between nominal variables (Furrer et al., 2008).

As well as multidimensional scalings, a MCA shows a graphic positioning for each variable based on its multiple correlations. This feature is especially useful for our analysis, which considers 10 categories, now assumed as variables. They all happen to have negatively skewed distribution. It means that they have non-normal distributions highly right concentrated (Field, 2009), since 84% of our fitting into a category frequencies focus on cut-outs posterior to 2006. As a MCA is not particularly affected by non-normality of data, we have chosen it to represent connections among our categories.

Interpreting the results of an MCA is relatively simple. If two variables have similar Count patterns, they will appear next to each other in the MCA. The further away two variables happen to appear in the MCA output, the lower the correlation between them in the data sample (Bendixen, 1995). Figure 2 shows our general MCA for every data on our sample. In such MCA, our categories appear as circles. The size of a circle is proportional to its number of appearances (frequency) on our database.

One prior procedure for the MCA consists on calculating the Eigenvalues curve. The eigenvalues scores show the percentage of explained variance, stating the number of dimensions that would better fit the data. Therefore, eigenvalues are a criterion to define how many explanatory dimensions could be stated prior to a MCA, as is usually done on factorial analyses. The values of the eigenvalues calculated for our distribution are 1.51, 1.39, 1.24, 1.13, 1.05, 0.9 and 0.84. Since there is no evident break on these values, we therefore chose to perform an MCA with two explanatory dimensions for graphical data representation.

One way to interpret the data in a MCA requires us to identify dimensions considering themes distribution. The next step would be to describe such dimensions in theoretical terms. Furrer et al. (2008) present an excellent use of this technique by describing two dimensions. In our case, however, we have 50% less variables than those authors. Therefore, we have based our analysis on two criteria: distance between points and distance from each point to the overall average point (0,0).

In our MCA, we see highly related themes, such as NSD and Customers or Knowledge and R&D. Those connections are expected considering the nature of such themes. The same may be stated for Innovation Efforts and Performance – two themes usually seen together in comparative studies. However, what could we learn from themes that appear far apart on the MCA?

Two issues call for our attention on the MCA. First, such analysis shows isolated themes, i.e., subjects that are not frequently researched together. Public Sector and ICT are the best examples. Secondly, the MCA shows non-isolated but unfrequently combined themes. Such themes show low variability in its combination to different topics. Knowledge, for example, appears far from the themes Customers, NSD, Innovation Efforts and Theoretical Advances and Modelling. From that perspective, we may infer the existence of gaps to be filled by studies that investigate, among others: the role of knowledge in New Service Development; forms of appropriation of knowledge from consumers or for consumers; or even knowledge as input for innovation. It also shows a possible gap for researches accounting for theoretical development involving knowledge.

Although inferences about gaps for future studies are relatively easy to state from a MCA output, caution is highly recommended. Although the MCA outputs allow us to map theme intersections and to see many possible gaps appear, not all gaps have theoretical relevance or even technical feasibility. R&D and ICT, for example, have low correlation. It means they have been poorly combined as themes on previous researches. But does it really point to a research gap? This is an answer to be given by researchers, since statistics only provide circumstantial evidence. As well as R&D and ICT, some extra unusual combinations on low-correlated themes may point technically coherent gaps, but not necessarily theoretical relevant gaps.

Figure 2. Multiple Correspondence Analysis for 209 papers on 28 years.

What if temporal perspective is applied to a MCA? Such technique pointed out positioning changes performed by each category throughout cutouts. Figure 3 shows the precise trajectory carried out by each single category. The small dot at the beginning of each arrow shows each category starting position in its first appearance on previously set cut-outs, since not all categories present themselves in every cut-out. The arrowhead stands for each category's last position. Figure 3 is far from revealing uniform trajectories. While some themes approach to each other or go into the same direction, others strongly repel. The common characteristics for our themes seems to be their positioning impermanence and their lack of trajectory uniformity.

Figure 3. Themes trajectories on MCA over 28 years.

Having the MCA results finally presented, we believe the data may reveal two more aspects concerning the service innovation research field. First, we may consider the number of publications produced by each of the countries appearing in our database. Those countries do not represent our authors' places of birth, but the countries where their research institutions currently operate. For multiple author's papers, research institutions for each author were taken into account. No distinction has been made concerning first, second or last authors. That way, one work is frequently representative of more than one country. From author's countries data, we have built a single list for which we calculated the top publishing countries. Our 209 papers have been assigned to 486 instances of countries. Figure 4 shows papers published by country. USA, UK and Taiwan are the top countries and have published respectively 16%,

14% and 8% of all papers. 38% of total world production on service innovation involves those three countries. 75% of our global production involves at least on of the top 10 countries. In total, 33 countries appear in our database having at least one assigned work.

Figure 4. Top publishing countries.

A little more about the service innovation production becomes evident by mapping top publishing authors in the field. We considered every appearance of an author in our database regardless of authoring position in a particular work. Therefore, the first author on a paper has been given as much value as its last. Therefore we generated a single list with total publications by author. Top publishing authors on service innovation are Alam, I., who has seven published works, Tsou, HT with 6, Chen, JS and Gallouj, F., with 5 each, Gottfridsson, P. and Rubalcaba, L., both with 4 and Hipp, C., Meigounpoory, M. and Scupola, A., with 3. We have also cared to point out the most widespread papers on service innovation. We have considered the number of received citations by each of the 209 papers in our database and formed a ranking. Such procedure showed the ten most cited papers in our field over the 28 years. Top cited works are shown in Figure 5: Gallouj & Weinstein (1997) has 1201 citations, Barras (1986) has 967, Muller & Zenker (2001) have 685, Barras (1990) has 505, Drejer (2004) has 495, Hipp & Grupp (2005) have 483, De Brentani (1989) have 444, Alam & Perry (2002) have 418, Scheuing & Johnson (1989) have 390 and Goes & Park have (1997) 365.

Since we have identified top cited papers on service innovation, as a last effort, we have highlighted them on our MCA analysis. Each paper position considers its assigned categories. Interestingly, the high concentration of papers in the first and second quadrants shows the thematic proximity between them resulting in higher correlation between these works when compared to papers appearing on third or fourth quadrants. The font size of each paper is proportional to its citations number. Colors are a resource for easy viewing and have no statistical meaning.

By investigating the main categories assigned by these 10 papers, we have identified the most frequent themes among them. Customers, ICT, Innovation Efforts and Performance are the most frequent categories. Interestingly, none of these 10 works mobilizes NSD category and only two of them mobilize Theoretical Advances and Modelling. It shows us that top cited papers are not necessarily those with proposals for theoretical development.

Figure 5. Top cited papers in MCA.

4 Conclusions

This work presents the effort to map the evolution of the service innovation theme of study over the last 30 years (1984–2014). A large effort has been conducted to identify, select and analyze papers published in open databases and directories. 209 papers have been selected and their data constitute the whole database used for all analyses described in the present work. Two main inquiries have been stated. First: what are the majors research themes explored in service innovation and how do they relate to each other? Second: which authors and journals publish more and which particular works have achieved higher degree of diffusion in the service innovation theme along the last 30 years?

As we moved forward on the analyses carried out on this paper, we have answered the first inquiry by showing 10 categories that correspond to the main themes explored by published papers on service innovation. Performance, Sectorial analyses and Innovation efforts represent the most popular themes on our field. Those themes appear respectively on 68%, 64% and 62% of all published papers over time (nonexclusive). The least representative themes happen to be R&D (13%), Public Sector (17%) and Theoretical advances and modeling (20%). These categories behaviors and peculiarities have been tested in several analyses.

Although studies in the field have been started in the 1980s, the occurrence of publications is highly concentrated after 2010 (60% of the papers fit here). As increasing in the amount of published papers over the last 30 years was not gradual, two indicators were built to help us understand this trajectory. Proportional Increase (PI) showed the number of appearances for each category in a specific cutout and Increase Overall (OI) summarized the overall trajectory of increases in PI for each category considering the range between its maximum and minimum values of Counts. Results showed us that while some themes began to appear late (such as Public Sector and R&D), other have experienced more stable growth from the beginning (such as Customers, Innovation Efforts and Performance).

By crossing OI, Counts and PI, we have established four groups in which categories were placed: **Founders with high growth, Non-founders with moderate growth, Late appearance with moderate growth and Late appearance and poor growth**. In order to identify how the ten categories relate to each other, we have performed a couple of Multiple Correspondence Analyses that showed interesting peculiarities of our field of study. There are isolated themes, such as Public Sector and ICT, that are rarely researched in addition to other themes. Otherwise, some themes are often combined to the same themes on researches, such as Innovation efforts and Performance. Such analyses allowed us to trace possible gaps to be explored by future studies. Thus, we may present a general research agenda composed by the following theme combinations, corresponding to actual gaps: R&D and NSD; R&D and Customers; Theoretical advances and modelling concerning R&D in services; Knowledge and NSD; Knowledge and Customers; Knowledge and Performance; Knowledge and Innovation efforts, etc. Readers may infer many more combinations by analyzing Figure 2.

The existence of so evident research gaps reinforces our impression of the service innovation study field as having its research lines still emerging or in consolidation phase. The analysis of positioning changes performed by each category throughout cutouts on a MCA (Figure 3) revealed mostly non-uniform trajectories, having themes approaching each other or going into the same direction, while others are strongly repelled from the others. Such fact led us to conclude that the general characteristics for our ten themes seems to be their constant change of combination with each other and their lack of trajectory uniformity. The most visible feature is the apparent consolidation of themes that, little by little, may be recognized as the more traditional on studies of service innovation: Performance, Sectorial analyses, Innovation efforts, Customers, NSD and Knowledge.

The second minor inquiry on this paper has been answered by showing the top publishing journals - Research Policy, Journal of Business & Industrial Marketing, Journal of Service Research, Journal of Services Marketing and Journal of Service Management -, countries - USA, UK and Taiwan -, authors - Alam, I., Tsou, HT., Chen, JS., Gallouj, F., Gottfridsson, P. and Rubalcaba, L. - and cited papers - Gallouj & Weinstein (1997), Barras (1986), Muller & Zenker (2001), Barras (1990) and Drejer (2004).

In summary, what do we see as future challenges after 30 years of research on service innovation? Which research questions emerge from our research? First, one should keep in mind that service innovation is a young field of study, having most of its works published only from 2010 on. The biggest part of the field history is currently being written in the present decade. Service innovation, as a field of study, is so recent that it would be premature to draw absolute explanatory dimensions to represent it. What we can point out, so far, is the existence of issues of greatest expression in the field - Performance, Sectorial analyses and Innovation efforts - and lower expression - R&D, Public sector and Theoretical advances and modeling. Likewise, we may account for some topics that happen to be traditionally studied together in order to present a research agenda based on the combination of themes that appear isolated on our analyses, having experienced few combination with each other. Having that well settled, we would point out the following three aspects as components of a research agenda for the study field:

- Studies concerning Public Sector are the latest trend in the field, having appeared only in the last two cutouts (post 2010). Thus, future research will find on this subject a subfield to be explored along with other themes. A priority question emerges: how does service innovation perform in the public sector?
- R&D is still an emerging theme for service innovation, having low incidence on published papers so far. It has also been poorly combined with other themes. It draws a second research question: how can we interpret, measure and compare R&D role on service innovation?
- Although customer roles on service innovation have received significant attention from previous studies, little or nothing at all has been researched about the role of these actors in generating and disseminating knowledge on service innovation process. In addition, little has been explored about their role in innovations generated in public service. A couple questions emerge: which new roles will customers play in highly knowledge dependent service innovations? And what role will citizens have, as customers, on innovations generated in public services?

Certainly, these three gaps do not address to every research gaps on the service innovation field, but we believe they may be useful for future discussions concerning the research directions for decades to come. For now, we choose to emphasize our main limitation on this study, which refers to the fact that papers published in not open journals could not be included. Such limitation shows us a future challenge: how will we ensure that the service innovation research production may be widely spread in the future? We would like to launch that question for the future discussions to be carried by researchers in our field.

Career Choice Factors and Job Satisfaction for Young Doctors in Romania

Ramona-Mădălina Moroianu, Oana Maria Lungu (Dragomir)

Bucharest University of Economic Studies, Romania

Among the core competencies of the SHRM (Strategic Human Resource Management) we should take into consideration the ones regarding finding, keeping and managing special skills, the impact and necessity of innovation, and also providing outstanding service within the Romanian medical system. Those elements may represent the main characteristics in order to provide and adopt good strategic policies within the healthcare system. Furthermore, given those aspects, young doctors in Romania may find the medical career appealing and developing new competencies and job satisfaction within the public and private hospitals in Romania.

Motivation of the medical staff is a poorly appreciated issue, nationally speaking, although the development of some motivation strategies will potentially lead to an increase in employee retention.

1 Current Human Resources Policy in The Healthcare System in Romania

"According to the Report of the Presidential Commission for review and development of public health policy in Romania (2008, p. 57) the following recommendations about the direction the human resources policy in healthcare should follow were made:

- Developing a coherent training policy,
- Development and allocation of human resources in health,
- Increasing the number of medical staff,
- Career development in the medical field.

Human resource planning should be a priority in terms of health sector policies. The need for human resource planning is vital because a health system which does not provide any analysis on the existing number of doctors, the needed number of physicians and specialist doctors in a particular area based on population health, the orientation of doctors towards specializations to meet the needs of citizens, is a healthcare system with no future" (Pupăză; Amalia, 2009).

As for directing doctors to rural areas, Galan proposed in 2009 (Galan; A. – 2009):

- Designing and implementing a control mechanism of the phenomenon of migration (internal / external)
- Involvement of local communities in attracting and retaining medical staff (especially GPs) in rural areas;
- Design a plan identifying training and career development opportunities in rural areas.

1.1 Medical Human Resources Development

The World Health Organization offers the following suggestions regarding strategic planning, training and medical staff development, both urban but mostly rural and / or in remote areas of Romania:

- Specific programs to support students from rural areas to enrol in school;
- Recruitment of staff from rural area and offering training programs;
- Early exposure to practical training in medical trials (possibly with the possibility of changing rural locations to achieve diversification);
- Introducing information educational programs;
- Involvement of rural communities in the recruitment and selection of students and future graduates;
- Providing mandatory benefits to applicants;
- Conditioning licensing and specializations on practicing medicine in rural areas for foreign doctors;
- Recognition of foreign awarded qualifications
- Supporting the development of initiatives for continuous training and career development;
- Opportunities for a flexible schedule for part-time jobs.

1.2 Remuneration of Doctors in Romania

The Ministry of Health, after talks with union representatives and medical professionals agreed since 2013 to implement a new way to pay staff according to the performances obtained. This decision, which was much needed for a long time, will be beneficial for motivation and will lead, in long-term, to better retention of doctors and other health care professionals working in hospitals in Romania stations: the salary will be computed as a fixed part and a variable part. The fixed part would be represented by the level established at a certain date, while the variable will be determined on the basis of four criteria: a) training; b) quality of work; c) the amount of work; d) retention/fidelization of staff. "

Another proposal made to Ministry of Health refers to the introduction of a private system of payment in public hospitals. This would cater to patients who are willing to pay for medical services to have access to consultations from doctors in the hospital, and those doctors would receive a certain percentage. This system, though successful in other countries, is a way of overcharging in favor of the public budget, according to the percentages shown (Money.ro – 2013).

Although we will not disclose actual figures in terms of remuneration of health professionals in their early career, we will discuss strategies that should be considered in terms of the remuneration of doctors with 3-5 years experience in field:

- Motivating salaries for practitioners in rural areas;
- Providing benefits, including support for relocation;
- Payment of salaries and motivating bonuses depending on performance;
- Diversified remuneration systems (including co-payment);
- Providing loans (for cars, houses);
- Providing scholarships for their family's education;
- Providing non-salary benefits.

2 Performance Management and Correlation of Career Choice Factors, Motivation and Employers Satisfaction

Using the theoretical support, we may illustrate that the young and un-experienced doctors have chosen their career due to their expectations regarding the personal development, access to technology, networking, job satisfaction when helping the sick people. As seen for all the domains of activity, there is always the tendency to make comparisons when referring to other on same professional levels or even on other fields.

The public medical system lacks the management pursuit for intrinsic and extrinsic factors (according to Herzberg theory), meaning developing optimum job relationships, work and efforts recognition, work security. One of the theories that most reflect the situation of the human resources within the medical system is the Equity theory (Adams theory). Having this theory as a major support, we developed the research study in order to show its applicability.

2.1 Methodology and Tools

Regarding the methodology, the research undertaken refers to the core subjects of medical career – the decision, satisfaction and performance. In order to obtain clear information, we divided the research in two different multiple-choice questionnaires, one about the influences of career choices, and the other shocking the link between job satisfaction and performance (Lungu; Oana Maria, 2014).

The results have shown that the choice regarding a medical career is not related to the involvement of family or friends, but more on obtaining a certain reputation and acknowledgement from the peers. Also, the perspective of a well-paid working place is a more important element in medical career choice. The greatest concern for all the people attending the research was the finding of a good working place (hospital) that offers the possibility and the necessary factors to develop a successful career with promotion possibilities and life-long programs.

As for the conclusions reached after evaluating the answers concerning the job satisfaction and performance, we have faced both expected and unexpected results. A large number of respondents agreed that they are please with all their working conditions, with their tasks, having the certainty that their work provides development of their working department. The econometric studies on the interrelation among career choice, job satisfaction and performance have led to many interpretations as the doctors provided a variety of answers and the study sample had a slightly reduced dimension.

The study that we conducted is primarily based on researching and identifying the factors that are most important for developing a career plan for young doctors. Thus, in this quantitative study, satisfaction and career decision are independent variables, while the employee's performance would be the dependent variable.

According to European studies (Eurofound, 2007), it was concluded that the level of satisfaction at work decreases with increasing levels of performance, experience or training. In other words, the more training employees have, the more it is likely to be less satisfied in their chosen jobs. From that to a decrease in motivation there is a very small step.

To find the best coefficients and indicators, we used the research study method. This is used mainly as a research method for social sciences because it has a high credibility and acceptance in academia. The main purpose of research studies is to generalize for a larger population sample based on the research results of a smaller sample of the population - in our case a given number of health professionals.

The independent and dependent variables of this study are:

- independent variables are in addition to the decision regarding the choice of a career in the medical field, remuneration and career satisfaction obtained that influence performance obtained under certain conditions by the medical professional - doctor;
- the dependent variable is the performance at work.

The data and information necessary for the study were obtained from filled-in questionnaires that were distributed to employees of the healthcare system. Among these employees we mention:

- Young residents in their first year of residency in certain specialties;
- Early career specialists who have received a work assignment after their specialty examination;
- Doctors working both in the public system and in the private one.

The research study was conducted on a total of 109 physicians (300 questionnaires were initially distributed) with different medical specialties, both in the public and the private sector (mainly public). In handing the questionnaire, they were assured of the confidentiality of the data and that this information will only be used for this research study.

The information and responses were summarized using Google tools and the verification of statistical connections was done using Eviews software.

To obtain the necessary data, we introduced the following tables with responses from the questionnaire on career satisfaction:

4. I am paid in accordance with the position (function) that I have.

- Yes - 1
- No - 2
- I do not know - 3

5. I am is satisfied with the benefits received.

- Yes - 0
- No - 1

15. On a scale from 1 to 5, 1 being very poor, 5 being very strong, how would you assess your competitiveness on the labor market?

- 1 - very poor
- 5 - very strong.

2.2 Results and Analysis

First, referring to the financial benefits, the respondents answered in equal proportions that they are both satisfied and dissatisfied, dissatisfied of the proportionality of the salary to the position occupied, but also of the other benefits received.

The vast majority of respondents (94%) are aware of their respective job duties and of the expectations others have in respect of the work.

About the conditions in the workplace respondents answered in a high percentage (74%) that they have a reasonable workload and the working conditions offer them a certain degree of comfort. As noted above, one of the motivational factors that lead to increased workplace satisfaction is the confidence that their work will be useful, productive and will lead to the development of their team and their institution. Thus, 81% of respondents answered that their work makes an important contribution of the entire department. Therefore there is no great desire to try other careers (77% gave a negative answer concerning a career change).

However, they do not wish this career for their children or other close ones, perhaps compared to other areas that are currently developing better and are offering more benefits (IT, services, etc.).

As mentioned above, there are areas adjacent to the medical system where doctors working with double majors work, like medical equipment and drugs sales or development of informational systems for hospitals and patients.

At question number 12, referring to the benefits, we received unexpected answers, meaning that the top preferences regarding the desired benefits are mentioned: retirement benefits (51%), annual leave (49%), assistance care (39%) and, of course, a flexible work schedule (50%). A very small number (10%) responded that they do not consider improvements necessary in this regard.

Other surprising answers, knowing the current situation and trend of migration of doctors were the question of looking for a job. 43% replied that they are not seeking other position and 36% said they would only apply if an opportunity arises.

We can conclude, by analyzing the responses received so far, that there is both a state of insecurity and a lack of information regarding the activity of young doctors in Romania. The responses we see, confusing and sometimes contradictory, make us believe that the development and pursuit of a career plan, in short and medium term is almost impossible. Similar results were obtained from other research on salary and job satisfaction (Rotilă; Viorel, 2013).

The responses received lead to the conclusion that the respondents did not choose a physician career under the influence of friends or acquaintances, nor out of a certain "obligation". Their parents career was not a factor of great influence, only 17% of respondents answered that it mattered a lot, and 31% said they were just a little influenced. Also, an encouraging aspect, teachers had a particular importance in choosing their careers, a sign that while controversial in recent years, the role of the educational institutions and of teachers in the development of young people is very high. Therefore, 29% of respondents said they were very much influenced by teachers, and 45% a little influenced by them. If about their medium's influence, within their family or friends, the answers were not positive in a large proportion,

respondents were strongly influenced by their school mediums, teachers, field visits and discussions with people in the field.

In terms of their choice of employment, its location relative to their home, the city center and other locations were not answers to denote significant influence (58% responded that they are not influenced by location).

We conclude that the large concern was thus to choose a job that provides the opportunity and the factors necessary for professional development, personal development, career advancement and deepening of knowledge. As we have seen, the majority of respondents were working in the public health system, meaning that they work in public hospitals in Romania (in the present case, Bucharest). We infer therefore that the choice of a good hospital, renovated, equipped with advanced equipment for diagnostic and treatment, with a productive management is preferred even if they are in remote or difficult to access locations. They preferred jobs and institutions that are offering higher wages. Moreover, nearly 75% of respondents chose this career and to achieve competitiveness thresholds in this field based on the possibility of obtaining a higher salary compared to other fields.

To the questions related to career choice, preferences for the medical field and having the qualities required to practice medicine we received mainly positive responses (86% of respondents said that they wanted this career from the beginning) and also said in large proportion that they consider themselves suitable for this career, being active, responsible people, willing to be challenged.

According to the national distribution of specialties, respondents were from dominant specialties: general medicine and surgery, followed by the rest of the specialties: dermatology, psychiatry, pediatrics.

Question 13, the last question, refers only to the factors that motivated respondents to choose a career in the medical field. As a first and important observation the salary was not a factor in the decision, which shows that in the beginning the choice for a medical career is based primarily on factors such as membership in a growing environment or an environment with challenging situations and tasks, while financial benefits occupy second place.

We can say that, according to observations made over time, the medical career was of interest to those who have many different expectations, but certainly not financial ones. It also notes the importance of working in a prestigious public hospital or a reputable private clinic.

The main choices regarding motivation in making a decision for a medical career, in Romanian institutions, include: providing opportunities for training and career development counseling (72%), reputation of employing company (63%), opportunity to face challenging and meaningful tasks (61%). We can also ascertain the desire and the doctors' tendency to prepare for an international career (55% of respondents chose as motivating element the opportunity to develop a career outside the country). In terms of choosing a proper job, and by that we understand the inclusion of young doctors and residents in well equipped hospitals, with opportunities to practice their craft at high standards, respondents highlighted as important elements like job security, promotion opportunities, with an emphasis on organizational culture and values.

Another topic increasingly discussed lately, covering all fields, refer to balancing professional life and personal life (61% preferred work-life balance, while 51% have focused on the system of rewards offered).

Even if the medical profession requires a certain imbalance between home life and the work program of a hospital, there seems to be a constantly growing interest in reducing this imbalance and promoting the allocation of more time for personal and family life.

3 Conclusions

In terms of performance correlation with satisfaction and compensation, by interpreting the results received we did not find a very close relation, so performance in the medical career in Romania is not directly linked to remuneration and satisfaction in the workplace. Therefore, as we showed before, choosing a career in the medical field depends less on pay and benefits than on providing non-salary benefits like the possibility to provide ongoing personal development programs and environments aligned with international standards.

The results of our research are consistent with what is currently going on in the research field as it tries to find some correlations as appropriate as possible in this respect.

“Research, promising at the start, led to great disappointment, proving that between satisfaction and performance there is not a simple and solid relationship and that job satisfaction is often less important in determining professional behavior than initially thought. Moreover, even where a positive correlation between satisfaction and productivity exists, we concluded that it is not always clear whether satisfaction and positive attitude, built on this basis, determine a rather high productivity or vice versa, high productivity generates high morale (satisfaction). Research in this area are ongoing and experts shall, in this context, develop patterns of correlation between productivity and satisfaction.” (R; Emilian, Tigu; G, 2004)

We conclude saying that according to the statistical tests the performance of physicians depends to a very small extent on how they are paid and on job satisfaction (more precisely, a 1% increase in performance is given a simultaneous increase in the remuneration of 0.45% and in satisfaction of 0.32%).

The role of ICTs in enhancing the service sector productivity in Palestine

Rabeh Morrar¹, Faïz Gallouj², Islam Abdeljawad¹

¹*An-Najah National University, Nablus, Palestine*

²*University of Science and Technology Lille 1, Lille, France*

1 Introduction

Information and communication technology (ICT) is undeniably a vital engine for economic growth in developed economies. It supports economic development through productivity enhancement, innovation and trade development (through new delivery processes). Moreover, ICT is expected to contribute to economic recovery by providing relevant solutions to the current world economic crisis.

In most developing countries, the ICT sector as a stand-alone economic sector is still under-developed compared to the ICT sector of countries which are part of the knowledge economy. Both the public and private sectors in developing economies are still consumers of technologies developed abroad and not ICT producers and innovators. However, over the past 20 years, some developing countries such as India, China, Malaysia and Turkey have improved their capacity to use the ICT sector as an important tool for economic development, in a way that sometimes exceeded the capacity of developed countries. The impact of ICT in developing countries depends on the synergy between ICT investment and long-term economic growth and stability. Moreover, ICT productivity depends also on the human capital development related to ICT usage skills. The adequacy of ICT investment and the efficiency of human capital were behind the significant improvement in the quality of life for large segments of people in countries like Vietnam and India.

Studies at the firm level provide controversial evidence that ICT implementation has positively affected the growth in productivity (Strassmann 1985, 1990; Bender 1986; Franke 1987; Gargallo-Castel and Galve-Gorrioz 2012). Despite the fact that the service sector is more ICT-intensive than the manufacturing sector (OECD, 2003), evidence of the ICT productivity from the service sector of developing countries is rare (UNCTAD, 2008; Meng and Li, 2002). Although increasing over the last few years, the limited number of studies on this issue mainly addresses countries characterized by a rapid ICT growth like China, India, Malaysia and Turkey. Regarding other underdeveloped countries, the relationship between ICT on the one hand, and productivity and economic growth on the other hand need more attention by researchers and policy makers.

This paper addresses this relationship for a special case of under developed economy i.e. Palestine where the economy is largely affected by the colonial measures of a military occupation. Palestine was forced to split into three distinct areas namely West-bank, Gaza, and Al-Quds. Despite the relative autonomy in economic decisions Palestine gained in 1993, this autonomy is very limited when it comes to inter-trade between the three areas. Other restrictive measures apply to foreign trade and to the use of third and fourth generations of mobile services to mention few.

In the course of the past twenty years, Palestine has experienced a high growth in its service sector, in comparison with manufacturing and agriculture sectors. The contribution of the service sector to GDP grew steadily, shifting from 50% in 1995 to 60% in 2009, and it now employs more than 65% of the labor force. However, the Palestinian economy experiences a weak productivity growth in the service sector in comparison with the manufacturing sector, which negatively influences the overall productivity growth of the Palestinian economy (Morrar and Gallouj, 2013).

In the last decade, Palestine has experienced a particular and continued increase in the utilization of ICT at the firm-level, especially in terms of computers, cellular subscriptions, Internet Wi-Fi, and networks. This is mainly due to the fast growth of the ICT sector in Palestine in the last two decades. The productivity of the service sectors which use more ICT is likely to grow higher compared to sectors which are low ICT-intensive (Morrar and Gallouj 2013).

In this work, the straightforward relationship between ICT and productivity growth of service firms is investigated in a very original context. Palestine is a country where data are lacking, The country is divided into 3 areas (Westbank, Gaza, and Jerusalem); each with its own political and economic condition, and has to support colonial and military restrictions. ICT can help to connect the different areas and to bypass many of these restrictions especially for service businesses. The remaining of this paper contains the following sections. Section two reviews the literature devoted to the relationship between ICT and economic performance at different levels of analysis: macroeconomic level, industrial level, and firm level. In section three, we present some statistics about the ICT sector in Palestine and its applications in the service sector. Section four discusses the empirical method (methodology used and data). In section five results are presented and discussed. The last section concludes the study.

2 Literature review

Theoretically, the channel by which ICT affect economic development is through building “knowledge based economy” and “information society”, in which information is an essential input for business processes and economic development. In practical terms, this happens through the employment of ICT tools which includes hardware, software, office automation, internet service, and telecommunication.

The relationship between ICT and economic performance has been extensively analyzed in the literature (Brynjolfsson and Yang, 1996; Motohashi, 1997; Kraemer and Dedrick, 2001; Jalava and Pohjola, 2002 ; Farhadi et al.

2012). While the results are overall mixed, most of the evidence after the mid-1990s confirm a positive impact of ICT on economic performance. Most of the early studies focused on measuring the impact of using computers on labor productivity ignoring the effect of non-computer ICT. One of the limitations to the realization of such studies was the availability of data.

Nevertheless, there is now a growing consensus about the positive relationship between ICT and labor productivity (Koellinger, 2006). This positive impact comes mainly from three sources (Pilat, 2004). First, it is due to the impact of ICT on capital deepening, which enhances labor productivity. Second, more production of ICT products is likely to increase the efficiency of labor and capital, or multifactor productivity in the ICT-producing sector. And third, using more and more ICT helps firms to increase their overall efficiency, for example, through lowering transaction costs, speeding innovation, increasing access to information and knowledge.

Empirical studies about the relationship between economic growth and the using of ICT are classified into three levels of analysis: macro, industrial, and firm level. At the macro level, Aghaei and Nasab (2009), Schreyer, et al. (2003), Van Ark, et al. (2003) and Jorgenson (2003) found that ICT investments increased capital and improved the growth in most OECD countries, taking into account the variation between countries. Oliner and Sichel (2000) using computer hardware, software and telecommunication equipment as indicators for ICT found a high impact of ICT on economic growth starting from mid-1990. In a similar study, Javala and Pohjola (2002) found that ICT was one of the most important factors in the U.S economic growth in the 1990s. There is a gap between developed states themselves. For instance, Daveri (2000) and Schreyer (2000) found that the contribution of ICT to economic growth is higher in USA than in EU.

At the industrial level, several studies showed that the growth in ICT sector significantly contributed to labor productivity and MFP in many developed countries. O'Mahony and Van Ark (2003), Pilat, et al. (2002) and Pilat and Wölfl (2004) found that in the service sector, ICT-based services rapidly grew in some developed countries like USA, France and Australia compared to other developed countries, which substantially enhanced the growth of labour productivity and MFP.

Compared to the two other levels, firm-level analysis is likely to be more rigorous in measuring the relationship between productivity and ICT usage. Firm level data can reveal the factors influencing the effect of ICT that cannot be captured at the macro or aggregate level, e.g. skills, organizational competences, and entrepreneurship. Also, firm level analyses consider the competitive impacts of ICT, e.g. the entry and exist of new firms and market share.

In this view, Atrostic and Nguyen (2002) found that using computers led to a 5% increase in manufacturing firms' labor productivity in USA. Arvanitis (2004) found that there is a high correlation between labor productivity and ICT investment at firm level in Switzerland. Atrostic and Nguyen (2005) used two different computer-related measures: computer capital and computer networks (how computers are used) to measure the relationship between ICT and labor productivity in the U.S manufacturing firms. They also found that computer networks added 5% to labor productivity in comparison with 12% in case of investment in computers (computer capital). Criscuolo and Waldron (2003) using a panel of manufacturing firms in UK, found that using E-commerce enhanced labour productivity between 7 to 9%. Gretton et al. (2004) using a firm-level data from the Australian firm found that ICT raised the annual growth of MFP by nearly two-tenths of a percentage point. Maliranta and Rouvinen (2004) found that the productivity of ICT-equipped labor increased by 8-18% in Finland after controlling specific firm and industry characteristics and also time effect. This effect was clear in ICT-producing services.

The influence of ICT investment on productivity growth varies greatly between sectors (e.g. industrial vs. service sector) and countries (e.g. developing vs. developed countries). Despite the consensus about the positive impact of ICT on productivity in developed countries, there is no consensus on ICT effect in developing countries. Dewan and Kraemer (2000) using panel data for 36 developed and developing countries between 1985-1993, found that the investment in IT capital has positively affected the output growth in developed countries, but this was not the case for developing countries. They attributed this gap to the low rate of IT capital in developing countries as well as to the lack of complementarity assets like human capital, infrastructure, and knowledge based structures. Edquist (2005) attributed this gap to the late introduction of ICT in developing countries. For example, until the late 1990s, Internet service was not found in many developing countries. Some studies revealed a negative impact of ICT on productivity. Lehr and Lichtemberg (1999) explained this negative impact by the limitations of using simple bivariate relationships, while Becchetti et al. (2003) attributed it to the lagged effect of ICT investments and its association with labor network externalities.

Thailand is one of the developing countries where the ICT was put in the core of government policies. It has considered ICT as a vehicle for social and economic development which plays a vital role in improving the competitiveness of domestic businesses (UNCTAD, 2008). Therefore, it has established the National Information Technology Committee in 1992 to promote ICT including members from both public and private sectors (Thuvasethakul and Koanantakool, 2002). Results of productivity analysis for Thai firms show that using computers and Internet as well as web presence are associated with high growth in labor productivity represented by sales per employee (UNCTAD, 2008). They also show that the effect of computers on productivity are higher than that of Internet and web. Computers' influence on productivity comes from their intrinsic characteristics such as storage capacity and processing and from their use as means for acquiring other complex ICT services such as Internet access and web presence.

Many studies confirm the importance of complementarity between ICT investment and other investments. The impact of ICT is apparent when ICT investment is accompanied by other investments and changes, i.e. “ICT primarily affects firms where skills have been improved and organizational changes have been introduced” (OECD, 2003).

In Canada, Baldwin *et al.* (1995) found that employment of advanced technology requires higher level of skills requirement. Gretton *et al.* (2004) also found that human skills, new innovation processes, advanced business practices and the application of new organizational changes are crucial for Australian firms to generate a positive influence of ICT investment on productivity growth. In France, Entorf and Kramarz (1998) explained that higher labor productivity is associated with more experience in using computer-based technologies. Charlo (2011) found that the innovation has no significant impact on productivity growth in manufacturing firms in Uruguay, but this is reverted when innovation interacts with investment in ICT. In a similar study, Koellinger (2006) suggested that innovative firms which invest in ICT are more likely to exhibit an increase in labor productivity, which confirms the importance of complementarity between ICT investment and other investments in innovation and human capital.

ICT is likely to be more employed in the service sector than in manufacturing (OECD, 2003). Moreover, there is a high intra-sectoral heterogeneity in terms of ICT intensity within the service sector. For example, financial services in many countries are among the service sectors that intensively employ ICT (OECD, 2004). Evidence from UK shows that financial intermediation is highly dependent on network technologies, much more than other service sectors (OECD, 2003).

More evidence related to services includes Gretton *et al.* (2004) who found a positive impact for ICT on MFP growth in many of service sectors in Australia and United States. Also, in USA, Doms *et al.* (2002) found that the replacement of traditional retailers by sophisticated services in the US retail sector over the 1990s was contingent with introducing new technologies and processes (and especially ICT). Maliranta and Rouvinen (2004) found that the impact of ICT on labor productivity in Finland was higher in the service sector than in manufacturing. A similar result was found in Switzerland by Arvanitis (2004) who found that the employment of Internet in the service sector was more important for service firms’ performance than for the manufacturing firms. This is explained by the unavailability of a desk job equipped by PC and Internet connection for many of the employees in the manufacturing sector. Farooqui (2005), using a sample of service and manufacturing firms, found that the impact of e-selling on labour productivity reveals positive sign in service firms (it boosts labor productivity by 4%) and negative sign in manufacturing firms. Hempell *et al.* (2004) confirm the importance of complementarity between ICT investment and innovation to obtain a positive impact of ICT on labor productivity in the service sector in both Germany and the Netherlands.

3 The ICT sector in Palestine

The Information and communication technology sector is gaining more and more recognition in Palestine. Economic experts commend ICT sector in Palestine for its viability and ability to prompt economic development and sustainable growth¹⁹⁹. ICT sector in Palestine gains its advantage from the specificities of Palestine economy: small with a young and well-educated population.

In recent years the ICT sector significantly expanded in terms of the number of firms, and foreign investments. The output of the ICT sector was estimated at \$588.9 million in 2010 by the Palestinian Central Bureau of Statistics (PCBS). In 2011 the contribution of ICT sector to Palestinian GDP increased from 0.8% in 2008 to 6.4% in 2011. A recent study by the Palestinian IT Association of Companies (PITA) confirms that international experts attested that outsourcing ICT services from Palestine is evaluated positively in terms of levels of quality, timeline and customer satisfaction.

The growth of the ICT sector is due to the change in the trend of many sectors to the modernization and novelty. Thus, ICT is employed in most of the productive sectors and along the supply chain of most companies. Meanwhile, national agencies such as USAID²⁰⁰ and GIZ²⁰¹ start supporting the ICT sector in Palestine as an official sector which will give new impetus for the growth and development.

3.1 The history of the ICT sector in Palestine

The Palestinian ICT Cluster Assessment (2006)²⁰² provides a brief background description and history about the ICT sector in Palestine. During the 1980s, the ICT sector was represented by a handful of companies which mainly distribute the services provided by Israeli dealers and had a limited experience in ICT services. Some software companies were involved in developing accounting-related packages to replace the Israeli accounting software programs used by local companies and hospitals.

In the 1990s and after the Oslo agreements, the ICT sector started to grow in response to the demand coming from the private sector (financial and insurance sector, telecommunication, etc.), local government, public administrations, universities and NGOs. The launch of the first telecommunication company (PALTEL) in 1997 highly contributed to the development of the ICT sector in Palestine. The Palestinian Internet service provider was also created and Internet

¹⁹⁹The Palestine ICT Cluster Assessment is an industry report published by USAID

²⁰⁰United States Agency for International Development

²⁰¹German Society for International Cooperation

²⁰²The Palestine ICT Cluster Assessment is an industry report published by USAID

became accessible to different stakeholders. By 2012, PALTEL had around 382,700 subscribers to fixed line and 165,000 to ADSL lines.

The ICT activities and the market demand are mainly concentrated in three areas: Ramallah, Gaza and Jerusalem. The main products of ICT firms are hardware products (direct agents or PC assemblers), software development, enterprise consultancy and Internet services and office automation equipment²⁰³.

During the 2000s, there is a sharp decline in ICT companies revenue from US\$ 120 million in 2000 to US\$ 87 million in 2003, because of the political instability of the second Intifida in 2001. Moreover, International companies such as HP, Timex and IDS shut down their sales operations in Palestine.

A report conducted by the Palestinian IT Association (PITA) in 2009 shows that 29% of ICT firms are mainly developing software, 28% are engaged in hardware sales, and 5% in manufacturing ICT products (Wihaidi, 2009). By the end of 2005, there were around 100 ICT companies, 150 Internet cafes and 150 computer stores in the Palestinian areas.

PITA statistics also show that, at the end of 2007, the ICT sector contributed about 10-12% of GDP with \$500 million market size. There were around 250 ICT firms, and over 5300 individuals working in the ICT sector. In 2009, according to World Bank database, ICT services exports increased from 5.4% of total Palestinian service export in 2008 to 6.0% in 2009. In 2010, there was a growth in the software development firms which represented 36% of ICT firms, whereas hardware firms, telecommunication firms and training firms represented 35%, 18% and 11% respectively (PITA, 2010). The number of employees increased to 6,400 in 2011 (PCBS, 2012).

3.2 The structure of the ICT sector in Palestine

Goods and services introduced by ICT companies in Palestine extend from telecommunications (fixed and mobile phone lines, Internet services, etc) through computers developers, equipment manufacturers and resellers, storage, and audio-visual systems, production of software for solutions and packages (projects and sales management, finance and accounting programs, education-related solutions, children education and entertainment, etc) to web products (web development, e-businesses, web portals development, ICT consultancy, etc).

3.3 Local demand for ICT

The demand for ICT goods and services has significantly increased in Palestine over the last few years as illustrated by Table 1.

In 2012, the PCBS developed the ICT Business survey, which mainly aims to provide a comprehensive statistical data about the main features of ICT means, accesses and usages in the Palestinian firms across the different economic activities, It also provides a statistical information for decision makers either in the public or private sector.

Table 1. Percentage of households with IT goods and services.

	2004	2011
Computer	26.4	50.9
Internet connection	9.2	30.4
Fixed phone line	40.8	44
Mobile phone	72.8	95

Source: PCBS (2004, 2011)

3.3.1 Usage of computer

Table 2 shows that 47.0% of the total number of firms in Palestine used computers in 2011. West bank has an advantage in the use of computers compared to the Gaza Strip (49.6% vs. 40.8%). The number of computers per 100 employees in Palestine is 22.3.

Table 2. Percentage of firms with IT goods and services.

Indicator	Region		
	Palestine	West bank	Gaza
Percentage of firms using computers	47	49.6	40.8
Percentage of firms using Internet	39.2	41.3	34
Percentage of firms using electronic transactions	11.2	10.8	12

²⁰³ <http://www.primuspalestine.com/>

Indicator	Region		
	Palestine	West bank	Gaza
Percentage of firms have Website	4.8	5.2	3.7
Percentage of firms engaged in R&D in ICT	2.5	1.5	5
Number of computers per 100 employees	22.3	21.5	25
Number of telephones per 100 employees	25.9	26.4	24.1
Number of mobile phones per 100 employees	40.2	37.3	50.3

Source: PCBS (2011)

There is also a high heterogeneity between economic sectors regarding computer use. Table 3 shows that financial intermediation firms and information and communication sectors are the main users of computer with 97.1% and 92.6% respectively using this tool. These percentages are consistent with the basically informational nature of these sectors.

The percentage of firms that use computer in the overall services is 50%, which is explained by the inclusion of service activities which are less ICT intensive like hotels and restaurants, sales and repair of motor vehicles, wholesale trade and public service. The industrial sector is characterized by the lowest score in terms of Internet use. This is related to the nature of the industrial sector in Palestine which mainly consists of traditional industries that mainly employ non-skilled labor.

Table 3. Percentage of firms that use computers by economic sector (activity) in 2011.

Economic sector	Percentage
Industrial	26.3
Constructions	90.1
Internal trade	49.9
Services	50
Transportation and storage	32.3
Information and communication	92.6
Financial intermediation	97.1

Source: PCBS (2011)

3.3.2 Usage of Internet

Table 2 shows that 39.2% of firms accessed Internet services in 2011, 41.3% in West Bank compared with 34.0% in the Gaza Strip. The lower rate of internet access is explained by the difficult political situation in Gaza which negatively affects most economic sectors and impede the ability of many firms to develop and employ ICT.

Regarding the differences between industrial and service sectors in using Internet, Table 4 shows that the gap between industrial and service sectors is lower in comparison with the gap in the use of computers. Information and communication and financial intermediation sectors are also the highest among other sectors in using internet in 2011 with 99.3% and 97.8% respectively; only 65.3% of industrial firms employ internet in 2011. According to PCBS, in 2011, 86.5% of the firms do not use Internet because it is not employed in their production processes, while 18.4% do not use it because of its cost.

Table 4. Percentage of firms that use computers by economic sector (activity) in 2011.

Economic sector	Percentage
Industrial	65.3
Constructions	92.1
Internal trade	85.8
Services	81.5
Transportation and storage	75.8
Information and communication	99.3
Financial intermediation	97.8

Source: PCBS (2011)

3.3.3 Electronic Commerce

Table 2 shows that 11.2% of firms in 2011 carried e-commerce transactions, with low difference between West Bank and the Gaza Strip (12% in Gaza vs. 10.8% in West Bank). According to PCBS, in 2011, information and communication technologies and financial intermediation were the main user of electronic transactions with 55.9% and 36.7 of the firms respectively. 31% of industrial firms used electronic transactions, which is considered a good ratio regarding the low implementation of E-commerce in Palestine. Only 4.8% of firms had a website (5.2% in the West Bank and 3.7% in the Gaza Strip).

3.3.4 Telecommunications

Table 2 reveals that the number of mobile phones in the firms was 40.2 mobiles per 100 employees in Palestine in 2011 (37.3 in West Bank and 50.3 in the Gaza Strip). The number of fixed telephones per 100 employees was 25.9 in the Palestinian firms at the same period.

The ICT business survey of PCBS shows that in 2011 around 70% of firms in Palestine use mobile phones to get information about goods and services, 46.5% to provide customer services, 31.2% to access banking or other financial services and 23.3% to interact with general government organizations. Only 9.2% of firms use mobile phones to access the Internet and 10.1% to send/receive E-mails.

3.3.5 Research & Development (R&D)

The same data from PCBS show that only 2.5% of firms in Palestine performed R&D activities related to ICT in 2011. This might be explained by the low concern in R&D either from the private or public sector and by the fact that most of R&D related to ICT in the Palestinian firms is developed out of Palestine. The R&D sector is the smallest sector in the Palestinian economy and it mobilizes a too weak amount of financial resources (Morrar and Gallouj, 2013).

Sectoral differences also manifest in R&D activities related to ICT. Around 32% of firms in the information and communication sector implemented R&D related to ICT, 21% in financial intermediation. Only 1.6% of industrial firms engage in R&D related to ICT. This confirms what we already outlined i.e. that the industrial sector in Palestine is a traditional sector with low employment of technology and of skilled labor. Furthermore the Israeli restrictions against the Palestinian economy makes the investment in R&D a non-profitable activity.

4 Methodology and empirical approach

In this section, we develop an econometric approach to analyze the relationship between ICT use and labor productivity in the Palestinian service sector. The model for estimating the complex relationship between ICT and economic performance should take into account that the relationship between ICT and economic development is a multi-dimensional process which must be discussed in several perspectives (e.g. economic, social and human development). Moreover, it must be based on a robust blend of both qualitative and quantitative data.

This paper adopts the productivity approach used in many previous studies (Gurbaxani et al., 1998; Ramirez et al., 2001). A Cobb-Douglas production function is used as the basic analytical framework as it is simple and it has empirical robustness in estimating firm performance. The logarithmic transformation of the Cobb-Douglas function provides a log-linear form of the production model as follows:

$$\ln(Q/L) = B_0 + B_1 \ln(ICT\ labor) + B_2 \ln(Capital\ intensity) + B_3 \ln(Telecom) + B_4 \ln(CompNet) + B_5 \ln(E-commerce) + B_6 \ln(R\&D) + B_7 \ln(ICT\ lab * R\&D) + B_8 \ln(Website) + B_9 \ln(Exports) + B_{10} \ln(Size) + B_{11} \ln(Gaza) + B_{12} \ln(Quds) + U_i$$

The dependent variable is productivity which is proxied by labor productivity. There is no consensus as regards the most relevant index for measuring labor productivity. It has been commonly measured in the literature using value added per employee or sales per employee. Value added is considered a more accurate measure of labor productivity because it subtracts the cost of intermediate consumption from the value of the sales. Therefore, we have used the logarithm of value added per employee to proxy for the labor productivity. *ICT labor* is the logarithm of the ratio of labor using ICT to total number of employees. The labor using ICT is proxied by the number of employees using computers during their work. *Capital intensity* is measured by the logarithm of the ratio of book value of assets to the total number of employees. *Telecom* is a dummy variable which equals 1 if the firm uses smart mobiles for activities other than sending and receiving calls. These activities include Internet access, emails, banking services, governmental services, offering goods and services and other activities that can be performed using smart-phones. *Comput* is the natural logarithm of the number of computers used by the firm. *Network* is a dummy variable that equals 1 if the firm has computer network of any type. *E-commerce* is a dummy variable that equals 1 if the firm uses the Internet to acquire information about goods and services, provides information about goods and services, buys goods or services online, or uses Internet banking services. *R&D* is a dummy variable that equals 1 if the firm implements a research and development project, and 0 otherwise. *ICTlab * R&D* is an interaction variable that measures the complementarity between R&D and the number of employees using ICT. *Website* is a dummy variable which equals 1 if the firm has a website. *Exports* is the natural logarithm of the export sales of the firm. *Size* is the logarithm of the number of

employees; *Gaza* is a dummy variable which equals 1 if the firm works in the Gaza Strip. *Quds* is a dummy variable which equals 1 if the firm works in Jerusalem.

4.1 Data and Sample

We will use firm-level data to investigate the relationship between ICT and labor productivity in the Palestinian service sector. Using firm-level data is advantageous over macroeconomic and industry level data (OECD, 2004) because it helps in understanding why high ICT investment may not lead to high growth in labor productivity (Solow paradox), as it can highlight the factors (skills, organisational factors, etc) which influence the relationship between ICT and productivity and can not be observed at the aggregate level.

Secondary data about both the dependent and independent variables are obtained from the PCBS. In 2012, PCBS implemented the ICT business survey for the first time to provide a statistical information about the use of ICT at both household and business levels in 2011. After data manipulation a total number of 793 service firms will be used to measure the relationship between ICT and labor productivity in the Palestinian service sector.

5 Results and discussion

Table 5 summarizes the results of the regression equation estimation. Four models are estimated using OLS based on the specification presented in the last section. Standard errors for the regression coefficients are robust for heteroscedasticity using White's method. The adjusted R-square for the four models varied between 0.15 and 0.259 which means that they explain around 15% to 26% of the change in the growth of productivity. Model 4 has the highest value of adjusted R² compared to other models. In model 4, most of the ICT indicators have positive impact on labor productivity for the Palestinian service sector. This is consistent with previous findings which outline that in order to increase their contribution to productivity, service sectors should invest far more heavily in new technologies, mainly ICT (Morrar and Gallouj, 2013 for the case of Palestine, see also x and y for the case of other developing countries like Thailand and India).

Table 5 shows that firms which use Internet for selling and purchasing services (*E-commerce*) achieved larger productivity scores than firms which do not use *E-commerce*. Possible explanations for this result may refer to the increase in the use of Internet by financial services and information and communication services. *E-commerce* can influence the business process by enabling the firm to access wider markets and new customers, by increasing the efficiency of business processes, and by allowing a cheaper and more efficient sourcing of materials.

The increase in *ICT labor* variable is found to improve the labor productivity. This is consistent with what Entorf and Kramarz (1998) underlined regarding French workers i.e. that they are more productive when they got more experience in using computer-based technologies.

The use of mobile phones in business activities including internet access, emails, banking services, governmental services, offering goods and services and other activities that can be performed using smart-phones. *Telecom* is found to be of high importance in improving the labor productivity of service firms. This can be understood once related to the high percentage of employees who use mobile phones to get information about goods and services (70%), to provide customer services (46.5%), and to access banking or other financial services (around 32%) (PCBS, 2011).

Despite the fact that 47% of service firms in Palestine use computers (Table 2), this paradoxically doesn't seem to lead to a positive impact on labor productivity. The regression coefficient for *Comput* variable is negative. This expression of the Solow Paradox might be explained by the lack of complementary assets like human capital, and knowledge-based structures. Employees in many service sectors like trade, hotels and restaurants, and personal services are non-skilled labor with very limited knowledge in computers and software.

R&D has a negative influence on labor productivity in the Palestinian service sector. This might be explained by the obstacles that limit the private sector in Palestine from benefiting from the results of R & D (El-Jafari et al. 2008): 1) the outcome of prepared research does not match the needs and requirements of the private sector, 2) the inability of research institutions to publish results of their research and studies, 3) research activity is restricted to universities in purely academic fields, 4) many of R&D activities in universities and research centers are not applicable, 5) lack of data and information. 6) the unappropriability of research methods to provide solutions to the problems faced by the private sector, 7) and the high costs of patents for many research studies.

The impact of ICT labor on labor productivity will improve if it is complemented by investment in R&D, which means that the R&D impact on firm productivity will be positive if it is complemented by labor with high intensity of ICT. This confirms the result underlined by Koellinger (2006) and Hempell et al. (2004) that innovative firms which invest in ICT are more likely to exhibit increasing labor productivity.

Table 5. Regression analysis for the ICT determinants of labor productivity.

All regressions are estimated using OLS regression. The numbers in parenthesis are robust t-statistic calculated based on White standard errors. ***, **, * indicate significance at 1%, 5%, and 10% respectively.

Our analysis shows that the use of websites by the firms do not improve their labor productivity. This might be related to the very low percentage of firms that have a website (only 4.8% in 2011 as appear in Table 2).

We also found that there is no significant relationship between using computer network and labor productivity. This is not consistent with works achieved in many other countries which confirm a positive relationship (Atrostic and Nguyen, 2002, Atrostic et al., 2004). In Palestine, this result might be explained by the fact that most of the service firms are micro firms (from 1 to 4 employees) or medium firms (from 5 to 9 employees) which are not able to employ computer networks or which are not in need for such networks.

For control variables, there is a positive and strong relationship between *Exports* variable and labor productivity which means that service firms which export are more productive than others. This positive impact of exports on productivity is highlighted by most of the literature whether it is concerned by developed or developing countries (Grazzi and Vergara, 2011; Calza and Rovira, 2011). In the last 20 years in Palestine the ratio of services to

industrial exports highly increased. According to PCBS statistics, it increased from 11.5% in 1997 to 46% in 2010 (PCBS, 2011).

As colonial measures divide Palestinian territories into three distinct areas, we investigate whether the geographical region has an effect on labor productivity. The convention of dividing Palestine into three separate areas is adopted by official statistics sources (PCBS 2012). The three areas are West Bank, Gaza and Jerusalem. Results in table 3 show that service firms which are located in Jerusalem are characterized by a higher labor productivity than the firms which are located in the West Bank and Gaza. This is explained by the special political situation of Jerusalem which is considered by the Israeli government as a part of Israel while the international community classifies it as occupied territories. Jerusalem is a tourist area where millions of tourists visit it yearly. Some service sub-sectors like hotels, restaurants, and transportation are more developed in Jerusalem than in the West Bank and Gaza due to the flourishing of tourism and free mobility of people and trade. This creates a high gap in demand between Jerusalem and the West Bank which positively impacts the labor productivity in the service sector of Jerusalem.

The low productivity of the service sector in the Gaza Strip compared with the West Bank is related to the very difficult political situation due to the blockade imposed by Israel and Egypt since 2006 which negatively impact all the economic sectors. Service sectors like financial services, wholesale trade, transportation, tourism and real estate have been hardly harmed by long years of blockade. Also, three Israeli wars against Gaza in 2008, 2012 and 2014 destroyed the infrastructure which is necessary for any economic development.

Finally, our analysis identifies a positive link between the size of the firms and their labor productivity. Large service firms in Palestine are characterized by a higher labor productivity than smaller ones. These large service firms include firms in telecommunication, financial and whole-trade sectors.

6 Conclusion

In this work, we have empirically addressed the question of the relationship between the use of ICT and the labor productivity in the Palestinian service sector. The results show that many of the ICT indicators have a positive impact on labor productivity. Using ICT (mainly Internet) in commerce (E-commerce) is one of the most important lever of labor productivity in service firms. The increase of the volume of ICT labor positively impacts the firm labor productivity. This means that service firms which are less ICT-intensive (for example in retail-trade, hotels and restaurant, sale and repair of motor vehicles) are less productive than more ICT-intensive firms (for example in telecommunication, real-estate, R&D and financial services). The use of mobile phones, for services other than send and receive calls, highly improves the labor productivity of service firms. This is related to the high percentage of employees using mobile phones for various purposes: to get information about goods and services, to provide customer services, or to access banking or other financial services. Conversely, it seems that using the website and computer network doesn't positively affect the labor productivity.

Regarding other control variables, our analysis underlines that large service firms achieve higher productivity levels than small ones, and that exports positively impact the labor productivity of service firms. Finally, regarding geographical differences in labor productivity, the analysis shows that firms in Jerusalem are characterized by a higher productivity scores than firms in the West Bank; firms in Gaza have a lower productivity compared to firms in the West Bank. This result is explained by the higher level of demand in Jerusalem and the hard political situation and blockade in the Gaza Strip.

Some policies need to be designed to enable the ICT sector, as a means of developing the Palestinian services, and applicable recommendations need to be made to policy makers to maintain the relationship between ICT institutions and the bodies of governance in a long-term economic strategy. First, financial and strategic commitments in governing institutions are crucial to support a knowledge-based economy. Second, the government should improve the fiscal and regulatory environment in ICT, through the reformation of ICT legislation (intellectual property rights, patents, etc), increased market competition, and tax breaks and domestic credit for ICT-intensive firms. Third, it should identify specific long-term plans for developing the service sector based on knowledge and ICT employment mainly in traditional services. Fourth, it is important to develop a closer link between public institutions represented by the ministry of Telecommunications and Information Technology and the ICT sector to develop the ICT infrastructure mainly in the Gaza Strip which was destroyed by the Israeli occupation. This requires the help of the international community to push Israel to allow for the Palestinian ICT firms to import the necessary equipment. Until now Israel does not allow Palestinian telecommunication firms to provide G3 Internet service for customers. Fifth, Service firms are necessary to build their future plans to be based on ICT usage, and employment strategy to depend on ICT-based labors. This needs the development of ICT infrastructure, more expenses on R&D activities related with ICT, and the increase in ICT training programs for present and prospected employees to offer more experience in using computer-based technologies. Sixth, it is important to denote the role of academics and research centers in delivering the vital role of ICT development in Palestine to policy-makers, in order to transform ICT strategies into real economic growth.

ANNEX: QUESTIONNAIRE FOR IT SERVICE PRODUCERS IN CHILE

This confidential survey is addressed to Chilean information technology companies. Its purpose is to determine the role of Quality Certifications (*Certificaciones de Calidad*) for exports. The findings will be presented to public entities and associations, along with recommendations. We would like to thank you for your support. As soon as this survey is completed, we will send it to your email address. Your answers to this survey are very valuable to us. Thank you very much.

Mark a X in the box, or write your answers accordingly.

1. Name of the company (optional): _____
2. Number of employees of the company (optional): _____
3. Contact email address (optional): _____

1. In order to identify your company's size, ¿What is your company's total annual turnover? (in UF)

- 2.401 – 10.000
- 10.001 – 25.000
- 25.001 – 50.000
- 50.001 - 75.000
- 75.001 – 100.000

2. ¿Does your company export information technology services? If the answer is NO, would you want to export?

Please comment

- Yes
- No

3. If your company exports, how long has it been exporting IT services?

- 0 - 2 years
- 2 - 4 years
- 4 – More years

If you were out of the export market, at what time and for how long was it: _____

4. From your annual income, what percentage comes from IT services exports?

- 0%-20%
- 21%-40%
- 41%-60%
- 61%-80%
- 81%-100%

5. ¿In the last 2 years, what have been the countries of destination of your exports?

6. ¿In the short and long term, what countries would you like to include in your exports?

7. ¿What sort of technological services are you selling on the domestic and/or foreign market? (and under what platform)

	Platforms								
	Microsoft	Unix	Linux	Oracle	IBM	SAP	Other		
Development and/or implementation of Software									
Customized development of Software									
Sales and Licenses of Software									
Infrastructure:									
• Hosting (shared hosting, cloud hosting, etc)									
• HouYesng									
• Data Center									
• Other									

• Techn. Market assessment									
• Other IT Consulting									
• Methodological assessment and Project management									
• Training									
• BuYesness Inteligencia									
• Other									
Systems Integration									
Support (Desk Services)									
IT Architecture									
Other									

8. What type of quality certificates does your company own and at which level is it? Regardless of whether you own a quality certification, which one would you like to obtain?:

	Obtained		In process	Desired / Future certification plan
	Year	Level of certification		
CMMI				
ITIL				
PMP				
ISO 20000				
ISO 27001				
ISO 22301				
ISO 9001				
Other				

9. What are your company's main incentives when it comes to obtaining a certification?

	YES	NO
Higher local market share		
Higher foreign market share		
Improvement and standardization of your processes		
Other (specify)		

10. For your business, What importance do you give to the following quality certificates? (regardless of whether you own or not a given certification)

	Very Important	Important	Neutral	Of little Importance	Not Importante	No Opinión
CMMI						
ITIL						
PMP						
ISO 20000						
ISO 27001						
ISO 22301						
ISO 9001						
Other						

11. Do you have a clear knowledge of the importance of the quality certifications if the countries to which you export?

- Yes
- No

If the answer is YES, please note:

	Latin America	Canada and the United States	Europe	Asia - Pacific	Other
CMMI					
ITIL					
PMP					
ISO 20000					
ISO 27001					
ISO 22301					
ISO 9001					
OTHER					

12. In case you have obtained a quality certification in your company, what consequences would you say it had:

	YES	NO	NO INFORMATION
Sales increase			
Export increase			
Reduction of project's delivery times			
Cost reduction			
Other (specify):			

13. In case you have never obtained a quality certification in your company; do you perceive it has limited the company's development?

- Yes
- No

If the answer is Yes, explain why:

14. What are the main obstacles that prevent you from entering a quality certification process? Mention a few.

	YES	NO	No information
Financing			
Lack of knowledge of the benefits of certification			
Insufficient Human Resources			
Falta de Equipo Tecnológico			
Not enough time to invest in this process			
Other (specify):			

15. Has the public sector somehow supported you in a certification process?

- Yes
- No

If the answer is Yes, mention the programs or institutions that have supported you:

16. Would you like to add something?

Thank you very much!

Innovation with effectuation: an opportunity for the public sector

Kirsti Mäensivu, Marja Toivonen, Karo Tammela

VTT Technical Research Centre of Finland

This paper focuses on new innovation models in the public sector. It analyses the specificities of the public sector – institutionalism and professionalism – as the context of innovation. On the other hand, it argues that entrepreneurial innovation processes combined with the perspectives of learning and networking are well applicable – not only in the private companies – but in public institutions as well. Based on this view, the effectual approach, closely linked to service-dominant logic (SDL), is examined as a theoretical construct and tested in practice. An ‘effectual-type’ process, in which a city administration collaborates with citizens groups to foster the mutual expansion of resources, is described as a case and the characteristics showing analytical generalizability are identified.

1 Introduction

In recent decades, innovation has been considered crucial for fostering the economic growth and welfare. The background of this emphasis is the rapid rate of change and the significance of knowledge in present societies. In the public sector, a specific need for innovation emerges from the challenge of providing services in times of increasingly wicked problems and scanty financial resources. On the other hand, a strong tradition of innovation is missing the public context: innovations have been mainly incremental and isomorphic, representing continuous improvement (Albury, 2005; Sorensen and Torfing, 2011). Their aim has often been to ensure the stability (DiMaggio and Powell, 1983). Path dependence (Aagaard, 2012) and homogeneity have strengthened the ‘status quo’ in public institutions (DiMaggio and Powell, 1983).

Thus, the concept of innovation is a ‘newcomer’ in discussions of the public sector in spite of the continuous emergence of incremental innovations (Windrum, 2008). In addition to the small changes, systemic changes characterise the public sector. They are usually called with other terms than innovation – for instance, ‘reforms’ or ‘policy changes’ (Christensen, 2012; Hartley, 2005; Hood, 1991; Langergaard, 2011).

The role of innovation has been promoted by the proponents of the New Public Management (NPM), which is the dominant public paradigm in many Western countries. The missions of this paradigm are to improve efficiency by marketization, private-style management, entrepreneurship, performance standards, and output/outcome control (Christensen, 2012; Hood, 1991; Pollitt, 1993; Tummers, 2013). While public services have traditionally been authoritative, rule-based and supply-driven aiming to ensure equity (Torfing and Triantafillou, 2013), NPM highlights deregulated and demand-driven services aiming to ensure efficiency and user satisfaction.

During recent years, a new framework of Network Governance (NPG) has been emerging parallel with NPM. It highlights inter-organisational cooperation (Osborne et al., 2012; Sorensen and Torfing, 2011). NPG assumes that working across organisational, professional and political boundaries will enable more efficient and effective policy implementation and service delivery (Christensen, 2012). In the framework of NPG, innovations refer to both transformational changes and continuous improvement (Hartley, 2005). They may occur at central or local levels in the perpetually changing context. NPG includes new tools to empower and engage stakeholders in the public problem solving and service production (Torfing and Triantafillou, 2013). This ‘Post-NPM’ seems to be more about working together in a pragmatic and intelligent way than about formalised collaboration across organisational, institutional and public-private boundaries (Christensen, 2012; Sorensen and Torfing, 2011, 2012).

This study aims to provide additional insights to the practical ways in which the NPM and NPG approaches can be integrated in the context of public innovation. At a more specific level, we examine a process model that would foster this integration. A long-lasting dispute in innovation literature has been between the STI model (science and technology-based innovation) and DUI model (learning by doing, using and interacting). Our starting point is the latter, as it takes into account important aspects raised by the NPG approach. It highlights competence building in networks, interaction with users, and empowerment of employees (Lundvall, 2007). The DUI model reflects the broadening of the view on the nature of innovation, and it is near to the ideas of open innovation (Chesbrough, 2006) and innovation democracy (von Hippel, 2005). In managerially oriented research, it is near to the studies on user-based and employee-driven innovation (Kesting and Ulhøi, 2010; Sundbo and Toivonen, 2011), which have aimed to concretise the coevolving of innovation with everyday activities.

Demands for an innovative stance create a strong pressure to public institutions to find new entrepreneurially oriented ways of transforming services and service delivery. Here, the public sector will undergo a paradox: entrepreneurship is ‘a science’ of turbulence and change. It does not highlight continuity and does not exist in static conditions (Arend and Chen, 2012; Chiles et al., 2009), typical of the public sector.

We examine the approach of effectuation as an answer to the last mentioned challenge (Sarasvathy, 2008). The effectual approach has close linkages to the basic thoughts of service-dominant logic (SDL) developed by Vargo and Lusch (2004, 2008). It also relates to the public sector applications of SDL by Osborne et al. (2012) and has similarities

with the views on institutional work by Lawrence and Suddaby (2006). These linkages are important for the examination of the public sector as an institutional context for innovations and entrepreneurship. We focus on several characteristics of institutions: the role of the agency, institutional work, and the role of professionals in transforming institutional practices.

From now on the paper has been structured as follows. In the second section after this introduction, we analyse the theoretical literature, focusing on the two topics that are most relevant for our study: the public sector as an innovation context and the approach of effectuation as an innovation model. In the third section we present our empirical research: we first introduce the case and our methodology and thereafter analyse the results. The fourth section includes our concluding discussion.

2 Theoretical background

2.1 Public sector as a context for innovations

This literature-based sub-section examines the public sector as an innovation environment. We start by analysing the central characteristics of institutions and then continue to the characteristics of actors. The latter part of this sub-section focuses on the issues of transformation and practices.

2.1.1 *The characteristics of institutions*

The main characteristics defining innovation in the public sector are its political and institutional contexts (Seo and Greed, 2002; Windrum, 2008). The trend to more entrepreneurial and innovative way to produce services can be seen as a policy change in itself and may as such promote a big challenge to the traditional institutional context of the public sector.

As an institution, the public sector is defined according to rules, norms and beliefs which describe the reality of the institution/organisation (Hoffman, 1999; Garud et al., 2007), reduce uncertainty, and direct the behaviour and beliefs of the actors (DiMaggio and Powell, 1983; Dorado, 2005; Scott, 1995). Institutional elements are regulative, normative and cognitive. Rationality plays an important role in the creation of formal organisations (Meyer and Rowan 1977) and provides, together with cultural-cognitive elements and resources, stability and meaning for the organisation and its social life (Scott 1995).

Friedland and Alford (1991) have adopted the concept 'institutional logics' to describe the various practices and beliefs of institutions. Institutional logics provide 'frames of reference that conditions actors' choices for sense making, the vocabulary they use to motivate action and their sense of self and identity' (Thornton et al., 2012, 132). This definition implies that *the change of the institutional logics* is a core phenomenon when a public organisation becomes more entrepreneurial and innovative.

In addition to rules and logics, the interrelatedness of institutions may have an impact on how various practices can be transformed. Interrelatedness refers to the relationships between different inter-institutional orders: family, community, religion, state, market, profession and corporation (Thornton et al., 2012). It demonstrates the partial autonomy of actors and organisations from other actors and organisations. The local community has a remarkable influence on how local institutions are enabled to change and transform their practices. The community embodies local understandings, norms and rules that become mental models upon which individuals and organisations define problems and situations (Marquis et al. 2007; Thornton et al., 2012).

Together with the interrelatedness, the complexity and multiplicity of institutional logics determine the possibilities to transform institutional practices. Institutional complexity describes situations in which divergent prescriptions from multiple institutional logics collide (Greenwood et al., 1996, 2011; Thornton et al., 2012). A multiplicity of logics is in play in any particular context (Greenwood et al., 2011), and its composition is constructed, not given (Thornton et al., 2012). This composition refines the agency as multiple and dynamic, and it looks at institutional work in the everyday practice of individuals coping with the institutional complexities of their work.

2.1.2 *Who is enabled to transform institutional practices*

Defining factors to transform institutions are 1) agency, 2) resources and resource mobilisation, 3) individual and institutional opportunities and 4) multiplicity, heterogeneity and the level of institutionalisation of the organisation (DiMaggio, 1988; Dorado, 2005; Seo and Creed, 2002).

Actors are only partially autonomous from the institutional structure (Seo and Creed, 2002). One crucial question is whether the institutional scripts and rules have been taken for granted (DiMaggio and Powell, 1983). Another issue is how the actors are able to change the institution (Lounsbury and Crumley, 2007). This is called 'the paradox of embedded agency' and it is closely connected to the concept of institutional entrepreneurship (Garud et.al, 2007). DiMaggio (1988) argues that 'new institutions arise when organised actors with sufficient resources see an opportunity to realise the interests they value highly'. Actors reproduce and maintain practices within the existing institutional logic, but they also have capacity to innovate and to mobilise resources to transform institutions (Dorado, 2005; Thornton et.al, 2012; Scott, 2008).

The nature of agency has been theorised from various standpoints. Agency can be habitual (Giddens, 1984), strategic (DiMaggio, 1988), and sense making (Weick, 1995). All three forms are simultaneously involved in agency, but one dominates. According to Emirbayer and Mische (1998), social actions (including innovation) are influenced by the combination of temporally rooted orientations. These orientations may inform actors from the past (habitual orientation), the future (capacity to imagine alternative possibilities) and the present (capacity to conceptualise past habits and future projects within the contingencies of the moment (ibid.).

Referring to Emirbayer and Mische (1998), Dorado (2005) suggests that institutional actors can adopt three different kinds of profiles in changing an institution: entrepreneurship, convening, and partaking. Smets and Jarzabkowski (2013) apply the categorisation into iterative, projective and practical - evaluative dimensions. The projective dimension supports future change and entrepreneurial and creative behaviour (Battilana et al., 2009; Lawrence et al., 2009). In the dialectical framework, the human agency is conceptualised as praxis and positioned as the essential mediating mechanism that links institutional embedded actor, contradictions and change. According to Seo and Creek (2012, 240): 'The possibility of institutional change is rooted in the aptitude and opportunity for praxis.'

Individual actors have a remarkable role in changing and creating institutional practices. In spite of that, the nature of institutional entrepreneurship is not individual, but collective. For instance, Dorado (2013) highlights that institutional entrepreneurship is a group-bounded activity: groups motivate, inspire, and enable the engagement. Seo and Creed (2002) pose the question about the conditions in which socially embedded unreflective actors become conscious of the social arrangements in which their interests are unmet, mobilise other similarly situated actors, and take collective action for change. The starting point for change is the extent to which groups are dissatisfied with how their interests are accommodated (Greenwood and Hinings, 1996).

2.1.3 *How institutions will be transformed*

Lawrence and Suddaby (2006) have introduced the term 'institutional work' to describe how actors build, sustain and change institutions (cf. also Lawrence et al., 2009). The concept aims to focus attention, not on the social structures, but on the processes, i.e. move from the institution in itself to the purposive action. Institutional work can be described with three characteristics 1) institutional actors are reflexive, goal-oriented and capable, 2) actors' actions are the centre of institutional dynamics and 3) structure, agency and their interrelations are captured (Battilana et al., 2009).

Institutional work has been an umbrella concept (Hwang and Colyvas, 2011). It highlights the question of how actors become motivated and enabled to change the taken-for-granted practices and norms of the institution they are involved in (Smets and Jarzabkowski, 2013; Seo and Creed, 2002). According to Thornton et al. (2012), decision making, sense making and collective mobilisation are the key elements of institutional work. They link together the dynamics of practices and identities.

The concept of institutional work has pushed the institutional theory towards practice-based views. According to Lounsbury and Crumley (2007), practice should be understood as a kind of institution in itself, including material and cognitive activities that are evolved and shaped by the broader cultural framework. Here, activities are interpreted in the same vein with Jarzabkowski (2005) and Engeström, (1987): they are actions and interaction between actors as they perform their daily duties and roles. Practice refers to activity patterns that are infused with broader meaning and provide tools for ordering social life and activity (Lounsbury and Crumley, 2007). Practice is a members' phenomenon – something that actors draw upon, monitor and orient to in real time interaction (Llwelllyn and Spence, 2009).

Based on these views, it seems natural to conclude that *the concept of practice integrates innovation theories and institutional theories*. It also provides conceptual tools to understand innovation processes in the real life context of the public sector. The recent discussion about the 'practice-turn' aims to connect the micro-level of individual activities with the meso-level of organisations and with the macro-level of the broader organisational (and institutional) field (Suddaby et al., 2013).

Currie et al. (2012) link the concept of institutional work with the sociology of professions (e.g. Abbott, 1988) to highlight the role professions as institutional change agents. They link institutional work to the situation where the professional dominance is threatened. They focus on three issues. Firstly, how different types of institutional work interact and cross categories of creating or maintaining institutions. Secondly, how the social position or status of actors frames the institutional work they engage in (intra-professionally and inter-professionally). Thirdly, how the institutional work of 'theorising' by professional elites appears particularly significant.

2.1.4 *Professionals as carriers of practices*

In the neo-institutional theory, professionals are seen as key agents of the social change (DiMaggio and Powell, 1983, 1991). Lawrence et al. (2013) specify subjects to be professionals and other actors associated with the professions, actors from the top of organisations and the interaction of individuals. Professionals consist of several groups: 1) service professionals, including old and traditional professions and new 'weaker professions' (Ezioni, 1969), 2) professions seeking the professional status (Llwelllyn, 2001), and 3) professions managing services (Noordegraaf, 2011).

Professionalism has used to be one of the most trust-producing, formal public structures (Misztal, 2002). Correspondingly, professionals have been considered to be 'the anchors of the order, someone trusted and respected, individuals given a status, autonomy and social elevation' (Dent and Whitehead, 2002, 8). Public services have been

developed by the strong input of professionals whose status has been legitimised by the scientific knowledge. Professionals have had the monopoly to the knowledge, social status and autonomy to make decisions and to choose the right way to act according to the profession's moral and cultural code (ibid.). Professionals are also seen as bearers of important social values (Tummers, 2013).

Suddaby and Viale (2011) identify four essential dynamics through which professionals reconfigure institutions and organisational fields. Firstly, professionals use their expertise and legitimacy to challenge the incumbent order and to define a new, open and uncontested space. Secondly, they use their social capital and skills to populate the field with new actors and new identities. Thirdly, professionals introduce new rules and standards that recreate the boundaries of the field. Fourthly, they manage the use and reproduction of social capital within a field. Professionals aim to establish professional control (Freidson, 2001) and occupational closure (Abbott, 1988) to govern themselves and to block the outside interventions.

Within the new governmental context (NPM and NPG), professionals are expected to be entrepreneurial, creative, and efficient lifelong learners and team workers (Dent and Whitehead, 2002; Tummers, 2013). According to Du Gay (1996), the principle of the new governmental logic is to create a new professional and managerial subjectivity (cf. also Pollitt, 1993; Du Gay, 1996, 2007; Halford and Leonard, 2002). These requirements may be in contradiction with the traditional values and rules of professionals and force them to make sense of the change in relation to their practices and to the individual and professional identity (Emison, 2010). From the viewpoint of the employees, new entrepreneurial expectations connected with the new managerial work appear as an identity regulation.

The contradiction realises when knowledge, being the main property on which the professionals base their decisions and choose the means to act, becomes challenged by the demand to cooperate with other professions and citizens. From the service point of view, the question is of the ability of professionals to share and transform their knowledge (cf. Vargo and Lusch, 2008).

New practices may threaten the power and status of elite professionals in particular (Currie et al.; 2012). The profession as an institution in itself demands stability, but innovation yields change (Emison, 2010). The expected changes do not take place without resistance (Wasserman et al., 2011). An additional challenge is that professionals have often difficulties to identify the policy programmes they are expected to implement (Tummers et al., 2009). It has even been argued that as a consequence of NPM, the relationships between politicians and professionals have moved from trust-based to a low-trust relationship (Windrum, 2008). The reactions of professionals to new demands are discussed from many perspectives in literature: NPM and resistance, managerial governance, the non-spread of innovations, and the professional self-regulation in a changing architecture of governance (Dent and Whitehead, 2002; Ferlie et al., 2005; Tummers, 2009).

Professionalization is a continuing process. DiMaggio and Powell (1983) regard this phenomenon as one important base that determines the isomorphic organisational change. Professionals transform services, but at the same time they transform themselves and their jurisdiction (Suddaby and Greenwood, 2005; Suddaby and Viale, 2011). Professionals are inhabitants of both the institution in question and the institution of their profession. In addition, they are citizens and inhabitants of their community. Professionals create and maintain these three environments/institutions but also disrupt them; simultaneously, they maintain and negotiate their roles and identities (Noordegraaf, 2011). They have to solve their relationships with the institution they work for, with their own and other professional groups, and with citizens and the community (Evetts, 2012; Noordegraaf, 2007).

2.2 Effectuation: a process with expanding cycles of resources

The approach of effectuation has its background in theories of decision making in situations of uncertainty, where decision makers are unsure about the consequences and preferences (Saraswathy, 2008; Saraswathy and Dew, 2005). These theories have also been important for the approach of service-dominant logic (SDL) in its foundational conceptualisation. For the specification of arguments of effectuation, an important source has been the empirical knowledge acquired from the behaviour of successful entrepreneurs. According to the developers of the effectual view, entrepreneurship is inextricably intertwined with uncertainty, i.e. entrepreneurial expertise means expertise in uncertainty (Read et al., 2009).

Effectuation operates through three logics when entrepreneurs produce new value (Saraswathy and Dew, 2005). These logics are 1) the logic of identity, 2) the logic of action and 3) the logic of commitment on stakeholders and value-creation. Each logic has complementary decision criteria: identity (who you are), action/knowledge (what you know) and commitment/network (whom you know).

Effectuation suggests the replacement of predictive logic with a means oriented approach to tackle uncertain market elements and to co-construct novel markets with committed stakeholders. It highlights that the cooperative shaping of the market, rather than a competitive scramble for (predicted to be) valuable resources, drives industry dynamics. The means oriented approach begins from available resources; goals emerge in the courses of action. An important point that the proponents of effectuation highlight is that any given resource can be made more or less valuable and more or less capable of producing long-term advantages: thus, *what people do with resources matters*. This approach clearly differs from the views that rely on linear processes, which start from the identification of an initial opportunity, set a goal, and aim to achieve it in a preselected market. (ibid)

Expanding cycles of resources characterise the activities in effectuation. There are three types of intangible resources with which the ‘effectuator’ co-creates new ends: new firms, new markets, and new products and services. These are co-created through commitments with a network of partners, investors, and customer stakeholders. Also the process of stakeholder acquisition is iterative and reflects the basic idea of expanding resources. Successful entrepreneurs usually build stakeholder relationships directly, one step at a time, as part of the process of creating a market, firm, or product. A result is that they are able to generate rich, first-hand knowledge related to the effort and will quickly have a sense of whether the business has real promise – relationships will create the market (Sarasvathy, 2008). Figure 1 presents the basic ideas of the effectual process (a simplified version from Read et al., 2009).

Figure 1. The main idea of the effectual process (Read et al., 2009; simplified),

An essential part of iterative processes is adaptive trial and error. It is necessitated by the uncertain, systemic nature of market creation. In this kind of a situation, predictive information does not support decision making in the best possible way; more reasonable is relying on strategies that enable direct control, co-creation, and transformation of situations towards positive outcomes. Quickly realised small successes and small failures help avoid the risk that some action would put the entire effort in jeopardy. Preparedness to considering alternative markets and changes in value propositions is a pattern that should be actively embraced, even if it necessitates product or strategy change. (Sarasvathy and Kotha, 2001)

Even though setting the goal and proceeding towards it in systematic steps is not an efficient way to tackle the unknown, an alternative approach must include enough structure to support the utilisation of resources and to foster collaborative creativity. This can be achieved via framing the problem in hand comprehensively: using a framework or schema within which specific decisions and their linkages to other decisions can be contextualised. The ability to group problems into fundamental categories and relate them to other problems results in knowledge architectures that link multiple decisions in the task domain over time, with feedback and interpretation – not isolated decisions. (Read et al., 2009)

The approach of effectuation has not been explicitly linked to the theories of innovation. However, this kind of linkage would be highly beneficial. We see connections between the effectuation model and the process model of practice creation by Lounsbury and Crumley (2007), the change model by Dorado (2005), the dialectical perspective to institutional change by Seo and Creed (2002), and the process model of legitimacy by Drori and Honig (2013).

We argue that the main principles of effectuation are applicable, not only in the market context, but also in the public sector where the need for innovation is as urgent as it is in private companies. Thus, we illustrate with our case study, how a public innovation process could be understood as an effectual process.

3 Empirical research

3.1 The case and the methods

Our paper includes a case study, with two phases, on the development of municipal services for children and young people in a middle-sized Finnish city where instead of the earlier, administrative division of these services into day care, schools, club activities etc., these services nowadays share an integrated framework for holistic wellbeing and form an integrated whole in suburbs. In addition to this renewal, the city has encouraged citizens’ initiatives regarding the development of services, and empowered employees to engage in experimental development.

The first phase of our study dealt with the so-called ‘mini-pilots’ -project that the city (the department responsible for purchasing services for children and young people) launched to foster small innovative experiments among citizens, companies, third sector organisations and city employees. The goal was to increase the knowledge concerning 1) the service needs of citizens and 2) the willingness of various actors to participate in the cooperative development of services. The mini-pilots experiments were carried out as by the initiators themselves in collaboration; the city provided seed money. The project produced 120 ‘mini-pilots’.

The need for the project emerged after the purchaser of the services for children and young people had launched a new service strategy. This strategy focused on service provision that could 1) promote the holistic wellbeing of children, young people and the family, and 2) be produced in cooperation with citizens and different service providers instead of the sector-based allocation of responsibilities. In this situation, the traditional way to forecast service needs and to produce or procure services on that basis was insufficient and inadequate. The city organisation needed new insights and deeper understanding to build an integrated service system rather than separate services (Osborne et al., 2012), and to base this system on the user and stakeholder value. The situation showed typical features of uncertainty (Read et al., 2009): the decision makers were ambiguous regarding the preferences and consequences. Thus, the mini-pilots reflected the organisation’s wider aim to transform services.

The second phase started when the provider organisation wanted to take a further step based on the results of the mini-pilots. At this stage, a more systematic mechanism was searched for: the aim was to provide – not only ‘nice additions’ to the service repertoire of the city – but to foster a more regular bottom-up input that could influence the ‘official service system’. The service provider had just launched an organisational transformation in order to promote holistic and cooperative services. This transformation included new wider collaboration at the suburbs level and a new management/leadership model. For this purpose, another more specifically defined pilot was planned together with researchers (the authors of this paper).

Here, the idea was to collect service initiatives from grassroots level and to combine them with strategic administrative aims in a multidirectional dialog. The focus was on school and day care services in two suburbs. *The effectual approach shown in Figure 1 was the explicit starting point.* The approach was tested in four workshops: the first one consisted of citizens and grassroots employees, the second one of school and day care managers, the third one of the administrative managers for children and youth services, and the fourth one of all these stakeholder groups. Due to the experiential nature of the pilot, the participants were invited – there was not an open call.

3.2 Results

3.2.1 Phase I: the mini-pilots

In order to be accepted as a mini-pilot, the applicants had to fulfil two requirements. First, there had to be at least two actors representing different actor groups. Second, the idea included had to be new, beneficial and replicable for children and young people. Regarding the contents, there were not specific restrictions because the aim was to encourage the emergence of a variety of mini-pilots. The actors were allowed to define the problem themselves and then implement the solution in the way they found most suitable. A project manager (agent) was hired to coordinate the project and a steering group was established to ensure its realization. The financial support for each mini-pilot was 500 euro.

The city compiled versatile documentary data about the mini-pilots. This data was in the form of case reports that covered 103 mini-pilots and included basic facts of them. We used this data as the starting point in our study. In addition, we observed some workshops held to support mini-pilots actors. In order to get deeper knowledge, we carried out 17 interviews between January and May 2012. Mini-pilots have been analysed applying the effectuation model and institutional theory.

Via the mini-pilots project, the city authority aimed to find new knowledge and other resources for solving the existing problems, and also succeeded in this aim. The results reveal that the composition of actors was very versatile: it included companies, public organizations (e.g. schools, libraries, retirement homes), non-profit organisations (e.g. child and youth organizations, sports clubs, pensioners’ associations), and individual citizens. *Mini-pilot actors can be described as ‘authorised with the given resources’.* This role is stronger than to the role of a consumer, user or a citizen as such. Professionals took part in the mini-pilots as facilitators, but they were seldom in an active role. Managers adopted more often the entrepreneurial way to act, and as they also possessed resources, they had a role of a gatekeeper.

Concerning the focus of the mini-pilots, the main finding was that the core service processes like curriculum/teaching in the classroom or actual care in the kindergarten remained untouched and outside of the mini-pilots. All in all, resources were mobilised and integrated to the core of services in four different ways: 1) to enrich the core activity of the service, 2) to support or supplement the core activity of the institutions, 3) to develop more radical boundary breaking activities, and 4) to strengthen the viability and cooperation within the broader community. Most mini-pilots were aimed to enrich and support or supplement the core of the services and communal resources. Two-three mini-pilots could be defined as radical boundary breaking activities, in which the actors were able to transform the core of service processes.

An illustrative, and also quite innovative, example of the mini-pilots was various activities aiming to increase dialog between the generations: make the seniors to interact with children and youth. Both generations benefited each other

with their own competences, and the younger generation became in a natural way familiar with the living in former times. Another innovative example deals with the activities carried out by an individual: a young unemployed man. He organised activities for his friends whom the employment officials had been unable to reach and engage. In this example, the roles of professionals and a lay person were exchanged, the professionals staying in the ‘back office’ and supporting the lay person.

Altogether the mini-pilots indicated more the need for different kind of activities to engage in than the service needs. The contents of the mini-pilots were more social and communal than professional. We were able to verify a finding by Battilana (2006): the lower position in organisation and community enabled to engage into experimental development like mini-pilots and to initiate radical changes into existent practices and to create new ones.

In Figure 2, we present the identified ways to integrate resources from the viewpoint of one actor (school). In the picture we have also illustrated what kind of institutional work – decision making, sense making, or collective mobilisation (cf. Thornton et al., 2012) is needed in order to enable activities like the mini-pilots.

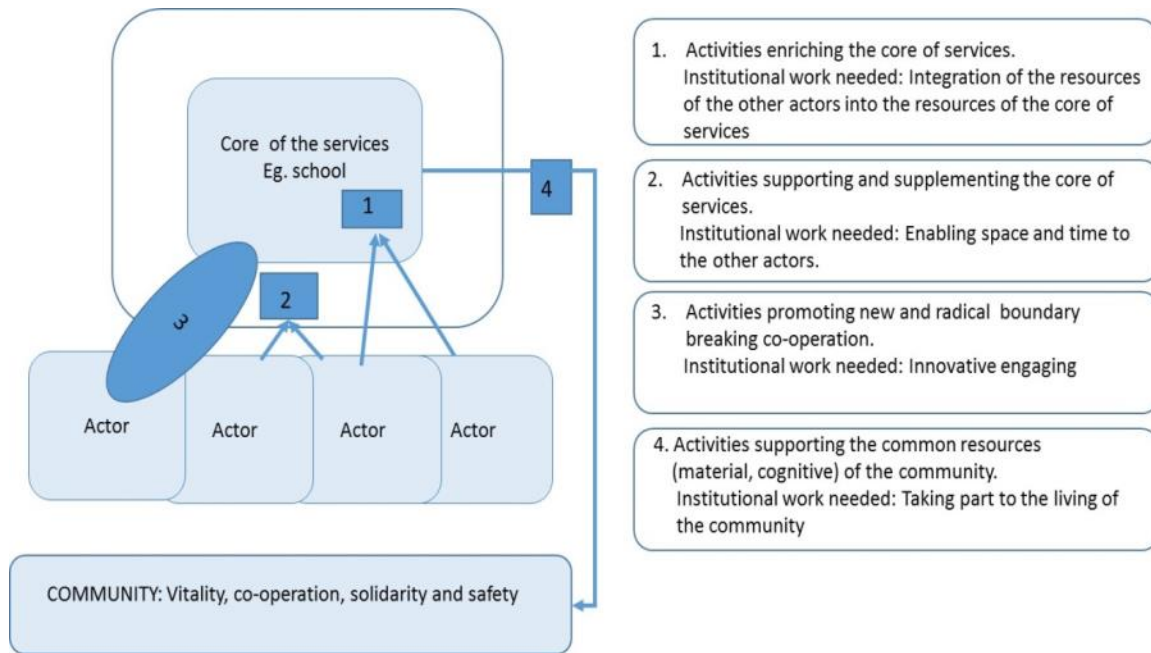

Figure 2. The focus of the resource integration based on the mini-pilots case.

3.2.2 Phase II: a further step with the effectuation process

The mini-pilots project showed several features of the effectual approach. Figure 3 summarises these features and concretises the problems, actors, means and goals with illustrative examples. In the evaluation discussions with the researchers, the representatives of the city authority expressed their willingness to take a next step: to experiment how the bottom-up collaboration with citizens could be encouraged by applying the effectual model more systematically.

Figure 3. Effectuation-based features of the mini-pilots.

As mentioned above, the mini-pilots created initiatives that were mainly outside the core of services. In the next stage, the idea was to broaden the experiments towards this core: the daily life of citizens and service organisations. This effort was used to support the organisation of services in a new way locally in suburbs. Support was needed because the new organisation requires innovativeness from the employees and emphasises collaboration both internally and externally.

Three workshops of different levels were organised in cooperation with the managers of the services for children and young people. The tasks for the workshops were set according to the effectuation model: who we are, what we have/know to go further, who we need to co-operate with, and what concrete deeds we are able to take up. The first level workshops took place in two different neighbourhoods. The second level workshops engaged middle management and the third level workshop strategic management. The researchers documented the discussions and circulated the summaries of the results from one level to the next. Finally, all the participants of the workshops gathered together in a common workshop.

From the research point of view, the final workshop was used to validate and supplement the data gathered in earlier workshops. The data has been structured according to three topics: 1) institutional conditions to enable innovations (logic of commitment, 2) agency (logic of identity and 3) focus of innovations initiated (logic of action). In the following we discuss these different topics one by one.

Conditions (logics of commitment)

The elements that seem to promote commitment of the stakeholders and citizens were the strategies of the city and the cohesiveness of the neighbourhood. A strategy which highlights cooperation was welcomed by the actors, and was experienced as a common resource. The slogan 'everyone is permitted to innovate' was seen to provide individual and collective wellbeing and relief in the work. On the other hand, the new managerial arrangements in the wider suburbs were not yet well understood, leading to some confusion about the activities that are desirable. At the same time, the strategic management group expected these kinds of initiatives to support the transformation. There was also difference in the commitment to the neighbourhood in the two suburbs. One of them was very autonomous and possessed a strong identity while the other neighbourhood was less coherent and expected external support.

Agency (the logic of identity)

Emerging actors within the further step – workshops were both citizens and professionals. Actors (citizens and grassroots employees) appeared as multiple level actors representing at the same time their personal experiences and knowledge's as parents, professionals, active citizens or politicians (cf. Sarasvathy and Dew, 2005; Osborne et al., 2012). The result resonates with the notion of the multidimensional nature of agency (cf. Smets and Jarzabkowski, 2013).

Possibilities to be an innovative actor was experienced (by the actors) to deal with easiness (not too much effort), freedom and voluntarism. Simple tools to promote cooperation were asked; how to get known the partners, how to build a network. We agree the notion that the cognitive and emotional efforts are necessary to gain reflexive awareness and engage innovation (Lawrence et al., 2013); Foss and Lorenzen, 2009). This means that arousing and maintaining the reflexive awareness and casting a glance at the future will be the critical question for managers in promoting bottom-up innovations in the context of traditional institution.

Focus (the logic of action)

In the workshops we could indicate four different levels of initiatives: 1) individually focused initiatives, 2) workplace and neighbourhood initiatives, 3) suburb level initiatives and 4) city level initiatives. The initiatives discussed in the workshops pursued mostly the first and second levels. On these levels, the actors seem to have a sense of possessing resources and autonomy to adhere the issues 'I just take a call and tell my idea'. Leadership of the own workplace was experienced as an important resource to encourage innovation, the slogan being 'leading from the centre with minimal regulations and pressures'. This resonates with the notion that small groups promote entrepreneurship (Dorado, 2013). In order to establish lower level initiatives as institutional practices, the institutional work of strategic and operational management is crucial. This means continuing interactions between micro-level, meso-level and macro-level (cf. Suddaby et al., 2013).

Issues from the third level (new suburb) were identified, but the alternatives and resources to handle with them didn't took the shape by actors. This may be explained by the novelty of the new arrangements in the suburb. Sense-making and sense-giving were asked from leaders and managers to make the new arrangements understandable. There were also some issues concerning on the broader cross-sector and city-level practices and policy (the fourth level). In these cases resources and coordination were asked from the high managerial level, 'from the city'.

4 Summary and concluding discussion

4.1 The ideal model to establish grassroots innovative activities

Our results revealed that innovative attitudes are quite general in such a public context that we examined: it was quite easy to encourage citizens and employees to be initiative. However, the activities emerged were small-scale trials. The small scale demonstrates that they were *performance-based activities* instead of institutionalised practices (a set of activities). They were local and pragmatic focusing on the tiny things/issues that improve the daily living of inhabitants and provide small varieties to the extant processes. Even though tiny varieties are essential to changes in the public sector (Aagaard, 2012), the impact would be much stronger if the grassroots initiatives could be *transformed into established institutional practices* that include employees, managers and citizens. Based on our results, we have built an ideal process model (Figure 4) that illustrates how such a transformation could take place and gain legitimacy by citizens.

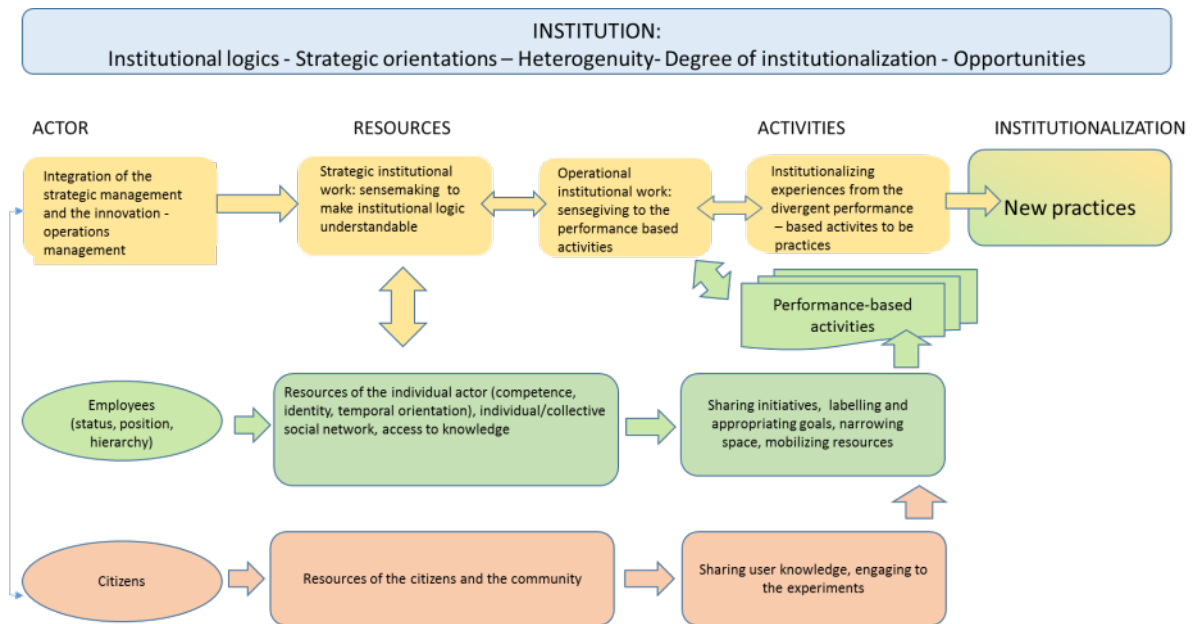

Figure 4. Institutionalisation of the performance - based activities.

We suggest that on the individual level as well as on the workplace and neighbourhood levels, actors experience themselves sufficiently autonomous and enabled to mobilise resources and engage in innovations. To become established as institutional practice, the various experimental activities from these levels should be put together and analysed by the strategic and operational management. These results are in line with the emphasis of earlier literature on the projective dimension that supports future change and entrepreneurial and creative behaviour (Battilana et al., 2009; Lawrence et al., 2009). Also the ideas of Thornton et al. (2012) are relevant here: the separation of decision making, sense making and collective mobilisation as the key elements of institutional work, which links the dynamics of practices and identities. To be successful entrepreneurial efforts has to gain legitimacy (Drori and Honig, 2013, Lounsbury and Glynn, 2001).

4.2 Concluding remarks and avenues for further studies

This paper has analysed innovation in public services from the effectual point of view. The activities that we examined in our empirical study were mainly external to the core services, aiming to support, enrich and supplement them. A question arises: what does this result tell about the characteristics of expected future services and what does it tell about the citizens' and employees' desire to become engaged?

The scale of activities describes the material and cognitive space where the actors have a sense of enabled entrepreneurs. The focus and scale may be understood in terms of a 'bandwagon process', in which participants negotiate the possible issue of cooperation. Fuglsand and Eide (2012, 419) highlight that on a bandwagon 'the different activities of different actors become structured around a common field of meaning'. Boundaries of the process may be mental, social or physical (Montgomery and Oliver, 2007). Boundary objects will be found by labelling (identifying the meaning of the interesting issue in question), by appropriating of the issue collectively to resonate with the community, and by narrowing the conceptual and technical space to make cooperation possible (Fujimura, 1992; Star, 1989; Corradi et.al., 2010).

Lounsbury and Crumley, (2007, 997) ask 'how the performativity driven variations in activities can spur field wide efforts to establish a new innovations as a practice'. We have formulated an ideal model (Figure 4) to describe the

development of performance based activities from the individual and group levels to the level of established institutional practices. We assume that it is the task of innovation management to formulate the central questions when enhancing public innovations. In order to promote innovations that start as small scale activities, the institution has to find actors who 1) are able to recognise the tiny elements of innovations, 2) to feed these (possibly delicate) elements, and 3) to carry on their implementation systematically.

In the first experiment of our study, the role of an agent was central for the operational management of innovation – this role can be interpreted in terms of meta-governance (Sorensen and Torfing, 2011). The agent was able to use institutional tools like structure and design of the organisation; political and discursive framework; and process management and direct participation (Sorensen and Torfing, 2011). The steering group involved was responsible for the strategic management. In the second experiment, both the strategic and operational managers were engaged in the effort.

Our results confirm several views presented in earlier literature. They are in line with the view of Arend and Chen (2012) about the importance of strategic management in entrepreneurship and innovation, and with the view of Sorensen and Torfing, (2012) about the importance of leadership. The central role of middle managers for the continuation of social initiatives was clearly visible. It confirms the view of Sharma and Good (2013) about the role of this group in maintaining the hybridity of profit and social logics. Our results also highlight the significance of innovative culture in the fostering of a systematic way to develop services, and point out the integration of operational service delivery and strategic service orientation (Teboul, 2006). Osborne et al. (2012), who apply service-dominant logic in the public context, summarise most of these factors in their emphasis on the simultaneous implementation of strategic orientation, marketing, co-production and operations management.

To become established as institutional practices, innovative activities need to be interpreted against the institutional goals, logics and expectations. In our case, these activities focused mainly on the boundary levels and produced intangible outputs that were social, organisational and individual in nature (cf. Hill et al., 2011; Osborne et al. 2012). The actors reported increasing wellbeing, joy and communal trust as the outcomes of the activities. A question arises whether these results are in harmony with the expectations, goals and logics of the institution. What is the added value they provide to the knowledge base of the strategic and operational management? In our case, the city was satisfied with the results and has continued to carry out mini-pilots 1) as activities in some suburbs and 2) as a model building which targets at systematic, experience-based service development for the provider organisation.

One more question to be raised based on our results concerns the increasing complexity of the institutions and the inter-institutional orders following many organisational changes. The emerging complexity raises questions about how to handle it: how it changes the innovation context. Actors may experience the changing environment as hazy and inchoate. They may not be able to imagine alternatives and opportunities, to know the resources to be used, and to have access to knowledge. Therefore, actors need an adequate organisational structure and support from the managers whose work is to interpret the divergent logics of complex organisations. It is important that the perspective of institutional dynamics and complexity is taken into account and linked to the issues of actors in their concrete daily work. This is a task for both the managers who create the innovation enabling institutions, and for the researchers who analyse these institutions (cf. Smets and Jarzabkowski, 2013).

Our study contributes to the effectuation model by highlighting two elements that are particularly relevant when this model is applied in the public context. Firstly, public innovations are collective activities of partially autonomous actors, which implies that effectuation has to be analysed as a collective activity, too. Secondly, effectuation reached in the individual or group level innovations becomes more general via institutional work. This means that also strategic and operational management processes should follow the effectual logic. Actually, in the public context the first question of effectuation ‘what we want to be’ should be supplemented with a question ‘what the institution wants to be’ (cf. Kodeih and Greenwood, 2014).

An important conclusion based on our paper is that the effectual approach provides an innovation process model whose main principles are applicable, not only in the market context, but also in the public sector. Even though the resource expansion in our case is still going, we have been able to make some initial observations that are crucial and whose validity in more general contexts could be tested in further studies. One such observation is the important role of improvisation, courage and tolerance towards failures as factors that favour the emergence of novelties. Another area for further research is the applicability of service-dominant logic (SDL) in the public sector. Our example illustrated the actions of citizens (users) as innovators and the role of public professionals (providers) as facilitators in the innovation process – a ‘work division’ that is in line with the foundational premises of SDL (Vargo and Lusch, 2004, 2008). Also the institutionalisation of the new practices is a topic in which our case has provided interesting material for the future research efforts.

Manifestation of Innovative Behaviour in Health Care Renewal Activities

Hannamaija Määttä, Kirsi Hyytinen, Sampsa Ruutu, Marja Toivonen

VTT Technical Research Centre of Finland

Health care systems are under significant development pressure due to the ageing of population and the problems of public financing, which is why service and social innovations are sought out for. A new model of chronic care, and integrated care programs based on it, has been applied in several countries. Innovations in public sector originate from usually unconnected impulses from employees interacting with customers on the grassroots and from managers implementing policy requirements. Often these innovations have been analysed as top-down activities leaving the initiatives arising from bottom-up to smaller attention. This paper examines the innovation capacity of a health care organisation implementing a CCM-based renewal through the lens of innovative behaviour. The focus in this paper is on studying how innovative behaviour is manifested among different actor to better understand the innovation potential within a public organization and reveal how this potential should be better supported.

1 Introduction

The role of innovations has become increasingly important when tackling with complex societal problems, particularly in the health care sector. Due to the ageing of population, there is a growing demand for health services while the public resources to maintain and develop these services are diminishing (Dunston et al., 2009). Efficient in-house processes are no more sufficient; now the crucial issue is the empowerment of citizens and collaboration with them.

As an answer to the challenges, health care organizations have begun to renew the health care provision by adopting so-called integrated care programs that highlight patient support and education, combined with structured clinical follow-up and case management; a multidisciplinary patient care team; multidisciplinary clinical pathways and feedback, reminders, and education for professionals (Ouwens et al., 2005). These programs, carried out in various countries, are based on *the chronic care model (CCM)* developed to improve the management of chronic illnesses through six cornerstones: utilizing community resources, developing health organizations, investing in self-management support, redesigning service delivery, employing decision support for professionals and utilizing clinical information systems. Segmenting the chronic patients according to the intensity of care needs is a part of the model. A three-group division – so-called Kaiser Permanent Triangle – is typical and consists of patients with multiple diseases, patients with high risks, and patients with a self-manageable disease (Bodenheimer et al., 2002).

CCM, together with the integrated care programs based on it, differs from the previous models of acute care and the expert-led health systems that have dominated: they are patient-centred (not sickness-centred), their focus is on planned, proactive care (not only on the acute, reactive care) and they provide support to the patient (not only diagnostic information). The key is to empower patients by treating them as experts of their own health and as partners in healthcare, and this is eventually expected to ease economic constraints in the health care sector (Coulter, 1999).

An important insight in the circumstances of ageing population is that the quality of life can be high even when a person has a chronic disease. Health does not only mean the absence of disease, but it includes capability to cope and function with everyday physical, emotional and social challenges (Huber et al., 2011). Many studies have examined how health systems could be rebalanced from addressing the treatment of acute illness to engaging citizens in promoting their own health. Studies on health services have usually focused on hospitals and specialized care, but the new integrated care programs have stimulated interest in the systems of primary care (Dunston et al., 2009).

To support the renewals in the systems of primary health care, service and social innovations are sought for. New ways of interacting and participatory processes are necessary for the creation of innovations in a multi-agent environment (Harrison et al., 2010). Innovations in public sector originate from usually unconnected impulses from employees interacting with customers on the grassroots and from managers implementing policy requirements (Sorensen et al., 2013). Often these innovations have been analysed as top-down activities leaving the initiatives arising from bottom-up to smaller attention (Windrum, 2008). In service innovations, practice-based innovation is of central importance and is greatly dependent on the creativity of front-line employees (Sorensen et al., 2013). The practice-based innovation impulses become crucial, especially in the implementation of new integrated care programs.

In our paper, the interest is on understanding these two unconnected views during the renewal activities based on CCM. We examine the renewal and change activities of a health care organization from the perspective of innovative behaviour (Kleysen & Street, 2001). Innovative behaviour has been studied in the context of knowledge-intensive business services (KIBS) for instance (Tuominen & Toivonen, 2011), but corresponding research in public organizations is missing. The focus in this paper is on studying how innovative behaviour is manifested among different actor groups responsible for the implementation of integrated care programs based on CCM. We argue that studying the innovation and change activities in the health care renewal from the perspective of innovative behaviour enables us to

better understand the innovation potential within a public organization and reveal how this potential should be better supported.

We have set the following research questions for our study:

- What kind of new innovative solutions are developed in the adoption of CCM-based integrated care models?
- What types of innovative behaviours can be found among different actors in the renewal and development activities?

In our analysis we will utilize the concept of innovative behaviour and its elements to study the change and renewal activities of the case organization from the point of view of different organizational levels. We will also utilize a multi-agent framework to analyse service innovation (Gallouj & Weinstein, 1997; Windrum & Garcia-Goni, 2008) to better understand the innovative behaviour categories associated with individual innovation (Kleysen and Street, 2001) in the health care renewal context.

2 Theoretical background

2.1 Innovative behaviour

To understand the renewal activities within the health care sector, we will utilize the theories of innovative behaviour in our analysis. Innovative behaviour, a concept arising from social and organisational psychology, can be defined as all individual actions directed towards generation, introduction and application of beneficial novelty at any organisational level (West and Farr, 1989; Kleysen and Street, 2001).

Studies of innovative behaviour have typically focused on incremental and process-related innovations at the shop-floor level of an organisation. The concepts of innovative work behaviour (IWB) (Axtel et al., 2000; Janssen, 2000; Ramamoorthy et al., 2005; Dorenboschet al., 2005) and individual innovative behaviour (De Jong and Kemp, 2003; Kleysen and Street, 2001) are neighbouring concepts in this area. In these studies the focus has been blue-collar workers in industrial organisations, knowledge-intensive, non-managerial staff in a government organisation, or co-workers in knowledge-intensive service firms (De Jong and Kemp, 2003; Dorenboschet al., 2005). Kleysen and Street (2001) have applied the concept of innovative behaviour to all kinds of innovations at both the worker and manager levels in various organisations.

Innovative behaviour studies also concentrate on informal innovative actions in contrast to formal innovation processes. It has been suggested that although innovative behaviours might not be formally required, the activities are important for organisations' survival. The emphasis of innovative behaviour studies has hence been on identifying the factors that enable and motivate employees to undertake these behaviours (Scott and Bruce, 1994; Janssen, 2000; Dorenboschet al., 2005; Ramamoorthy et al., 2005).

Kleysen and Street (2001) have identified five elements of innovative behaviour including a variety of tasks: 1) opportunity exploration: paying attention to opportunity sources; looking for opportunities to innovate; recognising opportunities; and gathering information about them; 2) generativity: generating ideas and solutions to opportunities; generating representations and categories of opportunities; and generating associations and combinations of ideas and information; 3) formative investigations: giving form to and fleshing out ideas, solutions, and opinions and trying them out through investigation: formulating ideas and solutions, experimenting with ideas and solutions, and evaluating them; 4) championing: socio-political behaviours involved in processes of innovation: mobilising resources; persuading and influencing; pushing and negotiating; and challenging and risk-taking; 5) application: behaviours whose aim is to make innovations a regular part of business as usual; implementing, modifying and routinizing (Kleysen and Street, 2001). These behaviours can occur simultaneously and iteratively among group context and individual actors during an innovation process (Kanter, 1988; Janssen, 2000; Axtel et al., 2000). The group and organisational factors become increasingly important as the idea proceeds from initiation to implementation (Axtel et al., 2000). The innovative behaviour elements are summarized in Table 1

Table 1. Elements of innovative behaviour (Kleysen and Street, 2001).

Innovative behaviour element	Description	Related tasks
Opportunity recognition	Travelling extensively through innovation opportunities in order to learn or discover more about them	<ul style="list-style-type: none"> ▪ Paying attention to opportunity sources ▪ Looking for opportunities to innovate ▪ Recognizing opportunities ▪ Gathering information about opportunities
Generativity	Behaviours directed at generating beneficial change for the purpose of growing organisations, their people, products and services	<ul style="list-style-type: none"> ▪ Generating ideas and solutions to opportunities ▪ Generating representations and categories of opportunities ▪ Generating associations and combinations of ideas and information
Championing	Individuals who emerge to take creative ideas (which they may or may not have generated) and bring them to life	<ul style="list-style-type: none"> ▪ Mobilizing resources ▪ Persuading and influencing ▪ Pushing and negotiating ▪ Challenging and risk taking
Formative investigations	Giving form to and fleshing out ideas, solutions and opinions and trying them out through investigation	<ul style="list-style-type: none"> ▪ Formulating ideas and solutions ▪ Experimenting with ideas and solutions ▪ Evaluating ideas and solutions
Application	Working at making innovations a regular part of business as usual	<ul style="list-style-type: none"> ▪ Implementing ▪ Modifying ▪ Routinizing

Tuominen and Toivonen (2011) have studied innovative behaviour in the context of knowledge-intensive business services (KIBS). They have argued that while there has been much emphasis on the operationalization of the innovative behaviour concept in previous literature, there is a lack of empirical insight into how innovative behaviours are realised in different organisational contexts and levels. We continue accumulating this kind of evidence in another sector. Using the categorization by Kleysen and Street (2001), we analyse renewal activities within health care to contribute to the understanding of how innovation occurs in public sector service organizations. In order to do so, we will first identify the outputs of the renewal activities to help understand what types of innovative solutions are developed by utilizing a multi-agent analysis framework to service innovation.

2.2 A multi-agent framework to identify service innovation

To understand the types of innovative behaviour, we first elaborate the created novelties by using a model for studying innovations in services (Gallouj, 1994; Gallouj & Weinstein, 1997) and its specific application in health care (Windrum & García-Goñi, 2008). The Gallouj-Weinstein model describes services as a set of final characteristics (user benefits), technical characteristics (production system) and competence characteristics, and defines service innovation as any change in these characteristics.

Windrum and García-Goñi (2008) argue that due to the specific nature of health care sector, the final set of service characteristics strongly depends on the competence of health professionals (i.e. human capital), and on the interaction between health professionals' competences and end-users. Following the classification of service innovations made by Barras (1986, 1990), they make a division into user-facing competences and supportive back office competences. User-facing competences refer to the knowhow and skills and interrelated technologies essential in providing final medical services to patients. Back office competences are the skills and administrative activities (e.g. patient booking system) that support the user-facing activity (Windrum & García-Goñi, 2008).

In our analysis of the actor preference and competence perspective, we propose a change to the original Windrum & Garcia-Goni –model: instead of seeing the service provider as a one entity (divided into front and back offices), the provider is divided into three groups: professionals (doctors and nurses), middle managers (responsible for development and implementation) and top managers (strategic managers, representing policy makers). The customers of health services are considered as the user group. In addition to the service characteristics, the core in the model is a multi-agent interaction in developing services. One of the values of this dimension is that it puts particular emphasis on the public sector's role in the innovation process.

Typically innovation research has been focused on the private sector innovation without putting too much effort to understand the role of public sector in creation of innovations. However, according to Windrum (2013), both political organizations and non-governmental organizations play an important role in innovation generation and dissemination as well as all agents inside a health organization: frontline workers and the managers should be motivated and skilled enough to ensure a successful implementation of innovation (García Goñi et al.,2008). In our paper, we acknowledge

the important role of public organizations, however, the focus from the perspective of innovative behaviour is on health service providers and users.

3 Research context and methodology

In this paper we have utilised a case study based approach (see e.g. Yin 2008, Eisenhardt 1989). We focus on studying the profound change process and renewal activities of a municipal health care organization in a middle sized Finnish city. To tackle the challenges the health care sector is facing today, the organization is comprehensively renewing its entire operational model and services following the principles of integrated care programs. The renewal has been going on since 2010 and is linked to a broader national exercise for social welfare and health care. However, the city's health organization has been exceptionally active in its innovation activities and learning about the newest developments of the CCM model and integrated care programs and in testing them in practice.

The key change following the principals of CCM is the renewal of the operational model of the health care organization and setting the management of chronic illnesses as the main goal. More precisely, this includes creating new service-oriented positions in the health organisation: service managers, service superiors and service coordinators as opposed to leading doctors and nurses. A part of the renewal is also the extraction of patients with chronic illnesses and multiple diseases from patients requiring acute care, and managing the patient flows by creating two care "channels" for these sub-groups and plans for a more versatile segmentation in the future.

The organization also invests and develops in services supporting self-management of patients, for example group services that are arranged for educating patients about their illnesses and about the prevention of further problems. Empowerment of patients a key element of the new activities, and is done with target-oriented phone calls by nurses to see how the care is proceeding. The focus is on taking a coaching approach to support patients in achieving goals. To support this, a responsible professional/professional group with whom the patient interacts directly regarding the issues concerning the treatment is assigned. Multi-disciplinary team work is an important part of the new model, which is expected to diminish professional hierarchy. The teams also collaborate with patients to support the holistic care - not focusing on one disease at a time. A systematic health plan, which is created in close collaboration between the professional and the patient according to goals set by the patient is essential in achieving long term health impact.

All these renewals in health care require new skills from the personnel, and the arrangement of workshops for the professionals about the re-organizing of care and new operation models around specific topics is a way of education, and also a means of encouraging dialogue between professionals of different areas. The utilization of new interaction technologies, the eHealth -system, is implemented to ease the communication between patients and professionals. Through the new system, patients are allowed to see their test results, treatments and health plans, and to transfer the measurements that they make themselves (e.g. blood pressure). Another important feature of the renewal is strengthening the collaboration with patient organizations, which can provide information, advocacy, peer support, training, rehabilitation and social events for patients.

Our extensive data on the case has been gathered during the years 2013 and 2014 and consists of primary data based on non-participant observations, action research, interviews, research diaries and documentation. It is supported by secondary data including documentation of the renewal process, reports, and learning diaries of some personnel representatives. To gain an extensive understanding of the renewal activities, observation, action-research and interviews have been utilized. The weekly meetings of two management teams responsible for the change process of the case organization were observed during February and June 2013. During the first three months, our research group observed without any participation to get an overall conception of the on-going transformation process. For the last two months, we then adopted an action research strategy: participating in the teams' conversations and pointing out problems related to the systemic change and solutions development. A detailed memo was created after every meeting.

The material gathered from the observations and participations has been further supported by individual face-to-face interviews (15 in total) with all the team members. These interviews were conducted in June and July 2013. The observations and action research continued until December 2013, and during year 2014 the gathering of the case material has continued in monthly workshops with the management team. We have seen this necessary in order to gain insight on how the innovative solutions and behaviour has developed throughout the process.

Our analysis will focus on four different actor groups; top managers, middle managers, professionals (doctors and nurses) and users. Since our data has been gathered in the management meetings, the information about professionals and users is indirect and based on the views of the members of the management teams.

4 Results

4.1 Identification of service innovations in health care renewal

The key change in service characteristics followed by the adoption of CCM in the case organization is the transition of the service relationship based on treating diseases and passive patient and nurturing doctor towards creating a service relationship based on empowering patients to manage their own health in collaboration with health professionals. This change influences the dynamics of power distribution between service provider and users greatly.

In the previous expert and sickness centred health service model the top management was relying in hierarchical processes in the operations. Imitating industrial models in patient processes to maximize cost-efficiency were dominant operational approaches. The new solutions based on CCM have changed the hierarchical structures towards encouraging and enabling collaboration between different organizational levels and different professional groups within the health care organization. This is visible for example in the renewal of profession titles from leading nurses and doctors to service managers. Emphasising service-thinking to strengthen the customer processes are the focus of development. From the perspective of middle managers, the old operational model resulted in seeing patients only as targets of care, and work days were filled with “putting down fires” and managing urgent issues in daily practises. Now patients are no longer seen as passive recipients of care but as active partners and resources in the care process.

Planning and coordinating services and customer processes enable moving away from only managing the “tyranny of urgent”. From the perspective of professionals the emphasis has long been on diagnosis-centred working and basing the competences strongly on medical knowledge, now the goal is to take a coaching and preventive approach to the care and increase know-how on service processes and user encounters. From the user perspective, the contact to the health experts usually happens when an acute health problem occurs. There has been great passivity regarding own health issues and patient have relied strongly on the care given by medical professionals. Now the emphasis is on planned collaboration with health activities complemented with own target oriented activities and taking an active role in promoting health. These above described actor preferences and competence changes are summarized in Table 2.

Table 2. A characteristics-based analysis of service innovation in the case: changes in actor preferences and competences.

<i>Actor group</i>	<i>Changes in preferences</i>				<i>Changes in competences</i>			
Top managers	TP ₁	Emphasis on hierarchy	TP ₁	Encouraging collaboration between different levels and different professional groups	TC ₁	Imitation of industrial models in patient processes, emphasis on cost-efficiency	TC ₁	Emphasis on service-thinking and strengthening customer processes
Middle managers	MP ₂	Seeing patients as targets of care	MP ₂	Seeing patients as partners and resources	MC ₂	Focus on managing the “tyranny of urgent” in the daily practises	MC ₂	Focus on planning and coordinating service and customer processes
Professionals	PP ₃	Emphasis on diagnosis-centred working	PP ₃	Emphasis on a coaching and preventive approach to care	PC ₃	Medical knowledge	PC ₃	Knowhow on service processes and user encounter
Users	UP ₄	Contact with a health expert when experiencing an acute problem	UP ₄	Planned collaboration with health experts combined with own activities	UC ₄	Passivity regarding own health; relying too much on professionals in the care	UC ₄	Taking active role and responsibility in promoting own health; target-oriented behaviour

4.2 Manifestations of innovative behaviour types

In our analysis we utilized the typology of Kleysen and Street (2001) and examined how these types of innovative behaviours occur in different actor groups during the renewal activities of the health care organization. All five types of the behaviour types could be identified, and similarly to the study by Tuominen and Toivonen (2011), we noticed that the behaviour types occurred iteratively and many overlapped each other. We will next present more precisely how each behaviour type occurred in the previously defined actor groups.

1) Opportunity recognition: In our case, the growing pressure to show productivity of health care centres, starting the national health sector renewal and internal management problems acted as key drivers for identifying new innovation opportunities by the top management. These activities were performed generally and related to specific problems in the health care sector. The role of top management was very central in searching for new solutions; the managing director, for example, travelled across the country and abroad to discover and learn how health care services are organized elsewhere. Also other members of the top management visited fairs and conferences abroad and brought back their insights and suggestions for further development.

The top management created a small R&D department working on the side of managers responsible for gathering knowledge on future trends and benchmarking other health organisation to support the managers' development work. Knowledge gathering activities, therefore, were of central importance in identifying new opportunities. The middle management also engaged in knowledge sharing activities, though these activities were strongly connected to the daily practises in the health operations. Many opportunities were identified through challenges in the daily activities and brought to the middle management's attention. Opportunity identification, therefore, occurred in learning from challenges in daily work practises and service events.

The professional's role was to recognize the challenges and reporting back to the middle management. This became crucial especially in the implementation of new working practises. User acted as resources for opportunity identification; feedback was gathered from the customers, however, not very systematically. Our case representatives reported about the problems in getting the personnel involved in the development work and seeking new opportunities, which was mostly due to the fact that developmental tasks were expected to be performed alongside regular care work. The new "licence to innovate" –culture was also new in the organization, and many employees focused on issues close to their own work without any link to the future developments.

2) Generativity: From the perspective of top management these activities concern very much the creation of new service solutions to challenges the health organization is facing. The new solutions have been developed based on various opportunities and examples identified in the beginning of the renewal process. The middle managers role in developing solutions has been bringing ideas regarding the daily practises to the management meetings for discussion and development. A central task has been creating work groups responsible for developing and implementing the ideas further. This was done in various occasions in multi-disciplinary groups, meaning that cross-professional collaboration was encouraged.

All the members of the management teams were able to contribute to the idea generation through e-mails, which were sent to team members for further improvement and idea generation. The professionals were able to participate in generating ideas and solutions through workshops created to increase the dialogue between managers and employees. This was a major improvement in the innovation culture, since before these events were merely lectures. However, challenges arose due to the lack of proper motivational activities regarding the workshops; in the beginning of the renewal process there were very few participants and follow-up after discussions were missing. Users had little role regarding the generativity activities, as they were not included in developmental tasks in the definition of new solutions.

3) Championing: The top managers had a key role in this activity, especially for the reason that innovation activities were new to the organisation and that kind of behaviour had not been expected before from the personnel. Championing plays a key role in an organization culture where innovation activities are new. Personal relationships, challenges of multi-disciplinary team work and new work practises created a lot of scepticism among the actor groups. The managing director of the health organisation had a management style of empowering all management team members to take responsibility and part in discussions. This was done many times by challenging the ideas and comments with a very strong, even conflict-seeking attitude in order to spark up ideas and conversations. Many reported the difficulty of having multiple strong-willed persons in the teams and pushing was considered to be a threat sometimes.

Challenging as a way of championing, however, was seen as a necessary mean for enhancing change especially when dealing with municipal decision makers. Responsibilities were divided equally among team members to enhance the development work. The top management team also had a mentoring program, where they acted as mentors to new service managers representing the middle management. The middle management had the important role of motivating the professionals to take new forms of activities into use and supporting them. Repetition and active support for the implementation activities was reported as most essential to keep the personnel motivated. The middle management's role was also to act as a bridge between the professionals and top management in selling ideas both ways, a role, which was considered to be very challenging.

There was great tension between the top management and personnel; the personnel felt that the managers do not understand the everyday work and they could not understand why the personnel was not feeling motivated enough to implement new solutions. The professionals performed championing activities by marketing new services to customers,

and were in key role in persuading and influencing them to utilize new service forms. They also created team spirit internally in multi-disciplinary teams, for example, after a successful piloting campaign of new e-Health service accounts, a nurse had made a cake with the phrase “Go us!” to congratulate the team. Users acted as targets of the championing activities of professionals in marketing new services.

4) Formative investigations: In our case organization this behaviour occurred through the evaluation of success of implemented services and concretizing the content of developed solutions by assigning employees responsible for it. The top managers conducted these activities by evaluating ideas brought to the table in management team meetings, sometimes with a very confrontational manner. Discussions in team meetings were very important in creating mutual understanding of how the services should be executed and implemented and decisions were made in the group. Describing the service and customer processes in detail was of great importance, and people in charge of the processes were also determined to ensure that ideas move forward. The middle managers’ role was discussing ideas in team meetings and also concretizing their content, and a key part of this was to bring the thoughts of the professionals to the table. The middle managers were in charge of arranging workshops for the personnel to get them more involved in developing new services.

Evaluation of experimentations also occurred, and one middle manager for example gained insight on how the new work activities should be utilized in all services the health organization is providing. A great realization was also the need for auditing the experimentation of new services. The professionals’ role in conducting formative investigation activities occurred through experimentation of new services in piloting campaigns, for example in e-Health account campaign and piloting the group services. In the group service pilot challenges arose due to the fact that the personnel felt that decisions are made top-down and the solutions are expected to be implemented by the personnel without empowering them in the process. Feedback was gathered from the group activities and it occurred that many of the groups are empty due to the lack of a marketing plan. A solution was created to this by the creation of a team responsible for the group service development (co-development). Users in these activities were the targets of experimentation and providers of feedback. They evaluated the group services, and the result was that out of 12 responses only one customer was satisfied with the service, other 11 were not.

5) Application activities: Tuominen and Toivonen (2011), however, suggested that modifying is not a sub-category of application but consists of iterative application, evaluation and idea generation throughout an innovation process. Similarly in our case study, these activities occurred during various phases in the renewal process. New work activities, for example, were constantly implemented and routinized, and the top managers acted as examples for the rest of the organization. It was important to get the commitment from the managers in order to change the working culture.

Middle managers, on the other hand, supported the implementation of new work practises and service solutions in the daily practises through creating new routines and modifying activities if necessary. Learning and educating the personnel was important, and the management arranged various workshops and created instructions to support the implementation. The professionals conducted application activities through implementing new solutions and users acted as targets and adapters of new work practises and routines.

5 Discussion and Concluding Remarks

In this paper we have examined the manifestation of innovative behaviour in health care renewal activities. The focus has been on primary health care organization adopting the principles of CCM in its operations. CCM and integrated care programs based on it have been adopted in several countries as an answer to the challenge of ageing population and the problems of public financing. Central elements in the renewals are the empowerment of patients, increasing cross-disciplinary collaboration among professionals and effective use of the new information technology systems. Traditionally, studies on health services have focused on hospitals and specialized care, but the new integrated care programs have stimulated interest in the systems of primary care (Dunston et al., 2009). There has also been active research focusing on the micro-level interactions in healthcare: service encounters and prerequisites for success in them.

In the public sector, innovations originate from two different directions; from the frontline employees who interact daily with the customers and from managers who are responsible for implementing policy requirements (Sørensen et al., 2013). The research focus has long been on top-down innovation activities, which is why there is a need to understand how the top-down and bottom-up innovation activities could be better integrated. In this paper we have argued that this is extremely crucial in the adoption of CCM-based solutions in health care, where the frontline personnel play a critical role in implementing new solutions. The innovation capacity of an organization can be studied through the lens of innovative behaviour. Innovative behaviour has previously been studied in the context of knowledge-intensive business services (KIBS) (Tuominen & Toivonen, 2011), but similar studies in the public sector are missing. Studying the innovation and change activities in the health care renewal activities enables us to examine the innovation potential within a public organization and to understand how this potential should be better supported.

We have carried out an empirical case study in Finland and examined the renewal and change activities of a primary health care organization from the perspective of innovative behaviour (Kleysen & Street, 2001). In our analysis we utilized the concept of innovative behaviour and its elements to study the change and renewal activities of our case organization from the point of view of different organizational levels. First we identified the new innovative solutions developed during the renewal process by utilizing a multi-agent framework to analyse service innovation (Gallouj & Weinstein, 1997; Windrum & Garcia-Goni, 2008). The key change in service characteristics was the transition of the

service relationship based on treating diseases and passive patient and nurturing doctor towards creating a service relationship based on empowering patients to manage their own health in collaboration with health professionals. From the perspective of different actor groups (top management, middle management, professionals and users), this means changes in power distribution between health professionals and users and stronger multi-disciplinary collaboration and customer-orientation in service processes.

Examining the five innovative behaviour types in the health care organization has revealed how different actors engage themselves in change and renewal activities in a CCM-based health care renewal. All five types could be identified from our case, however, the roles in the activities varied. The top managers acted as discoverers, developers and creators of new solutions, as well as champions and mentors to the middle management. Middle managers had the important and challenging role of acting as “bridge-makers” between top management and personnel as well as developers, champions and modifiers. The personnel acted mainly as adopters and implementers of new solutions, but had also the very crucial role of acting as champions to the customers in marketing new services. The results indicated that there is hidden potential for service encounter-based innovation within the renewal activities. Users in our case were in a more passive role regarding the renewal activities, and acted as sources and targets of development.

Studying the different actors in health care renewal activities revealed that innovative behaviour occurs in various organizational levels. From our results we can identify the nature of innovation occurring within renewal activities. The behaviours of different actors showed that innovation occurred mostly initiated by the top management, as directed innovation developed based on strategic concerns to external pressures (see Fuglsang & Sørensen, 2011; Sørensen et al., 2013). The developed solutions were mainly done in the management teams, after which they were brought to the professionals for implementation. Though the professionals and users engaged in the innovative behaviour activities to some extent, their main role was to act as implementers and adopters to the new solutions. Looking at the renewal activities from their perspective, the link back to the top management was quite weak, though the potential for service encounter-based innovation is evident. Like many other organizations, our case organization has not yet utilized this potential (see Sørensen et al., 2013), due to the lack of support structures and suitable mechanisms. We argue that the nature of public organizations creates extra challenges in the utilization of front-line personnel and users in innovation, as in health organizations this type of innovation activities are new and the development tasks are expected to be conducted on the side of daily work.

Sundbo (2006) has suggested that innovative service organisations consist of a dual structure; an informal social system that produces ideas and a management system that supports the personnel and selects the ideas to be developed. Following this, Sørensen et al. (2013) propose organizational conditions that are required for practise- and service-encounter –based innovation; the organisational support system and a front-line innovation climate, which require new capabilities. The support system has the important role of facilitating and encouraging creativity in the front-line personnel as well as integrating and selecting presented ideas in the development processes. The support system is defined by the organizational confidence and management’s trust in the employees’ capabilities; the correspondence capabilities, for example communication channels and the management’s ability to choosing among innovation inputs and ideas. The front-line innovation climate, on the other hand, greatly depends on entrepreneurial working values, social intelligent to understand, observe and take seriously the user’s needs and recognition incentives that motivate the personnel to contribute to the development activities. Tools for managing these kind of innovation activities need to be developed (Alam, 2006; Sørensen et al., 2013).

Considering this, we argue that CCM-based renewals cannot be successfully adopted without involving the personnel and users in the process. In the adoption of CCM-based solutions in health care, the modification and constant iteration is necessary – activities, which are highly dependent on the role of front-line employees. They have the important task of perceiving how the developed solutions actually work in practise and reporting back end-user perspectives for the further modification and development of services. Practise-based innovation processes based on the employees daily practises that result in small and unintentional changes in services based on user’s needs are important (Fuglsang & Sørensen, 2011) but have been ignored in service organizations for too long.

Our results highlight the importance of empowerment to encourage innovative behaviour, as all employees are expected to act as intrapreneurs in the organization. The top managers’ role becomes crucial in stimulating and controlling these entrepreneurial activities (Sundbo, 1996). Based on previous studies, it is necessary to focus on creating a suitable organisational support system that enhances and enables a culture of innovation. The organizational culture also needs to develop following direction of the paradigm change in public services, where the professionals and patients are no longer seen only as providers and users of services but resources for innovation in health care.

Health and healthcare services disparities in the Euro-Mediterranean Area

José Luis Navarro Espigares¹, Rosario Asián Chaves², Mikel Zurbano Irizar³, Teresa Fernández Fernández⁴

¹University of Granada, ²University of Seville, ³University of Basque Country, ⁴University Rey Juan Carlos

The objective of this article is to analyse the development of health services in the Mediterranean countries taking into account their contribution to the regional cohesion and economic integration. We reviewed the literature on health and economic development and explore the support to the health objectives in the context of Union for Mediterranean (UfM) agreement. We also studied the differences between two groups of countries, EU-28 and MENA (Middle East and North Africa), in relation to their social, economic and health profiles. Finally, we offer some economic and health policy orientations linked to the development of regional healthcare systems.

1 Introduction

Health is at the same time a component and a condition for economic development. Thus, the improvement of health is a central aspect in the Millennium Development Goals (MDGs). For this reason, this work analyses the development of services in the Mediterranean countries as an integrative factor in achieving the MGDs. The achievement of high quality healthcare services with more equal accessibility is a guarantee for progress and social cohesion. Therefore, cooperation in general and specifically cooperation in health care are considered urgent and unavoidable necessities in order to address the great inequalities that still exist in the modes of living, contracting illnesses and dying. In addition, the global improvement of living conditions and the lack of access to quality health services in many countries can mean the difference between life and death.

Our objective is to carry out a first approach to the study of health status and healthcare services in the Mediterranean area. The analysis of the evolution of the main social, economic and health indicators reveals a weak convergence process that makes it difficult to achieve greater social and territorial cohesion in the area.

The document offers, firstly, a review of the main relationships between health and economic growth. Secondly, we examine the intervention strategies in the area of health by the European Union. Then we carry out an analysis of the situation in the different countries of the studied regions (EU-28 and MENA²⁰⁴ countries). From the empirical point of view we analysed the relationships among health expenditure, health resources, their utilisation, the per capita GDP, and the health status of each country. Finally, we will present our conclusions and some guidelines for intervention in health policy from the perspective of integration and cohesion, both social and territorial, in the Mediterranean Area.

2 Healthcare services and economic development

Health and economic development are closely related. The World Health Organisation (WHO²⁰⁵, 1999) stated that health has huge economic value and that improvements in health have similar economic consequences to economic growth. They make it possible to escape from the poverty trap. There is a wide range of literature that relates health status in a territory with economic behaviour, conceived as economic growth or development.

Mankiw, Romer and Weil (1992) were the pioneers in extending the Solow economic model of growth incorporating human capital in it— a concept in which they included not only education but also health and nutrition. Other authors such as Fogel (1994), Barro and Sala (1995) continued studying the connection between health and economic growth, and at the end of the nineties and the beginning of the new millennium there was a quick development of these kind of studies (López-Casasnovas, Rivera and Currais, 2005).

Good health is a central component of welfare, but most of these studies justify the improvement of health as something positive in purely economic terms. The link between health and economic growth is made through the concept of human capital, which makes improvements possible in both individual productivity and growth rates of a country. Smith (1999) tried to explain the causality direction between health and economic growth through life-cycle models that relate health conditions with future income, consumption and welfare. Bloom and Canning (2000) reinforced this causality with an education factor. The higher the education levels are the greater the achievements of productivity and income levels are as well.

From a wider perspective of economic and social development, the WHO established in the Declaration of Alma-Ata (1978) the goal of attaining a health status that allows a social and economically productive life to all the people, considering it a fundamental human right (WHO, 1978). This relocation of health as a human right is directly linked to

²⁰⁴ Algeria, Egypt, Israel, Jordan, Lebanon, Libya, Morocco, Palestine, Syria, Tunisia, and Turkey.

²⁰⁵ WHO was set up on June 22, 1946 with the express purpose of achieving the highest possible level of health for all peoples, understanding that does not refer solely to the absence of disease or infection but to a state of full physical, mental and social wellbeing.

the human development approach promoted by the United Nations Program for Development (UNDP). The concept of human development promotes an expansion of human freedoms and the overcoming of the privations that limit the development of people. So, it is a priority to prevent the negative effects that situations of weakness of health services and other social and environmental determinants have on health.

Sen (1981) stated that health is one of the five instrumental freedoms needed for human development. In this context is where the importance of health for increasing the individual and collective capacities, defended by the theory of human development, begins to appear. Nussbaum (2002) specified a number of basic skills within the individual dimension of welfare pertaining to the human development approach, among which can be distinguished the possibility of being in good health. But individual welfare cannot be understood without framing it within the broader social dimension of the wellness process. This is where the need arises to take into account the collective capabilities that inform UNDP policies.

Human security is one of the axes considered within collective capabilities. This element has to do with predictability of human welfare, and it is especially vulnerable in a context of globalisation and economic and social crisis. Human security is embodied in the idea of freedom from fear, freedom from want and the avoidance of indignities (life of dignity).

The Human Development Report (UNDP, 1994) specified seven kinds of categories or threats to human security, including health security. So health is central to human security and development of human collective capabilities.

The importance of health in individual and collective capabilities justifies a broad analysis in which the state, the social agents, citizens, and the socio-institutional environment should be included. This analysis emphasises collective action and the obligation to have tools that facilitate the achievement of wellbeing in society (Wood, 2009).

In other words, the link between health and human development focuses the objective in expanding opportunities and capabilities of individuals and societies by guaranteeing both the universality of the right to health and the integrity of the health system and health services. This approach to health is holistic and multi-dimensional. It is based on the concept of patient-centred care and requires the state to guarantee universal access to health.

Compliance with these principles must be accompanied by inclusive public policies to improve access to health and the provision of related services in order to reduce social inequalities. Another axis of comprehensive intervention strategies is to promote social participation in health management and related services. The multidimensional perspective of health provided by human development requires taking into account some crucial policy elements, such as social and economic regulations with both national and international scope (The Lancet, 2014).

3 Health under the EU social cohesion framework

Social cohesion is one of the basic principles in the EU. Social protection systems are designed to offer risk protection in different spheres including health. Europe 2020²⁰⁶ Strategy and the Open Method of Coordination (OMC) for social protection and inclusion are the two main elements of the European framework to promote equity and social cohesion by means of sustainable and accessible protection systems as well as inclusive social policies.

The central axis of intervention is solidarity in health, i.e., reduction of inequalities in health within the EU. These inequalities undermine the efficiency and effectiveness of the European social model and erode social values²⁰⁷. And a wide range of causes is associated with these inequalities.

The current economic crisis affects negatively the provision of health services because of budget cuts that endanger the delicate balance in national health systems and increase health inequalities. This situation of greater vulnerability and increasing health inequalities within the EU can have irreversible consequences on social cohesion and productivity that can have negative long-term consequences on the economies of the member countries. Tackling health inequalities contributes, therefore, to the Community objectives of promoting economic growth and social cohesion.

The Commission for Social Protection (CSP) proposes several criteria for action to advance health equity, highlighting the incorporation of equality in health in the broader goals of social and economic development, the contribution of EU policies to reducing health inequalities, and the coverage of the needs of the most vulnerable sectors and groups²⁰⁸. In particular, it prioritises the need to ensure universal access to affordable and high quality health care, including prevention and health promotion, especially in the early stages of life. It also highlights the importance of ensuring coverage for all socioeconomic strata, particularly in rural and disadvantaged areas. In addition, a comprehensive approach to social determinants of health policy focused on both structural factors –life conditions or income policies– and discrete factors –exposure to risky lifestyles and risk factors– is emphasised.

Thus, policy coordination appears to be a crucial element for equal access to health and medical services. The Commission has identified a number of priorities: improving knowledge and information; establishing commitments

and agreements for cross-border cooperation; developing the contribution of different EU policies; and ensuring proper coordination between the national and the EU action plans to reinforce these priorities²⁰⁹.

4 EU cooperation policy in the Mediterranean

The Union for the Mediterranean promotes economic integration and democratic reforms in the 16 neighbouring countries to the south of the EU in North Africa and the Middle East. Cooperation agreements formerly known as the Barcelona Process were re-released in 2008 as the Union for the Mediterranean (UfM).

The re-launch was an opportunity to establish more concrete and visible relationships with the initiation of new regional and sub-regional projects with actual relevance to the inhabitants of the region. The projects focus on areas such as economy, environment, energy, health, migration and culture.

Along with the 28 member states of the EU, 16 Mediterranean countries in Africa and the Middle East are members of the UfM²¹⁰. Since 2011, the UfM strategy has been included within the structure of the Foreign Service of the European Union. Under the Treaty of Lisbon, this service channels all the foreign and security policy of the EU. With the EU support, a greater number of chronic diseases are treated in public hospitals and obstetric services in public hospitals have been improved. As a result, a greater number of births are attended to by trained medical personnel (MDG 4).

The Regional Strategy Paper 2007–2013 (RSP) provides the strategic framework for the programming of resources allocated by the EU for the Mediterranean region through the European Neighbourhood and Partnership Instrument (ENPI). This instrument provides coverage to the Mediterranean and Middle East, i.e., the members of the Euro-Mediterranean Society established in the Barcelona Declaration (1995). The Regional Strategy Paper and Regional Indicative Programme have been prepared in accordance with Council Regulation 1638/2006, which replaces the Financial Instrument for the region within the previous EU program for cooperation with Mediterranean countries (MEDA).

However, according to figures from the 2013 Annual Report on cooperation policies of the EU, the volume of resources really used in the Mediterranean region is well below that originally committed. In addition, health developments have a minimum financial impact.

5 Social, economic and health profiles

This section will address the quantitative study to analyse the trends in two groups of countries, EU-28 and MENA, in terms of chronological evolution and convergence –intra and intergroup. With this aim, the social and health context of the area is depicted and a descriptive analysis from the WHO databases, UNDP indicators, and the demographic data from the United Nations, World Bank, etc., is also offered as well as a cluster analysis. The analysis and variables have been divided into four areas (5.1 to 5.4).

5.1 Demographic and socioeconomic factors

There are numerous demographic and socioeconomic factors influencing the health status of the population in a given area. Here we have selected the most widely used in this type of studies, taking into account the limited availability of data²¹¹.

5.1.1 Raw birth and death rates

Among the demographic indicators, those related to natural population movements, i.e., births and deaths, for which birth rates and mortality rates were analysed, are particularly relevant. One of the demographic consequences of the progress of societies towards higher stages of development has been the declines in birth and death rates, giving rise to what has been called the demographic transition, which results in the aging of these societies.

Since the latter half of the last century, a downward trend of birth rates (BR) in both groups of countries has been observed. The MENA²¹² countries that started with clearly higher levels (between 33 ‰ in Israel to 53 ‰ in Algeria) than the EU-28, are currently presenting a BR well above those observed in European countries. (MENA countries maintain rates above 20 ‰ in most cases, while these rates in the EU-28 are around 10 ‰.).

As regards mortality rates (DR), in the mid-twentieth century, these were significantly higher in all MENA countries than in the EU-28 group, with the exception of Israel (the only MENA country classified by the World Bank in the group of "high income countries"). However, a significantly higher decrease in their evolution was noted in MENA countries, which currently places them with lower mortality rates than those of most EU-28 countries²¹³.

Figure 1. Evolution of BR and MR per thousand in the average of the EU and MENA. Source: Compiled from Population Data (UN, 2013).

5.1.2 Gross National Income per capita

Among socioeconomic factors, income level, measured by per capita gross income, is an indicator of the level of development that is widely used, as a measure of control over resources. Nevertheless, an increase in revenue without improvements in the levels of quality of life can occur. As the UNDP (2013) indicates, "what matters is not only the level of income but also the use given to such income. [...] the key is not in the process of maximising wealth but in the choice that countries make in transforming income into human development". At any rate, a lively discussion persists about whether there is divergence or convergence, i.e., whether the differences between poor and rich countries are increasing or are shrinking. Neoclassical growth models often predict that there will be convergence –that poor

²¹¹ Thus, although educational level would in principle be one of the factors to consider– given that education and literacy have contributed decisively to increasing the level of health by facilitating improvements in nutrition, hygiene and reproductive health–it has been postponed for further analysis with better data.

²¹² All have shown declines in birth rates of around 50% in the last 60 years, except Palestine (-30%), Israel (-36%) and Jordan (-37%).

²¹³ Most MENA lowered their MR more than 70%, or even as much as 80% like Libya. But comparing the MR can lead to confusion on a global analysis in which different demographic structures, in addition to the limitations in the sources used for country estimates, are not discussed.

countries increase their revenues²¹⁴ faster than the rich– but the reality, according to the most recent theories of endogenous growth, does not confirm this forecast.

Figure 2. Evolution of the average Gross National Income per capita and its coefficients of variation in the EU-28 and in the MENA. Source: World Health Organization (WHO), Global Health Observatory, Data Repository.

The evolution of per capita income in the period 1995-2011 shows an increase in the average rate of change of both groups of countries, the EU-28 (3.91%) and especially the MENA countries (4.49%), which started from significantly lower values. Regarding the deviations in income levels, the variation coefficients reveal that the dispersion in income levels is relatively higher in the MENA group, and in both cases these dispersions have been reduced in the period studied.

Beta-convergence is a particular measure that makes it possible to confirm the existence of convergence or divergence among income levels. We can say that there is beta-convergence²¹⁵ among the income levels of various countries if it is observed that poor countries have grown more than the rich, that is, if it can be shown that the fact of having a lower income is associated with higher rates of growth. In order to see this, the association between baseline per capita income –measured in natural logarithm– and variations on such income is analysed.

Figure 3. Beta convergence (per capita income [in NL] in 1980 and its variations until 2012). Source: World Health Organization (WHO), Global Health Observatory, Data Repository.

The negative slopes of the adjusted lines in the graphs show a weak convergence in both MENA and EU-28 countries. Similarity of these slopes indicates analogous speeds in the process of convergence in both groups. The issue is that the MENA start from much lower income and more dispersed values than in the case of the EU-28.

However, although there are large differences among groups of countries and regions, the most important ones are the existing inequalities within the countries themselves, as reflected by the values of the Gini coefficient of income. Higher values, the greatest inequality, are in MENA countries, mainly in Tunisia (41.4) and Morocco (40.9), although they are also high in some countries in the EU-28, especially in the newly incorporated (Lithuania, Latvia, Estonia) and between and outside the EU-15, in the Mediterranean area (Italy, Spain and Greece) (UNDP, 2013).

5.2 Health Status

As already discussed, health improvement is a central aspect to the MDGs, and in most developing countries the public sector stands as the main provider of these services. According to the World Bank²¹⁶, to reduce inequities, many nations have emphasised primary care, including vaccination, sanitation, access to clean water and safe maternity initiatives. In

²¹⁴ The growth rates of income influence many factors, such as political decisions of their leaders, the level of education of the people, technology development, etc.

²¹⁵ Defined according to Sala-i-Martin in 1990

²¹⁶ <http://www.bancomundial.org/es/topic/health>

this section, we will rely on comparisons between the values of the two indicators of life expectancy and infant mortality.

5.2.1 Life expectancy

Life expectancy (LE) is considered an essential component of the Human Development Index (HDI). In the past 50 years, LE has increased worldwide more rapidly than ever (IDB, 2008). In 2012, the average LE was 70.1 years, with substantial differences among countries.

Figure 4. Life expectancy at birth, 2011. Source: World Health Organization (WHO), Global Health Observatory, Data Repository.

According to WHO (WHO, 2013), the highest values of this indicator are in the group of EU countries that made up the EU-15 and in Israel, all with values above 80. The rest of the countries from the EU, Eastern Europe, together with the MENA have LE values of around 75 years, with Libya having the lowest value with only 65. But these LE levels have increased significantly in recent years, primarily in the MENA countries, which started mid last century with values well below 50, except for Lebanon and Israel.

5.2.2 Infant mortality

One of the most sensitive indicators of human welfare, also considered an important determinant of HDI, and fourth MDG, is child survival. According to UNDP (2013), in 2010 the global mortality rate of children under five was 55 deaths per 1,000 live births, although irregularly distributed by countries, so that the highest rate is for countries with a low HDI.

This scheme is basically apparent in the countries analysed. Thus, although rates have fallen significantly, the highest rates are shown in MENA countries with lower income and HDI values: Morocco (32), Algeria (30), Egypt (23), etc.

Figure 5. Trends in Infant Mortality Rate. Source: Compiled from Data Population (UN, 2013).

Poor child health may permanently affect the child's cognitive development and subsequently his or her labour productivity as an adult. Historically, a clear association between increased life expectancy and reductions in infant and child mortality has been observed.

In fact, if we perform a regression analysis of the LE data for 2011 of the countries analysed and child mortality rates for children under 5 years, we obtain a clearly significant model ($p = 2.7 \cdot 10^{-7}$ and $R^2 = 0.7242$) where the regression coefficient (-0.4288) indicates that there is an inverse relationship between IM and LE, that shows how IM rate reduces when LE increases.

5.3 Health services funding

In general, countries with higher public spending on health²¹⁷ and education have experienced higher levels of human development, although this may mask local variations (UNDP, 2013). We will focus mainly on the health expenses incurred by the public sector²¹⁸, and taking into account the intended population, i.e., per capita spending.

From the WHO²¹⁹ database of national health accounts we analysed the current situation and the evolution of health spending in the countries considered.

On one hand, we observed that higher levels of public spending per capita on health are in the EU-28²²⁰. European Mediterranean countries are in intermediate levels and the MENA at much lower values, especially Morocco, Syria and Egypt.

In both groups of countries, health expenses have increased significantly since 1995 to 2011, with the cumulative annual average change rates in Turkey (12.85%), Romania (10.95%), Lithuania (8.79%), etc., standing out; while those less advanced in this regard were Lebanon (0.62%) and Libya (1.34%).

Table 3 confirms that the public health expenditures have increased in the period considered, the average for the EU-28 being considerably higher than for the MENA, and that this difference has increased in recent years, and that discrepancies within groups of countries are much higher in MENA than in the EU-28. Furthermore, the convergence within the group of EU-28 has slowed with the crisis (from 2008), slightly increasing the distance between countries, while in the MENA it seems that the increase in the divergence has been greater and has occurred in the last two years.

²¹⁷ Total health expenditure is the sum of public and private expenditure on health as a proportion of the total population. It covers the provision of health services (preventive and curative), family planning activities, nutrition activities, and emergency aid designated for health, but does not include provision of water and sanitation.

²¹⁸ Public health expenditure consists of current and capital spending deriving from government budgets, external borrowing and grants (including international agencies and NGOs) and funding from social health insurance.

²¹⁹ <http://apps.who.int/nha/database>

²²⁰ Notable are the Benelux countries (Luxembourg, the Netherlands and Belgium), some Nordic countries (Sweden and Denmark), and Austria, Germany and France.

5.3.1 Cluster Analysis

To refine the convergence of countries in both groups, a cluster analysis as exploratory classification technique is performed, using the agglomerative hierarchical method, with data on health per capita spending of government (PHSp_c), the net income per capita (NI_{pc}) and LE and IM in 2011.

The dendrogram shows the first groups of countries based on these 4 variables, and from it, using the method of k-means partition algorithm we have opted for the 5 cluster model, considering that it best reflects the different typologies. This method offers slight variations in clusters, which are incorporated into the graphic dendrogram.

Figure 6. Groupings or cluster as the dendrogram resulting from clustering and k-means algorithm to 5 groups with data PHSp, NIpc, IM and LE 2011. Source: Elaborated with SPSS software package with data from World Health Organization (WHO), Global Health Observatory, Data Repository.

Thus, the 5 resulting clusters are the following:

Cluster 1: Germany, Austria, France, Luxembourg, the Netherlands and Sweden; EU-28 countries with higher levels of HPSpc (except Belgium and Denmark that are in group 2), higher levels of income, and high levels of LE and low IM.

Cluster 2: Belgium, Cyprus, Denmark, Slovenia, Spain, Finland, Greece, Ireland, Italy, Portugal and the UK; EU-28 countries along with Israel, most with high income, high health expenditures, high LE and low values of IM.

Cluster 3: Algeria, Egypt and Morocco; countries from the MENA group with lower health expenditures and income levels, low levels of LE and very high IM rates.

Cluster 4: Croatia, Estonia, Hungary, Lithuania, Malta and the Czech Republic; new members of the EU-28, with average income levels, not high health expenditures, intermediate values of LE and not very low IM, except for Czech Republic.

Cluster 5: Bulgaria, Slovakia, Latvia, Poland and Romania from the EU-28, and Jordan, Libya, Syria, Tunisia and Turkey, from the MENA group. It is a group of middle and low income, with lower values of LE than the rest of analysed countries, most of them with high values of IM, and all of them with low levels of PHSp.

5.4 Health system organisation: human resources and infant mortality

The debate on the determinants of health shows the limited impact of health services on the health status of the population. The good health of the population is an individual and collective objective sought for a long time.

In 1974, the Lalonde Report, entitled *A New Perspective on the Health of Canadians* (1981), showed, for the first time, from an industrialised country, that biomedical interventions (doctors services, hospitals, pharmacists, etc.) are not the main elements responsible for individual welfare, nor for improvements in the health status of the population. This report identified four areas that were interdependently responsible for the health of individuals: environmental aspects (physical and social), the human biology, lifestyle, and health services (quantity, quality, nature and relationships between population and health resources).

Therefore, health services are just one of many ways to maintain and improve the health of the population. In 1974, the Canadian government issued its advanced time approach. It is not just to provide health services in the traditional sense (beds, hospitals, operating rooms, etc.) but to provide educational services and information to protect the health of Canadians, making them partners of health professionals in preserving and improving their health status.

This approach established by the Canadian government inspired some principles in the Declaration of Alma-Ata (1978). There the rights and obligations of governments and population, with respect to health, the current health definition and the introduction of primary care as the level of provision of health services more tied to environmental determinants of health and citizens' lifestyle, were established.

The process of economic development in industrialised countries and the indisputable advances in specialised care have made us forget the crucial role of primary care services in maintaining the health of the population. In recent years, since the leading causes of death in OECD countries and the development process and changes in habits and lifestyles (Bloom et al., 2011) are linked, a renewed interest in educational services for the health-oriented population is emerging. Progress in cardiovascular diseases as leading causes of death among the population in developed countries creates a renewed interest in healthy lifestyles (Teo, K. et al., 2013).

The results in terms of health of the MENA countries are not solely determined by the development of health services. As noted, health is subject to multiple conditions with more weight than the development of health services in the classical sense. However, it is assumed that there is a clear impact of health services understood as development of health education.

Following this reasoning the relationship between the development of human resources for health services and an intermediate indicator of health outcomes with high impact such as the infant mortality rate is analysed. In this analysis, infant mortality (deaths under age 5 per 1000 live births) depends on the prevalence of doctors and nurses (density per 1000) independently. The descriptive analysis provides large differences in the outcome variable, the average infant mortality rate of 5.6 ‰ in EU28 countries compared to 20.5 ‰ in the MENA countries. These variations correspond to very different endowments in terms of personnel employed in health services.

The results of this analysis show a loss of intensity in the relationship between health workforce and outcomes in terms of infant mortality, as countries are acquiring a greater degree of economic development. The adjustment of a potential function yields a greater association in the MENA than in the UE28 countries. However, the association degree between each of the explanatory variables and the dependent one is strengthened when we include both groups of countries in the regression analysis.

In the graphs, the high level of association between the development of nurse staffing levels and the decline in the infant mortality rate can be observed. This fact is consistent with the development of primary care and its effects in terms of health education, a task mainly developed by the nursing staff. In terms of health policy and convergence between the two groups of countries, there is obvious room for improvement in MENA countries, where the insufficient development of a primary care system with a full territorial coverage is still indisputable.

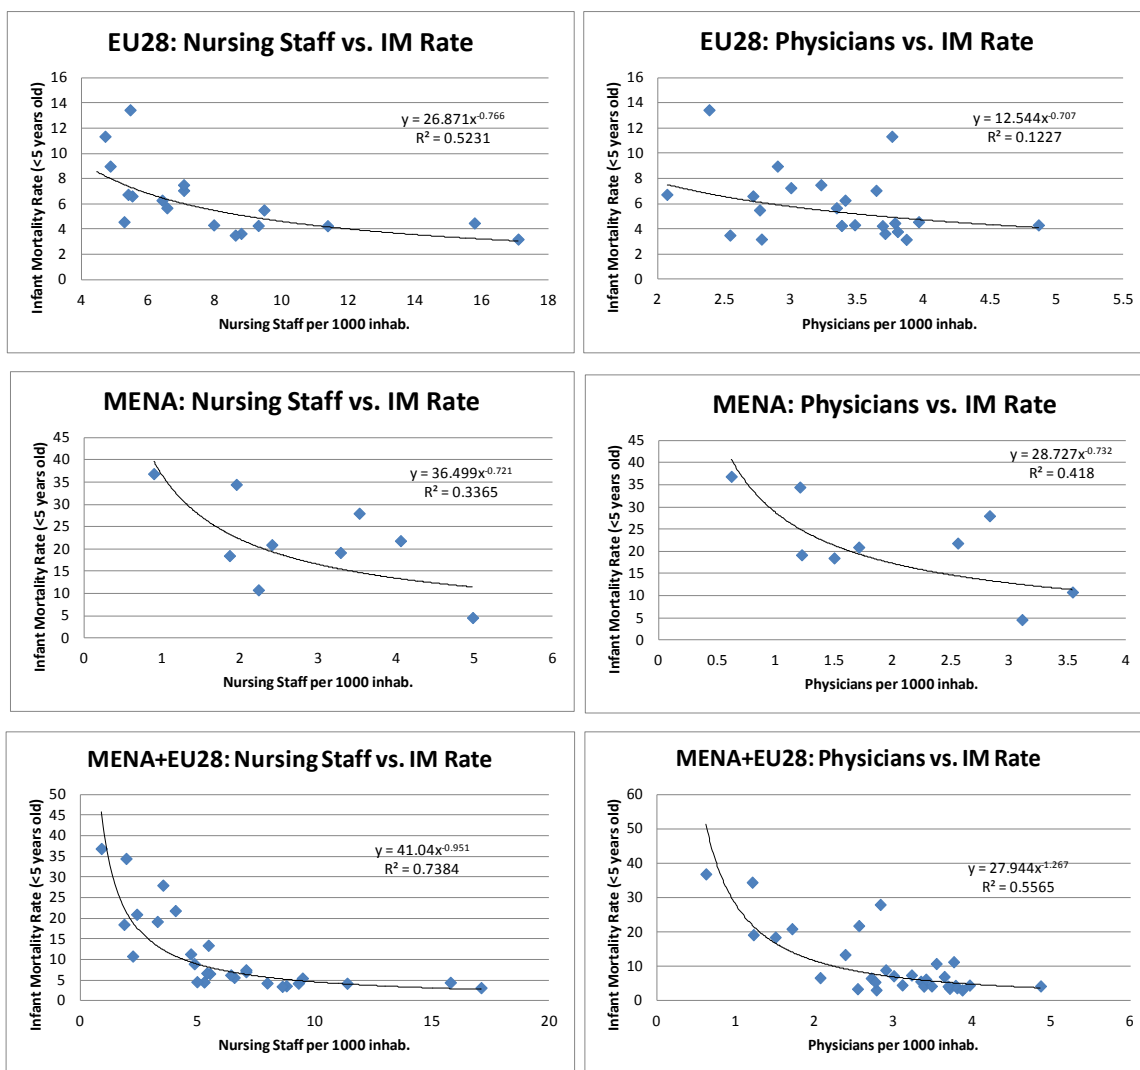

Figure 7. Medical staff versus infant mortality rate (IMR). Source: World Health Organization (WHO), Global Health Observatory, Data Repository.

6 Conclusions

In this work we have seen the evolution of the concept of health from a biomedical perspective to another more related to human development and individual and collective capabilities.

Given the exploratory nature of this study, our conclusions are not centred in the discussion of singular findings, but instead point out a number of key aspects that should guide the development of health services in the group of MENA countries.

As a final review of some key ideas presented throughout this work, we wish to emphasise the following:

- Health is both a result and a determinant factor for economic development. Hence improving health remains central to the MDGs.
- As usually happens in the development of economic growth theories, human capital has become a central element of the circular relationship: health-development-health.
- The importance of health goes beyond the individual component, in that it also links to socio-institutional elements of clear impact on economic policy and particularly in public policy: social participation strategies in the management of health and related services.
- As social policy, health policy is linked to the reduction of inequalities in health and access to health services. In this regard, the WHO has set the goal of universal health coverage.
- Within the framework of the EU, health inequalities have become part of cohesion policy. The Europe 2020 Strategy prioritises the need to ensure universal access to affordable and high quality health care services, including prevention and health promotion.
- Within the EU, health systems and associated services are a key area of attention in the cooperation policy for cohesion among the EU countries through the MAC method. The priorities of the MAC method are specified in the access, quality and sustainability of health systems.

- The volume of resources actually used in the Mediterranean region is well below the initial commitment and further developments in health have minimal financial impact.
- The social realities in terms of health are very different between the two groups, EU-28 and MENA. A large gap is observed in terms of life expectancy.
- Life expectancy is strongly associated with per capita income and the amount of public resources invested in health. The case of infant mortality is a clear example analysed in this work.
- The main concerns in terms of economic policy are also very different. While the EU-28 debates the viability and sustainability of universal and accessible health systems that absorb a high percentage of public resources, MENA countries have clearly inadequate human resource endowments in healthcare services that generate an unbridgeable gap in terms of health outcomes.

Once certain levels of quality in health services have been achieved, the allocation of additional resources does not necessarily lead to an improvement in health outcomes. However, the situation seen in the MENA countries has not yet reached this inefficiency threshold of public resources in health services. Therefore, our final recommendation advocates strengthened national efforts and cooperation within EU projects in the MENA countries' health services. These endeavours would have the aim of seeking to consolidate an effective primary care system with universal coverage and guaranteed accessibility.

Green Investments and Sustainable Healthcare Systems

José Luis Navarro Espigares^{1,2}, José Aureliano Martín Segura¹

¹University of Granada, ²Virgen de las Nieves University Hospital

The current economic crisis represents both a threat and an opportunity to design health systems for the future. In the context of advanced economies, health expenditures are rapidly increasing and great concern about their financial sustainability urges a new orientation. Most experts agree that sustainability is unlikely to be achieved through incremental changes. Transformative solutions will be needed, solutions that require cooperation across industry sectors and governments.

This work addresses the healthcare systems sustainability objective from the perspective of reducing the demand of health services. Cooperation across industry sectors is a crucial issue in achieving healthier populations that demand less health care.

This research work poses the question: how are green-investments affecting health and healthcare systems sustainability? Thus, we will try to quantify the financial impact of investments in eco-efficient technologies on healthcare costs and vice versa.

1 Introduction

To increase the sustainability of health systems is one of the four main objectives of the European Programme “Health for Growth”. The reason why EU emphasises sustainable health systems is based on four main challenges: an ageing population of the EU Member States, more effective but also more expensive health technologies, the need for progress in prevention of chronic diseases, and the global and cross-border health threats.

The current economic crisis represents both a threat and an opportunity to design health systems for the future. In the context of advanced economies, health expenditures are rapidly increasing and great concern about their financial sustainability urges a new orientation. Most experts agree that sustainability is unlikely to be achieved through incremental changes. Transformative solutions will be needed, solutions that require cooperation across industry sectors and governments.

To achieve a sustainable health system for the future, societies must reshape demand for health services, reducing the burden of disease by helping people stay healthy and empowering them to manage their health. Health systems can encourage people to develop healthier habits, incentivise healthier consumption, and develop an environment and infrastructure that facilitate population health.

This work addresses the healthcare systems sustainability objective from the perspective of reducing the demand of health services. Cooperation across industry sectors is a crucial issue in achieving healthier populations that demand less health care.

This research work poses the question: how are green-investments affecting health and healthcare systems sustainability? Thus, we will try to quantify the financial impact of investments in eco-efficient technologies on healthcare costs.

The next section is devoted to the methodology followed and presents the main hypotheses defended in the work. The third section offers a summary on what the literature says about our main arguments, which are the following: impact of economic activity on environment, impact of environmental issues on health conditions, impact of health conditions on health systems sustainability, and impact of green investments on health systems sustainability. The results section is based on costs of diseases and the opportunity to finance the transition towards a green economy. Finally, we will present some conclusions oriented to policy action.

2 Methods

By means of a literature review and some empirical estimation we will support the following sequence of hypotheses:

- Economic activity impacts on Environmental issues (literature review, IPAT theory).
- Environmental issues have relevant effects on health conditions (literature review, association IPAT/mortality).
- Health conditions are a crucial factor regarding the sustainability of health systems (literature review).
- Green investments can relieve environmental issues (literature review, empirical).
- Green investments can be a help to health systems sustainability (literature review).

First, we will present what specialised literature says about these relationships.

Then, with data provided by the World Bank, we will calculate the Ehrlich and Holdren index for all countries in the world during the period 1961-2012. This index (IPAT) represents the impact on the environment resulting from economic activity. It combines three variables— the population number, the consumption per capita (affluence), and the technology factor.

Next, by means of a panel data econometric model, we will study the association between this index and mortality rates. In accordance with Amartya Sen, mortality rate will be used as a proxy variable representing the health status of the population.

We will also relate the IPAT index with green investments, i.e., investments that enable economic growth and at the same time improve the environment.

By means of the previous relationships, we will discern the impact of green investment on the IPAT index and the impact of the IPAT index on the health of the population.

From a literature review we will obtain the relationship between environmental factors and health status and the relationship between health status and demand for health care.

3 Literature review

3.1 Impact of economic activity on Environment

As the 2002 United Nations Environment Programme (UNEP) Annual Report stated, the growing attention to issues of sustainable consumption is a natural outcome of decades of work on cleaner production and eco-efficient industrial systems. It represents the final step in a progressive widening of the horizons of pollution prevention— a widening which has gone from a focus on production processes, to products (ecodesign to lower product impacts), then to product-systems (incorporating transport logistics, end-of-life collection and component reuse or materials recycling), and to eco-innovation (new products and product-systems designed for win-win solutions for business and the environment). Action focused on consumption has highlighted the need to address the creation of new systems of production and consumption, systems that might be truly sustainable, environmentally, economically, systems that will enhance the quality and equality of cultural, social and physical existence for all people.

This report includes the consumption equation from Ehrlich and Holdren (Ehrlich and Holdren, 1971). This equation describes the relationship between population, consumption and environmental impact in approximate terms as the following:

$$TEI = P \times UC/ph \times EE^{-1}$$

Where TEI is total environmental impact, P is population, UC/ph is (average) units of consumption of products and services per head of population, and EE is the environmental efficiency of the production, use and disposal of those units.

This equation makes it easy to visualise the importance of considering levels of consumption of goods and services (per head) and the resources used (and waste generated) to produce those goods and services. The expression “patterns of consumption” is a term that seeks to capture both of these variables.

Consumption pressure per head describes the (aggregated) product of the two terms UC/ph and the inverse of EE.

It is from such an equation that the concept of factor 4 (etc.) emerges— being the level of change in EE that can be achieved through technical and organisational improvements (cleaner production, product re-design, etc.)

If the intent is to reach some specific level of TEI (say for CO₂ production) in a given period, then estimates of the likely population growth over that period, as well as the likely rise in the average level of consumption per head (from development, GDP growth, etc), will define the factor of improvement in EE necessary to compensate for this rise.

Arguments that arise over the role of population growth in environmental degradation can also be clarified with reference to this equation, since it is clear that the issue is the product of population numbers times the average consumption pressure per head. Rebound effects arise from a relationship between UC/hp and EE, where improvements in EE generate increased consumption per head.

Factor X and dematerialisation are two relevant concepts also included in this UNEP Report.

This technical improvement in the environmental /resource efficiency of production and products is encapsulated in two widely used concepts: Factor Four (also Factor 10, Factor 20, etc.), from Weizsäcker, Lovins and Lovins (1997) and their book of the same name, and dematerialisation.

Factor Four refers to a halving of total material input into the economy while doubling wealth and welfare.

Dematerialisation is more a general approach which proposes a progressive and significant reduction in material throughput in the economy, i.e., reducing material flows in production and products, whilst maintaining (or increasing) value.

Both of these concepts suggest a shift in the economy towards an increasing value for ‘natural capital’: ‘Natural capital includes all the familiar resources used by mankind: water, minerals, oil, trees, fish, soil, air... it also encompasses living systems.’(Hawken, Lovins, and Lovins, 1999).

‘Dematerialisation’ and ‘factor X’, like the umbrella term ‘eco-efficiency’ are strategies for delinking the economy from resource-use and waste-production.

After the initial formulation of the consumption equation, it was better known under a different formula, the IPAT equation. This equation represents environmental impact, (I), as the product of three variables, (1) population, (P); (2) affluence, (A); and (3) technology, (T). The IPAT equation and related formulas were born, along with the modern environmental movement, circa 1970.

IPAT is an identity simply stating that environmental impact (I) is the product of population (P), affluence (A), and technology (T).

$$I = PAT$$

Although generally credited to Ehrlich, Commoner also plays an important role in the formulation of the IPAT equation. Commoner's work in his popular 1971 book, *The Closing Circle*, became the first to apply the IPAT concept with mathematical rigour.

In order to make operational the three factors that influence I, environmental impact, Commoner defined I as "the amount of a given pollutant introduced annually into the environment." His equation, published in a 1972 conference proceedings (Commoner, 1972a), is the following:

$$I = \text{Population} \times \frac{\text{Economic good}}{\text{Population}} \times \frac{\text{Pollutant}}{\text{Economic good}}$$

Population is used to express the size of the U.S. population in a given year or the change in population over a defined period. Economic good is used to express the amount of a particular good produced or consumed during a given year or the change over a defined period and is referred to as "affluence." Pollutant refers to the amount of a specific pollutant released and is thus a measure of "the environmental impact (i.e., amount of pollutant) generated per unit of production (or consumption), which reflects the nature of the productive technology" (Commoner 1972a, 346).

Used in this way, the equation takes on the characteristics of a mathematical identity. On the right-hand side of the equation, the two Populations cancel out, the two Economic goods cancel out, and what remains is: I = Pollutant.

$$I = \text{Population} \times \frac{\text{Economic good}}{\text{Population}} \times \frac{\text{Pollutant}}{\text{Economic good}}$$

His main value, then, is to estimate the contribution of each of the three terms to total environmental impact.

$$\text{Pollution} = (\text{population}) \times (\text{production/capita}) \times (\text{pollution emission/production})$$

The very first time the reference $I = P \times A \times T$ appears in writing is as part of the Critique and Response in 1972, in which Ehrlich and Holdren take the previous Commoner equation from a footnote from *The Closing Circle* and, express it as $I = P \times A \times T$.

Since the 70's, different approaches and interpretations have appeared from the initial equation mainly regarding the environmental consequences of the various factors, P, A and T. During the 80's, special attention was paid to the T factor. In essence, a new generation of technological optimists finds that experiments in changing human behaviour to vary the course of P and A are highly uncertain. The concepts of the IPAT equation are at the core of the emerging field of industrial ecology in the 90's. Industrial ecology has been described as the "marriage of technology and ecology" and examines, on the one hand, the environmental impacts of the technological society, and, on the other hand, the means by which technology can be effectively channelled towards environmental benefit (Graedel and Allenby 1995). Graedel, however, has some revisionist thinking about A, the affluence term (Graedel, 2000). Graedel has suggested that the essence of the A term resides in its cultural and behavioural attributes.

In conclusion, this equation and its different interpretations underline the relevant impact of economic activity on environment. Technology, although associated with both disease and cure for environmental harm, is a critical factor in environmental improvement (Chertow, 2001). This emphasises the role of innovation (technological and social) in improving environment.

3.2 Impact of environmental issues on health conditions

In 1974 the Lalonde report *A New Perspective on the Health of Canadians* pointed out the existence of the so-called counter-forces which constitute the dark side of economic progress. They include environmental pollution, city living, habits of indolence, the abuse of alcohol, tobacco and drugs, and eating patterns. The report emphasised that physicians, surgeons, nurses and hospitals together spend much of their time in treating ills caused by adverse environmental factors and behavioural risks. It confirmed that self-imposed risks and the environment are the principal or most important underlying factors in each of the five major causes of death between age one and age seventy. So, unless the environment is changed and the self-imposed risks are reduced, the death rates will not be significantly improved. It presented the first proofs and measures on the total effect of air pollution on health, establishing a direct cause-and-effect relationship between air pollution and sickness.

The report introduced the term Health Field. The term "health care system" is limited to the system by which personal health care is provided. The term "health field" is much broader and includes all matters affecting health. Health field can be broken down into four broad elements: human biology, environment, lifestyle, and health care

organisation. These components have different importance in relation with the major problems of health: human biology (27%), **environment (19%)**, lifestyle (43%), and health care organisation (11%).

The environment category includes all those matters related to health which are external to the human body and over which the individual has little or no control. Individuals cannot, by themselves, ensure that foods, drugs, cosmetics, devices, water supply, etc., are safe and uncontaminated; that the health hazards of air, water and noise pollution are controlled; that the spread of communicable diseases is prevented; that effective garbage and sewage disposal are carried out; and that the social environment, including the rapid changes in it, do not have harmful effects on health.

The Lalonde approach can be considered innovative because it includes some social determinants of health into the concept of environmental conditions. In this sense it referred to economic deprivation, social change, new technologies, and the pursuing of private pleasure instead of common good.

Finally, it concludes that future improvements in the level of health of Canadians lie mainly in improving the environment, moderating self-imposed risks, and adding to our knowledge of human biology.

With Lalonde's Report a new line of research was opened and it continues nowadays. Currently, the World Health Organisation (WHO) promotes a number of studies on the relationship between environment and health.

Outdoor air pollution is a major environmental health problem affecting everyone in developed and developing countries alike. WHO estimates that some 80% of outdoor air pollution-related premature deaths were due to ischemic heart disease and strokes, while 14% of deaths were due to chronic obstructive pulmonary disease or acute lower respiratory infections; and 6% of deaths were due to lung cancer.

Some deaths may be attributed to more than one risk factor at the same time. For example, both smoking and ambient air pollution affect lung cancer. Some lung cancer deaths could have been averted by improving ambient air quality, or by reducing tobacco smoking.

A 2013 assessment by WHO's International Agency for Research on Cancer (IARC) concluded that outdoor air pollution is carcinogenic to humans, with the particulate matter component of air pollution most closely associated with increased cancer incidence, especially cancer of the lungs. An association also has been observed between outdoor air pollution and increase in cancer of the urinary tract/bladder.

Ambient (outdoor air pollution) in both cities and rural areas was estimated to cause 3.7 million premature deaths worldwide per year in 2012; this mortality is due to exposure to small particulate matter of 10 microns or less in diameter (PM₁₀), which cause cardiovascular and respiratory disease, and cancers.

People living in low- and middle-income countries disproportionately experience the burden of outdoor air pollution with 88% (of the 3.7 million premature deaths) occurring in low- and middle-income countries, and the greatest burden in the WHO Western Pacific and South-East Asia regions.

The latest burden estimates reflect the very significant role air pollution plays in cardiovascular illness and premature deaths – much more so than was previously understood by scientists.

Most sources of outdoor air pollution are well beyond the control of individuals and demand action by cities, as well as national and international policymakers, in sectors like transport, energy waste management, buildings, and agriculture.

In addition to outdoor air pollution, **indoor smoke** is a serious health risk for some 3 billion people who cook and heat their homes with biomass fuels and coal. Some 4.3 million premature deaths were attributable to household air pollution in 2012. Almost that entire burden was in low-middle-income countries as well.

The 2005 "WHO Air quality guidelines" offer global guidance on thresholds and limits for key air pollutants that pose health risks. The Guidelines apply worldwide and are based on expert evaluation of current scientific evidence for the following:

- particulate matter (PM)
- ozone (O₃)
- nitrogen dioxide (NO₂)
- sulphur dioxide (SO₂), in all WHO regions.

The paper from Lim et al. published in 2012 estimated deaths and disability-adjusted life years (DALYs, sum of years lived with disability [YLD], and years of life lost [YLL]) attributable to the independent effects of 67 risk factors and clusters of risk factors for 21 regions in 1990 and 2010. They estimated exposure distributions for each year, region, sex, and age group, and relative risks per unit of exposure, by systematically reviewing and synthesising published and unpublished data. They used these estimates, together with estimates of cause-specific deaths and DALYs from the Global Burden of Disease Study 2010, to calculate the burden attributable to each risk factor exposure compared with the theoretical-minimum-risk exposure. These calculations incorporated uncertainty in disease burden, relative risks, and exposures into our estimates of attributable burden.

Among other findings this article highlights that in 2010 the three leading risk factors for global disease burden were high blood pressure (7.0% [95% uncertainty interval 6.2–7.7] of global DALYs), tobacco smoking including second-hand smoke (6.3% [5.5–7.0]), and alcohol use (5.5% [5.0–5.9]). In 1990, the leading risks were childhood underweight (7.9% [6.8–9.4]), household air pollution from solid fuels (HAP; 7.0% [5.6–8.3]), and tobacco smoking including second-hand smoke (6.1% [5.4–6.8]). However, in most of sub-Saharan Africa, childhood underweight, HAP, and non-exclusive and discontinued breastfeeding were the leading risks in 2010, while HAP was the leading risk in south Asia.

Table 1. Global risk factor ranks with 95% UI for all ages and sexes combined in 1990, and 2010, and percentage change PM=particulate matter. UI=uncertainty interval. SHS=second-hand smoke. An interactive version of this figure is available online at <http://healthmetricsandevaluation.org/gbd/visualizations/regional>.

1990		2010		
Mean rank (95% UI)	Risk factor	Risk factor	Mean rank (95% UI)	% change (95% UI)
1.1 (1-2)	1 Childhood underweight	1 High blood pressure	1.1 (1-2)	27% (19 to 34)
2.1 (1-4)	2 Household air pollution	2 Smoking (excluding SHS)	1.9 (1-2)	3% (-5 to 11)
2.9 (2-4)	3 Smoking (excluding SHS)	3 Alcohol use	3.0 (2-4)	28% (17 to 39)
4.0 (3-5)	4 High blood pressure	4 Household air pollution	4.7 (3-7)	-37% (-44 to -29)
5.4 (3-8)	5 Suboptimal breastfeeding	5 Low fruit	5.0 (4-8)	29% (25 to 34)
5.6 (5-6)	6 Alcohol use	6 High body-mass index	6.1 (4-8)	82% (71 to 95)
7.4 (6-8)	7 Ambient PM pollution	7 High fasting plasma glucose	6.6 (5-8)	58% (43 to 73)
7.4 (6-8)	8 Low fruit	8 Childhood underweight	8.5 (6-11)	-61% (-66 to -55)
9.7 (9-12)	9 High fasting plasma glucose	9 Ambient PM pollution	8.9 (7-11)	-7% (-13 to -1)
10.9 (9-14)	10 High body-mass index	10 Physical inactivity	9.9 (8-12)	0% (0 to 0)
11.1 (9-15)	11 Iron deficiency	11 High sodium	11.2 (8-15)	33% (27 to 39)
12.3 (9-17)	12 High sodium	12 Low nuts and seeds	12.9 (11-17)	27% (18 to 32)
13.9 (10-19)	13 Low nuts and seeds	13 Iron deficiency	13.5 (11-17)	-7% (-11 to -4)
14.1 (11-17)	14 High total cholesterol	14 Suboptimal breastfeeding	13.8 (10-18)	-57% (-63 to -51)
16.2 (9-38)	15 Sanitation	15 High total cholesterol	15.2 (12-17)	3% (-13 to 15)
16.7 (13-21)	16 Low vegetables	16 Low whole grains	15.3 (13-17)	39% (32 to 49)
17.1 (10-23)	17 Vitamin A deficiency	17 Low vegetables	15.8 (12-19)	22% (16 to 28)
17.3 (15-20)	18 Low whole grains	18 Low omega-3	18.7 (17-23)	30% (21 to 35)
20.0 (13-29)	19 Zinc deficiency	19 Drug use	20.2 (18-23)	57% (42 to 72)
20.6 (17-25)	20 Low omega-3	20 Occupational injury	20.4 (18-23)	12% (-22 to 58)
20.8 (18-24)	21 Occupational injury	21 Occupational low back pain	21.2 (18-25)	22% (11 to 35)
21.7 (14-34)	22 Unimproved water	22 High processed meat	22.0 (17-31)	22% (2 to 44)
22.6 (19-26)	23 Occupational low back pain	23 Intimate partner violence	23.8 (20-28)	0% (0 to 0)
23.2 (19-29)	24 High processed meat	24 Low fibre	24.4 (19-32)	23% (13 to 33)
24.2 (21-26)	25 Drug use	25 Lead	25.5 (23-29)	160% (143 to 176)
	26 Sanitation	26 Sanitation		
	30 Lead	29 Vitamin A deficiency		
		31 Zinc deficiency		
		33 Unimproved water		

— Ascending order in rank
- - - Descending order in rank

Although, fortunately, both risk factors related with air pollution (Household Air Pollution and Ambient Particulate Matter Pollution) show a decreasing trend between 1990 and 2010, these two factors in sum represent in 2010 13.6% of total global disability-adjusted life-years lost.

Air pollution is already known to increase risks for a wide range of diseases, such as respiratory and heart diseases. Studies indicate that in recent years exposure levels have increased significantly in some parts of the world, particularly in rapidly industrialising countries with large populations. The most recent data indicate that 223,000 deaths from lung cancer worldwide resulted from air pollution²²¹ in 2010.

The specialised cancer agency of the World Health Organization, the International Agency for Research on Cancer (IARC), announced in 2013 that it has classified outdoor air pollution as carcinogenic to humans²²². After thoroughly reviewing the latest available scientific literature, the world's leading experts convened by the IARC Monographs Programme concluded that there is sufficient evidence that exposure to outdoor air pollution causes lung cancer. They also noted a positive association with an increased risk of bladder cancer. Particulate matter, a major component of outdoor air pollution, was evaluated separately and was also classified as carcinogenic to humans.

Volume 109 of the IARC Monographs evaluations is based on the independent review of more than 1000 scientific papers from studies on five continents. The reviewed studies analyse the carcinogenicity of various pollutants present in outdoor air pollution, especially particulate matter and transportation-related pollution. The evaluation is driven by findings from large epidemiologic studies that included millions of people living in Europe, North and South America, and Asia (Loomis et al., 2013).

In 2004, after the recognition that air pollution might have an impact on cardiovascular disease, the UK Department of Health asked the Committee on the Medical Effects of Air Pollutants (COMEAP) to advise on the possible effects of outdoor air pollutants on cardiovascular disease in the UK. The Committee formed a Sub-Group which reviewed the literature in detail and drafted a report. The Committee on the Medical Effects of Air Pollutants undertook an extensive review of the evidence for these effects, to assess possible mechanisms and identify areas for future research. In 2006,

²²¹ <http://www.iarc.fr/en/publications/books/sp161/index.php>

²²² The summary evaluation was published by The Lancet Oncology online on Thursday, 24 October, 2013.

eighteen months later, it published a report in which the state of the art in all respects was presented— short and long terms effects as well as the confirmation that modest reductions in exposure will result in significant health gains.

The principal conclusions of the report are that clear associations have been reported between both daily and long-term average concentrations of air pollutants and effects on the cardiovascular system, reflected by a variety of outcome measures including risk of death and of hospital admissions; these associations are likely to be causal in nature; and, although it is not possible to be certain which components of the ambient pollution mixture are responsible for these effects, it is likely that fine particles play an important role (Straif; Cohen; and Samet, 2013).

Another relevant environmental issue related to health is the exposure to chemical pollutant, the so called endocrine disrupters. The 2013 Berlaymont Declaration on Endocrine Disrupters expressed the concern of 89 scientists actively engaged in endocrine disrupter research. This Declaration gathers the conclusions of the scientific convention organised by the European Commission to discuss forthcoming policy initiatives for endocrine disrupters.

The Declaration confirms the concern about the prevalence increase of endocrine-related diseases, higher than it has ever been. The disease burden continues to increase in the EU and globally. Evidence is strengthening that environmental factors, including chemical exposures, play a role in these phenomena.

Some recent reports from the European Environment Agency, in a European Commission— a funded report and an assessment conducted under the auspices of the World Health Organisation and the United Nations Environmental Programme²²³— point out the incremental prevalence of endocrine-related diseases in the European Union and globally:

- In some EU Member States, large proportions of young men have semen quality so poor that it will seriously affect their chances of siring children.
- There is a dramatic rise in breast cancer in Eastern and Southern European EU Member States.
- With the exception of high prevalence countries such as The Netherlands and Austria, all EU countries are experiencing strong rises in prostate cancer. Similar trends exist for other hormonal cancers, including those of the testes, endometrium, ovaries, and thyroid.
- Neurobehavioural disorders, and thyroid diseases and disorders affecting brain development, represent a high and increasing paediatric disease burden in countries where these disease trends have been followed.
- The prevalence of obesity and its comorbidity factors, type 2 diabetes, and metabolic syndrome have increased dramatically in almost all EU Member States.

Finally, these scientists call we the European Commission to implement a regulatory regime that classifies endocrine disrupters by using weight-of-evidence approaches and to develop a targeted research strategy for endocrine disrupting chemicals (EDCs) as part of Horizon 2020.

3.3 Health systems sustainability and health conditions

In accordance with the Ladonde Report (1974), economic progress has brought to us an evident improvement in the health status of the population, but also some problems such as environmental pollution, city living, habits of indolence, the abuse of alcohol, tobacco and drugs, and non-desirable eating patterns. These counterforces have been at work to undo progress in raising the health status. Thus, they constitute the dark side of economic progress.

Nevertheless, from a different point of view, health is not just a value in itself. It is also a driver for growth. Only a healthy population can achieve its full economic potential. The health sector is driven by innovation and a highly qualified workforce. The healthcare sector is one of the largest in the EU. It accounts for approximately 10% of the EU's gross domestic product and employs one in ten workers, with a higher than average proportion of workers with a tertiary-level education.

Health therefore plays an important role in the Europe 2020 agenda. In its Communication of 29 June 2011 'A budget for Europe 2020' the Commission stressed that 'promoting good health is an integral part of the smart and inclusive growth objectives for Europe 2020. Keeping people healthy and active for longer has a positive impact on productivity and competitiveness. Innovation in healthcare helps take up the challenge of sustainability in the sector in the context of demographic change', and action to reduce inequalities in health is important to achieve 'inclusive growth'.

All these reasons explain why from the public and institutional perspective, sustainability of health systems is a permanent concern. The financial crisis has further highlighted the need to improve the cost-effectiveness of health systems. Member States are under pressure to strike the right balance between providing universal access to high-quality health services and respecting budgetary constraints.

 UNEP WHO (2013) State of the science of endocrine disrupting chemicals – 2012 (Editors: Bergman A, Heindel JJ, Jobling S, Kidd KA, Zoeller RT. http://www.unep.org/pdf/9789241505031_eng.pdf

In this context, the European Commission considers that supporting Member States’ efforts to improve the sustainability of their health systems is crucial to ensure their ability to provide high quality healthcare to all their citizens now and in the future. And, with this aim, in 2011 it launched the Health for Growth Programme. This Programme has four objectives and three of them maintain a close alignment with our hypotheses. They are to encourage innovation in healthcare, to increase the sustainability of health systems, to improve the health of EU citizens, and to protect citizens from cross-border health threats.

In this line, the Budget for Europe 2020 assigns the following funding distribution for the health objectives (Table 2):

Table 2. EU Budget for Health 2014-2020. Source: European Commission, COM(2011) 500 final.

Total proposed budget 2014-2020	€2.75 bn
of which	
• Food Safety	€2.2 bn
• Health for Growth Programme	€396 million
• Consumers Programme	€175 million

Most of the financial resources go to the Food Safety Programme, clearly oriented to cope with health problems derived from endocrine disrupting chemicals.

Not only are there institutional instances where concern is shown about sustainability of healthcare systems, but also private economic agent are alarmed about this worry. The World Economic Forum (WEF, 2013) considers that health systems sustainability is unlikely to be achieved through incremental changes. Instead, transformative solutions will be needed – solutions that require cooperation across industry sectors and governments, and thereby challenge the current boundaries of healthcare.

This report stresses the differences between “healthcare system” and “health system”. Both are often used interchangeably, but there is an important distinction between them. The healthcare system describes the institutions, facilities, and actors involved in delivering healthcare services. This report refers to healthcare system activities as supply-side. The health system denotes a much wider range of institutions and actors beyond the traditional so-called health sector, including actors who directly or indirectly influence and affect health in a society (e.g., food and beverage companies).

The health system is regarded as having a more balanced focus on both supply and demand, with demand referring to policies and services aimed at encouraging healthy lifestyles and preventing disease. Pushing the boundaries of the healthcare system to include a wider ecosystem of influences on health pushes stakeholders to better consider the demand side and questions the way in which governance of health is currently organised.

That demand side perspective is crucial for our aim in warning about the environment impact on health and health systems sustainability.

The Forum explored the fundamental influences on healthcare expenditure, creating a simple conceptual model of demand and supply elements.

Growing demand for healthcare is driven primarily by four factors: an ageing population, an explosion of so-called lifestyle diseases, a rise in public expectations, and a lack of value-consciousness among healthcare consumers.

On the supply side, the cost of care continues to rise, while resources are not allocated in the best way. The rise in unit costs is driven by the advent of new therapies and technologies, together with innovative strategies that focus on better outcomes rather than lower costs. This is compounded by poor allocation of resources in a healthcare delivery system often closed to change (because of vested interests), and an incentive structure that does not always reward value creation.

With the aim of identifying critical uncertainties, by means of interviews with experts, the Forum identified 20 drivers of change for health systems grouped into five dimensions. One of these five dimensions was the “environmental”, and it includes four key drivers: climate change, pollution and toxicity, incidence of infectious diseases, and population sanitation.

Health systems sustainability concern has also been treated from a more theoretical Economics perspective. The apparently unrelenting growth in the GDP-share of health spending (SHS) has been a recurrent issue of policy concern. Recent studies raise the question about the existence of an equilibrium limit (Ehrlich and Yin, 2013). This issue has been left open in the latest dynamic models, which take income growth and population aging as given (Hall and Jones, 2007). Ehrlich and Yin developed a human capital-based endogenous growth model treating these variables as endogenously determined. Their model expands the basic elements of the endogenous growth models of Lucas (1988),

Becker et al. (1990), and especially Ehrlich and Lui (1991) and Ehrlich and Kim (2007) to integrate health and life expectancy as a basic endogenous variable in addition to fertility and human capital formation.

The conclusion of their analysis also puts an emphasis on investments in children's survival to adulthood as yielding high social return because they protect, and thus induce, investments in the knowledge component of human capital, which promotes economic growth. By the same token, policies that induce larger investment in education increase the motivation to protect this investment by investing in life protection and adopting a healthier lifestyle, which promotes the probability of survival to older age. By contrast, the analysis indicates the limitations of health financing policies that encourage the use of remedial care services covered by reimbursement insurance policies, as these policies encourage excessive use of remedial medical services at the expense of the more individually and socially productive life protection and preventive medical care.

3.4 Impact of green investments on environment

In 2012, the OECD published a definitional paper (Inderst, Kaminker, and Stewart, 2012) that aims to provide a comprehensive review of the concepts and definitions related to "green" investments (also variously referred to as "clean", "sustainable", and "climate change" investments) that are currently used. The paper examines how "green" investments are defined across different asset classes (equities, bonds and alternative investments), as well as providing some estimates of the size of these investments. The paper concludes that, given the lack of consensus on the usage and definition of the term "green", the most productive approach could be to take an open and dynamic attitude towards definitions and standards, with international institutions and governments adopting a "governance approach to green investment". They propose taking an open and dynamic approach to definitions and standards based on the cause (i.e. green growth, climate change policy, etc.). The science and the general understanding of the environment, climate change, and resource scarcity are evolving as are clean technologies, which are being developed and scaled-up to deal with these challenges.

Green "investment" is a very broad term. It can be stand-alone, a sub-set of a broader investment theme or closely related to other investment approaches such as SRI (socially responsible investing), ESG (environmental, social and governance investing), sustainable, long-term investing, or similar concepts.

As an example, the IMF has provided a macroeconomic definition of green investment. A recent IMF Working Paper by Eyraud et. al. (2011) refers to green investment as "the investment necessary to reduce greenhouse gas and air pollutant emissions, without significantly reducing the production and consumption of non-energy goods". It covers both public and private investment. There are three main components of green investment. These are low-emission energy supply (including renewable energy, bio fuels and nuclear), energy efficiency (in energy supply and energy-consuming sectors), and carbon capture and sequestration (including deforestation and agriculture).

Investors' attention to climate change, resource efficiency and green issues in general, has been rising in recent years and investor initiatives in this respect are growing in support. The paper provides some indications on the market volume of green investments. It is important to note that green investment has traditionally been mostly embedded within a broader approach. In fact, the current investment volumes in ESG / SRI assets, estimated at over USD 10 trillion, are a multiple of those in "pure" green investments (estimated in the tens or hundreds of billions, depending on the definition).

In recent years, the debate has not been focused on the impact of green investment on the environment. Instead, green investments are considered to be the only ones viable for achieving economic growth. Economic growth and sustainability are interdependent—you cannot have one without the other—and greening investment is the prerequisite to realising both goals.

Dramatic upgrades in technology, skills, policies and business models, along with an aligned public consciousness, are needed for the transition to a green growth pathway. Infrastructure investment required for sectors such as agriculture, transport, power and water under current growth projections stands at about US\$ 5 trillion per year to 2020 (WEF, 2013b). Additional investment needed to meet the climate challenge—for clean energy infrastructure, sustainable transport, energy efficiency and forestry—is about US\$ 0.7 trillion per year.

Considerable progress has been made in transitioning to green growth. Global investment in renewable energy in 2011 hit another record; up 17% in 2010 to US\$ 257 billion. This represented a six-fold increase from 2004 and was 93% higher than in 2007, the year before the global financial crisis. Global agricultural productivity growth rates are exceeding overall population growth rates, and, since 1990, more than 2 billion people have gained access to improved drinking water sources. Energy efficiency is widely recognised as providing economic opportunities and improved environmental security, while the fuel efficiency of vehicles has more than doubled since the 1970s.

Such progress, however, remains inadequate. Progress in green investment continues to be outpaced by investment in fossil-fuel intensive, inefficient infrastructure. The challenge will be to enable an unprecedented shift in long-term investment from conventional to green alternatives to avoid locking in less efficient, emissions-intensive technologies for decades to come.

The Green Investment Report (WEF, 2013b) introduces several interesting definitions related to our objectives:

- Green growth: growth that eradicates poverty and reduces inequality, while combating climate change and respecting a range of other planetary boundaries.

- Green investment: a broad term closely related to other investment, approaches such as socially responsible investing (SRI) and sustainable, long-term investing. As in the case of most green investment, it is necessary to retrofit existing infrastructures and develop new ones.
- Infrastructure can be defined as the basic physical and organisational structures and facilities needed to operate a society or enterprise that enables economic growth and facilitates the everyday life of citizens. Infrastructure can refer to transport (vehicles, roads, rail), water, energy, and telecommunications.
- Green infrastructure: infrastructure that enables economic growth and at the same time improves the environment (quality of air, health of citizens), helps conserve natural resources, reduces emissions, and enables adaptation to climate change. Green infrastructure could include renewable and low-carbon power plants, sustainable and low-carbon vehicles and transport, and energy-efficient, climate-resilient buildings.

From a perspective more focused on health, the report *Transport for Health: The Global Burden of Disease from Motorized Road Transport* (Global Road Safety Facility, 2014) underscores the urgent need for green investments to spread improvements in transport pollution and safety across world regions. Road injuries now rank as the world's eighth-leading cause of death and the number-one killer of young people ages 15 to 24. While the disease burden attributed to ambient air pollution has declined among richer regions such as Western Europe and North America, over the last 20 years it has risen sharply in South Asia and East Asia has been seen.

Pollution from vehicles is the cause of 184,000 deaths globally, including 91,000 deaths from ischemic heart disease, 59,000 deaths from stroke, and 34,000 deaths from lower respiratory infections, chronic obstructive pulmonary disease, and lung cancer.

This report concludes that road injuries are a major contributor to the Global Burden of Disease. Thus, rapidly scaling up road safety programs alongside the expansion of transport is vital for saving lives while promoting development. Mitigating the health risks requires a long-term investment strategy to build the capacity of national institutions, so they can actively manage safety and mobility performance through targeted interventions. Its final recommendation is a systematic approach and a long-term investment strategy, rather than isolated efforts with specific interventions.

Housing is another field in which green investments are needed. Residential buildings contributed close to 18% of direct carbon dioxide emissions from energy combustion in 2008, with 11% due to household use of grid electricity and district heating, and the remainder due to emissions at household level (e.g. cooking and heating with gas, coal, oil, etc.) (WHO, 2011). At the same time, indoor smoke from solid fuel combustion is the eighth most important risk factor in burden of disease and is responsible for 2.7% of the global burden of disability-adjusted life years (WHO, 2004).

4 Results

A way to connect environmental problems and their root causes, according to the aforementioned IPAT equation, would be through the above scheme to make environmental degradation dependent on the number of people, the average of resources used by each person (measured by the GDP per capita) and the amount of environmental pollution per unit of resource (which could be measured by the number of tons of CO₂ per capita released into the atmosphere). Thus, in developing countries, the size of the population and the resulting degradation are often the most decisive factors. However, in developed countries, the main components are the high level of resource utilisation and the pollution generated.

With data provided by the World Bank, we have calculated the Ehrlich and Holdren index for all countries in the world (1961-2012). Then we compared the results, country by country, with mortality rates and R&D investments. Mortality rates, according to Amartya Sen (Sen and Kliksberg, 2007), give the best picture of health and disease levels in a population. We have also employed R&D investments in our comparison to reflect the efforts made by economic agents to improve the situation, by putting technological innovations in the service of sustainability.

We have made a first econometric estimation through panel data techniques. For this we used the data provided by the World Bank, from 1961 until 2012, such as GDP per capita, total tons of greenhouse gases that are released into the atmosphere per unit of consumption and total population, for each of the 205 countries registered. With these three variables, and following the Ehrlich and Holdren design, an index of environmental impact was built. Once this index was developed, we built a first model to analyse the relationship between the environmental impact index and mortality rates. This model ratifies a positive and significant relationship between index environmental impact and the mortality rate, indicating the damage that climate change is causing on mortality.

Dependent Variable: MORTALITY
 Method: Panel Least Squares
 Sample (adjusted): 1961 2012
 Periods included: 52
 Cross-sections included: 205
 Total panel (unbalanced) observations: 8368

Variable	Coefficient	Std. Error	t-Statistic	Prob.
INDEX_IMPACT	4.17E-10	1.26E-10	3.318459	0.0009
C	9.995998	0.027939	357.7751	0.0000

Effects Specification

Cross-section fixed (dummy variables)

Period fixed (dummy variables)

R-squared	0.840410	Mean dependent var	10.03761
Adjusted R-squared	0.835373	S.D. dependent var	5.628845
S.E. of regression	2.283865	Akaike info criterion	4.519846
Sum squared resid	42307.29	Schwarz criterion	4.735820

This model ratifies the impact of economic activity on environment and also the effects of environment on health as established in the literature.

In a second estimate, we analysed the relationship between the calculated environmental impact index and global investments in R&D.

Dependent Variable: RSDV
 Method: Panel Least Squares
 Sample (adjusted): 1961 2012
 Periods included: 52
 Cross-sections included: 205
 Total panel (unbalanced) observations: 8368

Variable	Coefficient	Std. Error	t-Statistic	Prob.
INDEX_IMPACT	2.82E-10	2.14E-11	13.19228	0.0000
C	0.113991	0.004754	23.97937	0.0000

Effects Specification

Cross-section fixed (dummy variables)

Period fixed (dummy variables)

R-squared	0.416135	Mean dependent var	0.142141
Adjusted R-squared	0.397707	S.D. dependent var	0.500709
S.E. of regression	0.388588	Akaike info criterion	0.977634
Sum squared resid	1224.763	Schwarz criterion	1.193608
Log likelihood	-3833.422	Hannan-Quinn criter.	1.051392
F-statistic	22.58170	Durbin-Watson stat	0.453008
Prob(F-statistic)	0.000000		

These results indicate that a positive and significant relationship is also observed, between these two variables. Thus, in general, those countries with greater environmental problems allocate more resources in R&D investments.

But our main concern is to quantify the effect of green investments on health systems sustainability, i.e., a quantification of healthcare costs reductions derived from the use of a technology with a higher level of eco-efficiency.

We based our analysis on two main environmental issues, air pollution and endocrine disrupting chemicals. The relationship between health systems sustainability and environment improvements is totally circular. Environmental improvements reduce premature deaths and health costs, and funds liberated from healthcare can be dedicated to green investments.

The economic analysis works with data obtained from the literature review that was carried out.

Economic cost of diseases can be calculated by two different methodologies. The first one is based on determining the theoretical value of DALYs lost due to environmental causes. The second one is based on computing the healthcare costs, direct plus indirect.

The literature estimates that additional investment needed to meet the climate challenge—for clean energy infrastructure, sustainable transport, energy efficiency and forestry—is about US\$ 0.7 trillion per year.

Furthermore, in accordance with the Global Burden of Disease Study for 2010, household air pollution plus ambient particulate matter pollution are responsible for 6.6 million DALY lost annually. If we adopt US\$ 30,000 as the DALY unit value, the result is US\$ 0.2 trillion per year, almost the third part of the needs for additional green investments.

From a different factor related to environment, the EU estimates health savings up to 31 billion per year possible from reducing EDC exposures. Out of an estimated cost of around EUR 636 billion for endocrine diseases, if EDCs contribute to only 2-5% of the total health costs from endocrine-related chronic diseases, an EU policy change such as the phasing out of these hazardous substances and promoting safer alternatives could save Europeans up to €1 billion each year in health costs and lost productivity.

To give a context to these figures, total healthcare expenditure in the European Union (EU28) in 2010 represented 9.5% of GDP (OECD Factbook, 2013), or €1,166 billion (Eurostat, 2012). The healthcare bill for chronic disease is €700 billion. (50) These figures do not include indirect health costs.

Finally, we will focus our attention on cancer, one group of diseases closely related to air pollution and EDC, and with a great economic impact.

The total economic impact of premature death and disability from cancer worldwide was \$895 billion in 2008. This figure, which does not include direct costs of treating cancer, represents 1.5 percent of the world's GDP.

Using a formula accepted by public health researchers and economists to measure the global burden of disease, there were 83 million years of "healthy life" lost due to death and disability from cancer in 2008.

The top three cancers that account for the highest number of healthy life years lost were lung cancer (15.5 percent), stomach cancer (9.6 percent), and liver cancer (8.6 percent).

The top three cancers that caused the most economic impact globally were lung cancer (\$188 billion), colon/rectum cancer (\$99 billion), and breast cancer (\$88 billion). All of them are closely related to air pollution and EDC exposition.

Cancer causes the highest economic loss of all of the 15 leading causes of death worldwide. The economic toll from cancer is nearly 20 percent higher than heart disease, the second leading cause of economic loss (\$895 billion and \$753 billion, respectively).

The US National Cancer Institute, with methodology based on cost of treatments, estimated for 2010 an annual cost of US\$ 124 billion for all types of cancer, of which more than US\$ 12 billion correspond to lung cancer.

Cancer cost the EU €26 billion in 2009, with health care accounting for €1.0 billion (40%). Across the EU, the healthcare costs of cancer were equivalent to €102 per citizen, but varied substantially from €16 per person in Bulgaria to €184 per person in Luxembourg. Productivity losses because of early death cost €2.6 billion and lost working days €0.43 billion. Informal care cost €3.2 billion. Lung cancer had the highest economic cost (€8.8 billion, 15% of overall cancer costs), followed by breast cancer (€5.0 billion, 12%), colorectal cancer (€3.1 billion, 10%), and prostate cancer (€3.43 billion, 7%) (Luengo-Fernandez et al., 2013).

This study also has a methodology based on costs. In a population-based cost analysis, authors evaluated the cost of all cancers and also those associated with breast, colorectal, lung, and prostate cancers. The study takes into account country-specific aggregate data for morbidity, mortality, and healthcare resource use from international and national sources. It includes healthcare costs from expenditure on care in the primary, outpatient, emergency, and inpatient settings, and also drugs. Additionally, the costs of unpaid care provided by relatives or friends of patients (i.e., informal care), lost earnings after premature death, and costs associated with individuals who temporarily or permanently left employment because of illness were also considered.

5 Conclusions

Currently most developed countries accept that Healthcare systems must adapt to demographic changes and a growing demand for care, and make the best use of innovative health technologies. Health system reforms must guarantee universal access to high-quality care and improve the efficiency and financial sustainability of the health systems.

In order to guaranty the financial sustainability of health systems, it is necessary to reduce the incidence of preventable diseases. Cancer, heart disease, diabetes, respiratory, mental, and other chronic diseases represent great suffering to citizens and come at a huge cost to society and the economy. In addition, most of these diseases maintain a growing tendency along with environment deterioration, climate change, and unhealthy lifestyles.

Greening global economic growth is the only way to satisfy the needs of today's population and up to 9 billion people by 2050. Nowadays, despite signs of increasing private finance into clean energy and other green investments, there remains a considerable shortfall in investment. Closing this gap is a collective task and one that we cannot afford to fail. Public finance, linked to smart, enabling policies, has a critical role to play. Given the scarcity of public funds, governments' contributions to closing the gap will depend on their effectiveness in mobilising private investment.

From the point of view of policy implications, the results support the need for inter-sector cooperation. Green investment is a broad term closely related to other investment approaches, such as socially responsible investing (SRI)

and sustainable, long-term investing. So its benefits are global and could liberate a huge amount of money from health systems. In this sense, promoting green investments in other sectors and vice versa can greatly reinforce the sustainability of health care systems as well.

Impacts of decentralization on hospital services in peripheral geographical areas

Fernanda Nogueira¹, Eda Souza², Cristina Castro-Lucas²

¹University of Lisbon, ²University of Brasília

The first Cancer Center outside a big city was founded in 2008 in Portugal, in order to save the patients from long commuting and to reduce financial and social costs to the State, the patients and their families. Given such a measure, the question is whether radiotherapy service became more efficient geographically speaking. As a result, this article aims to describe the decentralization impacts on radiotherapy service in this Cancer Center located in the Trás-os-Montes and Alto Douro region, in Portugal. A descriptive research was conducted, focusing on economic and social aspects. The data were collected through document analysis, and the sample consisted of 232 patients under treatment from July 2009 to June, 2010. The results indicate significant differences as the costs of the treatment center in the outskirts were compared to a center located in a large urban area. This difference would be even more significant if the inherent social costs of moving patients could have been taken into account.

Introduction

The debate on hospital management-related issues is intense. Some of the major issues include the quality and efficiency of services performed by healthcare providers. Health economics has gained autonomy and projection, with an ever-increasing highlight (Carvalho, 2008). Healthcare costs play an important role in overall resource consumption and public spending (Barros, 2006); cancer care is not an exception.

Regarding cancer, an increase in investments has brought scientific and technical development, especially in diagnosis and treatment care, eventually increasing their access to related patients. However, the same did not happen with radiotherapy (RT) services, as the available resources in Portugal are too centralized.

Cancer occurrence is measured per 100,000 inhabitants per year, often by incidence and mortality rates. The number of diagnoses or deaths are calculated respectively, in a given time period, within a population or region. Information on the cancer incidence is supervised by the International Agency for Research on Cancer (IARC) and covers about 21% of the world population. Regarding Portugal, the Regional Cancer Registry (ROR) is divided by area: north (Roreno), center (ROR center) and southern (south ROR). Actually, few countries hold a national registry (e.g. Singapore and Canada). In the United States of America (USA), these registries are in charge of the National Cancer Institute and the National Program of Cancer Registries of the Centers for Disease Control, which study or encompass approximately 95% of the US population (DeVitta, Lawrance and Rosenberg, 2008).

Due to the growing and aging population, and the cancer spreading into the Western lifestyle, an increase in number of newly diagnosed cases of cancer is expected – 12 million worldwide in 2007, 5.4 million in the developed countries and 6.7 million in the developing countries. Regarding cancer-related deaths – 7.6 million worldwide, 2.9 million in the developed countries and 4.7 million in the developing countries. Prognosis estimates, by 2050, 24 million new cases and more than 16 million deaths every year. Higher figures are expected for low and middle resource countries (DeVitta, Lawrance and Rosenberg, 2008).

In Portugal, the Northern Region Regional Cancer Registry – RORENO – plays a key role in providing accurate information through a deep analysis of epidemiological data on the disease. These registries are based on the population in the districts of Braga, Bragança, Porto, Viana do Castelo and Vila Real. The data are standardized through the direct method, taking the world and European population as the standard (Bento, 2009).

The first decentralized Cancer Center was inaugurated in 2008, in the city of Vila Real - northern region of Portugal. This Cancer Center was built in the Trás-os-Montes and Alto Douro Hospital Center, E.P.E (CHTMAD), outside any major urban centers. The purpose was to bring oncological treatment units close to patients, to prevent the patients commuting to the Porto city downtown, which is almost 100km away, and to reduce financial and social costs to the State, its users and their families. Ultimately, this cancer center would also expect to be an asset for the region.

After over three years since its inauguration, several questions have been raised: Has radiotherapy service become more efficient? Are there advantages in geographically decentralized radiotherapy services? Is the size of staff and equipment enough to meet the users' demands? These questions justify the objective of this research: to describe the decentralization impacts on the radiotherapy service provided at the Cancer Center at the Trás-os-Montes and Alto Douro region, in Portugal.

Oncological Disease and Healthcare Efficiency

The word cancer is often adopted to identify a wide range of diseases, which are malignant tumors are characterized by an uncontrolled growth and division of cells, which acquire the ability to multiply and invade other tissues and organs (Pazdur, Wagman, Camphausen, & Hoskins, 2009).

In 2005, the Northern Region Regional Cancer Registry - RORENO - estimated 12,950 new malignant neoplasia cases in the northern region, corresponding to an incidence rate of 455.3/105 people among males (7,219 new cases) - 56% cases; and 338.2/105 people among females (5,731 new cases) - 44% cases. It accounted for a 6% increase in reported cases for 2004 (Bento M. J., 2009). In that region, the most common diseases were colorectal, prostate, breast and stomach cancer. Together, they accounted for about half of the cancer pathologies in the northern region (Bento, 2009). By 2015, cancer cases are expected to grow 22% in people over 65, and a 50% increase is expected in people over 80 years of age. Such figures call for a demand for more new radiotherapy services (Coffey, Degerfält, Osztavics, van Hedel, & Vandavelde, 2004). Radiotherapy is a clinical and scientific modality targeted to the treatment of cancer patients. It requires ionizing radiation alone or combined with other treatment modalities (surgery, chemotherapy). In some cases, patients with benign pathologies may also be treated with radiotherapy. Radiotherapy focus on providing an accurate prescribed dose with a well-defined, minimal-damage amount to the surrounding tissues, aiming to eliminating the disease, prolonging survival, increasing quality of life, as well as achieving healing or palliative results and symptomatic relief (Williams & Thwaites, 2000). Radiotherapy may eliminate the disease, extend survival, increase quality of life or achieve curative or palliative results and symptomatic relief (Williams & Thwaites, 2000). However, it is a complex process, requiring expensive equipment such as a CT simulator, linear accelerator and a network planning system for efficient, accurate transfer of all treatment-related information of every patient (Williams & Thwaites, 2000).

Regarding human resources, international policies recommend that a specialist doctor be available for every 250 patient a year, three physics experts for each linear accelerator, and four radiotherapy technicians for every eight working hours. The three main modalities adopted in cancer treatment are surgery, radiotherapy and chemotherapy. The World Health Organization recognizes that at least 50% of all patients require radiotherapy at some stage of the disease (Coffey, Degerfält, Osztavics, van Hedel, & Vandavelde, 2004).

A study conducted by The Swedish Council on Technology Assessment in Health Care (2003) estimates that, among the cured cases, the cancer is cured in 49% of cases through surgery, 40% through radiotherapy alone or with other modalities, and 11% through chemotherapy alone or with other modalities. As increase of 20% to 30% in the number of required treatments is expected for the next 20 years (Slotman, Cottier, Bentzen, Heeren, Lievens, & van der Bogaret, 2005). As radiotherapy plays a major role among the limited healthcare resources, its cost-efficiency should be assessed for all clinical situations that might require its adoption (Ploquin & Dunscombe, 2008).

Because of healthcare spending and lack of resources, intensified by an increasing demand for cancer-related care and the expensive nature of the involved technology, most developed countries have been pursuing more efficient practices for this sector (Jacobs, Smith, & Street, 2006). This scenario justifies the purpose of this article, which is to identify the effectiveness of radiotherapy services for cancer treatment.

Radiotherapy Training Costs - An Economic Analysis

Every economic analysis focuses on different types of costs: the resources provided by a Healthcare System and the costs charged directly to patients (DeVitta, Lawrance and Rosenberg, 2008). Although several cost classifications may be adopted, Andrade (2010) adopts just two: direct and indirect. The direct costs regard the production process (admission, the personnel's working time, medication and exams) and treatment-related costs to be handled by the patients and their family (commuting, meals, accommodation, etc.). The indirect costs are related to the consequences of the production process, such as the loss of productivity in the patient's workplace and the patient and their family themselves, as well as the absenteeism. The indirect costs include also the time spent in commuting, the waiting time until the treatment begins, etc. (DeVitta, Lawrance, & Rosenberg, 2008). Pereira and Franco (2001), in turn, adopt the terminology fixed and variable costs. Fixed costs include all hospital, unit or service operations, and the expenses with infrastructure, equipment and salaries. Variable costs may vary according to the production, and depend on the outcomes, such as medical and clinical materials, consumables and fees. Other classifications may be taken into account: intangible costs, which are difficult to estimate, such as psychological costs, pain, loss, suffering, change of environment and social adaptation, etc.

Cancer patient-associated costs are social and financial costs handled by the patients and the involved society, as their treatment and commuting are covered by the national healthcare system and other subsystems. In most cases, all these costs are covered directly or indirectly with public funds (Cunha, 2011).

The price of a single radiotherapy session paid for each hospital is estimated by crossing a reference price called Homogeneous Diagnosis Group (GDH) 409 (Ordinance No. 132/2009, 2009) and the specific Case-Mix index. For users of other healthcare subsystems, that price does not depend on the institution (Ordinance No. 110-A/2007, 2007).

Before this service became available, the cancer patients who live in the Vila Real district had to commute an average of 150km in order to be treated. The distance traveled from their homes to their former treatment facility (another reference institution) called the Portuguese Institute of Oncology (IPO-Porto), located in the city of Porto, became unbearable, as most of these patients do not live in the city center of Vila Real. Such distance, as well as a lack of adequate transportation, worsened the patients' suffering conditions. All points mentioned above then justify the analysis of both economic and social costs of radiotherapy patients from the Vila Real district at the Vila Real Hospital, focusing on the current process and the process before such radiotherapy service was available.

Radiotherapy Service and the Region

Since the 1990s, the number of patients with cancer the northern region of Portugal has increased from 7,000 to approximately 23,000 cases. The number of registered patients in the district of Vila Real and Bragança accounts for small percentage, mostly below 5%. It should be noted, however, that the district of origin of 50% to 60% of those cancer patients is unknown. After the analysis of published records from the last five years (2001–2005), an average of 439 registered oncology-related patients were found.

Records from the Roreno showed an average of 439 cancer patients in the Vila Real district. 50% to 60% of these cases required radiotherapy, which was adopted (assuming that this average remained in the analyzed years) in 220 to 263 cases. However, apart from these figures, an average of 10,638 patients of district of origin unknown were registered in the northern region each year (2001–2005).

According to Table 1, over 727 cancer patients supposedly live in the Vila Real district, considering the number of patients without population registration. Such results infer that the decentralization of radiotherapy services at the CHTMAD meets the needs of patients from the Vila Real district. The CHTMAD service consists of a multidisciplinary team responsible of a specific activity in an efficiently workflow manner. Regarding the basic equipment, this unit is equipped with a high-energy linear accelerator and a TC/simulator. The physical devices are interconnected through information and communication systems in order to harmonize people and equipment-related processes (Cunha, 2011).

From the Study Objectives to the Sample Characterization

The abovementioned scenario justifies this study, which adopts an observational and descriptive-quantitative methodology and an economic approach. It aims to assess whether the decentralization of radiotherapy services at the CHTMAD, a new way of delivering healthcare services in a peripheral region of Portugal, has proven to be efficient, based on the patients' treatment and commuting costs (subsidized) at the IPO-Porto.

The objective of this study was to describe a new delivery of healthcare services by identifying the efficiency rates regarding their existence and functioning in various economic and social aspects. This objective resulted from questions such as: how efficient is this new, geographically decentralized modality of radiotherapy service?

Two cost equations were adopted, one for the CHTMAD and the other for the IPO-Porto. The dependent variable was the total radiotherapy service costs for each institution. This variable included fixed costs and variable costs of the radiotherapy treatment handled by the State, carried out in each institution, as well as the commuting costs. The overall costs consisted of personnel, equipment and commuting distance (in km)-related costs. Other attribute or characterization variables were considered, such as gender, age, pathological group, the patient's healthcare system, treatment sessions (total number based on outpatients and inpatients), new patients per month, district and town of residence.

According to Oncology Hospital Reference Network (RRHO), a protocol signed by the Ministry of Health and the CHTMAD in March 16, 2010 established that the CHTMAL would henceforth admit only patients from the Vila Real district (Ministry of Health, 2010). Based on this protocol, the CHTMAD admitted, between July 1, 2009 and June 30, 2010, 254 patients for radiotherapy service (according to internal electronic records from the CHTMAD RT service). The sample of this study selected 232 from these 254 cancer patients, who underwent the new treatment between July 1, 2009 and June 30, 2010, covering one year of analysis. Of the total sample, 224 patients belong to the National Healthcare System (96.6%) and eight belong to other healthcare sub-systems (3.4%). Data were collected through document analysis of records and data available in the institution's computer systems. The users' general and characterization variables were accessed. The data were computer-processed on Excel 2007 and SPSS (Statistical Package for Social Sciences) software, version 18.0.

Of the 232 patients in the sample, 98 were female and 134 were male. Their mean age is 66.81, the mode being 69 and the standard deviation, 11.53. The minimum age was 36 years and the maximum age, 96 years. 9.5% were born in the Bragança district, 82.3% in the Vila Real district (and the city of Lamego, as this city's hospital belongs to the CHTMAD, although the facilities are located in the Viseu district), 3.9% in the Porto district and 4.3% were from districts outside the northern region.

The most common carcinomas registered for the male patients during the analyzed period are prostate, accounting for 18.53% of the total cases. For the female patients, breast carcinomas were the most common, accounting for 17.67% of the cases, followed by rectum, anus and anal canal-related cancers, accounting for 14.66% of both genders. Finally, trachea, bronchus and lung tumors accounted for 13.36% of both genders.

On the (dis) advantages of the Availability of Radiotherapy Services in the Trás-os-Montes and Alto Douro Region

During the study period, 204 subjects were outpatients and 16 were inpatients. The remaining 12 were one or the other at some stage of radiotherapy. 6,117 treatment sessions were performed, 5,784 of which in outpatients (Hospital de Dia) and 333 sessions in inpatients. Of the 232 subjects who underwent an average of 26 treatment sessions, 125 had to commute (54%). Of the remaining 107 subjects, 16 were inpatients throughout the whole treatment (7%), so no clinical or social need of commuting was detected. The others did not have any transportation subsidy.

The total healthcare system costs regarding patient status (inpatient or outpatient) and the amount of treatments was estimated in €2,921,443.68 (euros). This figure was obtained by adding the multiplications of the number of treatments performed per patient per unit cost, taking into account their status (outpatient or inpatient) and the healthcare system to which they belong.

Commuting costs were estimated in €149,155.24 (euros). The data were collected from the CHTMAD central transportation department's computer system (SONHO), and took into account the patient's commuting distance (route: town of residence-CHTMAD-town of residence), waiting time and number of treatments. This figure was obtained by adding the multiplications of the number of treatments performed per patient per unit cost, taking into account their status (outpatient or inpatient) and the commuting subsidy costs in kilometers, based on the abovementioned route. The distance in km was calculated through a "Via Michelin" simulator (available on <http://www.viamichelin.pt/>), which selects the most appropriate route.

The final costs registered by the IPO-Porto were calculated by adopting the proportion applied to the CHTMAD, which paid the transportation companies. The amount reached €149,155.24 (Euro), accounting for 66.67% of the cost in km (€23,711.00). Therefore, based on the distance in km that the in-treatment patients would travel if they had to commute to the IPO-Porto, the value was multiplied by 66.67%, reaching a total value of €348,619.73 (euros). Once the cost of each treatment session is calculated according to the contract program (ICM) of each institution and the DRG, the final costs would also be different if the treatment were conducted at the IPO-Porto (Ministry of Health, 2009).

According to Table 2, the total treatment costs for the patients covered by the NHS are lower for the CHTMAD than the IPO-Porto, and below the reference price. The final treatment costs (commuting costs and treatment costs added) for the patients in the sample at the CHTMAD were €2,771,818.90. Healthcare system, treatment regimen and number of treatments per regimen were taken into account. If the same services had been conducted at the IPO-Porto, their final costs would have reached €2,921,443.68 (commuting costs and treatment costs added).

The average cost for each patient treated at the CHTMAD is approximately €13,235.34, which is the total spent on commuting (€149,155.24) added to the total spent on treatment (€2,921,443.68) and then divided by the number of patients (232). Conversely, if these patients had undergone treatment at the IPO-Porto, the average cost per patient would have reached approximately €13,450.17. The average treatment costs at the IPO-Porto were calculated by adding the total spent on commuting (€348,619.73) with the total spent on treatment (€2,771,818.90) and then dividing it by the same number of patients (232).

The difference between the average cost of each institution is of approximately €14.83 per patient. This figure was obtained by subtracting the average treatment cost per patient at the IPO-Porto from the average treatment cost per patient at the CHTMAD. Therefore, for those 232 patients, a total gain of approximately €50,000 was achieved. This amount could be applied to improve this and other services.

In addition to the actual and effective costs, if the social-related costs (commuting and quality of life) of which the patients were spared could be added to the equation, that difference would be even more significant. As a consequence, the new modality of radiotherapy service provided at the CHTMAD not only has added financial value to the region as a whole, but it has also improved the social welfare for its residents.

From the Discussion of Results to the Study's Main Findings

Based on the results previously shown, a discussion and a critical analysis may be conducted in order to compare the most significant data to some of the most relevant studies collected from the literature.

In short, the sample of this study accounted for 58% males and 42% females. The most common tumors were prostate (18.53%), breast (17.76%), rectum, anus and anal canal-related (14.66%), followed by trachea, bronchus and lung-related cases (13.36%). These data are similar to the incidence rates identified in the northern region of Portugal. Of the 170 subjects, 60 were over years-old, accounting for 73% of the sample. The period analyzed had 6,117 treatment sessions. 94.6% of which in outpatients and 5.4% in inpatients, accounting for an average of 26 treatment sessions by patient. Of the 232 patients in the sample, 39% have not been reimbursed for any kind of commuting for medical or social purposes.

The radiotherapy working steps and processes at the CHTMAD services are performed as described in the bibliography, from the diagnosis to the follow-up stages. Equipment and human resources are provided throughout all steps and actions for an accurate, efficient treatment.

After the abovementioned processes, some questions regarding the efficiency of such innovation and the implementation of a decentralized radiotherapy service might be answered.

In contrast with the IPO-Porto, the radiotherapy services at the CHTMAD, located in an inner region of Portugal (Vila Real), not only showed a lower cost, but they also managed to treat more patients, thus proving to be more efficient.

The average total cost per patient who underwent radiotherapy at the CHTMAD was approximately €13,235.34. If these patients had undergone treatment in the other reference institution (IPO-Porto), the costs would have reached approximately €13,450.17 per patient. These €14 per patient difference may not seem significant. However, as time and commuting-related social costs, loss of working time (for example, labor) and the patients and their families adapting to a quality of life are added, this difference becomes a lot more significant.

Moreover, Portugal accounts for around 4,000 new cancer cases per million every year. Given that the Vila Real district had about 225,000 inhabitants in 2004 (Correia et al., 2005), a total of 900 new cancer cases are expected in that district. Radiotherapy was expected to be necessary in 50% to 60% of these new cases (Pereira, Soares, Grilo, Lopes, Monsanto & Costa, 2008). This percentage accounts for 450 to 540 new cases per year only in the Vila Real district. Should the population of Bragança be taken into account, the figures would add up to 290-350 new patients every year. However, the one-year period sample (232 new patients out of 254) suggests that, despite the region's installed capacity, some cancer patients are still transferred to other service units.

The social cost of a region without radiotherapy services is translated in uncomfortable commuting for patients who are already under physical and psychological stress. It is worth remembering the impact of the loss of working days and hours (absenteeism) and the reduction of socialization on the patients' lives, as well as the family-related costs throughout the process.

Another advantage is that this new service provides both physical and human resources required for an accurate, precise radiotherapy treatment. As for the linear accelerator, the national recommendation establishes one device for every 400 cancer patients. This new facility complies with such norm, given that 232 cancer patients are treated every year. However, from a macro perspective, and taking the needs of all Trás-os-Montes region into account, this facility is short of accelerators, requiring not one but two devices (Nunes, et al., 2002).

In addition, the number of dedicated personnel (three full-time and one part-time physicians, and one full-time and two part-time healthcare physicists) surpasses the number of healthcare providers per patient treated every year recommended in international guidelines. The number of radiotherapy technicians is also in accordance to the recommended. If the whole region is considered, the number of professionals is appropriate.

Cancer is the leading cause of death and the second leading cause of death in the European Union (Coffey, Degerfält, Osztavics, van Hedel, & Vandeveld, 2004), accounting for approximately 4,000 new cases per million people, especially among the elderly. The aging population process may cause a significant increase in the number of cancer cases, which will eventually increase the demand for more and more efficient treatment units (Coffey, Degerfält, Osztavics, van Hedel, & Vandeveld, 2004). All considered, a network of integrated care for the cancer patients in the medium term is of utmost importance, so more unique, specialized cancer care units are added to the currently operational integrated units that provide primary, ongoing care. Thus, treatment and follow up conditions cancer patients must be improved, focusing not only on efficient, high-quality care, but also on close-distance facilities to the community.

This research aimed to assess the performance of a new form of providing radiotherapy services. To do so, it analyzed operational, economic and social aspects, as well as the location and the productivity conditions. The comfort and quality of life for the population were also taken into account, as this new service was closer to its users. However, the social cost for the patients who need to commute to other locations in order to undergo treatment needs further analysis. This issue should be the starting point of further researches.

The implementation of this new form of radiotherapy service in the city of Vila Real not only has decentralized the treatment process in large urban centers but has also provided comfortable conditions to patients throughout an average of 26 sessions (corresponding to 26 working days). Consequently, this new modality has shown cost-related advantages to the healthcare system, and has proven to be beneficial to those who need them.

Using Interactive Research and Constructive Method in Adapting Business Model Thinking to Service Logic

Jukka Ojasalo, Katri Ojasalo

Laurea University of Applied Sciences

The purpose of this paper is to increase the knowledge of application of interactive research and constructive method in adapting business model thinking to service logic. This paper explains how these empirical research approaches were applied in the development of Service Logic Business Model Canvas. The process took 18 months and involved a large number of practitioners from various industries as well as academics. As the result, this paper evaluates the usability of the interactive research and constructive method in the context of service research. It finds both advantages and challenges in using these methods.

1 Introduction

Qualitative research includes a large number of research methods. The most well-known methods are in-depth interviews, case studies, focus groups, observation, ethnography, grounded theory, and action research (Denzin; Lincoln, 1994). Crowdsourcing, netnography, sentiment analysis, hybrid textual analysis, and text mining are examples of new qualitative methods (Guercini, 2014). Two qualitative research methods have received little attention in the existing literature, namely interactive research (Gummesson, 2001, 38-41) and constructive method (Kasanen et al., 1993). These methods are potentially powerful when the purpose is to develop scientific theory and at the same time develop practically relevant constructions, models, or solutions. This paper relates to an empirical research in which these methods were used in adapting business model thinking to service logic. A new service design tool was developed in this project, called Service Logic Business Model Canvas (Ojasalo; Ojasalo, 2014). The literature includes very little knowledge of use and applicability of interactive research and constructive method. Thus, there is a clear need to increase the knowledge of this area. Our paper responds to this knowledge gap with the purpose to increasing the knowledge of application of interactive research and constructive method in adapting business model thinking to service logic.

The rest of this article is organized as follows. First, it discussed the nature of interactive research and constructive method. Then, it describes the empirical research process in which these methods were used. In this context, it also briefly explains the outcome of the empirical process. Then, based on the observations and experience during the research process, it evaluates advantages and challenges of using interactive research and constructive methodology in service research context.

2 Interactive and constructive methods

2.1 Qualitative research

The term “qualitative research” is an umbrella concept encompassing a wide range of different tools, techniques, and procedures (Punch, 2005; Creswell, 1998). Johnson et al. (2007) examined what academic disseminators, industry professionals, doctoral students, and experiences academic researchers understand with “qualitative research.” They identified eight dimensions characterising qualitative research:

- verstehen
- verstehen but with reflexivity
- general bag of tools
- a specific bag of tools with a distinctive role and use in management research: accessing organizational back stages
- exploratory research with regard to little understood phenomena prior to other (i.e. quantitative) research
- disposal category
- research that is not quantitative
- specific data collection techniques

According to Mills (1959), a common characteristic for all qualitative research is that it does not dissociate the analysis from the researcher’s experience. Qualitative research is based on subjective interpretation of data, and it has become a widely used approach particularly in social sciences and management research. Research in natural sciences tends to rely on quantitative methods and have its ideal in pursuing objectivity. Still, it is argued that no science, natural or social, can do without subjectivity (Gummesson, 2001). Creativity and lateral thinking, generating new theory and basis

for propositions, is subjective. Next, two qualitative methods are discussed in more detail. They are interactive research and constructive method. These methods are used in our empirical study.

2.2 Interactive research

Interactive research method was introduced by Gummesson (2001, 38-41). This research approach is based on interaction and communication with chosen relevant audiences. It ties together the process of knowing, the knower, and the known. The approach is based on various kinds of interactions, such as interaction between the researcher and the object of study and its actors; between one's consciousness and qualities of one's inner self; between substantive data and general concepts; between the parts and the whole; between words, numbers, body language and tacit language; and concurrent, non-linear and dynamic interaction between data collection, analysis, interpretation and conclusions.

In the interactive research, theory generation and theory testing are inseparable twins, not isolated consecutive stages. Through further theory generation in never-ending iterations the researcher gains a spiralling effect and builds a helix of continued development of knowledge. The researcher goes from pre-understanding to understanding, to a new level of understanding, and so on; and from substantive, specific data to concepts that serve as vehicles for reaching more general theory levels. This approach is governed by a humanist, hermeneutic and phenomenological paradigm, although elements from a quantitative and positivistic paradigm may be included.

Interactive research is an umbrella for well-known research methods, which are characterized by the earlier qualities. Examples of such highly interactive methods are case study, grounded theory, anthropology/ethnography, action research, and narrative research. Case study recognizes complexity and ambiguity, grounded theory lets reality tell its story on its own terms, anthropology and ethnography allow the researcher to be where it happens, action research makes it happen with reflecting, and narrative research makes the reality to come alive (Gummesson, 2001).

2.3 Constructive method

The constructive method is a research procedure for developing constructions, where constructions refer to entities that solve problems that emerge in running business organizations (Kasanen et al., 1993). An important characteristic of constructions is that their usability can be demonstrated through implementation of the solution. Sometimes constructions refer to principal solutions only, as the testing of their usability is not always possible because of resource and time restrictions. The constructive research means, in other words, managerial problem solving through the construction of models, diagrams, plans, organizations, etc. Still, it should be noted that not all problem solving and model building exercises are constructive research. According to Oyegoke (2001), analytic model building produces an elegantly proven problem solution which works in principle but whose actual practical adequacy usually remains unclear. Kasanen et al. (1993) argue that, a construction which works, is relevant and simple and easy to use. An essential part of the constructive approach is to tie the problem and its solution with accumulated theoretical knowledge. In addition, the novelty and the actual working of the solution have to be demonstrated. The construction should include new knowledge to both to the business and academic community. The characteristics of a construction of solution to a problem are practical relevance, theory connection, practical functioning, and theoretical contribution.

According to Oyegoke (2001), the constructive approach encourages co-production of knowledge between the industry practitioner and the researcher. The constructive approach is a method that can be used to develop social interaction among people, illuminating the flux of events and human action within the array of social agenda, practices and stakeholder relations. Constructive researchers rely on interpretative method by assuming that people construct and test solutions based on their interaction with the world around them. According to Kasanen et al. (1993), the research process of a constructive approach includes the following phases. Their order may vary from case to case:

- (1) Finding a practically relevant problem which also has research potential
- (2) Obtaining a general and comprehensive understanding of the topic
- (3) Innovating i.e. constructing a solution idea,
- (4) Demonstrating that solution works,
- (5) Showing theoretical connections and the research contribution of the solution concept, and
- (6) Examining the scope and applicability of the solution.

3 Empirical research process

The research process of the present study is illustrated in Figure 1. The phases of the research process are shown in detail in Table 1. The study is based on interactive research approach (Gummesson, 2001) where the empirical data is generated in interaction with researchers and relevant actors in respect of the purpose of the study. The research is affected by the researchers' pre-understanding. The process is a continuous interplay between data from interaction, existing theories from the literature, and researchers' interpretation. A new theory is developed as a result of these interwoven elements.

Figure 1. Interactive research process.

Pre-understanding refers to knowledge, insights, and experience of people before they engage in a research program or consulting assignment (Gummesson, 1991). It is also affected by the researcher’s attitude and commitment. The preunderstanding of this study is based on the theories on service logic (e.g. Grönroos 2006 and 2008), service-dominant logic (e.g. Vargo; Lusch, 2004 and 2008), and customer-dominant logic (Heinonen et al. 2010; Voima et al., 2010). It is also based on work in developing business models in practice with companies, particularly with help of Osterwalder and Pigneur’s (2010) business model canvas (BMC) as well as Johnson et al.’s (2008) business model framework. Based on the pre-understanding, the existing business model frameworks are too provider-centric and goods-dominant, and require further development and adaptation to service logic. The existing theories and literature used throughout the research process deal with service logic, SDL, CDL, business models, and service design.

The fundamental purpose of the current research is the same as the one of constructive research method (Kasanen et al., 1993). In other words, it aims to develop a construction that solves a problem that emerges in running a company. The construction in the current research is a revised version of Osterwalder and Pigneur’s (2010) business model framework, Business Model Canvas. The modifications aim at increasing the service logic-orientation of the original BMC tool. The research process aimed at a relevant and simple and easy to use construction. The present study included all the six phases of constructive research process suggested by Kasanen et al. (1993). During the process the problem and its solution were tied with accumulated theoretical knowledge. In addition, the novelty and the actual working of the solution were demonstrated. The last phases of the process aimed at showing and testing that the developed construction included new to both to the business and academic communities.

Table 1. Phases of the research process.

Step	Interaction of the research process	Outcome	Actors	Phase of the constructive research method
1	Discovering the knowledge gap and need for research (11 Oct. 2012, 2 hours)	Appointed ideation workshop	12 researchers	(1) Finding a practically relevant problem which also has research potential.
2	Interactive ideation, brainstorming, and development workshop (16 Jan 2013, 4 hours)	Initial development ideas, Canvas version 0.1	15 researchers	(2) Obtaining a general and comprehensive understanding of the topic. (3) Innovating i.e. constructing a solution idea.
3	Interactive ideation, brainstorming, and development workshop (5 Mar 2013, 4 hours)	Canvas version 0.2	15 researchers	
4	Interactive ideation, brainstorming, and development workshop (29 Apr 2013, 3 hours)	Canvas version 0.3	13 researchers	

Step	Interaction of the research process	Outcome	Actors	Phase of the constructive research method
5	Interactive ideation, brainstorming, and development workshop (30 Aug 2013, 4 hours)	Canvas version 0.4	9 researchers and 1 practitioner	
6	Interactive ideation, brainstorming, and development workshop (15 Sep 2013, 3 hours)	Canvas version 0.5	6 researchers	
7	Rapid test (“lean launch”) and further development of the SL-based business model canvas in 5 company cases (8 Nov 2013, 5 hours)	Canvas version 0.6	1 researcher and 22 practitioners B	(4) Demonstrating that solution works. (6) Examining the scope and applicability of the solution (3) Innovating i.e. constructing a solution idea.
8	Assignment given to 24 practitioners to test the SL- based business model canvas in their organizations (9 Nov 2013, 2 hours)		1 researcher and 24 practitioners B	(4) Demonstrating that solution works. (6) Examining the scope and applicability of the solution.
9	Interactive ideation, brainstorming, and development workshop (20 Nov, 2013, 3 hours)	Ideas for further development	6 researchers and 40 practitioners A	(3) Innovating i.e. constructing a solution idea. (6) Examining the scope and applicability of the solution.
10	Results and reflections from the 24 test cases of SL-based business model canvas (14 Dec 2013, 4 hours)	Ideas for further development	1 researcher and 24 practitioners B	(4) Demonstrating that solution works. (6) Examining the scope and applicability of the solution.
11	Further development of the canvas in interaction between 2 researchers, based on analysis of the data (generated in workshops and through testing) and understanding accumulated in the research process (incl. existing theories). Identification of the scientific contribution. Writing of research report (30 Sep 2013 – 28 Feb 2014)	Service Logic Business Model Canvas	2 researchers	(3) Innovating i.e. constructing a solution idea. (2) Obtaining a general and comprehensive understanding of the topic. (5) Showing theoretical connections and the research contribution of the solution concept.
12	Introduction of the finalized Service Logic Business Model Canvas for comments. Need to develop a light application version of the canvas. (7 May 2014, 2 hrs)	Ideas for finalizing the Canvas. Clear need to develop a light application version of the Canvas,	10 researchers, 7 practitioners A	(2) Obtaining a general and comprehensive understanding of the topic. (3) Innovating i.e. constructing a solution idea. (6) Examining the scope and applicability of the solution.
13	Development of light application version of Service Logic Business Model Canvas	First version of light application version	2 researchers	(3) Innovating i.e. constructing a solution idea. (5) Showing theoretical connections and the research contribution of the solution concept.
14	Testing the light application version of Service Logic Business Model Canvas (5 Jun 2014, 1 hr)	Ideas for further development of light application version	20 practitioners A, 1 researcher	(4) Demonstrating that solution works. (6) Examining the scope and applicability of the solution.
15	Finalization of the Canvas. Development of a light application version of the canvas.	Finalized light application version, finalized Service Logic Business Model Canvas and its application process	2 researchers	(3) Innovating i.e. constructing a solution idea. (2) Obtaining a general and comprehensive understanding of the topic. (5) Showing theoretical connections and the research contribution of the solution concept. (6) Examining the scope and applicability of the solution.

The initiation of the research process took place in an invitation based expert panel (Step 1) where 12 service researchers concluded that one of the most widely-spread business model frameworks, namely Osterwalder and Pigneur's (2010) Business Model Canvas, requires further development, particularly towards the principles of service logic. Most importantly, the researchers saw that the BMC is based on traditional provider-centered value-chain thinking where value is created inside a company through its activities and resources and then delivered to customers. For example, the terminology of BMC reflects the goods-dominant logic, for example the "Channels" block of the BMC describes how "value propositions are delivered to customers through communication, distribution, and sales channels" (see Osterwalder; Pigneur, 2010, 16). The BMC does not see customers as value creators, nor does it suggest how service could be embedded in customer's contexts, activities and experiences (cf. Heinonen et al., 2010).

The research process took 18 months and consisted of 15 steps (Table 1). The interaction in which data were generated and understanding increased consisted of ideation workshops. The process included twelve interactive workshops in which data from pre-understanding, interaction, interpretation and increased understanding, and existing theories were interwoven together. The research process was conducted in Finland and related to the activities of the Finnish Service Alliance. The other author of this paper planned the workshops beforehand and facilitated and documented them. The workshops were documented by writing notes during and after each workshop, by collecting all the raw material produced by the participants during the workshops (notes, writings, and drawings made by the participants), by taking photographs, and by recording the most important parts of the workshops. After each workshop, the business model canvas, which was the central researched object, was further developed based on the data and increased understanding generated in the interactive workshop. The actors of the workshops were researchers and practitioners. In this case, "researchers" include academic researchers from seven universities and other research related organizations. They were professors, senior researchers, doctoral students and coordinators of large national research programs. "Practitioners" refer to representatives from companies and other organizations (Group A). "Practitioners" also include master level adult students who conduct their studies alongside their full time job in companies and other organizations (Group B). 18 researchers and 106 practitioners participated in this process. Thus, altogether 124 persons were involved in the research process. The data were qualitative in nature, and its subjective interpretation took place during and after the interactive workshops both individually and collectively. In general, the emphasis shifted from theoretical thinking and model development towards practical model development and testing. The participants of the first workshops were mostly researchers (Steps 1-6) while the participants of the later workshops were mostly practitioners (Steps 7-10, 14).

The outcome of the empirical research process

As the outcome of the empirical research process, a new service design tool was developed, called Service Logic Business Model Canvas (Ojasalo; Ojasalo, 2014). The new canvas is a modified version of the original BMC and it has the following elements. Each element of the canvas is considered "from our point of view" and "from customer point of view." The elements are recommended to be developed in the following order, if there is no case-specific reason to develop the elements in some other order.

1. Customer's world and desire for ideal value
2. Value proposition
3. Value creation
4. Interaction and co-production
5. Revenue streams and metrics
6. Key resources
7. Key partners
8. Mobilizing resources and partners
9. Cost structure

The application of Service Logic Business Model Canvas includes three main phases:

1. Light application version of Service Logic Business Model Canvas
2. Information gathering and development work with selected service design methods
3. Full application version of Service Logic Business Model Canvas

The contributions of the research relate to four differences between the new canvas and the original Osterwalder and Pigneur's (2010) canvas. These contributions are explained in the following.

First, the developed Service Logic Business Model Canvas adapts the business model thinking to service logic. Each building block of the present canvas is adapted to service logic. The original Osterwalder and Pigneur's (2010) framework view the business from the provider viewpoint. The present framework has both the provider and customer viewpoints explicitly. When building a business model with help of the new framework, one has to consider how each element should be constructed and how they look like "from our point of view" and "from customer point of view". In this way, the present framework makes sure that the service logic is present in each phase and element in the business model development.

Second, the Service Logic Business Model Canvas is designed to be applied to each customer profile separately. The original Osterwalder and Pigneur's (2010) framework has the "Customer segments" element suggesting that the

other elements of the business model should be identical to each segment. This is often difficult or impossible while the characteristics of each segment may be very different. By using the framework individually to each relevant customer profile, it is possible to have a deep understanding of the customer logic and requirements of each profile. Consequently, in such a case the total business model may be a set of profile specific sub-models.

Third, the Service Logic Business Model Canvas gives a recommendation of the order in which the elements of a business model should be developed. The existing literature is contradictory when concerns the question, whether or not a business model's elements should be developed in certain order. Or should it start from certain defined element or activity? (cf. Johnson et al., 2008; Osterwalder; Pigneur, 2010). Our recommendation with the present framework is that the starting point should be in the block 1 describing the customer's world and then follow the given order. However, if there is case-specific reason to develop the elements of the business model in some other order, then we recommend following that order. Anyway, the process is likely to be iterative rather than straightforward (Demil; Lecocq, 2010, Kindström; Kowalkowski, 2014).

Fourth, the use of Service Logic Business Model Canvas includes both light and full application version. The business model development starts with light application version. The second phase includes information gathering and development work with selected service design methods. Based on this effort, a full version application of the framework is conducted, which results in possibly several detailed business models, one each targeted customer profile. In some cases the light application version may be the only effort, for example when there is no time for full version application or when there is not enough resources for research and development work.

4 Result: Evaluation of the usability of the interactive research and constructive method

Next, we evaluate the usability of the interactive research and constructive method in adapting business model thinking to service logic. The evaluation is based on our own experience and interpretations throughout the research process. Based on this, the above research methods have the following advantages and challenges.

4.1 Advantages

The advantages of the interactive research and constructive method were

1. Multidisciplinary and cross-industry research collaboration
2. High motivation and commitment of parties to research project
3. Rich data, innovative new ideas
4. Continuous critique of findings and ideas
5. Gradual build-up, validation and triangulation of the findings and theory

A clear advantage of the methods used was the **research collaboration of people from different backgrounds**. The people involved both practitioners and academics. Practitioners came from various industries and responsibilities, thus allowing a large spectrum experience, knowledge and opinions to be shared on service business during the research process. Also, the academics came from different universities and research organization with varying research backgrounds and interests. This diversity of participants involved in the research process made possible to learn from others and develop and test own ideas. As a consequence, they were highly **motivated to** commit themselves to the research process. Moreover, the diverse backgrounds of participants resulted in **extremely rich data**. This enabled new exploratory findings, development ideas, and interpretations which would have been unlikely to be found with other research methods.

Another advantage of the method was the **continuous critique of findings and ideas** that emerged during the process. Participants gave immediate critique if someone made an interpretation they did not agree. The data were also analysed between the interactive workshops, and the findings from previous workshops were discussed and criticized in the next workshop. They were criticized by both academics and practitioners. As the theory and the new ideas were built up gradually under continuous critique, they were also **validated** much more strongly than many academic theories. As the critique and comments for improvement came from practitioners from several industries as well as multidisciplinary group of academics, the theory was also effectively **triangulated**. The continuous critique and evaluation of findings increased the quality of the research.

4.2 Challenges

The challenges of the interactive research and constructive method were

1. Effort and time for organizing the research process
2. Discrepancy in communication and use of terminology between participants
3. Dealing with abstract theories with practitioners

Effort and time required to organize the research process represented a clear challenge. Our research required a longer time to refine the theory in an iterative stepwise process, 18 months. Scheduling the workshops was not easy

because of the number of participants. Also, documenting the discussions, notes and graphical illustration from workshops required substantial effort.

One challenge in working with participants with heterogeneous backgrounds related to **discrepancy in communication and use of terminology**. The difference was observable particularly between practitioners and academics. Academics used more accurate language and wanted to maintain conceptual clarity. Practitioners, on the other hand, tended to express their ideas more loosely and inaccurately. This caused some challenges for discussion and theory development.

Our research aimed at adapting business model thinking to service logic. Service-based business logics (Vargo; Lusch, 2004; Heinonen et al., 2010, Grönroos, 2011) are scientific theories and consequently rather abstract for many practitioners. **Explaining their principles to practitioners and bringing them down to a concrete level** was a challenge during the research process.

5 Conclusions

The purpose of this paper was to increase the knowledge of application of interactive research and constructive method in adapting business model thinking to service logic. The paper explained how these empirical research methods were applied in the development of Service Logic Business Model Canvas, and evaluated their usability. As a result, it found out that the advantages related to multidisciplinary and cross-industry research collaboration, high motivation and commitment of parties to research project, rich data, innovative new ideas, continuous critique of findings and ideas, as well as gradual build-up, validation and triangulation of the findings and theory. Challenges on the other hand, were effort and time required for organizing the research process, discrepancy in communication and use of terminology between participants, and dealing with abstract theories with practitioners.

Beyond customer solutions – materials producer facilitating value co-creation in industrial networks

Lauri Orkoneva, Ville Eloranta

Aalto University

The manufacturing companies are trying to avoid the effects of increasing competition and commoditization of their businesses by shifting their focus to customized solutions and customer relationships. However, the management of the relational processes is becoming challenging, as the companies lack the required capabilities and resources to master the solution provision alone. This means that the customer relationships must be exposed to other actors which compromises supplier-customer relationship based competitive advantage.

Therefore, in line with the developments of the strategic management research, the solution network literature is suggesting that the manufacturers should look beyond the dyadic relationships when seeking to establish competitive advantage. The increasing specialization of actors and growing need of complementarities may open potential for new modes of operation, extending beyond traditional solution-oriented business models. The theory seems to propose that the network approach may make it possible to reach a new kind of service-enabled competitive advantage, originating from the network structures that firms are able to control. However, these approaches been analyzed only anecdotally in current literature.

Based on an empirical case study involving a large materials producer company in construction industry, and multiple supplementary case companies in the same network, we suggest that along solution providers, solution networks need also actors who facilitate the development of the networks, integration of resources, communication between the actors, and organization of the operations. In this setting the firm is not developing its own service and offering, but instead provides a platform that helps other firms to develop solutions and enables customers to find and utilize them efficiently. With this approach the “solution platform provider” is able to use its network as a source of competitive advantage. Furthermore, this mode of operation may actually transform a physical material producer – for which the movement towards service and solution business has been challenging – into facilitator of industrial ecosystem.

1 Introduction

The research stream of manufacturers' servitization and service infusion (Vandermerwe & Rada, 1988; Wise & Baumgartner, 1999) describes how manufacturing companies are trying to avoid the effects of hypercompetition (i.e., rapid and dynamic competition characterized by unsustainable advantage) and the commoditization of their businesses by shifting their focus to customer relationships. In the discourse, instead of unique products or processes, the relational process between the supplier and customer, i.e. solutions (Gebauer, Gustafsson, & Witell, 2011; Gebauer, 2008; Kindström & Kowalkowski, 2009; Mathieu, 2001; Neu & Brown, 2005) is seen as the fundamental building block for the sustainable competitive advantage and the antidote to hypercompetition.

However, recent developments in the service infusion discussion argue, that the management of the relational process itself is becoming more challenging, as the companies lack the required capabilities and resources to master the solution provision by themselves. Therefore, in the manufacturing context, the solutions are increasingly delivered in service and solution networks (e.g. Henneberg et al., 2013, Gebauer et. al 2013), in which actors share resources and capabilities in order to produce the best possible solution for their customers. Thus, in order to deliver the solutions, co-operation and resource integration is needed with potential competitors in the same industry. This means that the customer relationships, and most importantly the cumulative history underlying those relationships, must be at least partly exposed to other actors, which then compromises the longer-term protection of the competitive advantage.

Therefore, in line with the developments of the strategic management research (Adner & Kapoor, 2010; Iansiti & Levien, 2004; Moore, 1993; Teece, 2007), the solution network literature is suggesting that the manufacturers should look beyond the dyadic relationships when seeking to establish competitive advantage (Bastl et al.,2012; Barquet et al.,2013, Gebauer et. al 2013; Kowalkowski et. al 2013). Especially efficient management of industrial networks could generate beneficial results. The increasing specialization of actors and growing need of complementarities may open potential for new modes of operation, extending beyond traditional solution-oriented business models.

This suggests, that along solution providers, solution networks need actors that facilitate the development of the networks (e.g., bridging structural holes), integration of resources, communication between the actors, and organization of the operations. In this setting the firm is not developing its own service offering, but instead provides an environment

(building blocks, infrastructure, etc.) that helps other firms to develop solutions and enables customers to utilize these solutions. It appears that there is a clear need for more detailed contributions in this area as, most interestingly, these new roles might be especially appealing to the firms which have found it difficult to establish close enough contact with the end customer, develop solution offerings, and thereby also comprehensively “servitize” their offerings. Current service infusion literature states that this seems to be the case especially in the upstream actors of the industrial networks – the actors who seem particularly vulnerable to the effects of hypercompetition (Thomas & D’Avenie, 2009).

Furthermore, the rapid developments in the field of manufacturing-related information availability and sharing (managerially discussed, e.g., using terms such as the “Internet-of-things” (e.g. Atzori et al., 2010) and “industrial Internet” (Evans & Annunziata, 2012) may speed up the development toward even more complex industrial networks, calling for new ways of managing the solution networks – and also potentially providing strong strategic benefits for companies mastering the capabilities of orchestrating these networks.

ICT and high-tech industries have managed effectively orchestrate agile service networks (Bourdea & Lakhani, 2009). Also these industries have encountered resource and capability fragmentation and the complexity of the management of industrial networks. In these industries, there has been industry restructuring, which has created new business potential and new roles in industrial networks. The companies have successfully adopted so called platform-typed business models, in which firms create foundations or components on top of which other firms in the ecosystem then build customized solutions (Baldvin & Woodard, 2009). In these networks, the companies develop complex relationships between many parties in their networks and are thereby able to build competitive advantage.

Therefore, we take the concept of platform as a theoretical lens and explore what kind of possibilities upstream actors have in manufacturing related solution networks regarding sources of competitive advantage. The platform literature suggests that platforms are often formed around solving systemic problems of fragmented industries (Gawer & Henderson, 2007). Therefore, in order to elaborate the possibilities that the platforms concept could offer in terms of gaining competitive advantage via network orchestration, our research questions are as follows: “What are the systemic problems in the construction industry? How can a servitizing manufacturer build competitive advantage with platforms in the manufacturer’s service and solution provision context?” The questions are addressed with an empirical study of an upstream material manufacturer in the construction industry developing new platform-based modes of operation. The data gathered from this main case is supplemented by secondary data from other companies in the construction industry. With this data, the potential of platform-based business models is analyzed from the perspective of competitive advantage.

2 Theoretical background

In this study we are elaborating the competitive advantage the manufacturing firms can achieve by orchestrating the service and solution networks with a platform strategies. To establish the theoretical ground for our study, *we will review the theories of gaining competitive advantage in highly competitive (hypercompetitive) environments, with special focus in manufacturing industries. Then, we will link the strategic discussion to the literature on manufacturer’s servitization, which is describing the manufacturing industry’s answer to the hypercompetitive developments in detail. Finally, to form a ground for the theoretical lens of this study, we will review the platform discussion – first in the more general level, and then, with the special focus on manufacturers’ service infusion context.*

2.1 Hypercompetitive environment and the manufacturing industry

Recent theoretical research indicates that many industries have become hypercompetitive, which has led shifting towards more temporary advantages as well as increasing structural instability (Thomas & D’Avenie, 2009). D’Aveni et al. (1994) defined hypercompetitive industry as ‘characterized by intense and rapid competitive moves, in which competitors must move quickly to build advantage and erode the advantage of their rivals’. The literature indicates that bold, frequent and aggressive competitive moves of rivals create a condition of constant disequilibrium and change (D’Aveni et al., 1994). This sort of competitive environment increases possibilities of challengers rapidly to overtake the leaders even without their notice (Smith, Ferrier, and Grimm, 2001).

Strategy literature has argued and empirically verified that hypercompetitive environment restricts the strategic choices that firm can make (D’Aveni et al., 2010; Eisenhardt & Bourgeois, 1988; Eisenhardt, 1989). This means that different types of strategies seem to be successful in dynamic and stable environments. In addition, the phenomenon is not limited to some specific (e.g. high-technology) industries but can be seen across a broad range of industries (Wiggins & Ruefli, 2005). Thus, although skeptics have proposed that the term hypercompetition is ‘a self-inflicted wound, not the inevitable outcome of a changing paradigm of competition’ (Porter, 1996), it seems that in many industries the sustainable competitive advantage is increasingly hard to achieve, and firms need to alter their strategies to avoid commoditization.

The manufacturing industry has also been affected by the development toward hypercompetition (Thomas, 1996) and the companies are looking for ways to prevent the competitive dynamics from escalating to perfect competition. Industrial manufacturers are striving away from product-based businesses towards customized services and result-driven solutions – i.e. building competitive advantage on customer relationships, and thereby developing “antidote for hypercompetition”.

2.2 Movement towards relationships, services and solutions in the manufacturing industry

The manufacturing industry's movement towards customers is extensively discussed in manufacturers' servitization and service infusion literature (e.g. Baines et al., 2009; Vandermerwe and Rada, 1988). From the strategic perspective, the discussion has followed the paths directed by strategic management scholars, both trying to intensively explore the sources of competitive advantage and its sustainability (Barney, 1991; Dyer & Singh, 1998; Eisenhardt, 1989b; Porter, 1980; Richard A. D'Aveni, Giovanni Battista Dagnino, & Ken G. Smith, 2010; Rumelt, 1984; Teece, Pisano, & Shuen, 1997; Teece, 2007; Wernerfelt, 1984). Throughout the service infusion discussion, the role of the dyadic relationship between the supplier and customer has been emphasized. According to the discussion, customer relationships create the most value and offer an inimitable resource for the company, protecting from fierce competition. It is even argued that all manufacturers must become solution providers, and the dynamic capabilities of relationship management are the necessities for competitive advantage.

However, in recent service infusion discourse, the network perspective to service management has challenged the firm boundaries in dyadic relationships. The services are increasingly innovated and provisioned in inter-firm networks. Thus, the relationships between suppliers and customers are in many cases shared, as well as related capabilities and resources. Therefore, most recent studies of service infusion strategies have shifted the focus towards gaining competitive advantage from inter-organizational relationships and networks. Service infusion scholars also adhere to the later themes of strategy stream focusing on the role of systems perspective, emphasizing the connections between the firm and the ecosystem (Adner & Kapoor, 2010; Iansiti & Levien, 2004; Moore, 1993; Teece, 2007) it occupies. Moreover, the latest service infusion literature seeks competitive advantage from new, value-enhancing combinations of actors (Bastl, Johnson, Lightfoot, & Evans, 2012; Gebauer, Paiola, & Saccani, 2013; Kowalkowski, Witell, & Gustafsson, 2013), as well as the dynamic capability of network orchestration.

2.3 Platforms, and their applications in manufacturer's service and solution business context

Platforms have many different definitions depending on the age and context. Over the last decades platform literature has shifted the focus from the context of physical products into abstract business environments and platforms are considered to provide the base of core components in which different actors can provide complements and increase collective value of platform. Platform is referred as a system, which solves systemic problems of ecosystems by technological element. For example, Gawer & Henderson (2007) described platforms as:

“... define a product as a platform, when it is one component or subsystem of an evolving technological system, when it is strongly functionally interdependent with most of the other components of this system, and when the end-user demand is for the overall system, so that there is no demand for components when they are isolated from the overall system”

Platform has been proven suitable operation model in hypercompetitive environments, especially when companies are trying to take steps towards service business (Chesbrough 2011). Platforms provide a practical and effective structure for the different actors of the business ecosystem to be involved with the value creation (Iansiti & Levien, 2004). It is notable that the value is not captured only by the owner of the platform. Instead, even end-users may participate in a process of value co-creation and benefit from it. The success of the ecosystem is dependent of how value networks are created and extended. Thus, platform ecosystem is very volatile: it either rises fast or dies quickly.

Taking the service and solution business perspective, according to Nishino *et al.* (2012) platform-type service system provides a bundle of multiple products and services, which is sold to end-users. (Eisenmann, Parker, & Van Alstyne, 2008). Platform offers a solution to drastically changing business systems in the age of new technology and open information. In traditional business approach value is created at upstream and consumed downstream, where as in platform allows users to create and consume value. To simplify, platforms provides three new perspectives to business:

- Understanding how new technology and information change business ecosystem over time
- Allowing and encouraging users to create and consume value
- Enabling creation of transactions without the need of more resources

Platforms seems to provide advantages when the system is complex but its requirements are heterogeneous, future technological developments are uncertain and the system must adapt to unanticipated environmental changes (Sawhney, 1998). In hypercompetitive environment platform-type service or solution systems provide security since a large network of organizations addresses the rapid technological changes. Also, the external innovators that platforms provide can increase the value of product significantly. Companies usually struggle to open their product development to external world but in a platform-type service system the owner of the platform is able to combine the innovativeness created by freedom (Boudreau & Lakhani, 2009) and a control to orchestrate network operators (Gebauer et al. 2013).

In manufacturers' service infusion literature platforms are often referred as ICT environments, which combine both technological infrastructure and opportunities for service delivery (Brax & Jonsson, 2009). However, the concept of platform has been also used in the context of service modularization (Pekkarinen and Ulkuniemi, 2008). In addition,

platforms have been seen as way to link, cooperate and innovate new services (Palo and Tähtinen 2011, Den Hertog et al. 2010). In addition, the most recent discussions (Gebauer et al., 2013; Lay et al., 2013) have suggested that service networks could be orchestrated by platforms, and some firms might be able to coordinate these platforms. However, due to the diversity of the terminology, a more detailed view on the role of platforms in creating sustainable competitive advantage for the industrial manufacturers has not been formed.

3 Methodology

The research uses case study methodology from Yin (2009) as it suits empirically novel research problems well (Eisenhardt, 1989a). The case study method has proven to be effective in unexplored and original research problems. It allows researchers to discover and theorize phenomena that are not conceptually understood (Eisenhardt, 1989a). The disadvantage of the method originates from the difficulty in judging if the results of the study apply to more general contexts.

3.1 Case selection and data collection

Case companies were selected according to the criterion of supporting our theoretical suggestion that the orchestration industrial networks possess untapped potential for manufacturing. The primary case company, called MaterialCo, is a large materials producer firm with large-scale global operations in construction industry. The firm is considering the possibilities to gain sustainable competitive advantage from service and solution networks, and is planning to use platform business models in building the network utilization approaches. The companies for the complementary cases were selected to provide a comparative perspective that could be used to deepen our analysis of MaterialCo's case and reveal more information about different approaches. All complementary firms have already established platform business in industrial services but are currently operating on a much smaller scale than MaterialCo.

Data collection and analysis were executed over a three-month period in 2014. The research was conducted in five stages. We began the study by performing an extensive bibliographic review of multiple topics in the platform literature across servitization, service infusion as well as strategic management. The second stage comprised sixteen initial interviews with participants from three companies from the upstream construction networks, including MaterialCo. The interviews were conducted with members of various levels of the case organizations, including senior executives, product managers, salespersons, factory managers, and industry experts. All the interviews were conducted during face-to-face sessions that were tape-recorded and transcribed. Each interview lasted an average of one and a half hours (ranging from 45 minutes to two hours). We used thematic coding for analyzing the contents of the interviews (Gibbs, 2008; Miles & Huberman, 1994). Interviews were continued until the point of saturation was reached where unnecessary information began to appear frequently (Corbin & Strauss, 2007).

In a third phase we validated the collected insights from interviews with some of the informants. After the preliminary findings from the MaterialCo case, we concentrated on the complementary cases, which consisted of several relatively new companies that operate in the construction business. Companies were analyzed based on public information, such as websites, articles, and business journals. During the fifth stage key findings of the study were discussed with experts from MaterialCo to verify and further elaborate the findings.

3.2 Data Analysis

After the information was collected from interviews and data transcription was carried out. The process proceeded as follows:

- Reading through the transcriptions in order to obtain a good overview of the material.
- Determining the categorization and coding.
- Coding a few interviews with chosen criteria.
- Re-evaluating the categories again to match the answers provided by the interviewees
- Coding the rest of the material.

Data analysis was executed by manually by converting the data to separate areas. Finally, the analysis included follow-up discussions to help verify and calibrate the findings.

3.3 Trustworthiness, credibility and reliability of findings

To assess the trustworthiness, credibility, and reliability of the findings, this research study employed multiple approaches based on established procedures adopted from the literature (e.g., Yin, 2009). Involving experts and key informants to review the data and analysis provides a strong basis for the process. Also, multiple perspectives help to determine saturation. The criteria of fit, understanding, generality, control, credibility, transferability, dependability, confirmability, and integrity is shown in Table 1 (Flint et al. 2002; Storbacka 2011).

Table 1. Assessing the reliability and validity of the study.

Criteria	Explanation	Method of assessing in this study
Credibility	Extent to which the results appear to be acceptable representations of the data	Three months conducting interviews in the field; preliminary results were discussed and verified with key informants
Transferability	Extent to which findings from one study in one context will apply to other contexts	Sampling across different positions and business lines within one organization; multiple smaller examples confirming the findings from the main case
Dependability	Extent to which the findings are unique to time and place; the stability or consistency of explanations	Strong interest toward internet-of-things related business models at the time of the study may bias results
Confirmability	Extent to which interpretations are the result of the participants and the phenomenon as opposed to researcher biases	Results were audited by several key stakeholders and experts
Integrity	Extent to which interpretations are influenced by misinformation or evasions by participants	Interviews were professional and anonymous
Fit	Extent to which findings fit with the substantive area under investigation	Case selection was conducted carefully to give a complete picture of the area of interest
Understanding	Extent to which participants buy into results as possible representations of their worlds	The key interviewees were offered preliminary findings and asked to comment on and verify their accuracy
Generality	Extent to which findings discover multiple aspects of the phenomenon	Interviews were long and open to capture the insights from a broader perspective. Interviewees were chosen to capture all the viewpoints of the topic
Control	Extent to which organizations can influence aspects of the theory	Participants had an opportunity to refine the theoretical suggestions

3.4 Case descriptions

3.4.1 Case MaterialCo: seeking competitive advantage in hypercompetitive environment

MaterialCo is a material and component producer for the construction industry. Due to increasing competition, the company has been strongly challenged in simple and inexpensive materials. The high manufacturing costs cause difficulties for MaterialCo to match the current price level set by companies from developing countries. The company has invested heavily in R&D and has launched a new type of construction material as well as the production process required to manufacture it. The material provides features that make it possible for use in building innovative structures with contemporary architectural and design characteristics. However, according to the case evidence, the characteristics of the material lose signification after a certain level; with MaterialCo’s product, this “good enough” level is relatively easy to accomplish.

After a certain point, the quality or the product itself does not provide any advantage. – Director, MaterialCo

It seems challenging for the MaterialCo to build long-term competitive advantage with its products or the production process itself. Nonetheless, the company is willing to develop the construction materials to a more advanced level, and thereby differentiate the product. However, MaterialCo has realized that the product development will only provide short-term advantage. The informants agree that even if MaterialCo is able to build completely new products with superior characteristics, the competitors are able to overcome the quality gap in a relatively short time period. This is because the regulation and practices of the construction industry make it challenging to make new materials inimitable.

In the construction business you can’t protect your product with patents. If you do so, the customers are afraid to buy materials without real competition between producers even if the product is better. – Director, MaterialCo

Thus, a longer-term advantage must be found elsewhere. Resource-based strategies offering processes to produce differentiated products and effective materials seem not sufficient. Therefore, the company is seeking competitive advantage from the solutions and services around the materials. Unfortunately, the construction business creates limited possibilities for MaterialCo to build dyadic relationships in the supply network, through since it is cost-effective for

investors and construction companies to let material producers compete with each other to lower the price. The different actors often optimize their own earnings without optimization for the best overall solution, which seems to prevent strong relationships to emerge especially upstream.

The construction business is local, fragmented. It doesn't provide the best overall solutions for users or buyers. Different operators are optimizing their own benefits, and in order to break the current situation, you need to shake the flow of the building process. – Vice President, MaterialCo

According to the case evidence, it is very difficult to answer to this challenge. However, MaterialCo is planning to create a new kind of collaboration around their new products by utilizing a platform approach in service and solution network orchestration. The goal is to solve the systemic problems of the construction industry and operate as an “enabler” between different actors of the network. By increasing the lifetime value of the final product and positioning itself in a central position in the solution network, MaterialCo believes that it will be able to enable longer customer relationships with the key players of the network.

3.4.2 Complementary cases: utilizing the development of ICT and available customer information

The complementary cases represent the same operational environment but from a different angle. While the construction industry is considered a conservative business where changes take a lot of time, the development of ICT and smart buildings have created dynamic networks of solution providers to the downstream of the construction business in a short amount of time. New solution providers have been able to involve end-users in value creation and rapidly increase the utility value of buildings.

Five years ago the construction business was about how good of a plot you can get and how well you build your building. But five years from now it will be about how well you handle and coordinate building information during and after the building phase. – Account Manager, Supplementary Case Company

We analyzed twelve companies that have successfully managed to make an entry into the construction value network. The biggest factor behind the success of these companies has been the utilization of customer information, such as energy consumption and humidity. The development of ICT-systems and sensing of physical artifacts (related to buildings) has allowed new actors to gain access to once hard-to-gather or proprietary information at a tolerable cost. This has created networks where some companies enable access to the data and some companies build customer solutions based on gathered information.

In the context of the complementary cases, it is *noteworthy that the mere access to customers' information was once used as a source of competitive advantage, which afforded the supplier of a product or system (buildings in this case) a better position than its competitors.* However, the protection customers' information seems no longer provides a competitive advantage.

A summary of supplementary case companies is presented below in Table 2. Table includes business areas, offerings and annual revenues of the companies.

Table 2. List of companies.

Firm	Business	Offering	Sales
Company A	Electricity control	Devices, software and services that enable smarter and easier energy consumption	11K
Company B	Building system maintenance and industrial services	Automation and energy consumption, maintenance solutions for buildings	2,5Mrd
Company C	Data acquisition from sensing devices	Embedded control systems, smart building, building automation, data acquisition from vehicles	214K
Company D	Energy consumption	Solutions for energy-efficient property management and access to the global online service	391K
Company E	Air handling and heat recovery systems	Solutions and systems for fresh and clean indoor air	12M
Company F	Security solutions for physical places	Solutions for security technology, door automatics, locking, and time and attendance systems	32M
Company G	Energy efficiency in buildings	Estimations and designs of building service systems before construction phase, management of maintenance	24M

Firm	Business	Offering	Sales
Company H	Provide user interfaces for sensor data	Provide user-interfaces and data warehouse services to sensor data	92K
Company I	Energy efficiency	Solutions and services around wireless sensors	132K
Company J	Develop tools for monitoring production processes	High-tech products and services for online monitoring and imaging of high temperature processes	-
Company K	Software technology for the Internet of things	Smart homes, remote control of energy consumption, lighting control	217K
Company L	Energy efficiency	Real-time energy monitoring for different houses	217K

4 Findings

Due to the exploratory design of this research, a detailed illustration of the case findings is required. In this section, the findings related to the two research questions are described and analyzed thoroughly. First we take a look for systemic problems in construction industry. Then, we present how manufacturers utilizing platforms could solve the problems and how the providers of platforms could benefit from situation.

4.1 Systemic problems of the construction industry

4.1.1 New information-driven business models require more integration

According to the cases, the information regarding the construction outcomes (buildings) and their users has become a foundation for new business models, facilitating the entrance of new companies to the construction market. These new actors focus both on the development phase of the building and the maintenance period that has received less attention in the past.

Online information is coming and sensors will provide more and more data. It will change the construction business. – Senior Vice President, MaterialCo

You need goals that extend throughout the life cycle. – Vice President, Technology and Product, MaterialCo

The data reveals that the new entrants are innovating and providing new services that mainly target the end user process development and optimization. In the core of these new business models is allowing end users to access information (e.g. regarding energy consumption), and providing analytical tools and applied solutions based on the insights that the provider and customer acquire together. What seems to be common is that most of them are combining different (and novel) information sources, such as weather forecasts, electricity consumption, and even location services. Most importantly, the informants agree that while the information retrieval issues (such as adding sensors to the building and combining data from multiple sources) currently do not pose severe issues that would inhibit the development of the new business models, it would be most cost-efficient to implement data-gathering tools during the installation of the building. However, none of the smaller companies included in our sample had the opportunity to influence the building construction to make this happen.

Many operators have an interest to collect data from the building process and there should be some universal ways to do it. At least at some point there will be. – Account Manager, Supplementary Case Company

Systemic problem 1: While the role of customer information is rising in the business models of construction industry, the lack of technical integration between different actors providing this information is inhibiting the solution innovation and business model development

4.1.2 ICT-tools restrict the innovation in the upstream of the value network

According to the informants, the importance of ICT has increased constantly over the last decades in the construction industry. For example, majority of building projects gather information to common interactive building infrastructure modeling tool (BIM) throughout different phases of the construction process starting from designing till actual building stage. While at the moment ICT is considered to be just in a supportive role in construction it is possible that in a future the actual building has significantly less important role in construction projects.

Information models are not utilized yet in the maintenance process but it will be used in next few years. – Software Technology Manager, Supplementary Case Company

Five years ago construction business was about how good plot you can get and well do you build your building. But five years from now it will be how well you handle and coordinate building information during and after the building phase. – Account Manager, Supplementary Case Company

However, especially new products are difficult to implement in mainstream BIM systems. It seems that the ICT tool development, although being crucial, does only seldom lead to dominating positions in the industry networks. The lock in to current ICT solutions, such as BIM software seems to be so high that new entrants find it challenging to take over larger parts of the construction process. As the one of the informant from supplementary case company stated: “The switching cost for BIM is so high that I doubt our company would even consider changing it.”

Systemic problem 2: While ICT-tools have enhanced the construction process significantly over the recent years, they still just optimize existing (conservative) processes and procedures. The innovation in the upstream of the value network is thereby restricted.

4.1.3 There are problems in resource-efficiency

Based on the evidence, it appears that the fragmentation and suboptimization of the industry is at least partly inhibiting the efficiency of the industry-wide processes, as well as the value creation opportunities for all stakeholders and the overall quality of the end products. Currently, the fragmented construction industry does not provide the best overall solutions for investors, which often increases costs during the maintenance phase. However, there seems to be large interest in utilizing the development of ICT and “smart” products (or in this case smart buildings) to solve the resource-efficiency issues. By “smartness” the informants refer to the ability of the buildings and construction components to transmit information about wear and tear, analytically planning the maintenance operations, and also developing better quality products. For example, major renovations, such as plumbing projects, can be executed far less expensively when construction companies or designers leverage existing building infrastructure modeling as well as building usage information. Especially for the material producers, this information decreases the logistics cost and makes it possible to supply materials just in time.

Naturally there is an enormous amount of data and information inside ICT systems. We should build some kind of tools to process it. When analyzed, the results would be incredibly valuable for business. – Director, MaterialCo

Anyone who holds the information about the building has significant advantage over the other competitors when you need to repair or install new things in the building. – Software Technology Manager, Supplementary Case Company

At the moment, there is no party that could naturally assume the role of generating the “big picture” that is needed to develop smart buildings further. Investors and other operators do not want to commit to just one party providing the prerequisites for “smartness.” In addition, especially the investors seem to be more interested in construction process optimization than the building lifetime value development. Due to these reasons, no party has been able to fully utilize secondary markets that actually provide even more turnover than the manufacture phase of the building. The developers, architects, designers, investors, and construction companies themselves also focus just on optimization of their own parts of the process. The BIM providers, described earlier, have managed to enter the market by binding different actors together with common design models in the development phase of the buildings. But again, the maintenance phase of the building continues to receive very little or no attention.

It is easier to make a development with the investor and commit it to process than it is with the operator who does the construction. – Product Group Manager, MaterialCo

Investors are increasingly interested about information modeling, but usually they are not exactly sure what they really need. – Account Manager, Supplementary Case Company

It is difficult get our hands in the secondary markets. We haven’t found the way to do so yet. – Senior Vice President, MaterialCo

However, there still seems to be potential to take a resource-orchestrating role in the construction industry. According to the case evidence, the problem of resource efficiency may become more and more visible in the future, particularly as the buildings and the construction process produce increasing amounts of data that 1) shows the problems to the end users paying the final invoices and 2) slowly reveals the possibilities for improvement. For example, as the building information models become more detailed and sophisticated, new possibilities are revealed when other types of “smart building” data is combined in the models. The position of industry orchestrator is open to a party who can 1) gather data; 2) bridge structural holes in the construction industry inhibiting the resource efficiency; and 3) show the benefits to the users and the investors of the buildings.

Systemic problem 3: The construction industry is affected by suboptimization and opportunism of individual actors. ICT is providing tools to increase the resource efficiency (e.g. with smart buildings) and creating opportunities for new business especially in the maintenance phase of buildings. However, this requires resource-orchestration among many actors of the construction industry, and no actor has been so far able to take the orchestrator role.

4.2 Opportunities for platform providers

In this section we answer to the second research question, and present three types of platform models than can, according to the evidence and theory, provide potential sources of competitive advantage for the manufacturers in the construction industry.

In line with the theoretical reasoning presented in the first sections of this paper, the findings seem to suggest that it might be possible for the industrial manufacturers to base their competitive advantage on effective management of industrial networks and ecosystems. Building on the identification of the systemic problems of the construction industry, three modes of operation are identified. These findings reveal how a so-called solution platform approach may concretely extend the possibilities for the servitizing manufacturer, especially in the upstream of the value chain, and provide new sources of sustainable competitive advantage in a dynamic and networked environment. Three, platform-based operation modes are described next.

4.2.1 Resource-optimization intermediary platform

The first option, acting as a resource optimization intermediary, would leverage the material producers' central position in the industry by synchronizing the actors' operations, making the resource slack (identified in systemic problems) visible, and optimizing the resource usage among different actors. In practice, this may mean analytical and design tools, as well as tools that help co-operation between different actors. The possibility to deliver these tools is enabled by the cumulative and real-time information gathered by the sensing technology that is included in the construction material itself. From the strategic perspective, the company is helping the networked actors to enhance the valuability of their resources and to identify new resources and resource slacks. The sustainable competitive advantage is built on the dynamic process of gathering knowledge about the potential optimization possibilities of the network.

4.2.2 Platform for resource and actor combinations

The second option, based on the formation of new resource and capability combinations, would intelligently combine the service innovation and provision together. With this mode, the materials provider would not be just optimizing the current actor network and making it more effective. Instead, the firm would form an innovation platform, on which actors can meet and form new innovations by combining their resources and capabilities. More concretely, the material producer would give access to the ready-made smart technologies included in the construction material and facilitates open innovation of the construction ecosystem. The materials producers could also develop the pilot solutions on their own, thereby acting as a catalyst for the innovation.

4.2.3 Industry restructuring platform

The third mode of operation is then more about restructuring the construction ecosystem itself. With the help of information that the smart construction materials are able to gather and the analytical tools with which this information can be processed, the material producer could identify the structure of the construction ecosystem itself, information asymmetries, and even potential opportunities. By providing access to the information and analytical tools, the company could develop a dynamic capability of sensing, seizing, and reconfiguring the social network of the different actors and their resources in the industry. Reflecting the theories of strategic management, this might provide the materials producer with an agile and sustainable source of competitive advantage.

5 Concluding discussion

There has been an emerging interest towards network approach in the manufacturers' service infusion literature. This discourse has indicated a clear need to develop strategies around the network approach that help the manufacturing industry differentiate and overcome increased competition. However, consensus on how this should be done has not been formed. The present study aimed to deepen the current understanding of manufacturers' abilities to gain competitive advantage in the hypercompetitive environment. Our analysis states that leveraging solution networks have the ability to provide competitive advantage, while platforms might to be an effective tool to gain it. Furthermore, our study indicates that especially upstream actors should, instead of developing own solution offerings, consider developing so called solution platforms that provide prerequisites for solution provision for the actor network, and bind number of solution providers together. In other words, the upstream actors should analyze how their business could be a platform for other firms efforts in the same industrial network.

To further elaborate these directions, we have suggested three different modes for manufacturers to solve the systemic problems in the industry. The three modes are: 1) resource-optimization intermediary platform, 2) platform for resource and actor combinations and 3) industry restructuring platform. It appears that all these modes of operation are practically information-driven. In the modes, the upstream actor perceives the physical object almost as a side product, and the information provided by the smart technologies, especially the cumulative history over time, provide the potential competitive advantage. Moreover, the benefits of the information are leveraged not by protecting information, but by giving access to it (at least partly) to the external actors. This is a remarkable shift from the product-driven model in which the competition is based on product arguments, such as weight, cost, and structural features. Furthermore, this is a shift from the dyadic solution model in which the company is jealously protecting the customer relationships and intentionally building information asymmetries in the relationships to ensure the best stake of co-operation.

Thus, according to the case evidence of this study, it clearly appears that the solution business is possibly extending its dyadic focus in value creation. Of course we still perceive that delivering customized solutions and “servitizing” the offerings remains relevant. However, the manufacturers’ service infusion discussion should be complemented with other approaches based on amore systemic perspective. Based on the results of this study, we suggest that besides solution providers, scholarly discussion of manufacturer service infusion should also include solution platform providers, which provide the prerequisites for solutions and facilitate the formation of service networks and ecosystems. Although these two strategies form a systemic combination, it is important to reiterate that the logic of value creation as well as the source of sustainable competitive advantage is very different among the options.

Mapping value network and multiple stakeholder values for developing a new service: An industrial case study

Katariina Palomäki¹, Katri Valkokari¹, Marika Ryyppö²

¹VTT Technical Research Centre of Finland, ²Vapo Oy

The understanding of value has changed, and in addition to customers, the role of also other stakeholder groups in the value creation has been emphasised. This case study presents a way in which stakeholder values can be taken into consideration in new service development process. The paper employs the case study methodology, and the case data was collected from workshops, interviews and thematic discussions. The main result of this case study is the description of the new service development process that considers stakeholders and multiple stakeholder values.

1 Introduction

The understanding of value has changed due to ‘global competition, changing markets and new technologies, opening new ways of creating value’ (Normann; Ramírez, 1993). It has been viewed and studied through many lenses: The service-dominant logic (SDL) approach highlights value co-creation and the concept of value-in-use, thus considering not only a company but looking also outside the company boundaries, mostly customers. In the new service development (NSD) approach, in turn, the value capture is based on inter-organisational planning processes that should be carried out in close collaboration with customers. However, in addition to customers, the role of also other stakeholder groups in the value creation has been emphasised as stakeholders are now paying increasing attention to the business, and especially to the responsibility of companies, and are calling for environmentally and socially responsible business. The concepts of corporate social responsibility (CSR) and sustainable development, among others, have risen to depict the expectations that business life and companies now face: responsibility for their impacts on society, and a broader understanding as well as the consideration and involvement of stakeholders (see e.g. Boutilier, 2009; COM, 2011).

Bringing together these perspectives opens up an opportunity to explore value-based new service development. Exploring the challenges and opportunities of shared value creation not just between customers but also among multiple stakeholders is important in the transition from a company-centred perspective towards a network perspective. Besides the network-view on value creation, the concept of a business ecosystem sees companies’ business environment as a larger entity, a value system, in which all stakeholders co-produce value and also capture the value from the co-operation thus creating a constantly co-evolving relationship (Moore, 1996). The new perspective on doing business is valuable for companies as identifying and understanding the interests and motivation of all parties involved also opens up possibilities of foreseeing new business opportunities and possible development paths (Geels, 2004; Antikainen et al., 2013; Valkokari et al., 2014).

Because of the networked business environment, now the success of a firm is greatly dependent on its collaboration with other organisations – whether in its close value network or in the wider business ecosystem – that have an influence on the creation and delivery of its services or products. As the traditional focus on firms as discrete entities becomes increasingly inappropriate, multiple values and conflicting interests must be considered at both the value network and business ecosystem level (Valkokari et al., 2012). With sustainable business models, companies seek to go beyond delivering economic value only and aim to generate environmental and social value for a broader range of stakeholders, thus creating competitive advantage through superior customer value while contributing to the sustainable development of the company and society (Lüdeke-Freund, 2010; Schaltegger et al., 2011; Bocken et al., 2013).

In the case this paper presents, the new service being developed is the case company’s first opening to implement a new service based on the vision of the improvement of the state of water systems and preservation of clean natural water. The case study presents a way in which stakeholder values – a key aspect of sustainability – can be taken into consideration in new service development process, and especially in one of its stages, the analysis stage. Thus it aims to identify and explore multi-stakeholder value at network level. For this purpose, the value mapping tool (Short et al., 2012; Bocken et al., 2013) plays a key role in creating a deeper understanding of multiple values across the network. Since the paper concentrates on the development process from the viewpoint of understanding stakeholder value, it excludes any detailed discussion of the service concept development or each stage of the service development process. The paper addresses the following research question: how can multi-stakeholder value across the value network and business ecosystem be identified and explored in a new service development process?

This paper begins by presenting the background to the case and the current understanding of the main themes of the study. The materials and methods chapter elaborates on the research process, and presents the value mapping tool on a more detailed level. This is followed by a brief discussion of the case findings, after which the paper concludes with a final discussion, outlines lessons learnt, and presents further research suggestions, and limitations.

1.1 Background to the case

The case company is a bioenergy supplier and developer that is now developing a new knowledge-intensive service concept for natural water treatment. A clear need for renewal, new openings and new business has been acknowledged in the case company. Thus, the new service development is seen as an important model to learn from in the development and renewal of the whole company.

The new business is based on the water treatment expertise that has been gained in the responsibility and sustainability measures within the company's core business within which this kind of expert service has been given in internal projects. This expertise is now developed and productised in order to be sold as a service to external customers who have similar challenges with natural water. Hence, the service development process now is different, too, as the in-house expertise now needs to be modified into a form of a service offering that can be sold to external customers.

The case company aim is that the new service would be applied to benefit society also in a broader sense through the improvement of natural water and that the service complies with the definition of a sustainable business model presented before: it not only delivers economic value to the case company and to the customer through improvement in productivity, but it also prepares the way for companies acquiring environmental licences and delivers environmental value through the protection and conservation of water, thus contributing also to societal wellbeing, among other values. The new service and its value need to be argued and justified to the various stakeholder groups in the business ecosystem of the company. The case company needs to be able to assure its stakeholders and open up discussions with them, as well as breaking through to the market with the new service concept. Consideration for and dialogue with the stakeholders make demands on both the new service concept and for the new service development process.

The current business of the case company is heavily dependent on its value networks that operate at a very regional level and are extensive. Also, the implementation of the new service requires building and governing an extensive network and thus consideration of multiple stakeholders who are affected by the service and have special interests in the company. At this point, the suppliers and other network actors have not been defined, but the concept is being tested in pilot projects in which already familiar partners are used. Now, as the development process is still ongoing, understanding the values and interests of the stakeholder groups as well as influencing and assuring them of the benefits of the service is in the key role.

2 Current understanding

2.1 New service development and stakeholder perspective

There are a number of models that aim to describe the new service development process. Johnson et al. (2000) present new service development as an iterative process cycle that is divided into four stages, namely: development, analysis, design and launch. At the development stage of a new service, new ideas are screened, and winning concepts are developed and tested for feasibility. Those concepts that pass this stage are then considered in the analysis stage in which their potentiality as part of a profitable business venture as well as the value network structure and information flows are considered. After this, successful concepts move to the design phase where a new service product and process is created and field-tested with appropriate personnel training and a marketing campaign. At the design stage the service is planned and defined with such specificity that it can be implemented at the next stage. At this stage, a mapping technique called service blueprinting with which the service process can be visualised in a process flow chart, can be used. Finally, a proven new service is given a full launch. (Shostack, 1984; Johnson et al., 2000.) The work and discussions carried out in this case study focus on the analysis stage of the new service development process.

The role of customers has been recognised as important for the success of a new service development. Typically the more successful new service developers have efficiently utilised information about the customer in idea generation, business evaluation and marketing plan preparation (Martin; Horne, 1995). Especially the first steps of the new service development process are known to require a deep understanding of the customers' behaviour and needs, production, and business processes (see e.g. Ojanen et al., 2008). Understanding the customer in terms of his expectations, quality perceptions, and values is said to be the key to commercial success. It is important to involve the customer in the actual development process. (Edvardsson et al., 2007.)

However, apart from the customers, the company needs to monitor and understand its environment and changes and trends in market (Edvardsson et al., 2007). The network perspective related to sustainability highlights considering stakeholders in a broader sense, thus including actors other than the direct members of a value network (i.e. lead producers, their suppliers and customers) (Boutilier, 2009). When doing sustainable business, companies need to understand not only customer value but multiple values for different stakeholders.

2.2 Value networks and multiple stakeholder value

A value network generates economic value through complex dynamic exchanges between customers and suppliers. Möller et al. (2005) propose a value system continuum when discussing the value creation potential of different kinds of value systems and networks. The continuum is a simplified illustration based on assumptions about how stable and well-defined versus emergent and still rather unstructured the value systems are (Möller; Rajala, 2007). In the context of

this case study, value networks present well-defined supply networks, and a business ecosystem can be defined as a broader value system in which all stakeholders act (Palomäki et al., 2011; Rana et al., 2012; Valkokari et al., 2013). The literature on service-dominant logic highlights that all value is co-created (Vargo; Lusch, 2006). Nevertheless, a consistent understanding of value and value co-creation remains missing (Grönroos; Voima, 2012). Furthermore, prior service literature do not often emphasize the network context in which value creation often takes place (cf. Gummeson, 2008), while the focus is in service provider – customer dyads. In the present networked economy the focus should be on reinventing value in terms of the value-creating system itself where different actors – suppliers, business partners, allies, stakeholders, and customers – work together to co-produce value (Saarijärvi et al., 2013).

The value network actors are both directly and indirectly connected to each other. Still, companies should be able to manage these collaborative settings in a way that allows each party to profit from being involved in the value co-creation. Thus, the core capabilities of the partners involved in value creation should be complementary, in order it to be possible to create superior value (Kothandaraman; Wilson, 2001). All in all, the final value that end customers of the value-creating networks want determines the nature of the member actors' operation and the role that will be valued by the other network members.

The scope of value needs to go beyond customers, immediate partners and shareholders. This involves identifying stakeholders in the business ecosystem of the company and their needs to gain precedence in the development of sustainable solution through business model innovation (Valkokari et al., 2013). This implies the need for improved and broader understanding of multi-stakeholder value – both exchange value and use-value. Furthermore, it is important to seek opportunities for alignment and exchanges between stakeholders (Rana et al., 2012). In order to develop sustainable business models, there is a need for better visibility of stakeholders in the business environment. To answer this need, this paper uses the value mapping tool for exploring a broader set of stakeholders and their value perspectives (Short et al., 2012; Bocken et al., 2013).

3 Materials and methods

The case study methodology is employed in this paper. It is suitable for analysing situations that include complex and multiple variables and processes by asking ‘how’ or ‘why’ questions about events over which the investigator has little or no control (Yin, 2003).

The case data was collected from multiple sources: workshops with company representatives, interviews and thematic discussions. The following figure (Figure 1) presents the new service development process and its stages, and the steps in the case study.

Figure 1. The new service development process and the progress of the case study.

Prior to the case study, the case company had already conducted strategic discussions regarding service development in the development stage. This study focuses on the analysis stage regarding which two workshops were organised, in addition to which interviews were carried out. The workshops provided the case study information on the value creation from the stakeholder perspective. The case company is continuing the development process in the design phase with more detailed planning on the content of the service as well as on the sales and marketing process, among other important issues. In the chapter that follows, the research process is presented, after which the value mapping tool is discussed at a more detailed level.

3.1 The research process

Within the new service development process of the case company, two workshops were organised with the company representatives. In the first workshop the key theme was value mapping. The goal was to recognise stakeholder groups relevant to the new service and to prioritise them according to their level of interests and power. This stakeholder analysis group work was carried out with a fourfold table with the above-mentioned factors as its axes (cf. Mitchell et al., 1997). After this, a value mapping exercise was carried out. In this, the value mapping tool (Rana et al., 2012; Short et al., 2012; Bocken et al., 2013) was utilised to recognise the value experienced by the stakeholders that was most relevant to the new service. Through the use of the tool the benefits and challenges from the viewpoints of the different stakeholder groups were also discussed. The tool is described more in detail in the following chapter. Five company representatives took part in the first workshop. The key result of the first workshop, the completed value mapping tool, gave a broad view to the issue of stakeholders and the positive and negative value they could experience.

The second workshop deepened this understanding by considering value from the viewpoints of three important customer groups. The first group work covered listing the elements of the new service concept. After this, the customer value of each element was discussed. Discussion was documented into an expert service–customer value table. The second part of the workshop went more deeply into the sales process of the new service. Nine company representatives took part in the second workshop.

This paper focuses especially on the stakeholder value perspective which was contributed by both of the workshops. Understanding the stakeholder value, and taking this understanding to the new service development process work is in the main focus of this paper. However, as can be seen from the workshop descriptions above, the whole case study process was broader, focusing not only on the value mapping, but aiming to support the new service development in the case company more broadly. Therefore, with the focus on the analysis stage of the new service development process, a detailed discussion on stages following the analysis stage (such as the development of the sales process or the service concept on a more detailed level) are excluded.

In addition to the workshops, five interviews were also carried out in the case. The interviews covered the following themes: sustainable development as a part of business, networks and sustainable development, product and service development, asset management, the value of sustainable development, and future needs. In this paper, especially the findings from the themes of sustainable development as a part of business, networks and sustainable development, product and service development, and future needs are discussed in respect of the change that is taking place in the company, in particular. The results and findings of the interviews are utilised in this paper in order to open up the background of the company as well as the motivation and the starting point for the new service development process.

Also, several thematic discussions were carried out throughout the process relating to the planning of the case process and the workshops and to the handling and discussions of the results.

3.2 The value mapping tool

In the first workshop, whose progress has been briefly described above, the value mapping tool (see Figure 2) was used (Short et al., 2012; Bocken et al., 2013). Originally, the tool has been developed for business modelling for sustainability, and it aims to assist companies in embedding sustainability into the core of the business model through an improved understanding of the value proposition. It takes the network perspective, and helps in analysing sustainable value creation opportunities from a multi-stakeholder perspective and understanding the positive and negative aspects of the value proposition of the value network. (Bocken et al., 2013.)

Figure 2. The value mapping tool (modified from Bocken et al., 2013; Evans et al., 2013).

In practice, the tool is used in a workshop-type of setting. Ideally, each stakeholder group considered relevant to the business would also be represented in the workshop. After introducing the tool and the context in which the tool will be used, the unit of analysis (e.g. product, service, business unit) should be defined. Then the stakeholder groups are identified and placed on the segments of the tool, and the purpose is discussed. Brainstorming is then used to populate the tool and its layers. (Bocken et al., 2013.)

In this case study, the value mapping tool was utilised in the new service development process to help identify and explore the values of stakeholders, i.e. how they would benefit from the new service and what negative outcomes there might be for them. In the value mapping tool exercise of this case study, the stakeholders were chosen based on the previous prioritisation discussion, placed on the segments, and then discussed in a brainstorming session. The discussion was documented. The guiding questions for this exercise were (cf. the descriptions of the elements in Bocken et al., 2013; Evans et al., 2013):

- Purpose: The purpose and the vision of the new service, especially from the viewpoint of responsibility and sustainability.
- Value captured: How the value of the new service for the stakeholders of its network could be added?
- Value destroyed: What values are in danger of being destroyed? Which stakeholders does this concern? How the negative consequences could be affected?
- Missed value opportunities: What positive influences, stakeholder opportunities have not been utilised and highlighted in the service concept yet? How could this be done?
- Value opportunities: Are there still some value opportunities that have not as yet been acknowledged that could bring new value to stakeholders?

In addition, the participants were asked to discuss what measures should be taken in order to move on the circle towards the higher value experienced, and thus to be able to add value to the stakeholder group in question. As a concluding discussion for this exercise, the participants were asked to review the value map as a whole, and discuss whether any of the groups now stood out in a new light or whether the order of importance had changed, and what conclusions could be drawn.

4 Case findings

In addition to identifying the stakeholders in the network of the new service concept, it is important to know and understand their needs, interests and motives in relation to the service concept. In the first workshop, the value network of the new service was depicted, based on the work that was already carried out in the company. The following figure (Figure 3) presents the stakeholder groups in the network and broader business ecosystem of the new service.

Figure 3. The network and business ecosystem of the new service.

Group work on stakeholder analysis that followed (Figure 4) looked into the importance of the different groups to the implementation of the new service in order to give the company a better understanding of how to proceed with contacting and discussions with the groups, and which ones especially need special attention.

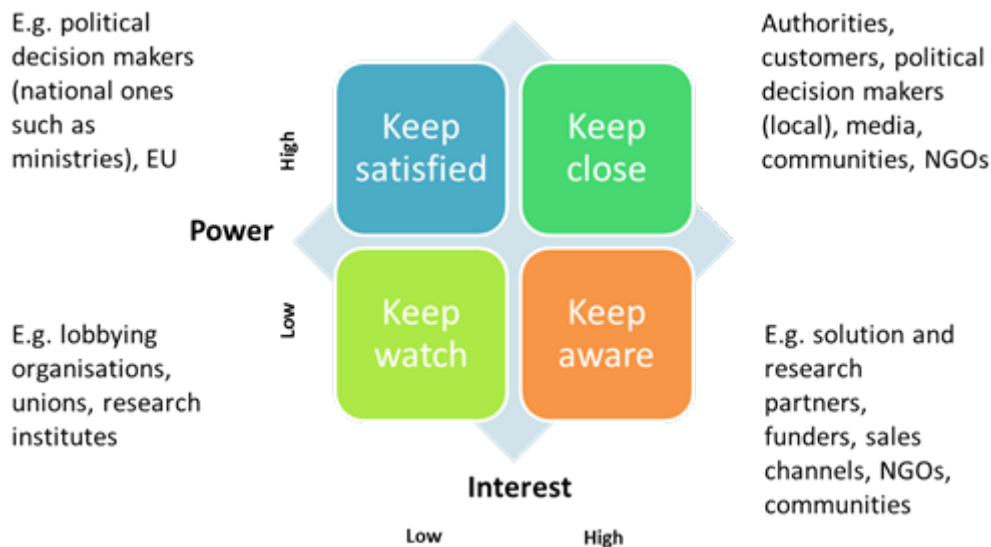

Figure 4. Stakeholder analysis.

Keeping these discussions in mind, the workshop proceeded to the value mapping exercise. With the greater aim of the company to be able to influence and get the stakeholders committed to the new service once it is launched, the value of the new service experienced by the different stakeholder groups was assessed and discussed. The findings were entered on the value map (Figure 5).

Figure 5. Some examples from the value mapping tool exercise for the new service.

As a conclusion to this exercise, the findings were discussed together, especially from the viewpoint of what could be changed or done better in order to bring more value to the stakeholders relevant to the new service. Also, the connections between the different stakeholder groups were brought up.

The first workshop created an understanding of the value network and broader business ecosystem of the new service concept. In practice, the identification and prioritisation of stakeholder groups and the value mapping gave the case company inputs to their influencing and communication planning. Taking the standpoint of each stakeholder group and considering the benefits and challenges, and value experienced of the new service supports the understanding of how different groups should be approached and engaged in discussion, and also the actual service development work.

The first exercise of the second workshop resulted in a list of possible service elements that the company could offer under the new service concept. The suggested service elements included support in applying for funding and subsidies, the preparation of calculations, reporting and modelling, impact assessments and consulting services, to name a few. For each of the named service forms, values for the key customer groups were discussed. This discussion brought up customer values such as ease, cost effectiveness and savings, lower risks, complying with regulation, less bureaucracy, clear processes, access to the right people, authorities and other companies through the networks of the case company, competitive advantage, etc.

The findings of the second workshop supported the case company in their work in describing the service concept and its main elements, marketing and sales planning (especially the work on customer value), communication planning, sales material as well as defining the sales process. The workshop gave the company tools for the further strategic development work.

5 Conclusions

The main result of this case study was the description of the new service development process that considers stakeholders and multiple stakeholder values. The findings of the study highlighted that a multilevel approach that extends also to the analysis of other stakeholders and their values instead of to customers only is required in order to explore the business opportunities and challenges on network level and to achieve systemic change towards sustainable value-based business models within the networked business environment.

The contribution to the theoretical discussion in the field of new service development lies in the stakeholder perspective. Both value co-creation and new service development discussions are very customer-focused: in value co-creation literature value in-use is emphasised, whereas new service development stresses involving customers in the process. The meaning of also considering other stakeholder groups in the business ecosystem and the value they

experience is important, because in a networked business environment, offering services causes a need for a new kind of distribution of work, thus changing actors' business logics. Also being able to develop responsible service business requires this kind of broader consideration of the business environment and of the stakeholder value not just from an economic perspective but also from environmental and social perspectives.

This case study gave the company the possibility to explore and analyse the multiple value perspectives and interests of stakeholders, especially from the viewpoint of responsibility and sustainable development. Thus, the study gave the case company tools that support the company in its efforts to develop service offerings and business that considers its business ecosystem and that delivers economic, environmental and social value to stakeholders. For the case company, the new service development process has been an important step in renewing its offering and operations, and the study presented a novel example of how to refine in-house expertise for a service for external customers. The case company also benefited from the case study in several concrete ways: e.g. the stakeholder analysis and value mapping supported planning how to communicate with stakeholders, and the customer segment analysis especially supported sales and marketing planning.

The lessons learned from this process could motivate and encourage broadening the service offering of the company further in the future, and work as a model for other new service business openings that are modified from internal services to external customers. To take this further, the company may need more resources and investment in R&D activities as well as development of the processes. As strong emphasis on services requires a change in the role of a company from an expert to a customer's problem solver, the company representatives selling the new service may need to adapt their mind-set according to the new role. This may also have implications for the sales process development currently ongoing in the case company.

In the future, the company continues to work with the service development process. After the main components of the new service concept have been described, the work may continue with more precise descriptions of the business models of each service element, and with evaluating their value to the most relevant stakeholders thus attaining a more detailed level in the analysis. Each service element is valuable in a different way, and thus also the ways they affect stakeholders are unique.

This paper has only discussed some parts of the new service development process, mainly those that dealt with identifying and exploring multi-stakeholder value at network and business ecosystem levels. An interesting further study idea would be to follow the process and the launch and implementation of the new service. However, at this point it is impossible to say yet how this new service opening will affect the company as a whole. In the future, studying the concept of multi-stakeholder value would also be interesting. Questions such as how it could be defined or measured are just some important viewpoints on this issue.

There are also some limitations regarding the use of the tools. Naturally, the company has continued to work with the workshop findings but with the limitation of just two workshop days, these discussions and iterative rounds are not part of the material of this case study. In addition, involving stakeholder representatives in this discussion would be important and very beneficial, especially in the case of the value mapping tool. Getting stakeholders more involved in the new service development process is a challenge to be considered also for the case company in the future. It is possible only if the factors that motivate stakeholders are truly understood in the company and communicated to the stakeholders. To achieve this, the company needs to start with inter-company discussions. The workshops and related discussions carried out in this case study have laid a foundation and given new tools and ideas to the company representatives for this communication and for the continuing service development.

The need for Evidence Informed Practice in foster care social services

Monica Pedrazza¹, Sabrina Berlanda²

¹University of Verona, ²University of Trento

We present a case study involving a regional child welfare service in Italy. The limitation of financial resources motivated the local agency's management to systematically explore the information and data flow on foster youth in charge by the service. A qualitative exploratory analysis on perceived information/data flow within the whole service referring both to content and structure, was carried out. Core categories of data shared within the service were identified. Critical Incidents within the inter-services information flow were codified and highlighted that evidence based evaluation and communication in health service was associated with a relevant percentage of perceived critical issues. Future research should be addressed to improve evidence informed practices in child welfare.

2 Introduction

1.1 The regional child welfare agency

The context of our study is the regional agency of child welfare in Trentino South Tirol. 150 social workers are active in 2014: 1258 minors are in charge of the service and are eligible for out-of-home placement or already placed in group homes residential centres or day-care services (day time homes) (Table 1). The out-of-home placement service assigned 64% of foster youth to foster home and the 36% to group home for daytime care service. Removal from unsafe home environment should ensure children's wellbeing. Given the great number of different guidelines and standards for out of home placement, individual discretion of social workers remains a critical component of decision-making processes (Chor; McClelland; Weiner; Jordan; Lyons, 2013. Bickman; Karver; Schut, 1997. Pedrazza; Trifiletti; Berlanda; Di Bernardo, 2013).

The agency requires the contribution of four different services: the social service; the educative service (which provides for residential homes, day-time care homes services for foster youth and domestic care service); the health service (medical professionals) and the educational service (nurseries, kindergartens and schools) (Figure 1). 2144 practitioners and professionals are active in the agency in 2014: 150 case workers, managed foster youth cases with the active, recursive and mainly in protocols regulated and registered contribution of 529 educators, 650 teachers, responsible for Special Educational Need-pupils, and 815 medical professionals.

Table 1. Number of children in foster care social service.

Services type	Number of children in charge
Residential Services	103
Daytime Services	971
Home Help Services (family support)	184
TOTAL	1258

A pie chart illustrating the distribution of children in foster care. The chart is divided into two segments: a blue segment representing Residential Services at 36%, and a larger orange segment representing Daytime Services at 64%. A legend below the chart identifies the colors: a blue square for Residential Services and an orange square for Daytime Services.

Figure 1. Foster care social services.

70% of the total number of children in charge of the service are also classified as pupils with special educational needs (Table 2).

European countries estimate the number of SEN (pupils with special educational needs) pupils from less than 1 per cent in some countries to more than 20 per cent in others. Variations appear to stem from differences in how individual countries define SEN and whether estimates are based on administrative sources used in some government agencies or national cohort or survey data in others. To overcome issues with international comparisons the OECD has devised a framework of A, B and C categories where Category A refers to a disability from an organic impairment (Disability); Category B refers to intellectual, behavioral or other learning difficulties (Difficulties); and Category C refers to difficulties because of social disadvantage (Disadvantage). Large differences remain, however, even when using the SENDDD (Disability, Difficulties and Disadvantage) categories (OECD; 2005. Banks; McCoy, 2011, 1-2).

Table 2. Trend in the number of pupils with special educational needs (SEN – Category C).

Type of school	Percentage of pupils with SEN (Category C) 2012/2013	Percentage of pupils with SEN (Category C) 2013/2014
Primary school	1.50%	1.54%
Middle school		2.80%
Vocational school	1.46%	2.87%
High school	0.17%	0.27%
TOTAL	1.10%	1.62%

2 Theoretical Framework

2.1 Decision-making process in child welfare agency

The local social work agency deals with decision tasks concerning the relational and social rather than the physical world. In addition the social reality, it deals with, consists of foster youth and families of origin who usually attach very differentiated meanings to their home behaviour (Mead, 1934). The agency's staff should analyze and decompose the social and health situation of the child and the family into its parts and elements in order to accomplish the rational analysis of the all system.

In addition social workers have to deal with a double commitment: on the one hand they have to promote emancipation and autonomy, on the other hand they use means of social control and strive also for social order in domestic inter-personal context (Gambrill, 1997). The subjective perceived conflict related to such different aims and goals cannot be rationally and/or by authority resolved, and so the tendency towards intuitive decision-making processes is likely to be high (van de Luitgaarden, 2009. Hammond; Hamm; Grassia; Pearson, 1997).

Hartman (1992) and Leung (2007) describe this specific goal of social service as a paradox: in their dealing practice, social workers have, on the one hand, to believe in their expert knowledge referred to their understanding of the client's situation. On the other hand they are committed to core values of care and social justice and should take into account client's values and perspectives.

The co-constructive decision-making process within the agency shouldn't be exclusively an application of the so call "expert knowledge", it should rather include client's issues in the whole inter-services evaluation of the child's situation.

The agency's staff as any child protection organization is heavy in procedural documentation (Gambrill; Shlonsky, 2001). In addition the high documentation demand is associated with high caseload and high turn over staff. Last but not least, high sensitivity to negative media exposure attributes higher desirability to supervision than to continuity of expertise (Munro, 2009).

Von Malmborg (2007) explored the role of Local Authorities in actor-networks related to regional sustainable development. In their potential ability to stimulate learning and innovation for sustainable development Local Authorities can act as "teachers" or "tutors" in networks. They typically support incremental innovation rather than radical system innovation, stimulating long-term changes. Empirical studies suggest that the active participation of Local Authority as "teacher" in the network is associated with closer collaboration between all members. In our study Local Authority of the child welfare agency played the role of "teacher" referring to two different goals:

- 1) it supported follow up actions after the introduction of a new tool at the educative service level of the agency;
- 2) it supported a qualitative exploratory study of the inter-services information/flow within the agency.

Both goals were achieved with the support of academic researchers involved from the beginning of the intervention as partners in the following paragraphs described action research.

2.2 Data collection and flow of information on foster youth

In their face to face daily practice social workers have to understand the users' social situation and personal condition trusting in their own ability to analyze collected data and information with respect to problem natures, targets, methods of intervention and intervention stages (Reid, 2002. Pincus; Minahan, 1973). They are committed to take care of the user avoiding judgment, as Leung (2007, 192) argues they "are committed to core values of care and social justice and the belief that they should not participate in any oppressive practice".

The initial assessment, the evaluation of situations before intervention, the diagnostic-evaluation *in itinere* and the outcome evaluation, which typically allows team members to determine the conclusion of the social service intervention, are crucial aspects in child welfare (Boutanquoi; Bournel-Bosson; Minary, 2013). In order to achieve these goals professionals develop tools, which are meant to be a guide for collecting data and organize information. Data and information from different services, health, care, educational and social, have to be gather at the intra-service level and shared at the inter-services level, in a meaning-making dialogue where the agency's knowledge is produced. This dialogue is not a simple exchange of information at a cognitive level, it implies interpersonal perceptions of emotions and attitudes (Leung, 2009).

The epistemological premises guiding knowledge production practices through assessment tools of each service operator, social, health professionals and educational practitioners, vary relating to the following aspects:

- Epistemological premises and theoretical frameworks;
- Setting;
- Method;
- Context and content of outcome evaluation;

These different perspectives (Table 3 and Table 4) are necessary in order to enable the service as a whole to gather and organize data and information on foster youth relating to each aspect of their life and assets.

While within each service assessments and outcome evaluations are congruent with epistemological premises and methods, we often notice that the final inter-services outcome evaluation cannot be congruent with each one of the different approaches: health-care, social, educational and care. There is a need for co-construction of shared meaning in order to integrate the high amount of information and data flowing from different services to the social work case-worker who is entrusted with the responsibility of general coordination.

According to Leung (2009) practitioners apply, modify and share tools according to their needs.

The tacit dimension of knowledge is linked to the implicit premises each professional adopts, and it orients interpretation practices relating to "what others know" referring to each case. As Tsoukas and Vladimirou (2001) argue such knowledge is difficult to be verbalized.

Table 3. Knowledge as a product.

Child welfare services	Expert Knowledge	Setting of data collection	Method	Focus	Protocols
Medical professionals	Evidence based practice (EBP)	Formal (Objective/ Clinical Descriptive)	Quantitative	Physic and Psychological Health	
Teachers	School records and Written reports (related to standard in education)	Formal (Objective/ Comparative evaluation)	Quantitative	Learning Cognitive and affective development	
Case workers	Explanatory statements and Memo/evidence informed practice (EIP)	Both formal and informal (Relational)	Quantitative Qualitative	Safety and social integration	
Educators	Narrative reports (user-centered practice)	Both formal and informal (Relational)	Qualitative	Autonomy and wellbeing	

Table 4. Knowledge as a process.

Child welfare services	Shared data/information	Sharing Environment	Protocols
Medical professionals	Inventories, certifications, assessments Results of medical check-ups and treatments	Technological means Rare face to face encounters	
Teachers	Reports	Face to face encounters and records	
Case workers	Narratives and Reports	Face to face encounters and reports	
Educators	Narratives and Reports	Face to face encounters and reports	

As shown in Table 3 and Table 4, we argue that data and information on foster children as a product of each professionals’ work experience can be located on a continuum flowing from “vivid” evidences (Munro, 1999) resulting from rigid and officially prescribed protocols to more “abstract and dull” (Munro, 1999), usually overlooked data, resulting from *relational* practices and subjectively interpreted evaluations (Ellström, 2010), where improvisation is often required.

Tools facilitate the organization and collection of data and equip the observation activities. Boutanquoi, Bournel-Bosson and Minary (2013) argue that the use of tools raises several questions:

- the items used are related to cultural and social norms, not always shared by families and professionals;
- tools often reinforce individual and specific professional competences rather than facilitate the co-construction of meaning and significance of data on foster youth;

- data and information on foster youth are the starting point but a second relevant achievement has to be addressed to: one should contextualize them and thereby ascribe them meaning (Boutanquoui; Bournel-Bosson; Minary, 2013).

2.3 Knowledge Management in Social Service

We regard at knowledge as an ongoing "social accomplishment moving, fluid and embedded in social relationships" (Leung, 2007. Orlikowski, 2002. Styhre, 2003).

According to Leung (2009) knowledge management can be seen as lying on a continuum from knowledge-as-an-object to knowledge-as-a-process. The first is referred to information, procedural and theoretical knowledge. The second encompassed skill enactment, practice reasoning, work process knowledge and value sharing process. Between these two types of knowledge Leung identifies the role of tools and mental models constituting the so call "Knowledge-in-midway".

According to Lee and Austin (2012) the building of a knowledge sharing team is based on two main activities: 1) the type of information professional managed (managing what we know); 2) the integration of what others know into the organization. The first activity is related to the explicit information in agency's and professionals' documentations. "Integrating" refers to the tacit knowledge held in the procedural and declarative memory and experiences of the staff.

According to Ipe (2003) organizational culture influences knowledge sharing by the nature of knowledge and the opportunity organization gives to share. Personal motivations are also a relevant factor involved in the sharing practices.

Data in the child welfare agency can thus be classified relating to their nature and to the type of sharing opportunities in which they can be integrated in the global inter-services assessment and evaluation of the child. In the Italian regional child welfare agency two types of data can be identified: on the one end of an hypothetical continuum we find medical professionals gathering vivid and concrete data on minors from a basically positivistic and biomedical prospective. The medical approach is thereby conceived as a merely cognitive and rational enterprise. On the opposite side of the continuum we find educators concerned with a great amount of relational issues, gathering data from a mainly humanistic and psychosocial perspective combining ethical values as "autonomy and self-fulfillment" with minors needs and preferences (Table 3 and Table 4).

Knowledge as a product shifts (Table 3) from the by medical professionals' Evidence Based Practice shaped, quantitative data, to the educators' *narratively* and *Grounded Theory* based, qualitative data pole. Looking at the agency's knowledge-as-a-process (Table 4) we realize that data and information are shared in quite polarized types of environments: on the one hand medical professionals tend to attach greater importance to technological means, on the opposite pole educators usually prefer face to face encounters.

3 Research

An institutional/political mandate, which usually introduces innovation in public sector, (Mergel; Desouza, 2013) involved academic researchers and the regional child welfare agency. In the present study researchers were asked to play a mediating role between agency's management and professionals/practitioners. Their action-research activities had to support the child welfare agency and its professionals to optimize inter-professional data handling and reporting procedures, being the decision making process in child welfare the result of several complex inter-professional activities (Nouwen; Decuyper; Put, 2012). After a two-year's supervision extended to educative care service practitioners (from 2008 until 2010) a new tool for systematic observation of minors' behavior was introduced.

The employee driven innovation (Høyrup, 2010) let two consequences come through:

1. The introduction of the new tool (Pedrazza; Berlanda, 2014) activated a subtle competition under the very differently organized residential and daytime services from the third sector. In fact their survival depends on the public social service local department's trust in their reliability and effectiveness. The economic crisis puts pressure on state budgets and induces changes and innovations which seek to cut costs while often increasing the quality of the service provided (Gallouj; Zanfei, 2013).
2. The local agency/department of child welfare expressed interest in the third sector organization's innovation and asked researchers and case workers team to start research activities and dissemination activities to optimize the information flow on foster youth at a provincial level, involving different professionals and all third sector organizations. A sort of domino-effect (knock-on effect) started and many third sector organizations shifted from a "pure" narrative and qualitative approach to a more quantitative/systematic way to evaluate their intervention on foster youth, so that similar new tools were introduced and implemented.

Researchers were asked to assess the impact of the implementation of the new tool.

In order to achieve this goal the researchers' team started an exploratory qualitative study to identify the features of the information flow under different professionals and practitioners involved in the agency.

3.1 Sample

Nine focus group were carried out, involving 97 professionals (Figure 2). Each focus group involve from 10 to 12 participants at a time. Participants were selected according to following criteria: 1) personal intrinsic high motivation to take part to the research, 2) 10 years experience gained in the local child welfare agency, 3) their distribution within each territorial service belonging to the agency. Costs of the investigation was supported by a local private foundation (CARITRO, 2013, Trento).

Figure 2. Sample: focus group participants' distribution.

3.2 Method

Data were collected in February-May 2014.

Main objective of this exploratory and co-constructive procedure was to shift tacit knowledge from its implicit towards its explicit and reflective dimension.

Low structured focus groups were carried out in order to explore following aspects:

- core category and focus of systematic observation of minors state, attitudes and behaviors relating to each professional/practitioner (indexes of foster youth wellbeing);
- characteristics of the information flow: formal (planned meetings) *versus* informal context (i.e. phone calls, informal meetings which not always are put on records) of communication; /technologically mediated *versus* face to face encounters.
- information's flow emergent critical incidents (Flanagan, 1954).

We followed Smith's (1995) procedural and methodological recommendations for analyzing qualitative data drawn from focus group transcripts. We read the transcripts numerous times, during which we noted everything that seemed interesting or significant, listed the themes that emerged and examined the relationships between them, in an attempt to understand exactly what the interviewees had said in order to interpret their interviews appropriately.

According to Dey (1993) qualitative analysis involves breaking up the data into smaller units then reassembling them in new ways. During the classification process (software N-vivo8) we assigned the data to categories on the basis of relevant characteristics and meanings. The categories gather together similar responses based on the principle of content equivalence/similarity. We identified salient themes, recurring ideas or language, and the belief patterns that connect workers with the context. We generated categories ad hoc for each theme via an inductive process (key words or abbreviations). Each minimum unit of meaning is classified by attributing one or more categories to it.

Analysis was structured around three conceptually progressive coding operations (Strauss; Corbin, 2008): 1) open or substantive coding, 2) axial coding, and 3) selective coding. At this point, all the categories have been determined and the links between them have been established.

During our analysis we attempted to identify the most important meaning categories to explain the content of the data, and assembled them into super-ordinate categories.

According to the qualitative analyze through N-Vivo software we were also able to identify the *parent categories* and the *child categories*.

4 Results

4.1 Core categories of professionals and practitioners' systematic observation and data collection on foster youth

According to the Nouwen, Decuyper and Put (2012) model of effective decision-making in child welfare teams *alignment* is a central feature of the *team architecture*. We looked for alignment opportunities distinguishing (relating to each different professional or practitioner) the focus of each professional's observation practices. The highest level of alignment opportunities corresponds to the highest overlapping's degree of variables and foster children's issues. Redundancy offers a wide range of alignment opportunities.

The informal domestic context of the care service allows practitioners to focus on foster youth autonomy and wellbeing in daily interactions. Social competence in domestic and informal context, trust in adults and peers, and routines were codified as parental nodes. Child nodes are presented in Figure 3.

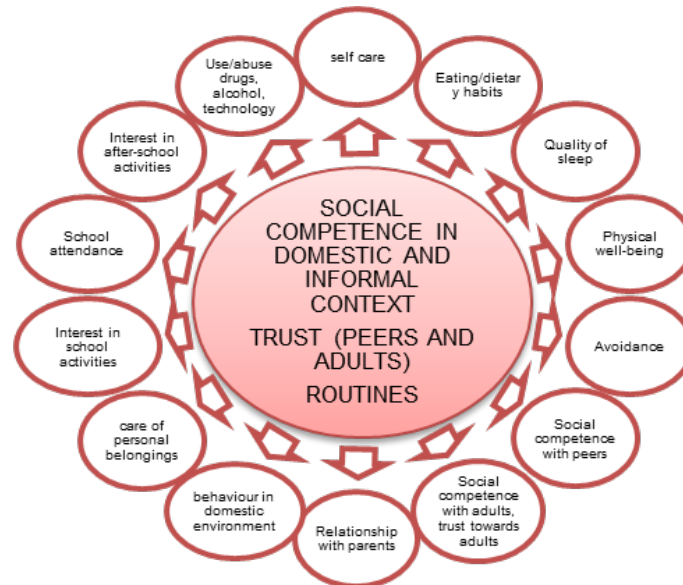

Figure 3. Core category of educators' systematic observation and data collection practices on foster youth.

The recursive interactions between users (children and family of origin) and case worker allow the latter to gather data/information on foster youth which we organized and codified around following parental nodes: informal and formal network, parental skills, and autonomy and wellbeing. Child nodes are presented in Figure 4.

Teachers focus their attention on children gathering information and data on school performance and attendance, and social competence in structured and less structured environment. Child nodes are available in Figure 5.

Medical professional focus their attention on foster youth in order to assess and classify their mental, emotional and physical health. Child nodes are presented in Figure 6.

Figure 4. Core category of social workers' systematic observation and data collection practices on foster youth.

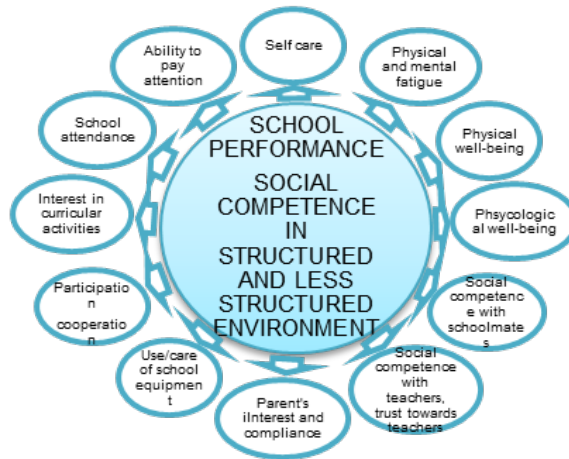

Figure 5. Core category of teachers' systematic observation and data collection practices on foster youth.

Figure 6. Core category of medical professionals' systematic observation and data collection practices on foster youth.

Alignment opportunities have been identified among professionals, each one moving from his/hers own theoretical framework and experience identifying injury indicators and well being indexes in foster children. Partial overlapping and redundancy are detectable above all between teachers and educators (self care, school attendance, interest in curricular, extracurricular and after-school activities, social competence). Medical professional's observation partially overlaps with case-workers evaluation of parental skills and child physical wellbeing. The common highest overlapping area including all professionals and practitioners refers to child's social skills, with particular reference to trust towards adults and peers, self-care and self-confidence.

4.2 Communication flow in child service

We also analyzed the communication flow and its characteristics: its formality or informality and redundancy, where high redundancy corresponds to high informal communication needs.

Formal settings of communication are typically regulated by agency's protocols. In accordance with those protocols inter-services communication settings and opportunities should offer practitioners and professionals sufficient time and space for exchanging data, experiences and for integrating their own knowledge with others' knowledge and perspectives on foster youth.

An extensive and multi-disciplinary review of team decision-making in child welfare allows Nouwen, Decuyper and Put (2012) to propose a framework as guideline to evaluation and analysis of the whole process. Authors underline that very few study analyzed the explicit team decision-making process. They propose an effective decision-making team framework which encompasses the above mentioned *team architecture*, referred to committed professional, trust and alignment, and *team learning*, referred to collective information processing and shared mental models.

According to this model we distinguished formal from informal communication opportunities and settings constituting the *topos* where mental models are shared and discussed.

Figure number 7 illustrates that there is not significant differences between the percentage of formal and informal communication. Medical professionals are exposed to the highest percentage of formal communication with other professionals and practitioners, whereas educators are involved in the least amount of formal communication opportunities. It is of interest to underline that existent formal protocols shared by all professionals and practitioners are clearly not sufficient to reduce information redundancy in the inter-professional information flow. In fact professionals undertake a high amount of informal interpersonal direct contacts.

Although engaging in a high amount of formal and informal communication medical practitioner exhibit the largest percentage of critical incidents. The high registered redundancy in the communication flow, made explicit by the large number of informal meetings, seems to simply multiply the number of inter-professional communication opportunities without supporting mutual understanding and without meeting inter-professional information and cooperation needs.

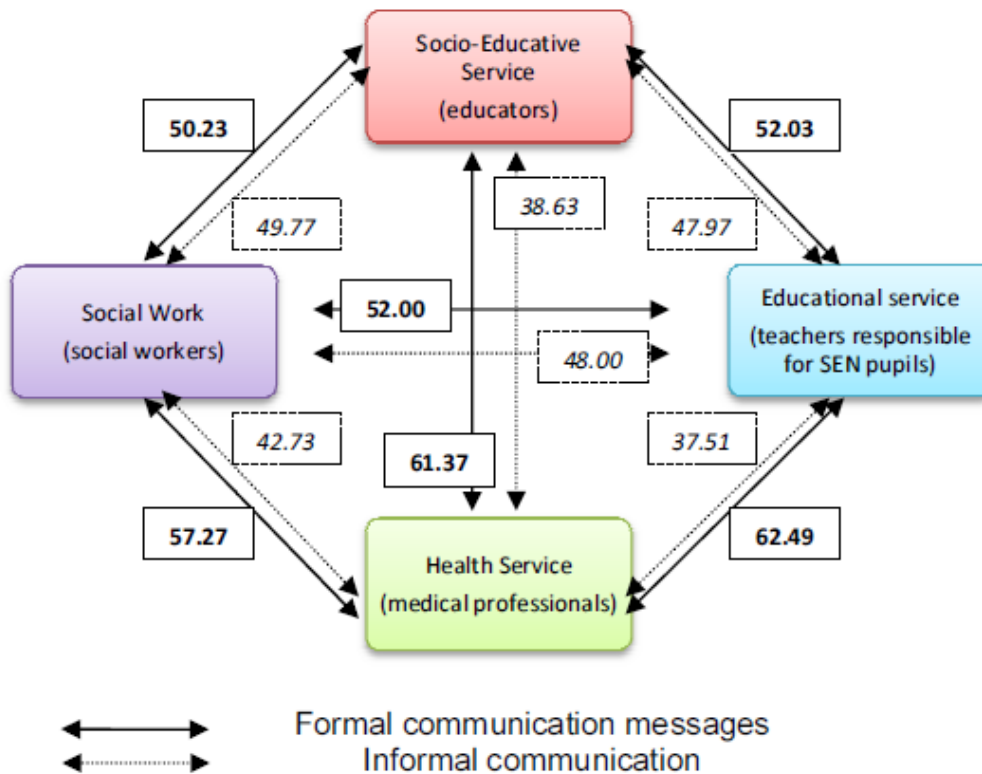

Figure 7. Communication flow in foster care social services.

4.3 Critical incidents in the communication flow

Inter-services communication's critical incidents (Figure 8) refer to perceived critical issues including lack of trust (38.8%), problematic sharing practices (37.3%), uneven service structure (15%), and lack of intrinsic motivation (8.9%).

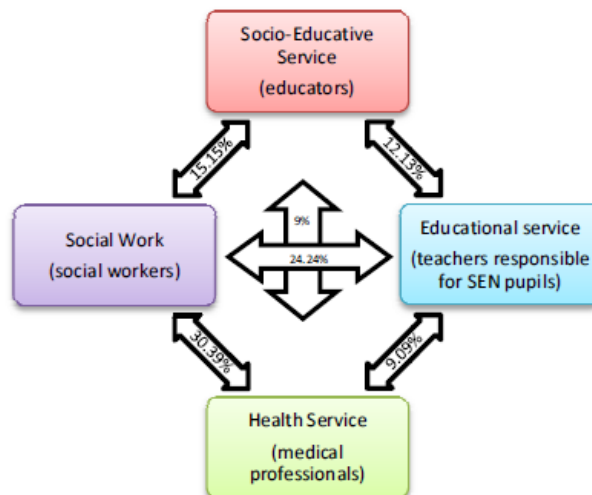

Figure 8. Critical incidents in inter-services communication.

Integrating inter-services and intra-service critical incidents (Figure 9) we identified the following distribution: 36% of critical incidents occur in communication practices involving medical professionals, 33% refer to case workers, 22% to teachers and 9% to educators.

Figure 9. Critical incidents in intra- and inter-services communication.

Our findings (listed in Figure 10) are consistent with literature: medical professionals are unlikely to report on child abuse or fail in updating child protection treatment trajectories. They fail (Vulliamy; Sullivan, 2000) because of lack of confidence in child protection services, (Kalichman, 1993. Zellman, 1990); because of ethical considerations related to confidentiality (Kalichman, 1993) and because of high perceived costs of the reporter (Zellman, 1990). According to Vulliamy and Sullivan (2000) this is an international issue that cannot be addressed only by institutional protocols.

- Reluctance and extreme caution in reporting maltreatment on child abuse and neglect issues to case worker (consistent with Vulliamy and Sullivan, 2000)
- School administrative staff's preference to ask for neuropsychiatric evaluation and medical assessment of the child (in order to be eligible for financial support)
- Law 104/92 requires the participation of medical professionals in school staff meetings in order to provide support for pupils with SEN and disabilities. Because of reported lack of time, medical professionals typically don't comply with this national regulation.
- When diagnosis are requested medical professionals appreciate written communication rather than face to face communication with other professionals.
- Physicians often fail to report on children in charge of the service because of ethical consideration related to confidentiality (also reported by Kalichman, 1993).
- Physicians fail to report on children because of high costs to the reporter such as time spent making reports and court attendance (also reported by Zellman, 1990).
- Medical professional perceive high work-overload, they are not available even for planned meeting (school and socio-educative care service)
- Partial overlapping of private and public service (medical professional availability in public service is limited because of their engagement in private medical practice)
- Despite facilitating and speeding up interventions, protocols tend to discourage professional from looking for support and from exchanging experiences, evaluations and information on foster youth.
- Medical professionals often meet teachers' need for neuropsychiatric evaluation rather than educators' need for more integration of information and sharing about opportunities for parents' support and economical support to families.

Figure 10. Health Service's referred Critical Incidents (referred to child welfare agency's issues).

5 Discussion

One of the aims of the introduction of the new tool for systematic observation in the socio-educative care-service was to align educative service assessment procedures to the often over-estimated evidence base practice in social and health service.

Despite this, the follow up, after introduction of the tool, is associated to a high amount of critical incident ascribable to the health service which usually focuses on adopting the findings of empirical research, promoting thereby a reductionist view of human behaviour (Angel, 2003). Child welfare is too complex to benefit from an emphasis on only empirically proved programs (Collins-Camargo; Sullivan; Murphy, 2011). As above mentioned van de Luitgaarden (2009, 3) states that social work is to be placed closer to the intuitive pole of the cognitive continuum than to the analytical pole. The basic elements that are needed for any effective decision making process are not identifiable with any sort of objective statements and thus are always subjective, relative and debatable. Medical professionals meet

other professionals' needs for assessment and evaluation, but are seldom available for deeper meaning co-construction and sharing. Their EBP is often too mechanistic and ignores sometimes the unique characteristics both of the user and of the other practitioner medical professionals have to share information with (Nevo; Slonim-Nevo, 2011).

Low rates of medical professionals' availability to integrate their data with needed information, could be ascribable to following factors:

- The regional child welfare agency we are dealing with, is a public service and medical professionals devote part of their work-time to private practice.
- Intuitive reasoning, needed in social service, tends to be biased towards "vivid" and concrete evidences (Munro, 1999). Medical assessments and evaluations are concrete enough and therefore, probably, overestimated in their informative potential.
- Cognitive biases (e.g. egocentric bias) are rampant (Leung; Tong, Ho, 2004. Gilovich; Medvec; Savitsky, 2000) in any negotiation including overestimation of own inputs (Lerner; Somers; Reid; Chiriboga; Tierney, 1991. Ross; Sicoly, 1979), overconfidence in own arguments (Bazerman; Neale, 1982) and false consensus effect (Ross; Green; House, 1977).

Case workers have to strive hard in order to integrate the wide range of data they deal with: subjective, narratively produced and intuitively elaborated data of educative care practitioners (e.g.) and concrete and "vivid", but often not contextualized, medical evaluations.

Further studies on the "information flow" in child welfare are needed because literature references show that group members' estimations are more accurate, that is cognitive biases can be reduced, being error a function of *information access* and *interpersonal ties* such as trust and confidence (Kitts, 2003).

5.1 Implication for practice

Literature (Epstein, 2009. Franklin; Hopson, 2007. Brownson; Fielding; Maylahn, 2009. Collins-Camargo; Sullivan; Murphy, 2011) indicates one should move from a pure evidence-based practice to an informed based, knowledge-based practice that encompasses both reflective and empirical types of knowledge allowing socio-educative, educational, social and care practitioner to perceive themselves, in front of medical professionals, as knowledge makers and not just knowledge takers. In addition EBP implementation in mental and social services is often related to concerns about large amount of training demands, impact on work load, decreased job autonomy, increased stress, which typically increase staff turn-over (Aarons; Fettes; Flores; Sommerfeld, 2009. Masatti; Sweeney; Panzano; Roth, 2008).

Internal and external stimuli toward value driven strategies in pricing

Natalia Reen¹, Magnus Hellström¹, Kim Wikström^{1,2}

¹Åbo Akademi University, ²PBI Research Institute

For many industrial service companies widely applied cost based approaches to pricing of their services at best limits the companies' growth, but even more often creates a significant barrier to compete with more cost efficient Eastern suppliers that are also more flexible in pricing. Despite of investments into new value driven approaches and effort to research and develop industrial service concepts the shift toward new pricing models remains difficult. The objective of this paper is to discuss the challenges and opportunities with pricing of industrial services in order to develop them into stimuli toward value driven strategies in pricing, and also propose some practical advice how to proceed toward value driven models in pricing.

1 Introduction

By providing services in addition to their products, manufacturers aim to implement a strategy to repel competitive pressures from global competition and to compensate for the decreasing margins of their industrial products (Sawhney, 2006, Vandermerwe; Rada, 1988, Wise; Baumgartner, 1999). Manufacturing companies are inspired by professional service companies that, compared to manufacturers, typically require lower fixed capital investment, frequently provide a more predictable stream of revenue, and often generate higher profit margins (Ostrom et al., 2010). Several positive consequences have been connected to the development of services by manufacturers, including extra invoicing, enhanced profitability and performance, a more steady cash flow, and a better corporate image (Mathieu, 2001, Kuusisto; Mayer, 2003, Malleret, 2006, Kohtamäki; Partanen; Möller, 2012).

However, there is a strong opinion, supported by a growing research body, that only a few manufacturers have achieved the ambitious financial objectives related to services (Gebauer; Fleisch; Friedli, 2005). According to Gebauer et al. (2005), the paradox of industrial services is that manufacturing companies make large investments in the development of services without generating adequate return on them. Researchers and practitioners admit that one of the major reasons for that is in pricing. The pricing mechanisms of most of the traditional service organizations are not based on a sophisticated understanding of the specific customer value they deliver, but instead on more general and simplistic approaches such as cost-based pricing plus considering the competition's prices (Zeithaml; Bitner; Gremler, 2006, Monroe, 1989, Tung; Capella; Tat, 1997). Thus, the service suppliers deliver additional value to the customers by services, but they are not able to benefit fully since they are not able to measure and utilize value for pricing, and therefore they have to compete based on low price and cost efficiency.

Building a comprehensive pricing method for services is a challenge for firms; many authors associate the challenges in service pricing with different aspects of complexity (Mitra; Capella, 1997, Dearden, 1978, Lovelock, 1981, Thomas, 1978, Berry; Yadav, 1996, Docters et al., 2004, Cooper; Jackson, 1988, Cowell, 1984, Bolton et al., 2007). However, as recent research shows (e.g. Reen, 2014, Reen; Windischhoffer; Wikström, 2010) the actual reason is a lack of value driven strategy in pricing and cost-oriented mindset of industrial companies. Markets, technology development in low cost countries, emerging new business models – all create stimuli toward the development of new value driven pricing strategies. And the companies who will be able to implement such strategy create unique competitive advantage that is built on customer relations and the company's new capabilities. Therefore the objective of this paper is to discuss the challenges and opportunities with pricing of industrial services and systematise them in order to develop them into stimuli toward value driven strategies in pricing and also propose some practical advice how to proceed toward value driven models in pricing.

2 Literature review

A growing share of services in national economies poses the questions how to describe and manage services, and reveals that existing product-oriented theories and models are not precise for services (Egan, 2001). Despite the increasing attention from the researchers to the service phenomena, service research still lacks such fundamentals as an univocal definition of service (Edvardsson et al., 2005, Vargo; Lusch, 2004, Grönroos, 2000), and a common understanding of the actual relationship between concepts of service, product, good, process, and customer (Laine et al., 2004). However, there are two widely accepted statements about services:

1. Customers play a crucial role for value creation in services (e.g. Brady; Davies; Gann, 2005, Ulaga, 2003, Lapierre, 2000, Walter; Ritter; Gemünden, 2001, Grönroos, 2000);
2. Services should be studied using multiple discipline approach (e.g. Spohrer, Maglio, 2010, Ostrom et al., 2010).

Researchers emphasize the significance of investments and effort that industrial companies are making while developing services, but there is no univocal opinion about whether companies get adequate return on these investments (Malleret, 2006, Gebauer et al., 2005, Grönroos, 2000, Oliva; Kallenberg, 2003, Anderson; Narus, 1995). One of the reasons why there are not enough evidences of profitability of industrial services is that the research field of pricing of industrial services is underdeveloped and lacks empirical studies (Indounas, 2009, Lukassen; Wallenburg 2010). Service research has for a long time focused on trust, commitment, satisfaction, loyalty, and perceived quality effects of service strategies, however, monetary effects and metrics required to do related measurements have not been developed (Grönroos in Ostrom et al., 2010).

There are different approaches to pricing in modelling of modern service-system ecologies, coming from different disciplines. Marketing and behavioural science focuses on customer perspective on service systems and takes a value-based view on pricing and quality as a measure. Operations and management science stands on provider positions and measures productivity by cost-based pricing methods. Strategy and learning science look from competition perspective and apply strategic pricing in order to achieve sustainable innovation (Spohrer; Maglio, 2010). Since service research requires a multi-disciplinary approach, it makes sense to combine different approaches to pricing in order to study problems of pricing in the industrial service sector.

Ideas of value based pricing for services are discussed by researchers in terms of output-, performance- and result-based contracts (Ng et al., 2009, Kim; Cohen; Netessine, 2007, Roegner et al., 2001, Lusch; Vargo, 2006). The general logic behind such pricing is to describe value created for the customer using different KPIs in contract. The value-based pricing process consists of two major steps: a value assessment study and the linking of customers' payment and customer actual realized value. However, customer involvement in the value creation process (value co-creation, co-production), complexity of the relationship and importance of relational factors of value make such pricing approach to be challenging, and therefore, relatively unpopular method for services (Ng et al., 2009, Sharma; Copalkrishnan, 2010).

The focus on pricing research should be shifted from actual methods of pricing to the factors that affect pricing decisions and pricing activities that help to arrive to the correct decision (Ingenbleek et al., 2003). Successful pricing model can be seen as an open system (Scott, 2003) where internal features best match the demands of their environments.

The literature provides the following frames for the research of pricing of industrial services:

1. Following the convention for service research, pricing should be studied from multiple discipline views, which means that pricing model should have marketing, strategic, and managerial domains (e.g. Spohrer; Maglio, 2010, Ostrom et al., 2010);
2. The researchers agree that building of comprehensive pricing for services is a challenge for the firm (Mitra, Capella, 1997, Dearden, 1978, Lovelock, 1981, Thomas, 1978, Berry; Yadav, 1996, Docters et al., 2004, Cooper; Jackson, 1989); many authors associate the challenges in service pricing with different aspects of complexity (Cowell, 1984, Mitra; Capella, 1997, Dearden, 1978, Lovelock, 1981, Cooper; Jackson, 1988, Bolton et al., 2007);
3. In order to overcome the challenges with service pricing the researchers suggest developing systematic approach including pricing process with respect of costs, objectives and other service characteristics (Zeithaml et al., 2006, Lovelock, 1992, Avlonitis; Indounas, 2006, Cowell, 1984, Dutta et al., 2003, Bonnermeier et al., 2010);
4. It is essential for service pricing to establish a link between pricing and value proposition (Lusch et al., 2007);
5. The importance of relationships in services necessitates the inclusion relational value components, i.e. trust and commitments, into pricing (e.g. Selnes; Hansen, 2001, Elfenbein; Zenger, 2009, Cornet et al., 2000);
6. Managers should step out of the widely applied simplistic cost-based pricing methods if they want to fully benefit from service developments and receive adequate compensation for the investment that are needed in order to develop and sell services (Tung et al., 1997, Shipley; Jobber, 2001, Gebauer et al., 2005, Jobber, 2004, Morris; Fuller, 1989, Anderson; Narus, 1995);
7. Value-based methods are difficult to design and implement unless entire logic for pricing of services will be changed toward created by services value (Ng et al., 2009, Roegner et al., 2001).

The present paper continues the prior research into the pricing of industrial services done by Reen (2014) and Reen, Windischhofer, and Wikström (2010). These authors proposed new value driven logic for pricing of industrial services, which is built on three fundamental statements:

- The relational component of value provides significant impact on pricing of industrial services. Customer retention, satisfaction, trust, and commitments have direct impact on a company's profitability. Investment in the development of relationships is a profitable business for both the supplier and the customer, and therefore pricing should not only focus on monetary income but also on relational value.
- For the industrial solution that includes services, the subject of pricing is not the solution itself, but the value proposition created for this solution;
- The pricing process of industrial solutions considers all participants of the value creation process and analyses their value.

Systematic combining of the results from data analysis with the theoretical findings revealed four general reasons behind the reported pricing challenges: issues with trust, different aspects of complexity, organizational immaturity as a service provider, and lack of the necessary competences and capabilities. These four reasons have been used as the dimensions for an initial construct for further analysis of the pricing problems, and, finally, the general model has been developed. The model comprises three main components. In order to develop successful pricing approach companies should:

- Adopt value-driven pricing logic;
- Establish pricing process and governance;
- And cope with multiple factors affecting pricing decision.

In order to manage the pricing factors, to collect the needed data, to analyze factors, to make pricing decision, to monitor results and perform corrective actions, companies need a process that eliminates the obstacles presented by the different functions and activities, and helps to handle them in a systematic way (Figure 1).

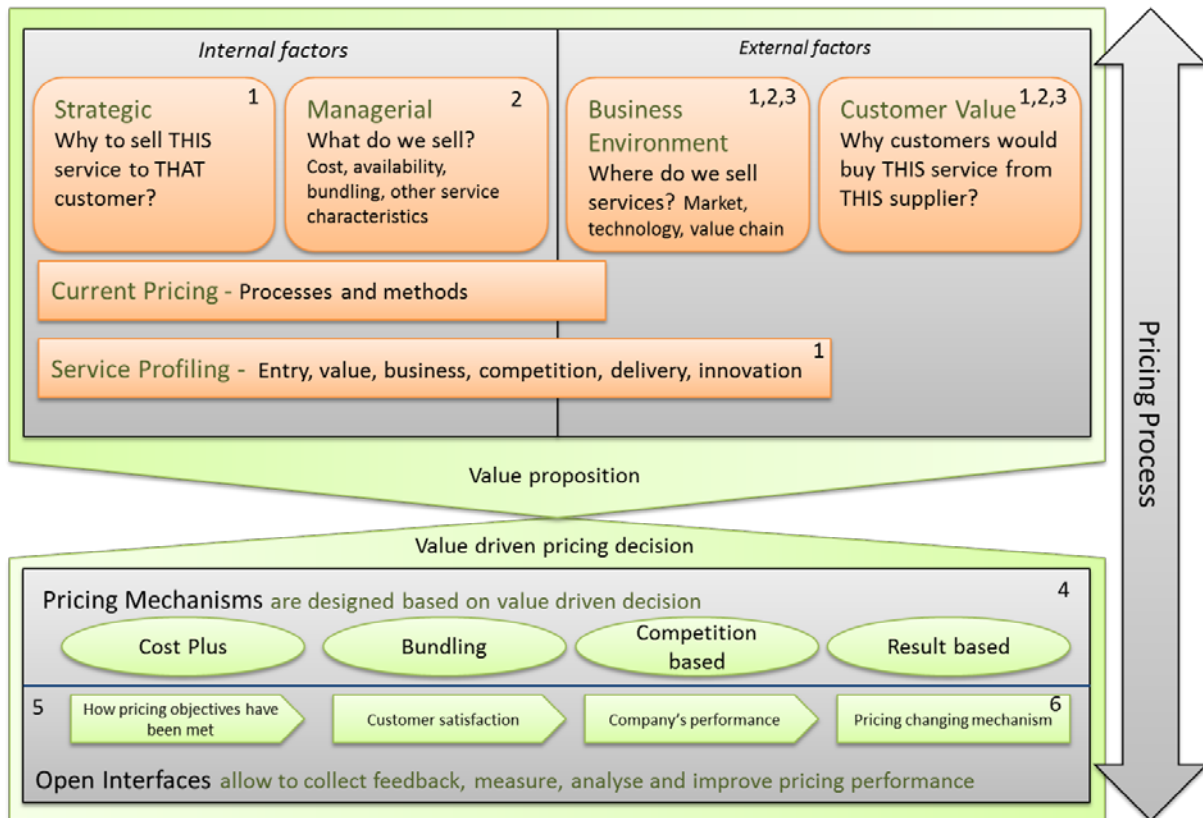

Figure 1. Factors for pricing decision.

3 Research approach and methods

This is a case study that combines data and analysis from different cases. Five organizations have been examined during years 2008–2009 and the last one is an ongoing case that started in year 2013. Such longitudinal approach ensures validity of the research, not the least in terms of topicality of the problems defined.

The data is comprised of qualitative data from interviews and workshops with employees and customers of the case companies, archival data and company reports, business cases, development plans, quantitative data from surveys and checklists, and financial data. The method of analysis can be referred as a systematic combining. It employs abductive matching technique and includes elements of qualitative content analysis, grounded theory, narrative inquire, recursive abstraction methods.

Due to multiple labels that are used to describe development of services for manufacturing companies and the relative novelty of ‘servitization’ research should use a collaborative approach that allow researchers not only be in continuous contact with industry representatives, but also participate in business processes and see the picture ‘from inside’, employing ethnography-like approaches. For example, researchers should see what are norms and factors that affect management decision to select the service for further development and sales, to set up pricing, to process customer feedback.

The research approach of the current paper can be described as follows. There is a new case study (Case T) performed for another industrial company (The Company) that recently started to develop a new pricing strategy. The Company is a large IT service and product supplier. The Company has identified a need to develop value based pricing

and launched a project that aim to identify current problems with the pricing, analyse them, develop a solution, and apply it widely. The project has several stages – data collection, analysis, piloting, and roll out to production phases. 18 interviews with the company’s top managers representing all business units, 5 workshops, several regular meetings and 4 customer interviews have been performed in order to collect pricing problems and best practices. Interviews have been performed according to developed questionnaires.

The results from the prior research have been utilized in a following way (see Figure 2):

1. The observations from Case T have been compared with prior research (Reen, 2014, Reen; Windischhofer; Wikström, 2010).
2. The similarity found in interviews and analysis allowed to use a model developed in prior research for the current Case T.
3. The model has been adapted for The Company’s context. There are several pilots that aim to clarify and learn more about current problems and possible solutions for The Company’s pricing.

The project is ongoing and the results are expected after year 2015. However, the intermediate results, as well as pilots’ results, bring a lot of input to the developed earlier pricing model, and demonstrate how new pricing logic can be implemented in practise.

Figure 2. Research process.

4 Empirical part

4.1 Description of Case T

The renewal of the company’s management model implied the transformation, which set projects to the core of financial and management accounting and changed the costing and follow-up structures significantly. This major operational and financial change increased threat of revenue leaks.

The Company has performed a study in order to identify, quantify and capture those potential revenue leaks. From an operational perspective seven key improvements areas were identified that either have a direct or an indirect impact to revenue leakages, one of which is pricing. Already at this stage of the research it became clear that company’s pricing practices are somewhat inefficient and complex. For example, wrong unit pricing for hours is a significant source of revenue leakages with a total share of 34% of identified leakages. Overall, it was noticed that the pricing process is unclear and there is a lack of customer value view in current pricing.

Data has been analysed and all pricing problems have been grouped into 3 areas that proposed to be work packaged for the next project phase:

- Pricing governance, process and roles;
- New value driven logic
- New pricing enablers, e.g. tools and methods.

In the area of pricing process and governance it was found that the company has neither centralized governance for pricing nor an end-to-end pricing process. Each unit has its own way to handle pricing issues, and though there are some good practices, there is no systematic way of transferring knowledge within the company. For example, one service line has developed solid methodology for setting up internal recommendations for price, but it was not used by other service lines. Some managers are aware about value driven pricing approaches, but lack of guidance and instructions make the development and application of performance based methods impossible.

Regarding pricing logic, it is clear that current pricing practices are cost oriented and a value (both customer and the company) driven approach is missing. Moreover, all the company’s support and control functions are developed in order to support a cost-driven mindset and positive cash flow. For example, contracts that would bring benefits in future cannot be accepted as financial control system requires certain approved margin for each deal. The Company is not too successful selling its competitive advantages. For example, customization is sold based on time and material even though it might require the company specific competence and capabilities. Customer relations are not utilized for pricing purposes. There are very contradictive opinions about how pricing should be managed on company levels. One group of respondents think that additional pricing responsibilities should be divided between heads of business units.

Another group thinks that this is close to existing approach and no changes will happen if to continue like that. They believe that The Company should create a separate unit – pricing office that support and enable new way of working.

There is no pricing strategy (or when people discuss pricing strategy, they are talking about different concepts) nor common terminology. Attempts to develop good strategy in pricing are often challenged by existing frame agreement. Pricing is seen as an internal issue; it is not common to ask why customers buy from The Company. Often the only applied strategy is to sell the same solution to everyone and apply the same pricing.

The Company is by tradition a low risk tolerance firm, which makes it impossible to develop value-sharing models since it implies risk sharing with the customers, and risk will increase.

The development of value based methods in pricing is challenged also by fragmented knowledge in customer business. It is sometimes so that The Company knows even better than the customer about overall industry rules and practises. However, there is a lack of knowledge about how customers in practise are using the company's services and products. Moreover quality criteria are not developed toward end users.

There is a lack of tools and methods needed for value driven pricing, such as a value quantification tool, a market price database, price efficiency analyzers, and customer needs profiler.

It seems that competitors are better not only in terms of price level, but in general flexibility for pricing. Asian companies can and are willing to offer similar products at lower prices and taking more risks and responsibilities for the end results.

Customers are in general positive about the company's services. They definitely appreciate attempts to develop value driven strategy, but they believe that The Company should learn more about the customer's business, to take quality from an end user perspective and to be ready to share risks with customers.

4.2 Analysis

The analysis of all data including internal and customer interviews, materials from workshops and preceding project results, revealed that there is no single reason for insufficient intelligence in pricing. The problems with pricing belong to different domains, and therefore to the different company units.

The challenges and observations from prior research and Case T have been summarised according to the certain areas related to pricing and compared as it shown in Table below (see Table 1).

Table 1. Summary of challenges and findings from prior research (Reen, 2014, Reen; Windishhoffer; Wikström, 2010) and Case T.

Area	Prior research	Case T
Pricing strategy	The pricing mechanism, which should support a certain strategic goal, lacks input data for further development. There is a need to clearly define goals for selling certain services to certain customers (why do we want to/need to/can sell this service to a certain customer).	Often strategy is to sell the same solution to everyone and same pricing. Pricing is our internal issue, we don't ask why customer buy from us. People understand by pricing strategy different things. The company does not have clear and formal links between company strategies and pricing methods.
Offering scope	It is important to identify major service characteristics such as costs, innovations, risks, availability, modularity, customization, standardization, and to define service deliverables, as well as to communicate value in terms of customer's needs.	The company needs to improve offering development process, to create generic concept of product structure, to use the same tools and methods for calculating costs of components, market price benchmarking. It is needed to educate people about value selling.
Contract development	It is of paramount importance for the supplier to understand the customer's business logic, and yet create transparency by inviting the customer into the process of designing a pricing mechanism. The supplier and customer define together measurable performance targets by identifying what affects performance and what can be measured. The supplier fails to communicate the value of the service to the customer due to a lack of transparency in the offering, lack of faith by the supplier to deliver on promises.	We should be open with customers regarding pricing. We have very different views and customer business awareness depending on industry. It will be big effort to convince customers that we are capable to develop value based models.

Area	Prior research	Case T
Pricing approach	There is a lack of knowledge and experience in service business in general, and innovative service marketing methods in particular.	Sales are not ready for value-based pricing; they should be educated, The Company's support functions should really support it.
Measuring of pricing efficiency	Performance enhancing effects are difficult to prove and measure due to complexity and lack of sophisticated data gathering and measurement techniques.	It is hard to determine the company's impact on customer performance in order to get a share of it. Should be agreed on level of contribution to enhanced performance and how to share risks.
Price change	The Change Management Phase is often ignored in pricing issues, which makes the pricing outdated in terms of the changing business environment, such as new strategic objectives, new competition, changing service scope, or overall market conditions.	Existing long term frame agreements limit proper reflection of strategy in pricing approach.

Thus the analysis revealed the similarity of the problems and needs of pricing that have been discovered and discussed in prior research with the problems and stimuli toward new pricing strategy development of Case T.

4.3 Results

The distribution of the problems with pricing in Case T across company functions, the similarity of the problems with referred prior research (see Table 1), such as lack of value view in pricing approach, lack of pricing capability in the company, complexity of value-based contracts and others, allows us to suggest using pricing model, developed in prior research, for the Case T purposes. The model comprises of three main components – pricing process, factors, and logic.

Though The Company does not have end to end pricing process, the adaptation of six-step generic process developed in prior research does not seem to be a difficult task. However, the main challenge is to determine and nominate ownership for the process. In other words, governance model that assumes new centralized unit, proposed for pricing management tasks, has been challenged and received a lot of different feedback. The main challenge is that centralized unit does not fit into current decentralized organizational structure. Management expressed a belief that each industry-based division has its own pricing practises and methods and thus unified pricing methods and processes are not able to reflect specific market conditions. However, many researchers (e.g.Dierickx; Cool, 1989, Dutta et al., 2003) see pricing as a capability, which is difficult to imitate and which can bring unique competitive advantage for firms. Developing such a new capability as mastering of value based pricing requires clear roles, responsibility, and ownership in order to manage all aspects of complexity, novelty and uncertainty. Technically new capabilities should comprise of new process, methods, as well as new tools and instruments that should help, for example, to quantify customer value, to provide the best view on market prices, to suggest the best discounting policy, and to analyze customer relationship strength.

Factors that affect pricing decisions are subdivided into internal and external factors. Such subdivision is mainly driven by different management practices, is applied to internal and external issues, and lies behind the organizational structure. On a general level, the analysis of internal factors affecting pricing, both strategic and managerial, reflects the supplier's ability to develop and deliver services. The analysis of external factors, the business environment, and the customers, reflects the supplier's ability to compete with services and correspond with customer needs.

The model (see Figure 2) has been applied and adopted for CaseT in terms and conditions of The Company context and processes and visualized as it is shown on Figure 3.

Figure 3. COSE model – Customer, Offering, Strategy, Ecosystem.

Cost based approach dominating in the company put focus on resources, costs, and other service characteristics that affect cost of development and delivery. Other factors related to corporate strategy, customer value and need, and ecosystem were omitted or entirely ignored for pricing decision. At this point it is not clear how should be the proportions of these segments be derived from business context, but indeed they should be harmonized and serve the best and justified results of pricing decision.

One of the most important tasks in order to develop and implement new pricing strategy is to develop and apply value driven logic. It implies designing and adaptation of new principles of value driven logic in pricing for organization, to withdraw from widely dominated cost-based practises, to ensure that other related processes and functions are also involved and support new logic. This is again an argument toward establishing a dedicated organizational unit that would develop and perform all needed for such transformation capabilities.

4.4 Pilots

The main ideas with pilots were to get a concept proof on smaller scale and with minimised risks, to learn more in-depth certain business cases and apply for them new pricing methods, e.g. to perform “an evolutionary” and incremental changes in pricing strategy. The overall expected business benefits from pilots were:

- To achieve savings and earnings on knowledge creation by reduction of percentage of repeating of creating of existing knowledge from 20% (average in industry) to lower and by increasing knowledge base and developing unique competences and new capabilities related to pricing that can be even sold;
- Savings on purchase of needed tools for pricing process by developing current best practises into tools and making justified decision on which pricing tools still needs to be bought – selected subcontractor has pricing tools that can be adopted for the company needs;
- To see immediate results and feedback from pilots, no need to wait for one year when new concept will be roll out to production; therefore, the concept can be updated and the company will learn from mistakes on smaller scope.

There is a list of approved pilot cases (see Table 2) with their own goals, input for pricing model and context.

Table 2. List of pilots.

Case	Goal	Input for the model
Customer 1	To clarify tools and methods needed for making result based contracts, to productise existing best practises	Specification for tools and methods: cash, revenue, risk scenario simulation; method of KPI co-creation; estimating and negotiating impact level on service performance, measure KPIs with customer
Service line	Internal pilot, to adjust existing best practices of pricing process for other units and offerings	Unified in-house developed method for recommended price, full stack concept for offering structure
Customer 2	To develop pricing intelligence for one customer, to create first VB contract with this customer	Mapping of different pricing logics to offering; models with value sharing KPIs
Customer 3	To be innovators in pricing in Financial sector	Industry specific value-based contracts
Customer 4	To learn how to mitigate shared risks	To create methods of managing shared risk in value-based contracts
Customer 5	To get higher cash flow from big deals	New earning logic
Customer 6	New types of contracts – higher involvement to customer business	To develop relationship into element of pricing model
Customer7	To develop value-based selling capability	New selling capability

4.5 Summary of results from pilots

Piloting is the current stage of Pricing Strategy project and the results are intermediate. However, additionally to the expected outcomes and planned goals the pilots provided a lot of food for thoughts that has to be processed and utilized for new pricing initiatives.

There are contracts that include KPIs and the goal of pilots was to learn best practices about existing approaches, conceptualize knowledge and distribute to the whole company. Thus the pilots should contribute to developing of generic KPI based pricing models and to collecting of requirement specification for the required instruments. The important deliverable is a developed process of defining, evaluating, and selection of KPIs for contract.

The pilots revealed additional challenges with value based pricing. KPIs that have been used in the contracts were not actually performance sharing KPIs. They were more or less quality KPIs that regulate bonus/penalty system, exploited for the contract. The customer refused to share gained performance since according to their opinion the company would get too much, and the similar services could be obtained from other suppliers with traditional cost-based model for pricing, which seems to be more beneficial for the customer in this case. In practise, when The Company proposed the contracts with “mixed” pricing approach (there is a fixed price plus quality KPIs) some customer expressed a concern that fixed part already has a profit margin. In fact The Company does not carry any additional risks. From the customer point of view to pay extra from shared benefit only makes sense if risks are shared. However, fixed part of mixed contracts decreases the risks for the supplier, not for the customer. Why the customer would share the results with the supplier if the risks are not shared?

Another disadvantage was in difficulties to define high level use cases for pricing tools. Account team members have worked according to the established cost based processes and performed well according to them. They don’t have any needs for new tools and methods, or they didn’t see these needs. Only few enthusiastic persons were able to guide pricing project toward certain tools, such as portfolio efficiency measurements, cash flow and revenue simulators.

One of three of The Company’s service lines in order to systematise offerings and develop unified approach to cost calculation and market price benchmarking developed internally the process and tools for so-call price recommendation. The goal is to calculate costs of offering components in a similar way, benchmark components and solutions with other similar offerings, and create price notification for sales teams. In order to apply these process and methods to other service lines, it is necessary to have the same view on product and service structure in all the company units. The concept of “full stack” solution, used in the piloted service line can serve this goal. In practise, the several attempts to leverage full stack solution for other business unit have failed. Technical experts from both units don’t see any technical

problems to do that, though there wasn't any technical document how to do that. But the problems seem to be on organizational level, despite on optimistic attitude of pilot participants.

The conclusion has been made that there is a need for centralized pricing governance that this kind of important initiatives would not be only intentions; there should be an authority to make it happens and provide needed support. It was decided to propose a separate project in order to find resources, mobilize people and have decision making process. After full stack concept will be applied widely a pricing pilot will be resumed in order to improve recommended price method, and redirect it toward value driven approach.

In the forest industry development of value sharing contracts is ongoing issue. The main driving force from customers to develop such contract is high level on uncertainty and risks in their business. Even new customers are willing to make result based contracts (which is rather unusual since such contracts often require high level of trust). The main competitive advantage of The Company in this area is deep knowledge of business context and local presence. However, the obstacle is traditional conservatism of forest companies, which makes the process of changing pricing models slow and uncertain. However, there are ideas and prototypes for value sharing contracts in the area. The company has deeply studies customer operations on customer site, and offer services that can optimise customer business. This is definitely a candidate to develop value-based sharing model. Customer benefits, such as cost savings, logistic automation and simplification have been quantified. Currently it is important to evaluate potential KPIs and select manageable amount of KPIs for contracts and achieve on that mutual agreement with the customer.

The last at this point but not the least comment from pilots is about the scope of supplier responsibility. Sharing value based contract should imply high supplier responsibility for the end result. In practice it might mean that quality criteria should be developed based on end users' criteria, e.g. if the supplier is providing part of the customer e-mailing system, quality should not be described as availability of certain mail servicers, but ability of system end users sent and receive e-mails.

5 Conclusions

There are internal and external stimuli that create needs and pressure for industrial companies to move away from cost-based pricing approach toward value driven strategy in pricing.

One of the external stimuli is competition. Cost based pricing focuses competition on low costs, rather than on actual service value. This creates disadvantages for both, the customers and the suppliers. The suppliers aim to decrease own cost of production instead of looking for the opportunity to create additional mutual value for themselves and for the customers. The customers are not able to recognize potential and future value of the services when justify their purchasing decision purely on price level.

Another external stimulus is co-creation. In industrial sector there are emerging business models when the customer and the supplier together create a certain product and service. The level of involvement and impact on each other business are already used as KPIs for value-based contracts. For future research it would be relevant to through further case analysis identifying different categories of KPIs connected to different types of business context as a basis for value benefits and sharing targets in contracts.

Higher risks in business environment require development of result-sharing contracts. Customers want to get guarantees for the end results by sharing risks with the suppliers in uncertain situation. This is especially valid for new relationships. In mature relationships trust can mitigate risk levels to some extent. New customers require more "tangible" promises in their contracts.

It is sometimes more difficult to recognize internal stimuli for moving toward value driven strategy. Specialists, sales and offering managers are working according to their processes and routines, and typically don't realize any needs for changes and new approaches. On the strategic level it is clearer that in order to increase win rate and reduce revenue leakage some development should be done in pricing area as well. However, there is no univocal opinion how to do that, what exactly should be done, and who is responsible for new pricing strategy. Responsibilities and roles create additional challenge on the way to develop value based pricing. Traditionally, pricing responsibilities were within sales and product teams due to high dependency to the service cost structure and the fact that actual price discussion with the customers happens during bidding phase. However new value driven approach requires new capabilities, e.g. new methods, tools, and competence. These capabilities should be developed and delivered across the company in all units, and thus should be managed centrally, especially during transition period. Otherwise, there is a very high probability that without centralized ownership the process of value driven pricing will not be taken in use due to complexity, lack of clear instructions, lack of systematic knowledge in value driven approach, and low priority compare to "low hanging fruits".

Industrial services, as well as services in general, imply close relationships and have been widely conceptualized based on value co-creation processes. However, pricing of services entirely omit relationship elements in existing models. There are obviously other difficulties on the way to develop value driven pricing, such as complexity of industrial service context, immaturity of industrial service organizations, and a lack of needed competences. However, the main obstacle on the way to break through from cost dominance in pricing methods is a lack of value driven logic in organizations, which is visible through redundant risk management processes, simplistic sales teams performance measurements, rigid financial control systems, and cost oriented organizational structures.

Implementation Prerequisites of Electronic Procurement of Services

Ute Reuter

VWA-University of Extra-Occupational Studies Stuttgart, Germany

Service procurement is a business function of increasing importance, is highly suitable for integration of electronic support, but suffers from severe research deficits. As yet, implementation prerequisites of electronic procurement of services are obscure and not quantifiable at all. In this research project, organisation, formalisation and specialisation of procurement and standardisation and strategic importance of the procured services are identified as relevant implementation prerequisites. Measurement models for these prerequisites are established and quantitative-empirically proven. As such, this paper is a major step towards a more rigorous investigation of electronic procurement of services.

1 Introduction

Service procurement is a business function of increasing importance (Hallal et al., 2010; van der Walk, 2008). At the same time, procurement is highly suitable for integration of electronic support (Wu et al., 2003). In contrast to this, questions of service procurement suffer from severe research deficits (van der Walk, 2008; Bals, 2008; Lavie; Miller, 2008; Bensch; Schrödl, 2011; Reuter, 2013).

This lack of scientific studies in service procurement is confronted by the research project on hand, which concentrates on the organisational structural and service-related implementation prerequisites of electronic procurement of services. This research project is situated at an interface area between procurement, innovation and service research, integrating aspects of business informatics as well.

Furthermore, a clearly defined research framework and clearly operationalized dependent and independent variables are the prerequisites for empirical testing of assumptions. Suitable operationalisation implies the existence of statistical measurement models. As yet, no such measurement models exist for the implementation prerequisites of electronic procurement of services.

Therefore, the main objectives of this research project are twofold: First, to identify the organisational structures within a company which seem to be relevant for the implementation of electronic procurement of services from a theoretical perspective. And second, to establish and validate measurement models which allow testing for the connection between these organisational and service-related structures and the implementation of electronic procurement of services from a quantitative-empirical perspective.

The actual implementation of information and communication technology (ICT) in the procurement process leaves much to be desired (Quale, 2005). Improvements can only be achieved if a so-called "internal customer satisfaction" (Croom; Brandon-Jones, 2007: 295) with the (potential) implementation is reached. Ellram and Zsidisin (2002) propose that the degree of closeness between the purchasing company and the (potential) subcontractor strongly determines the tendency to use electronic procurement. This means that purchasing partners who implicitly trust each other are more likely to use electronic procurement of services. Kumar and Chang (2007) analysed the cost savings potential of reverse auctioning. Rajkumar (2001) for example elaborated on the importance of system integration for electronic procurement and concluded that the ICT systems of purchasing company and subcontractors have to be compatible for successful electronic procurement implementation. Emphasizing a more theory-based approach, Bartezzaghi (2007: 195) proposed that "it is necessary to consider the state of the art in innovation adoption and diffusion models, with a specific focus on ICT" in order to explain electronic procurement implementation.

All in all, purchasing of services is not adequately investigated in literature (Azadegan; Ashenbaum, 2009; Bensch; Schrödl, 2011). Especially under-researched is business-to-business service exchange (van der Valk; Wynstra, 2012). And electronic procurement of services is even less well studied (Reuter, 2013).

2 Theoretical Foundation

The resource-based view (RBV) (Collis, 1991; Grant, 1991; Barney, 1991; Hamel; Heene, 1994) is the theoretical foundation of this research project. Basically the RBV is apt to analyse procurement processes (Mol, 2003). But the RBV consists of many different research perspectives. Therefore, it has to be made clear which of these perspectives are basic to this research project. In order to understand how a company is really working, intimate knowledge of organisational processes is crucial (Levitas; Chi, 2002; Rouse; Dallenbach, 1999). Therefore, the process-oriented perspective (Foss; Stieglitz, 2010; Gavetti; Levinthal, 2004) is chosen as analytical lens.

Furthermore, the access to external resources has a direct influence on strategic decision-making within a company (Gilbert, 2005). This holds especially true as the resources of the purchasing company and the external resources from subcontractors and intermediaries are vital for the whole procurement business. However, cross-company resource

requirements are often conflicting with internal needs (Easton, 1994). Hence, the importance of relational aspects (Lavie, 2004; 2006; Freiling, 2008) has to be acknowledged. Reuter (2013) for example offered insights into electronic procurement of services from a relational resource-based perspective. Relational resource-based perspective in this case depicts the integration of the relational view (Dyer; Singh, 1998) into the resource-based view (Lavie, 2004). This line of theory integration is especially apt as purchasing and supply management research is, at the moment, not able to provide insights into the management of subcontractors as external resources (van Weele; van Raaij, 2014).

Azadegan and Ashenbaum (2009), for example, developed a four-category schema of electronic procurement of services publications. This research project is part of the second category as it focusses on electronic procurement application users. The precise research question which is answered in this paper is:

Which prerequisites can be identified for the implementation of electronic procurement of services?

Two different approaches serve to answer this research question. First, organisation structure is analysed in order to find relevant implementation prerequisites. Second, the special nature of services is taken into account. Theoretically founded constructs and variables are derived in the following two subchapters. The hypotheses are constructed as correlation hypotheses (Bortz; Döring, 2005).

2.1 Organisation Structural Implementation Prerequisites

In resource-based argumentation, organisational capital is a resource which encompasses reporting, planning, controlling and coordination systems (Barney, 1991; Brynjolfsson et al., 2002). Lev and Radhakrishnan (2003) see organisational capital as an agglomeration of technology, business practices and processes and their actual implementation. Bozbura and Beskese (2007) focus on the influence of organisational creativity on organisational capital. To sum this up, Burns' and Stalker's statement is still true: „There is no single set of principles for 'good organisation', an ideal type of management system which can serve as a model to which administrative practice should, or could, in time approximate" (Burns; Stalker 1995, xxi). However, the organisation structure of a company is an important component of the procurement function within this same company (Lambert; Knemeyer, 2007).

The company specific organisation structure directly influences scale and scope of innovative action within a company and has a strong influence on the implementation and the extent of application of electronic procurement tools (Reuter, 2013). Hence, the innovation orientation of a company can be perceived as structure dependent. Organisational structures influence capabilities, motivation, orientation and attitude of employees. The organisation structure shows furthermore if the company has adaptive capacities and if the employees are able to implement new ideas (Thompson, 1965). "A firm's [...] norms, guidelines, databases, organisational routines and corporate culture, as well as its strategic alliances" (Férrandez et al., 2000, 82) are understood as organisational capital. Furthermore, a firm's sustainable competitive advantage depends on this organisational capital (Makhija, 2003). Organisational capital consists of different structural dimensions. Centralisation, formalisation and specialisation are very important in this context (Jansen et al., 2006).

A lot of companies organise procurement in a centralised way within a specific procurement department (Axelsson; Wynstra 2002). The head of the procurement department is part of the firm's management team and the procurement experts within the procurement department are human capital of the firm (Axelsson; Wynstra, 2002). The employees' direct influence on strategic procurement leads to easier implementation of new ideas which in turn enhances the innovation potential in procurement (Hull; Hage, 1982). Especially in the implementation of new technologies and software solutions, learning effects show. From a financial perspective, centralisation is beneficial as well. Centralised procurement improves the bargaining position of the firm. Demand bundling allows better procurement conditions in general and discounts in software procurement in particular (Brandel, 2010).

Hypothesis 1: Organisation of procurement is a relevant construct in measuring organisation structural implementation prerequisites of electronic procurement of services.

Employees do their work in accordance with the roles ascribed to them (Hage; Aiken, 1967). Roles are understood as "standardized patterns of behavior" (Katz; Kahn, 1978, 43) which are related to their underlying function (Sine et al., 2006) and clearly describable (Hickson, 1966). The more specific a certain task – such as electronic procurement of services - is, the easier it can be unambiguously described. Task specificity can be described as the basis for role description.

However, a low degree of formalisation in role description leads to confusion and disarray which in turn gives rise to role ambiguity (Sine et al., 2006). In a formalised organisation structure, each employee knows what to do (Mintzberg, 1979). This simplifies decision making (Sine et al., 2006) and organisational learning. Organisational learning and sustainable development both depend on tasks, rules, methods and orders that are put into writing (Child, 1972). All in all, role description is an important part of organisational capital (Black; Lynch, 2005) and facilitates electronic procurement of services.

Formalised rules are part of the organisation structure (Pugh et al., 1963). Rules adhere to the accomplishment of certain tasks (Dalton et al., 1980) – such as electronic procurement of services - and describe the extent of routine behavior in these tasks (Child, 1972). Also, task specificity increases the formalisation potential of rules. The more specific the task 'electronic procurement of services' is, the easier it is to define rules which are relevant to all tasks of

this specific nature. To abide by these formalised rules is vital for the viability and operability of a company (Hage; Aiken, 1967).

Hypothesis 2: Formalisation of procurement is a relevant construct in measuring organisation structural implementation prerequisites of electronic procurement of services.

Specialised employees are important resources of a firm. Organisations learn from the experiences their employees have made in former electronic procurement assignments. Especially in electronic procurement of services, specialisation of employees is crucial for the efficiency of the procurement process as the knowledge basis expands and the number of specialists rises as well. The more employees of the procurement department are specialists in electronic procurement of services, the higher seems to be the importance of electronic procurement of services within this firm (Reuter, 2013).

Hypothesis 3: Specialisation of procurement is a relevant construct in measuring organisation structural implementation prerequisites of electronic procurement of services.

2.2 Service-Related Implementation Prerequisites

Constitutive characteristics of services can lead to notable differences in the implementation of electronic procurement of material and services. Procurement of services needs more information on the services-to-be-procured than procurement of material (Oman, 2008). The consideration of service-related aspects is a major success factor in procurement of services (Large; König, 2009).

The degree of standardisation of services determines if the services-to-be-procured can be adequately compared with each other. In spite of numerous examples of service standardisation efforts, efficient, practically relevant approaches were not to be seen in the past (Segev et al., 1999) and are still rare now (Reuter, 2013).

Before services can be procured electronically, their standardisation degree is clarified. The most important question in this respect is if the service is standardised. If yes, the degree of standardisation can be identified. The higher the degree of standardisation already is, the more efficient the self-same service can be procured electronically without further amendments. In this case, the describability of services plays an important role. Describability determines if the service is procured externally or produced in-house in the first place (Holcomb; Hitt, 2007). The risk of potential inefficiencies caused by inadequate description of services is minimized if highly standardised services are procured (Ancarani; Capaldo, 2005).

If not, the degree of standardisation is zero. Then, standardisation potential is sought after. The higher the standardisation potential, the better are the chances to successfully procure the self-same service electronically. The employees in the procurement department can identify the services with the highest standardisation potential. In order to generate such a service ranking, the employees have to know the services in question really well. Otherwise, misunderstandings are preprogrammed. In the worst case, such a misreading can result in the procurement of services which do not meet the quality standards of the procuring company. Or the company who wins the bid (in case of an electronic auction) is not prepared to produce the offered services in the relevant time-frame because of time-consuming adjustment necessities (Reuter, 2013).

Hypothesis 4: Standardisation of services is a relevant construct in measuring service-related implementation prerequisites of electronic procurement of services.

The above-mentioned constitutive characteristics of services determine the degree of strategic importance of the services in question (Daub, 2009). The higher the strategic importance of a certain service is, the lower seems the incentive to procure this self-same service externally. Concurrently, if the extent of external procurement of a service is low, the utilization of electronic procurement is even more improbable. The strategic importance of services (Aurich et al., 2010) seems to be another viable implementation prerequisite of electronic procurement of services.

Hypothesis 5: Strategic importance of services is a relevant construct in measuring service-related implementation prerequisites of electronic procurement of services.

3 Empirical Methodology

Measurement models for the different variables are created. The measurement models are based on reflective, multi-dimensional constructs (see Figure 1). In the following subchapters, these measurement models are refined and quantitative-empirically proven.

Figure 1. Measurement models.

3.1 Operationalisation of Constructs

Table 1 provides an overview over the constructs which represent the organisation structural and service-related implementation prerequisites in the hypotheses.

Table 1. Operationalisation of constructs.

construct	indices / items	derived by	reliability proven by
organisation	strategic dimension of centralisation	Hage; Aiken, 1967; Pugh et al., 1968	Dewar et al., 1980: Cronbach's alpha 0.92
	operative dimension of decentralisation		
formalisation	formalisation of roles	Dalton et al., 1980	
	compliance with rules	Hull; Hage, 1982	
	task specificity	Aiken; Hage, 1968	Dewar et al., 1980: Cronbach's alpha 0.76
specialisation	number of specialists	Pugh et al., 1963; Child, 1972	Sine et al., 2006: highly reliable
standardisation	describability	Holcomb; Hitt, 2007	
	functional specificity	Ancarani; Capaldo, 2005	
strategic importance	rarity	Barney, 1991	Poppo; Zenger, 1998: Cronbach's alpha 0.82
	value	Aaker, 1989; Coyne, 1986	Nothnagel, 2008: reliable
	imitability	Nothnagel, 2008	
	substitutability	Coyne, 1986	Nothnagel, 2008: reliable

As a rule, all indices are built from several items (Curtis; Jackson, 1962). Furthermore, all underlying items are adjusted to the context of procurement of services.

3.2 Preparation and Execution of the Survey

Previous to the execution of the survey, a reliable method of data gathering was found, the relevant population was identified, the random sample was drawn and a preliminary survey was carried out. According to Deutskens et al (2006), an online survey is as reliable as any postal survey. Therefore, data gathering was executed online. Zikmund (2000) characterised the relevant population as a group, whose participants share commonalities, which are relevant for a certain statistical examination. In this case, the relevant population was the group of all facility management service providers in Germany. The exact number of participants in this group could not be distinguished. Therefore, a random sample was drawn from several sources. Hoppenstedt database, recent market studies of the German journal "Facility Manager Magazin" and the so-called 'Lünendonk-Liste' were exploited. In addition, the members of the German "Qualitätsverbund Gebäudedienste" were integrated as well. Thus, 1.048 facility management companies in Germany were identified as relevant members of the random sample.

During the actual survey, the researcher has no possibility to intervene. Therefore, the design of the questionnaire is highly important and the exact meaning of items is extremely relevant in the development of measuring models. Hence, a preliminary survey was carried out in order to rule out any misunderstanding and ambiguity (Rossiter, 2002). As a result, several items were rephrased and the length of the questionnaire was reduced considerably.

The online survey itself took place in May and June 2011. The EFS survey tool was used to carry out the poll. 131 of the companies represented in the random sample completely answered the questionnaire. This is important as the overall response rate determines the representativity of the gathered data (Armstrong; Overton, 1977). The overall response rate was 12.5%. A good deal of quantitative-empirical research in procurement published in international journals sports similar response rates (e.g. Nguyen; Harrison, 2004; Rao; Holt, 2005; Sanders; Premus, 2005; Tracey; Tan, 2001; Frohlich; Westbrook, 2001). Hence, 12.5% are an average, but still meaningful response rate (Röderstein, 2009).

To rule out any unwelcome side effects, the companies which took part in the survey were controlled for company size (Hallal et al., 2010), company age (Aiken; Hage, 1968) and size of the procurement department (Jansen et al., 2006). None of these control variables had a significant influence on particular answers.

3.3 Evaluation of the Survey Results

One prerequisite of reviewing correlations between constructs is the validity of the reflective measuring instruction: „Validity is represented in the agreement to measure the same trait through maximally different methods" (Campbell; Fiske 1959, 83). A valid measuring instruction measures what is intended to measure (Field, 2011) and is situated within the subject area of the relevant construct (Combs et al., 2005). It is the question which items reflect existing correlations the best. An answer provides explorative factor analysis.

Explorative factor analysis is applicable if more than 100 questionnaires are analysed (Hair et al., 2010) and at least four items are used to build a construct (O'Leary-Kelly; Vokurka, 1998). Furthermore, the existence of correlations between items is another utilisation requirement. According to Field (2011), Pearson's r has to be at least 0.3. All three basic requirements are fulfilled for the items in question. Therefore, explorative factor analysis could be used to assess the relevance of the proposed constructs in measuring organisation structural and service-related implementation prerequisites of electronic procurement of services.

Two different manifestations of explorative factor analysis are known: main axis method and main component method. The goal of this research project was to reduce data but to conserve most of the variables variance. Hence, the main component method (Hair et al., 2010) was used. In a first step, the number of relevant components was derived with the so-called scree-test (Field, 2011). Most of the variables could be described through one single component. For those which could not, factor rotation was used (Reuter, 2013). Furthermore, the items' factor loading was taken into account. According to Hair et al (2010), factor loading has to be at least 0.5, if 120 to 149 questionnaires are considered. Therefore, nine items with factor loadings below 0.5 were eliminated.

In a second step, factor analysis was run again with the remaining items only. Factor loadings showed that all items loaded highly on the respective factors: results were all above 0.5. In literature, the interpretation of extracted communalities is inconsistent. Field (2011) labeled extracted communalities of < 0.5 as not acceptable. However, he also indicated that it is up to the researcher whether extracted communality or factor loading is used as decision criterion. Hence, most of the items exhibit high enough factor loading and high enough extracted communality to qualify as relevant. Eight items are relevant for their factor loading alone. The factor loadings and extracted communalities in question are displayed in table 2.

Table 3 gives an overview over the second circuit of explorative factor analysis and its results. The highly significant results of the Bartlett-test show that multicollinearity was evident for all tested items. Furthermore, the suitability of the random sample was tested. The Kaiser-Meyer-Olkin (KMO) criterion is designed to do just that (Hair et al., 2010). According to Field (2011), results of > 0.5 are acceptable. Hence, data showed that the random sample is highly suitable to test the researched hypotheses.

Furthermore, the reliability of the measurement models was tested. Cronbach's alpha was used to illustrate the constructs reliability. Following Nunnally and Bernstein (2008), the results for Cronbach's alpha are considered to be acceptable if higher than 0.6. As all results were considerably higher than this threshold, all (sub-) constructs were

proven to be reliable. The results for both the multi-dimensional and the single-dimensional constructs are displayed in table 3.

Table 2. *Extracted communalities and factor loadings.*

	STAN_06	0.699	0.836

Let us take a look at the organisation-structural implementation prerequisites first. The construct of organisation of procurement featured an average suitability of the random sample of 0.752 (KMO-criterion) and explained an average of 72.496% of the existing variance. Cronbach's alpha ranged between 0.755 and 0.950 which is really outstanding. All in all, organisation of procurement was identified as a relevant construct in measuring organisation structural implementation prerequisites of electronic procurement of services. Hypothesis 1 was confirmed. Formalisation of procurement as a construct exhibited an average suitability of the random sample of 0.843 (KMO-criterion). An average of 67.237% of the existing variance could be explained with the respective construct. The results for Cronbach's alpha ranged between 0.819 and 0.966. Both results were even better than the above-mentioned results. Formalisation of procurement was identified as a relevant construct in measuring organisation structural implementation prerequisites of electronic procurement of services. Hypothesis 2 was confirmed. Furthermore, the results concerning specialisation of procurement also justified hypothesis 3.

Table 3. Explorative factor analysis and results.

implementation prerequisites	construct	sub-construct	explained variance (in %)	Suitability of the random sample (KMO-criterion)	Cronbachs alpha	significance (Bartlett)
organisation-structural	organisation of procurement	strategic centralisation	83.483	0.829	0.950	0.000
		operative decentralisation	61.510	0.675	0.755	0.000
	formalisation of procurement	formalisation of roles	66.981	0.779	0.819	0.000
		compliance with rules	65.119	0.815	0.865	0.000
		task specificity	69.612	0.934	0.966	0.000
	specialisation of procurement		63.631	0.802	0.847	0.000
service-related	standardisation of procured services		75.768	0.830	0.893	0.000
	strategic importance of procured services		52.977	0.775	0.815	0.000

In what concerned the service-related implementation prerequisites, the results for standardisation of procured services clearly indicated that hypothesis 4 was confirmed. A small question mark remained when analysing the data for strategic importance of procured services. The mere results indicated that hypothesis 5 is supported as well. However, the relatively low explained part of the existing variance (52.977% only) pointed out that strategic importance of the procured services was by far the weakest of the researched implementation prerequisites.

To sum this up, explorative factor analysis showed that the theoretically derived measurement constructs were highly suitable to depict the implementation prerequisites of electronic procurement of services. The partitioning into organisation-structural and service-related implementation prerequisite proved to be justified as well.

4 Conclusion

4.1 Summary of Results

Process-oriented, relational and resource-based reasoning identified organisation, formalisation and specialisation of service procurement as relevant organisation structural prerequisites for the implementation of electronic procurement of services within a company. From a service-related perspective, the degree of standardisation and the strategic importance of the procured services have explanatory power for the question of implementing electronic procurement of services.

These five theoretically founded implementation prerequisites were operationalized and statistically tested. Explorative factor analysis identified the items which were apt to describe the constructs. Most of the theoretically derived items passed quantitative-empirical testing with flying colours. The KMO-criterion showed that the used items were highly suitable to measure the random sample. Cronbach's alpha values between 0,755 and 0,966 showed that the built constructs were highly reliable.

All in all, the implementation of electronic procurement solutions of services holds a lot of potential for future use in business-to-business procurement. The construction of reliable measurement models in the research area of electronic procurement of services is a major step towards a more rigorous investigation of this important topic.

4.2 Restrictions and Further Research Necessities

This research project has certain restrictions which should be discussed. The measurement models were constructed with a quantitative-empirical survey within the facility management branch in Germany. This limits the generalizability of the research results. Therefore, the constructed measurement models should be tested again for other branches than the facility management branch and / or within other countries than Germany. This would lead to more generalizable results.

Also, concerning the strategic importance of procured services on the usage of electronic procurement of services, the role of this implementation prerequisite should be further investigated.

Business Model Canvas as ‘a thought experimentation model’ in search for a service-based business logic

Päivi Ristimäki¹, Helen Reijonen², Harri Rynnänen³, Raija Komppula²

¹University of Eastern Finland, Aducate, Center for Training and Development, ²University of Eastern Finland, Business School, ³Solenovo Ltd.

Abstract

The aim of our study is to look into the meaning of Business Model Canvas (BMC) and of peer group dialogues to learning processes of three Finnish firms participating in a service business training program. We inquire the relevance of these learning tools as mediators for reconceptualize a vision for service business logic. Our study highlights that BMC was 'a thought experimentation model' that oriented the participants towards service logic by classifying and sorting out elements of business vision leaving, however, open how a concept-level and systemic business idea can be conceptualized. Thus peer dialogues and other supplementary tools visualized and materialized the actual transition between the product-based and service-based logic.

1 Introduction

Since the beginning of the third millennium Service-Dominant Logic (S-DL) (e.g. Vargo & Lusch 2004) and Service logic (e.g. Grönroos 2008) have been hot topics in business literature. The focal idea is that offerings intertwining both products and services act as instruments of value creation and based on this idea firms are looking for ways to offer unique value that separates them from competition. The search for a competitive advantage emerges as well in long-term inter- and intra-organizational learning processes as in strategic planning and implementation of managerial decisions and goals. In dynamic business environments collective learning has become a key driver of organizational transformations and, therefore, there is also a need for an expansion of methods and tools of managerial and organizational learning as the complexity of business activity increases (Virkkunen & Ahonen 2007). Furthermore, the improvement of performance demands comprehensive changes in production procedures that in turn highlights the need to integrate the principles of scalability and mass-customization with proactive and agile work that benefits from digital technology and co-configuration with customers and business partners and results in customer-intelligent offerings (Victor & Boynton 1998). Therefore, the formation of a service-based business logic means that the business goal is expanded through concept-level development that is triggered by creation of new tools and exploration of new opportunities from everyday business practices, for example business events, collaborative and partnering dialogues and experiential business actions (McGrath 2010; Ristimäki 2014).

A generalized instrument in business literature and in organizational practices that integrates both strategic and operational business perspectives and conceptualizes the dynamic nature of value creation is the concept of business model (see a review of the concept in Zott, Amit & Massa 2010). Based on the idea that the purpose of businesses is to create value and make revenues from that value. Shafer, Smith & Linder (2005, 2012) have defined it “as a representation of a firm’s underlying core logic and strategic choices for creating and capturing value within a value network”. Our interpretation is that this definition emphasizes a dynamic and systemic nature of business, because the logic of activity refers to the generalized sets of principles and routines prevailing in the organizational reality of organizing and managing business activity. Additionally, the strategic choices are made at everyday level of decision making which Spinosa, Flores & Dreyfus (1997) call “everyday history-making” (see also Engeström 2004). Therefore, we claim that the systemic nature that the concept of business model embeds is not simply related to explication of cause-and-effect (cf. Shafer, Smith & Linder 2005), but to the dialectical relations between different elements of organizational practices that need to be reconfigured when the logic of business activity is to be transformed.

Many recent studies of business models describe, but cannot explain how a comprehensive transformation proceeds, because of lack of empirical evidence on business logic transitions. However, in realities of firms transformation of business models generate tremendous changes in the logic of value creation and in work practices as Victor & Boynton (1998) have presented. Based on longitudinal case studies they have depicted a strategic path in business development and conceptualized it to include five strategically different generic successive logics of doing business and producing products. Also Sosna, Treviño-Rodríguez & Velamuri (2010) show in their case study that the transition from a business logic to another takes years or even decades without permanent, “final” solutions. Thus, in recent business literature the idea of sustainability of business models is related to the transient competitive advantage (McGrath 2013) that for its part is based on ideas such as “strategic agility” (Doz & Kosonen 2008), “discovery driven approach in business models” (McGrath 2010) or “action-based competition” (Madhok & Marques 2014).

2 Focus of the study

In this interdisciplinary study we have adopted the idea of Baden-Fuller & Morgan (2010) who interpret business models as tools that enable business actors to reframe new business solutions and due value-creating constellations with actions of innovating, prototyping and experimenting of new business elements. Here we conceptualize business models as tools that mediate collective learning and strategic business development. Instrumental, visualized application of business models introduces business actors with potential elements of new business model before too much practical effort or financial investments are made (McGrath 2010).

For the analysis of this study we have selected three firms that participated in a training program organized to facilitate the firm's efforts to advance the transformation of business activity towards service-based logic. At the initial stage of the program participants were offered the Business Model Canvas (Osterwalder & Pigneur, 2010; named BMC hereafter) as a materialized form of the conceptual tool of Business Model to illustrate firm's prevailing business logic and a preliminary business idea of an envisioned future. After the first training period of three training days a peer group dialogue meetings were held to support the modeling of their new strategic ideas of service business. The purpose of applying BMC in the beginning of the training program was to enable the business actors to materialize initial business ideas triggered by the first three training days. During these training days the generic building blocks and strategic aspects of service business had been introduced. The discussion in the peer groups was supposed to support the participants in the identification of potential elements in service business.

The purpose of our study is to explore how BMC and peer group discussions work as tools or mediators when contemplating to move from the prevailing business logic to a new one. We examine how service business logic could be explored with BMC in each firm and how reflection and discussion in peer group meetings contributed to the conceptualization of service-based business and supported to "office desk exercise" of making plans with BMC. Furthermore, we elaborate what kind of mediating role BMC model had for the business actors and for their business.

3 Conceptualization of service business logic transformation

The focus in service business logic lies on adapting to and working proactively in changing conditions and with customers' needs, instead of classifying offerings into physical goods and services. According to Edvardsson, Gustafsson and Roos (2005, p.118), "service is a perspective on value creation rather than a category of market offerings". The key notion is that although a customer buys products or services, they are both consumed like services (Grönroos, 1978; Grönroos, 2008; Gummesson, 1995, Vargo and Lusch, 2004). In another words, those goods or services are ultimately bought to serve the customer's processes and to create value in those. Thus, the customer service has been conceptualized as a service logic according to which both goods and services act as instruments of value creation. Therefore, new concept like the digital age concept of "platform" reflects a tendency to conceptualize for example the use value based on collective innovation and continuous learning from and with customers and partners without dichotomous separation of materiality in the product.

In general, when taking an evolutionary perspective for the concept of service the meaning of it has during the digital era expanded from actions in the customer interface towards more comprehensive interpretation of service orientation in business practices i.e. the earning and value creation logic of businesses. Therefore, there is a need for understanding and interpretation of the more complicated business totalities and disengagement from business functions based thinking that originates from mass-production period and that can hinder relevant theorization of service logic of the digital era. We claim that relevant theorization is related to the issue that the principles of service logic contradict the principles of mass production that emphasize internally driven competitive advantage of mass products, cost efficiency, scalability of production and price. Nevertheless, a transformation from mass-production based logic to service based logic is not a transition from the first to the latter, but an integration of the principles of both logics and application and innovation of a novel base for managing value creation and competition. Therefore in this study the transformation towards service business logic is highlighted with an interdisciplinary sense. We take the concept of learning not only as notion to be added to but a theoretical concept entailing also a paradigm of learning and the academic discipline of activity theory with historical and contextual emphasis in the analysis of the data. The business theories and empirical data offer this study the contexts that are interpreted and analyzed.

4 Tools as mediators for learning a service business logic

In an established business, new business logic cannot emerge and become generalized at once. The emergence of a new logic is usually embedded in deviating actions that challenge the prevailing practices and norms. The deviating actions form the „germ cell activity“ for a new logic through which the novel principles are created. Later these new principles can become generalized as the new nature and new forms of business practices. A comprehensive transformation from a logic to another includes a construction of a new systemic entity with new relationships of interaction. Therefore, for finding a new germ cell for business it is focal to critically question prevailing logic and generalized business thinking. Thus, there is a need for new tools that mediate explorative actions and new modes of thinking. The learning of a new logic can be depicted as an evolutionary process that is characterized by interplay between reobjectification and retooling of business activity. New tools as mediators of learning are needed to solve the discrepancy between the

emerging new customer demands or business conditions and firm’s prevailing logic of business. New tools bring forth new qualities that cannot be visualized with the tools of prevailing logic. (Virkkunen & Virkki, 2014; Ristimäki, 2014)

Osterwalder’s (2004) theorization of the concept of Business Model is materialized in the Business Model Canvas that is a tool for managers to identify their business ideas and the modes of value creation and to characterize a potential value creation logic (see also Osterwalder, Pigneur & Tucci, 2005). For portraying the prevailing business logic and designing potential new components in value creation the researchers have presented a canvas with nine fields of key themes that follow a purposeful order. The model of the BMC is depicted in its original structure in the following picture as illustrated by Osterwalder & Pigneur (2010).

BUSINESS MODEL CANVAS

8. KEY PARTNERS Who are our Key Partners? Who are our key suppliers? Which key resources are we acquiring from partners? Which key activities do partners perform?	7. KEY ACTIVITIES What key activities do our value propositions require? Our distribution channels? Customer relationships? Revenue streams?	2. VALUE PROPOSITIONS How do we help the customer? What value do we deliver to the customer? Which one of our customer’s problems are we helping to solve? How do our value propositions differ from the ones of our competitors? How do we measure the value delivered to the customer?	4. CUSTOMER RELATIONSHIPS What kind of customer relationships do different customer segments expect? What kind of customer relationships do we already have? How expensive are they? What are the switching costs involved for the customer?	1. CUSTOMER SEGMENTS For whom are we creating value? What is the main problem of the customer?
	6. KEY RESOURCES What key resources do our value propositions require? Our distribution channels? Customer relationships? Revenue streams?		3. CHANNELS How are we reaching the customer? Which channels are the most important for the customers? How are telling our value propositions to customers? How are sales organized?	
9. COST STRUCTURE What are the most important costs inherent in our business model? Which key resources are most expensive? Which key activities are most expensive?		5. REVENUE STREAMS On what is the price of the products and services based? For what does the customer pay? How do our actions affect the everyday of customers? How do we prove the effect? How would the customer prefer to pay?		

(Osterwalder & Pigneur, 2010)

Figure 1. Business Model Canvas (Osterwalder & Pigneur 2010).

Viljakainen, Toiviainen & Aikala (ibid.) has extended the BMC model proposing a business model construct that integrates a service logic. They claim that a dynamic presentation of the model calls for highlighting customers and partners role in the components of the BMC model without making the model as a tool for managers not too complicated. Also McGrath (2010) suggests the promotion of outside-in focus as the basic idea of business models in making sense of the strategic aspects of the business. However, McGrath also points to the centrality of the experimentation as »the real business model« can only be discovered in the changing realities of the firm.

Our perspective of BMC model is related to the purpose of the BMC model in the specific context of the training program. We propose that the BMC model was a »thought experimentation model« (Miettinen 2000) that enabled the participant of firms to elaborate a potential working hypothesis for future business actions and to test the hypothesis with their colleagues in the light of the knowledge achieved at that phase of the training program.

5 Data collection, methodology, and data analysis

The description of the training program

The training program including five training periods with three training days in each period started in February 2014 and ends in March 2015. During each of the training days an academic or an expert consultant gives a lecture on the subject at hand and in some of the days also visiting speakers from different firms present case-examples. The training days include a lot of peer discussion among the participants and different presenters. Furthermore, two actors from the University of Eastern Finland take part in the training program. Their role is to facilitate and support the learning

processes of each participant by provoking thoughts, discussion and actions for example by providing different assignments. The BMC was given to the participants as an assignment tool during the first training period that dealt with the basics, strategy and change required by moving towards service business.

Activity-oriented case study approach

In order to study Business Model Canvas as ‘a thought experimentation model’ when moving towards service business, we utilized action research approach and the case study strategy (Miles and Huberman 1994; Yin 2008). In action research the researchers are actively engaged with the research object and work with the participants to develop their business (Eriksson and Kovalainen 2008). Action research is not a method but a systematic approach, a variety of data collection method may be used (Eriksson and Kovalainen 2008). In this study we applied action-research that intertwined analysis of firm’s narratives and peer groups’ collective dialogues with activity-theoretical approach that conceptualize tool-mediation in activity (see Kajamaa 2012). We approach the data as a multiple case study, for which three intrinsic cases were selected from the participants of the training program. According to Eisenhardt (1989, p. 543), case studies have the potential to capture the dynamics of a studied phenomenon and he defines case study as “a research strategy which focuses on understanding the dynamics present within single settings.”

The multiple case approach is employed, since it offers contrasting results from dissimilar fields of business. Thus, more comprehensive understanding on the studied phenomenon may be gained. The unit of analysis is the learning process towards service business in a firm. The selection of the cases to be studied is based on the following reasons. First, the case firms have made an apparent decision to move towards service business. Second, the firms are exemplar on their own industry field. Finally, the selected cases form an ensemble in which contrasting results may be derived. Based on the criterion, three cases were selected to be studied. The first case is the subcontractor for metal plants, the second case is the energy infrastructure building firm, and the third case is the tourism services firm.

Analysis of the data

The analysis of the use BMC model in three case companies and testing the business ideas in peer group dialogue meetings is divided in three phases. First we give a short description of the data of each firm including narrative scripts of the prevailing business challenges and aspects of future vision presented by actors of the participating firms. Thereafter we present our analysis of firms’ business logic and the transformation of logic as presented with the BMC and in peer dialogues and evaluate the use of the tools. Finally we evaluate the mediating role of the BMC model and peer group dialogues for learning. The three companies come from the following industries. In the parenthesis there are the code names used in the following empirical section of the study:

1. Subcontractor for metal plants (Metaloy)
2. Energy infrastructure building firm (Eninfra)
3. Tourism services firm (Touriserv)

In the following figure we have positioned the three firms in a four-field matrix adapted from Storper (1996) that represent business logic as »economies of conventions« that set rules, conditions and generic principles for demand and supply of products and services. Storper calls the different fields with different logics of business interaction as »worlds«. Thus the division between the worlds is based on axioms of supply and demand. The supply is either of standardized or specialized products and services. The demand is for generic or deciated products and services. Thereby, the four-fields are »the industrial world«, »the market world«, »the interpersonal world« and »the world of intellectual resources«. We use this matrix and the axioms embedded in each world to interpret the transformation of the business logic in our analysis of the three case firms.

Figure 2. The Case firms in their business logics in the “matrix of worlds”.

6 “Thought experiments” in three case firms

Subcontractor for metal plants (Metaloy)

In the training program participated the CEO of a metal industry subcontractor. First he expressed their prevailing blurred position and indefinite future business position in the markets with the following words:

»We operate in a zone of uncomfort, because we do not have a single product of our own. How do we then servitize our business?«

However, he himself then specified that they are a service firm, because what they offered were services to machinery companies in forms of welding, mechanizing and painting. The analysis of researchers regarding the firm’s BMC reveals that at this »thought experimentation stage« firm’s vision of a new business logic constituted mostly of list and single generic descriptions and qualitative indicators of the object of business activity that, however, formed an entity and direction for the future. This materialized in the formulation of a new slogan for the firm and services clearly named as a guiding elements for a service logic. The new slogan: »METALOY– from parts to ensembles« served as a title that gathered together packaged service that the firm was planning to offer for their customers.

The CEO told that one concept in the training program had evoked him. For him the concept of »hybrid organization« was a clue to a new business model. The notion of hybrid organization had mediated him a new concept-level business idea of becoming a broker the deals with customers’ subcontractors. An illustration of this business idea is presented in the following figure as it was drawn in a additional paper that was included with filled assignment of the BMC model. For the researchers BMC assignment was much easier to interprete with this concept-level visualization of the two business logics – the one of today and the one potential for the future – that Metaloy’s CEO and his colleagues had illustrated in the paper. The picture helped to pull together the systemic nature and principles in the logics and to figure out the singular descriptive notes written in the BMC Model.

Figure 3. Metaloy's visualization of firm's concept-level transformation towards service-based logic.

Energy infrastructure building company (Eninfra)

There were three participants from the energy infrastructure building firm in the training program. Consequently although they all filled their own BMC and brought their own thoughts in it, it was clearly shown in their writings that they had discussed the matter together. Also in the peer discussion all three contributed to the joint presentation.

At present the firm has few customers and it is heavily dependent on one big customer. They have a history of a close relationship with that customer, but recently the customer has shown a desire to scan also alternative service providers. Due to governmental regulations all the suppliers in the industry tend to offer same kind of products and services which has lead to competing mainly with the price. At this situation it was seen that it is quite easy for the customer to change the supplier. Thus, the focal question presented in the peer discussion was:

»... how could we lead the customer in the direction that it could decide to continue with us and not seek for alternatives...«

The basis and need for the change in the business logic was a need to develop current customer relationships and look for new customers. In line with this, the main theme in the peer discussion related to customer relationship management. Already in the BMCs the three participants expressed the need that in the future customers should be segmented and more effort should be put in managing and developing the customer relationships systematically. It was also pointed out that the formulation of value proposition and how it is expressed to customers should be sharpened. In addition, it was brought up in the BMCs that in the future the perspective of customers' customer and customers' goals and needs are meant to be taken into account better. These were the things that are somewhat lacking at the present.

The peer discussion concentrated on themes such as the meaning of personal relationships and creating stronger bonds with customers. The question »what is the thing that we can offer more than the neighbour« was brought up. In order to find the competitive advantage, the significance of knowing the customer, having customer insight and proactively respond to customer signals was recognised. The representative of the firm said that the change itself forms a challenge in moving towards service business.

»... reaching the understanding in our organization and then starting the change and through that managing it. That is probably one challenge.«

The BMC had been a thought provoker. One of the representatives of the firm said that although the themes brought up by the BMC are »truisms in managing a business«, the questions presented in it made him evaluate the business operations. Answering the questions had stopped him to ponder the issues thoroughly.

Tourism services offering company (Touristserv)

In the beginning of the peer group discussion the CEO of the tourism service firm explained that several changes concerning tourism, marketing and personnel have lead to a need to develop the firm's business logic more focusedly towards service business. The old way of doing business relied on being actively present in different kinds of media, exploiting the tools of mass marketing and thus grabbing the attention of the customers. The value promise given to customers was formulated in the BMC as »one call, get it all«. So after the customers took the initiative to contact the

firm, then it would provide them with easy and quick service meeting all their needs. However, the image of the destination was seen to limit the spectrum of customers interested in it.

»Our profile is a one of a party place for wealthy personnel or firms and that partly results in that the big mass won't come here.«

The CEO expressed that the new vision that guides the development of the firm is its want to have a holistic view on customer relationships. Moreover, it wants to take a step further and change its business concept so that it serves better the customer's customer.

»And when the customer's customer is satisfied so are our customers and that brings money to all of us.«

How the firm plans to achieve this goal is to recognise how it can take a more active part in the end customers' process from rousing the initial interest to making them want to come back after leaving the destination. The value proposition formulated in BMC was transformed into »providing customers with memorable experiences which create positive energy to carry them in their every day lives«. The firm wants to be seen as a service provider who offers holistic service that recognises and meets the individualistic needs. At the same time the basis of pricing is meant to change from history-based calculations into the valuation of the customer experience provided.

The BMC served as the initiator in the peer discussion. The discussion started with a review of the current situation and a recognition of the drivers behind the need to change the business logic. There were also some tension to be seen that was brought up both by the change drivers and the actual change planned. One of the main concerns that the CEO talked about in the peer discussion was the question how the firm should position itself with regards to its network partners and competitors as it moves towards service business logic. In this change the firm wants to take into account the actions and reactions of the actors in its network. Consequently, in the BMC describing the new vision more attention was paid to taking a more comprehensive look on the partners and their significance.

The new vision of the firm was clearly stated in the BMC and also in the discussion. The change of focus on the end customers and their entire service process was highlighted. Thus, the peer discussion revolved around themes relating to customer segmentation, customer relationships, marketing channels and the message conveyed to customers. With regards to attracting new customers brand and image issues were brought up.

7 Learning tools for business logic transformation in three firms

The focus of our analysis is on the meaning of learning tools that assisted to reconceptualize the business logic and to perceive the transformation needed between the prevailing logic and envisioned logic. The BMC model and the peer discussions are elaborated here as intertwined but separate tools of learning that contributed to each other. In the analysis we show that even new tools were needed to create and grasp the idea of envisioned business logic. Thus all the used tools contributed to each other, for example, by giving historically and contextually loaded meaning to business modelling. In this chapter, we firstly elaborate firm by firm what can be discovered from firms' interpretations of their envisioned business logics and what was the meaning of the tools in illustrating the components of that vision. Thereafter we present the relevance and some developmental needs of learning tools used to help business logic transformation.

In Metaloy the vision of service business logic means a transformation from a subcontractor of massproduced services for metal plants to a partner with subcontractors. As the picture that the CEO included in the BMC assignment illustrated the metal plants had several subcontractors that usually were SMEs. Thus the core idea in the value creation of the new service logic in Metaloy embedded a change in division of labour between the contracting metal plants and subcontractors. A transformation of logic would turn Metaloy from operating at massproduction based logic into a new type of logic that is based on expertise in services, parts and assemblies that the subcontractors supply to metal plants. Our interpretation is that the concept of hybrid organization would denote in the case of Metaloy the expertise of a metal industry broker and a trusted partner. The picture drawn by the CEO illustrated this concept-level transformation which could not have been grasped and perceived with the BMC. Therefore two additional tools were used in Metaloy in mediation of a comprehensive change in business logic. The notion of "hybrid organization" acted as a trigger that mediated the reconceptualisation of the service business logic, which was materialized as a business logic in the picture. In the picture a the envisioned business logic as concept-level illustration showed changed principles and relations of the actors in the network of metal industry.

In Eninfra the challenges of the prevailing business can be seen as twofold. First, in the energy industry there are rules and generalized practices that guide the selling of the infrastructure services. Furthermore, practices in customer relationships had long roots in the history of the firm. Both of these challenges resulted in an outwardly directed and fixed business model without much flexibility to find a competitive advantage or an opportunity to differentiate the value proposition. Therefore, Eninfra could not aim at a complete transformation of the business logic but was striving for an extension on the tools and practices that would strengthen customer loyalty. The services were highlighted as an opportunity to maintain close customer relationships and convince customers to retain.

In Eninfra BMC model was used as a tool for expressing multivoicedness of the three participants in finding a shared understanding of the key issues related to the new business logic. However, not all of the components in BMC

model were equally important for Eninfra as the change of logic would not be very dramatic. Therefore the value proposition was a central indicator of the future direction for the business of the firm. The dialogues in peer groups then convinced the three participants that they had found a right track with their business ideas. The logic based on close business relationships was to be expanded with actions that would deepen customer understanding and give Eninfra more opportunities to deal with increasing customer demands.

The reason for the Touriserv's participation in the training program was the changing business circumstances. The marketing of services of the tourist resort was now partly at the hands of a new actor which changed the position of the firm in the network of actors of the tourist resort. Therefore, the Touriserv had recently also reorganized its business. The purpose of integration of different business units was to enhance the creation of customer value from the first contact to the last. Furthermore, the CEO of the firm expressed a need to renew the image of the firm in order to attract especially family market and increase the occupancy rate during the winter season. As the markets were not static a closer customer relationships and more customer value understanding were needed to increase customer retention and to expand the customer base. The customer understanding was expected to be gained through focusing on the end users and developing a more customer value-based approach. In this firm the of business logic was transforming from a market-based into a visitor-based one.

BMC model for Tourserv was an initiator to capture a more customer-centric business idea. However, only in peer dialogue the conflicting background as a driver for searching for a new competitive advantage and new business ideas was manifested. The changes in the business circumstances had emerged quite suddenly and were expected to have longstanding impacts on Tourserv. Therefore, there seemed to be a greater need for additional elaboration of the business vision and actions needed in finding a sustainable solution for the business. This need was brought up in the encounters with Touriserv's CEO that followed the peer discussion.

The analysis of the three cases indicate that BMC enables to make categorized comparisons between components of prevailing and envisioned logic, but does not enable to identify other indicators that could highlight the actual need of change and differences between the logics and, thereby, specify a new potentiality in service business logic. In our analysis we were able to find the indicators that explained the need for and extent of the transformation of business logic. The narratives of all three cases highlighted the contextual indicators, historically emerged business circumstances and business position as drivers for the transformation of logic and as factors that set limits for development of a business logic. Therefore, we saw that the »scale of perception« of a new vision is bound to the contents of BMC that does not necessarily allow to grasp the hypothesis of a comprehensively new concept-level transformation of business logic as the case of Metaloy revealed. With the BMC the critical questioning of the prevailing principles of business logic remains also undone. In Metaloy there was a motive to make a full-scale change in the business logic and the use of an additional, »self-made« visualization was needed to grasp this change. Thus in Metaloy the BMC model acted as a complementary instrument to concretize this change. We follow Engeström et al. (2005) and interpret the concept of hybrid organization as »a sign tool« which act as an initial idea of the germ cell for interpretation of »where to« the firm is heading to. Correspondingly the self-made visualization of the old and new business logic that the CEO drew was a system model and a mode of prototyping to explicate both »what« the old and new images of the business are and will be and »why« the principles of the logic needed to be transformed. Because the CEO had used concept-level tools with the BMC the group dialogue was not only one space for orientation to service logic with peers, neither was it only space for drawing ideas but a space to test a potential business idea.

Instead, in the cases of Eninfra and Touriserv the BMC acted as an orientation model for less dramatic changes in the business logic, and more or less as an indicator to strengthen firms' prevailing business positions. Therefore, the BMC was applied as a situation-specific and structural tool to fill the gap between the demands of the increasing competition, complicating business circumstance and dealing with the service offering that would satisfy these demands. Thus the peer group dialogues revealed that all the components in BMC were not equally relevant to the case firms when dealing with the new business idea and transformation between logics. However, in accordance with Viljakainen et al. (2013) for all the cases the value proposition component was a most relevant in BMC as it seemed to crystallize the purpose of the business logic and the basis for transformation towards service business logic.

8 Concluding remarks

All cases explicate that the BMC was used for different purposes under diverse circumstances of business. Even though all firms shared a need for development of service logic the building blocks of development were based on different components and emphasis. We suggest that BMC tool had a mediating role that made it easier at the initial phase of the training program to sort out and categorize the business logic transformation and to orient the firm to service logic.

With evidence of these three cases we claim that there is a need for various learning tools to reconceptualize the change of a business logic. We propose that an additional systemic model is needed to reveal the systemic and dynamic nature of the transformation of a business model. There is also a need for a tool to mediate the need to develop the business logic. This tool could highlight the driving forces of the firm specific business circumstances as well as the drivers and triggers embedded in changing business environment. Such a tool should also enable critical questioning and reasoning of the change needed for reorientation and learning of new principles and practices that the new business logic calls for. We agree with Viljakainen et al. (2013) that tools should not be too complicated and suggest that it is important to look for several tools that fit with the particularity of each firm and its business circumstances.

Answers to the questions of „where-to“, „what“ and „why“ could be found with the thought experimentations. However, the question of „how“ remains unclear. Furthermore, referring to von Hippel and Tyre's (1995) observations that the real problematization of an uncharted terrain can only take place in the realities and practical encounters of the firms. Therefore, all of the questions for the case firms were put into a new trial with a new assignment that followed the assignments of thought experimentation. The participants of the training program were proposed to pilot some new business ideas at the interface of the customers.

Networked business models: A case study from the wind power industry

Helena Rusanen, Päivi Jokela

Turku School of Economics

The literature on business models recognizes model development as a networked process involving various actors but providing little empirical evidence on how the process evolves, particularly concerning service-based models. Focusing on a project business setting in the emerging Finnish wind power industry with its various actors, we examine the dynamics of model development and analyze how business models evolve as a networked process between business actors. According to the study findings, the network actors are extensively involved in each other's model development and in particular in defining the contents of the service offering, which also influences each other's strategy.

1 Introduction

The growth of a knowledge-based service economy has led to a situation where innovative efforts in businesses are to a large extent related to the innovation of new service offerings (Howells 2000). At the same time, the deregulation and globalization of service markets as well as the internationalization of service providers have led to increasing competition in services industry (Stevens;Dimitriadis 2005). As a result, service providers and public institutions are putting effort into raising competitiveness through innovations that aim at providing outstanding value to customers (Bougrain;Haudeville 2002; European Commission 2011). Extant research suggests that this necessitates more than only renewal of the contents of services. The change should take place through rethinking of business models (Normann 2001, 81–82; Chesbrough 2006, xiii).

According to extant research, companies developing service-based business models need to design their value propositions around the customers' businesses and processes. This calls for development of a dynamic portfolio of offerings where the content differs according to the customer and changes along with customer needs (Kindström 2010). The studies have generally examined the business model from a single firm perspective where the business model provides a tool to analyze the firm's way of conducting business or business logic (Kindström 2010; Palo;Tähtinen 2013). Several studies have, however, suggested that innovation can succeed only if relevant resources are shared, combined, and developed between actors (Pittaway, et al. 2004; Cassiman;Veugelers 2006; Rusanen, et al. 2014). Resources are typically in the possession of various business units of firms (Swan, et al. 1999; Hansen 2002) and in a variety of firms and other organizations (Oerlemans, et al. 1998; van de Ven 2005). Therefore, actors increasingly lean on networks to access resources (Pittaway, et al. 2004; Lind, et al. 2012; Rusanen, et al. 2014), which increases their dependence on the network partners (Möller, et al. 2005). This holds especially true with services that support customers' value creation processes and are typically provided by a network of actors (Lusch, et al. 2010).

Apart from some recent studies (e.g., Palo;Tähtinen 2013), the network has not been part of the business model literature. Although extant research posits that the network has a notable influence on the actors involved (Rowley 1997; Zaheer;Bell 2005), academics have paid scarce attention to the influence of the network on the business models of the actors. Similarly, research on service-based business models remains underdeveloped, while the focus has been on product-based technology business (Kindström 2010). Thus, there is a need to incorporate both the network element and the services perspective in the research of business models.

The purpose of this study is to explore the role of the network in business model development at service provider firms. This study adopts a view that emphasizes the role of the business model as a communicator of business logic and as a tool in its management, from design to implementation (Osterwalder 2004). We approach the topic with the following subquestions:

- What are the drivers of business logic change in service firms?
- How do the network actors influence each other's business models?

This is accomplished by drawing on a longitudinal case study that examines innovation of service offerings together with new business models in three focal business-to-business companies and their networks in the field of wind power services.

This study contributes to the business model literature by demonstrating how the network influences the development of business models in service firms. It broadens existing knowledge especially on the role of networks in business model innovation and in the development of solutions and service portfolios.

The paper is organized as follows. The literature review section provides an overview on the extant value and network-oriented business model literature, on network perspectives in business model innovation, and on business model development in services. The following section describes the empirical research methodology. Then, three cases illustrating innovation of service offerings and business logics in networks are presented. This is followed by the findings. We conclude the paper with implications for research and practice.

2 Literature Review

2.1 Value and network-oriented business models

Interest in studying business models followed the expansion of Internet-based business, which provided a platform for multiple variations in firms' business logic (Pateli;Giaglis 2004; Zott, et al. 2011). Business models have been studied in various fields with different perspectives (see Shafer, et al. 2005; Zott, et al. 2011; Palo;Tähtinen 2013). This study takes the value and customer-oriented approach to business models (Pateli;Giaglis 2004).

Business models are typically seen as a critical link between strategy and operations in the organizational entity (Wikström, et al. 2010). Shafer et al. (2005) define a business model as a representation of a firm's underlying core logic and strategic choices for creating and capturing value within a value network. To a great extent, business model research has adopted the perspective of an individual firm (Wikström, et al. 2010; Palo;Tähtinen 2013). Business models have been described as a tool for individual firms to analyze and develop a way of conducting business, ranging from business model design to its implementation through infrastructure and processes, and simply communicating it to external parties (Osterwalder 2004). The rooting of models in e-business enabled this approach: a company defined its value offering and on the secondary phase, identified the entities and their contribution that would be needed for the total value creating system (Tapscott, et al. 2000, 15).

The extant studies, extensively focusing on business models as a static construct, include detailed reviews of the models and their value-creating elements. Among those elements the most regularly counted are strategic objectives, value proposition, revenue logic, target market, resources and key activities, value chain or net, and partnerships (Osterwalder 2004; Pateli;Giaglis 2004; Morris, et al. 2005; Shafer, et al. 2005; Nenonen;Storbacka 2010; Zott, et al. 2011).

The locus of decision making is in the firm developing the offering, and the assumption is that any component needed is available and can mechanically be added to complement the core offering. The value net consisting of suppliers and partners is viewed as a part of the firm infrastructure or architecture, providing access to external resources that for an individual firm ultimately serve as a source of competence (Osterwalder 2004; Morris, et al. 2005).

On the other hand, individual firms have been seen indirectly influencing each other's business models through market practices. Here the business model serves as a central construct in explaining the formation and evolution of market configurations (Nenonen;Storbacka 2010). According to this view, the market actors negotiate through their business models which aspects of their resource and capability configurations are being used and how they interact for value co-creation. Through their resource and capability configurations, the actors consequently participate in shaping the markets. Even an individual actor can influence other actors' business models if it is able to initiate changes in market practices.

These two perspectives, the wider network of partners as a source of resources or firms influencing networks of the business actors that operate in certain industries, markets, or their intersections, form the dominating views on networks in business model research. Recognizing the significance of networks for business actors in designing and implementing their offerings, we suggest that these limited views can be revised to better correspond to the networked reality of many business sectors. When networks as structures replace part of a firm's internal activities and resources, this releases the firm to focus on its core but also increases its inter-dependence. Consequently, business models are no longer independently manageable by individual firms but require coordination and cooperation.

2.2 Business model innovation with a focus on networks

Business model innovation can be defined as the search for new logics of a firm and new ways to create and capture value within its value network (cf. Shafer, et al. 2005; Zott, et al. 2011; Casadesus-Masanell;Zhu 2013, 464). Business model innovation is increasingly seen as the key factor behind firm performance and takes place when the firm pursues transformation and renewal (Ireland, et al. 2001; Demil;Lecocq 2010; Zott, et al. 2011). Business models may be developed in response to internal or external drivers (Kindström;Kowalkowski 2014), such as technological change, change in customer demand, or change in the social or legal environment (Osterwalder 2004).

Development of a business model requires profound customer, competitor, and supplier information and intelligence that may consist to a significant extent of tacit knowledge (Teece 2010). Some business model studies have responded to this challenge by focusing on business network research, which emphasizes the importance of the resources that the actors combine in order to provide new constellations and create value for the end customer and each network actor (Håkansson;Snehota 1995; Möller, et al. 2005).

By eradicating the boundaries between the different groups of external parties, the channels and partners are treated as a wider network element by Nenonen and Storbacka (2010). Taking a value creation perspective on business models, they suggest that there is shift from a business model being a static tool for the firm's internal use toward networks consisting of external actors that participate in creating value. This implies that the model as a construct should be externally orientated, mapping the key relationships and their functions that a firm has in its value network. Also according to Magretta (2002), business models inherently emphasize cooperation, partnerships, and joint value creation.

A pioneering study is an empirical examination of the networked business model development by Palo and Tähtinen (2013) that takes place with a strategic net of actors with the aim of developing, producing, and marketing a technology-

based service. The networked business model describes how the strategic net creates value instead of focusing on a single firm. Palo and Tähtinen propose that the business model development is dynamic rather than static, referring to the constant need to adapt the business model according to the environment and changes in the net. The business model is transformed through various encounters between the business network actors involved in the model development.

Focusing on technologies and ideas that are accessed and exploited from outside or given to others to be used, Chesbrough (2006; 2007) introduces the concept of the open business model. The idea is to be able to make effective use of open innovation by extending it to also include business model innovation (Chesbrough 2006). Business model innovation calls for establishing co-development relationships between actors that aim to create and deliver a new product, technology, or service together (Chesbrough;Schwartz 2007). The business models of partners are integrated during co-development, which increases the chances to sustain or even expand the co-development partnership in the future (Chesbrough 2007).

2.3 Business model innovation with a focus on services

Firms inventing themselves and their offerings anew promote addressing the customer needs and capturing the value in competitive markets. The literature on business models has recently recognized the shift from firms that provide services to complement their physical product offerings toward service offerings in the center of the value offering as such an action (Kindström 2010). The framework of Bessant and Davies (2007) includes different types of service innovations that can also be used to analyze the business model when there are changes with regards to (1) the service offering, (2) the service creation and delivery process, (3) the context of the service, or 4) whole paradigm changes.

Palo and Tähtinen (2013) suggest that the service business model evolves through service development, pilot, and market phases intertwined with simultaneous business net development and opportunity recognition. The business model evolves constantly during these phases instead of merely being the end result of the development.

A service business model can be divided into ten fundamental elements, similar to other commonly mentioned model elements: (1) strategic objectives, (2) structure, (3) offering, (4) revenue mechanism, (5) development process, (6) sales process, (7) delivery process, (8) customer relationships, (9) value network, and (10) culture. Strategic decisions set the foundation for service innovation. The organizational structure may either inhibit or promote innovation, and therefore the structure should be organized so that service innovation can take place. Offering refers to services that the firm intends to offer and to the development of a coherent portfolio of services. The revenue model includes pricing strategies and methods. The development process aims at concept development. The sales process includes, e.g., methods to sell services, incentive systems, customer involvement, and ways to communicate with customers. The delivery process consists of service delivery organization and interactions with customers. Customer relationships refer to depth, intensity and duration of customer interaction (Kindström;Kowalkowski 2014). The value network is a network of actors that co-produce and exchange service offerings and co-create value. Typically a value network consists of supply chains, but also customers can be important co-creators of value (Kindström 2010; Lusch, et al. 2010). Culture refers to establishing a service culture inside the organization (Kindström;Kowalkowski 2014).

An integrated perspective on services integrates innovations in various elements of the business model. Firms pursuing service innovation thus need to address the above elements of the business model (Kindström;Kowalkowski 2014).

The need for integrating a network of actors to stimulate service innovation development and adaptation has been long recognized. Services developed to support customers' actions require relationship orientation and from the service provider's perspective, knowing customer processes (Frambach, et al. 1998). The growing tendency of providing solutions and complex systems has further consolidated this need of more tightly integrating the networks of actors (Naude, et al. 2009). Research using a network perspective on development of solutions and services suggests that a process perspective is relevant because it emphasizes customer participation (Tuli, et al. 2007; Naude, et al. 2009).

Going beyond customization and integration, the process steps that can be added are requirements definition, deployment, and post-deployment (Tuli, et al. 2007). Defining requirements in a nascent industry can be particularly challenging; finding an optimal combination of technologies and services and offering them to customers who may not be fully aware of all the options requires multilateral interactions to collect and amalgamate the dispersed views of the actors (Lambe, et al. 2000). In the deployment stage, when delivery and installation take place, the customer requirements are often clarified (Tuli, et al. 2007; Naude, et al. 2009). When services form the business model core offering, deployment and post-deployment can merge; maintenance service is an add-on for products but can represent an offering in its own right.

The earlier view on developing new business emphasizes the formal evaluation of business opportunities through feasibility analysis, due diligence, and by using the stage-gate model. Stage-gate consists of several evaluation phases that the business idea must pass in order to proceed toward the markets (Ardichvili, et al. 2003). The more recent view is that opportunity recognition and business idea refinement for services can be approached by using a networked business model as a dynamic device (Palo;Tähtinen 2013).

Recent research on service innovation points out that the customers participate in developing services (Kindström 2010). The relational orientation and networking practices when designing service offerings are needed because service providers have to know the total operations and profitability of their customers. Service offerings typically penetrate

deeper into the customers' operations than product offerings, requiring more extensive coordination. Similarly, the organizational interfaces often entail both operational- and strategic-level interactions (Kindström 2010).

Figure 1 provides a tentative framework of business model innovation in services. It illustrates the connections between the chosen business model elements, strategy, network, and service innovation when developing a business model. The figure has been drawn on the basis of the extant literature.

Business model elements and connections between strategy, network and service innovation

Figure 1. Framework for business model innovation in services.

In the business model, firm strategy is converted into applicable model components. While the network component is part of the business model, network actors at the same time shape the model and its value offering in particular. The strategy of each individual firm is influenced by the network. The phases of development, deployment and post-deployment that are typical to project business are included in the framework as it is suggested that the model can be described from the process perspective and the actor involvement in the model development can be examined in each phase. Certain model components can be associated with the phases, but the linkages are guiding and not definitive because, e.g., the flexibility of the service offering allows modifications on the later phases and the network component can contribute to other parts of the model throughout the project life cycle.

3 Methodology

3.1 Research strategy

Applying qualitative methodology, the study is constructed as a multi-case study (Stake 2008, 123) with three innovation projects in networks as empirical cases: two service portfolio development projects and one solutions development project. The study follows explorative and descriptive strategy (Saunders, et al. 2012, 171). Case studies are typically conducted when exploring networks and relationships as they provide the means with which to develop a multidimensional perspective on the phenomenon in a specific context (Järvensivu;Törnroos 2010). Qualitative case study research is employed in this study as it enables exploration of business model development by building understanding on the innovation processes with various informants involved (Silverman 2006, 349; Pratt 2009).

This study applies process research when studying the cases; that is, three innovation projects in networks. Process research studies how events emerge and evolve over time in a context (Halinen, et al. 2012). Process research enables exploration on the innovation process in networks in this study.

The case companies are Finnish firms operating in the wind power industry. In-depth interviews among firm key decision makers serve as a primary source for the data collection. The link between theory, empirical phenomena, and method is formed by applying an abductive approach (Kovacs;Spens 2005; Dubois;Gibbert 2010). The abductive research process comprises constant iteration among the research steps (Eisenhardt 1989).

3.2 Empirical cases

When choosing the cases for this study, it was important that the phenomenon of interest – simultaneous business model development and service development in networks – clearly existed (Stake 1995, 56; Dubois;Araujo 2007). Therefore, cases were selected by employing purposive sampling. The aim was to find rich cases that would help fulfill the research objectives (Silverman 2006, 306; Dubois;Araujo 2007).

The service was to be designed in a network comprising at least three organizational actors (see Möller, et al. 2005). The cases needed to be such that a pilot version of the service was available to enable a study on the actual innovation and business model development process. It was necessary for the innovation process to still be under way in the chosen cases so that the informants could better remember the innovation process and so the cases could be followed in real time.

A multiple case study creates a more robust theory as it is more deeply grounded in varied empirical evidence. Multiple cases enable broader exploration of research questions and theoretical elaboration. In multiple-case studies, the choice of cases is based more on the contribution to theory development within the set of cases than on the uniqueness of a case (Eisenhardt; Graebner 2007). Table 1 provides an overview of the three focal case companies Alpha, Beta, and Delta, each of which ran one innovation and business model development project.

Table 1. Overview of the focal case companies.

Firm	Alpha	Beta	Delta
Industry	Design, construction, installation, management, and maintenance services and information system solutions within the energy, telecoms, and manufacturing sectors	Manufacturing of fastening technology for concrete connections and composite beams for slim floor structures	Engineering, design, and consultancy services within the energy industry, traffic infrastructure, manufacturing, civil engineering, and the environment
Number of employees in 2013	2,800	1,100	1,400 (subsidiary)
Turnover in 2013	325 M€	126 M€	105 M€ (subsidiary)
Operating range	North Europe	Global	Finland
Business development projects addressed in this study	Service portfolio for wind power construction and production	Foundation solutions for wind turbine towers	Service portfolio for wind power construction and production

The two wind power service portfolio cases and solutions for wind turbine foundations represent service innovation in an emergent business field. Only at the end of 2008 did the government of Finland approve the long-term climate and energy strategy, which was based on objectives proposed by the European Commission regarding the reduction of emissions and promoting renewable energy. The directive demanded that Finland had to increase the share of renewable energy to 38 percent of its total energy consumption by 2020. The Finnish government set the objective that six terawatt hours (TWh) of energy would be produced by wind power in 2020. This would mean more than 800 wind power plants with the capacity of 2,500 megawatts (MW) in total (Tarasti 2012).

Alpha’s service portfolio for wind power construction and production is developed both inside the firm in various business units and with customers, suppliers, consultants, and university students. The service portfolio can be characterized as an architectural innovation that bundles existing services and also an innovation in processes and organization of existing services (Gadrey, et al. 1995). Inside the portfolio, a radical innovation (de Brentani 2001; Gallouj 2002, 72) also occurs (i.e., the wind power portal).

Foundation solutions for wind turbine towers formed a new field of business for the fastening technology firm Beta, which, together with two consultants, innovated a new kind of on-shore foundation in which Delta is the main consultant with a new relationship to the fastening technology firm. The first foundation prototype was tested and further developed with the new customer Alpha. At the same time, services concerning the foundation were developed so that the foundation could be provided as a total solution. The foundation solution represents a radical technology innovation that opens new business opportunities (de Brentani 2001; Gallouj 2002, 72; Möller, et al. 2005).

Delta’s service portfolio for the wind power industry is predominantly developed in various business units within the company but also with foreign sister companies. The aim is to build a total package comprising a variety of existing services for the wind power industry. Delta’s service portfolio development represents process excellence and flexibility that calls for a process improvement capability. However, it simultaneously provides a new solution that supports customers’ businesses and also necessitates capabilities for incremental innovation (Möller, et al. 2005). The service portfolio can be characterized as an architectural innovation that bundles existing services and also as an innovation in processes and organization of existing services (Gadrey, et al. 1995).

3.3 Data collection

Case study data were collected longitudinally in three service innovation projects between January 2010 and December 2012. As the research included multiple cases and studied a strategic phenomenon (i.e., business model development

and innovation), interviews comprised the primary data source (Eisenhardt;Graebner 2007). This study collected data at intervals of approximately a year between 2010 and 2012. For a period, the duration of data gathering was approximately one month in each case. Altogether, 18 interviews were conducted, some of which discussed two different innovation projects. Ten interviews were related to the service portfolio development at Alpha, six interviews discussed foundation solution development at Beta, and eight interviews dealt with service portfolio development at Delta (see Appendix 1).

This study applied qualitative interviewing (Warren 2002, 83). The interviews were conducted in the form of guided conversations (Yin 2009, 106). Similar to a conversation, every interview was newly constructed. Each conversation was unique; the researcher matched the questions to the respondents' experience and expertise (Rubin;Rubin 2005, 4, 12). Qualitative interviewing can be employed to describe various events and processes. The interviewer seeks depth, detail, and richness in interviews, which is also termed "thick description" (Rubin;Rubin 2005, 5, 13). Therefore, interviews were based on three kinds of question: main questions that guided the conversation, probes to clarify answers or request further examples, and follow-up questions that pursued the implications of answers to the main questions (Warren 2002, 86-87).

Most of the interviews were conducted face-to-face at the respective company's premises, and a couple of interviews were conducted by phone. The interviews lasted between 50 and 150 minutes. Interviews were audio recorded and transcribed verbatim.

Secondary sources included workshops with the case companies, observations in the wind power workshop of the consulting firm Delta, information on websites and in the business press, as well as information on industry in general. Each data source helped make the phenomenon visible in a different way and provided a more in-depth understanding of the focal phenomenon (Denzin;Lincoln 2008, 5, 7).

3.4 Data analysis

Data analysis began with a coding and categorization procedure. The research questions guided coding and creation of categories from the beginning. First, various actors that influenced business model development in each innovation case were sought. Extant literature on business model development in services and networks provided the lenses through which the data were analyzed. Data categorization was first made on the basis of Kindström's and Kowalkowski's (2014) division where a service business model is divided into ten fundamental elements: strategic objectives, structure, offering, revenue mechanism, development process, sales process, delivery process, customer relationships, value network, and culture. Each of the three innovation project cases were separately analyzed, and the possible influence of the found network actors were examined in connection with all ten service model elements. The data were coded employing NVivo10 qualitative data analysis software. On the basis of the analysis, the elements were subtracted to cover the ones where network actors played a visible role. According to the principles of qualitative research analysis, data were then compared with data, with existing theory, and with results from previous research (Marshall;Rossman 2006, 156).

4 Case Study

4.1 Alpha's service portfolio for the wind power industry

4.1.1 Alpha's business model innovation – new business in a new industry

Alpha is a Finnish service integrator specialized in project management in the energy, telecommunications, and manufacturing sectors. The company has capabilities in design, construction, installation, management, and maintenance services as well as IT services in the energy sector. For Alpha, the expansion to wind power was a worthy business option, and Alpha's decision to take it up was partly driven by institutional decision making as the Finnish government had announced its commitment to promote renewable energy production by 2020.

Alpha's experience from setting up and maintaining power plants for the traditional energy companies formed a foundation for extending its service business toward new energy solutions. The environmental goals of Alpha's new and potential customers and their interest to produce energy in a cleaner way in particular encouraged Alpha's move to the wind power business. Service and business model development for wind power was started with a core team consisting of managers from different business units of Alpha and a newly appointed business area director for wind power. The corporate management formed a steering group that commented on the team's proposals. Later, project teams were appointed to manage the capabilities and combine them into new services. The corporate management approved the project plan. In two years Alpha had identified ten different entities that formed its service offering. Internally, the life cycle of the wind power production was a starting point for the project team in garnering the capabilities.

4.1.2 Network actors influencing model development

Alpha's aim to develop an encompassing service portfolio was supported by a cooperative approach, also stated as a leading concept in the firm's strategy. For the firm that was transforming itself into a service integrator, it was critical to

involve the customers and the key partners and suppliers in the development. In addition to the service offering, Alpha also asked for their feedback on the internal process and system development. These actors included: 1) investors interested in funding the new opportunities but lacking experience from clean energy business and therefore seeking a comprehensive service covering all the phases of the life cycle; 2) energy companies expanding their business to wind power; and 3) turbine manufacturers. As a result of the internal work and response of the network, the different service modules were further elaborated and modified in terms of their content and processes.

4.1.3 *Defining the offering with the customers*

A careful market study helped Alpha to define its value offering. The existing and potential customers were asked systematically about their plans for new projects, challenges in wind power, and the services they might need. The view of the customer was emphasized in the new service development. Alpha's business area director for wind power noted: "Our firm does not work in such a way that first we would develop here something and then we would sell it, but the development is always linked in some way to solving the problems of the customer." Alpha's task was to convince the customer to buy the service, as the sales director of Alpha observed: "Our operations are based on outsourcing, which means that we suggest to the customer not to do this by itself but let us do it."

As a service integrator, Alpha took responsibility of the interfaces with other suppliers, thus widening the set of services toward customers. For the customer, the added value was clear as they had only one partner needed for discussions. Alpha's R&D director explained: "Our starting point is that we want to be a service integrator so that the customer can hand over to us a great amount of tasks that we do not deal with internally but we will oversee their integration to the customer operations."

Alpha's advantages included tailoring specific customer solutions and high-level services that overcome in-house production and being able to carry risks and to operate in a cost-effective way. Sharing the risk in terms of costs that might exceed the planned costs was concretely carried out in Alpha's business relationship with one of its customers. Conversely, the company was able to reap bonuses if the costs were lower.

Alpha's customers were positive about the firm's interest to understand their needs. However, many of the customers were at the same time also providing services. Alpha had to consider the customer preferences for in-house service production and to refrain from offering overlapping services. For the customer, defining the offering was about finding an optimal solution. "When one's organization is built and developed, of course it has its price. If we buy from outside, it also has its price. It's about finding a balance and considering the model that fits" (Alpha's energy producer customer). For example, project planning was excluded from Alpha's services because that was defined as the customer's domain.

Meetings with the customers, however, opened avenues for new innovative services. Development of software, a wind power plant portal, was, for example, driven by the customer's need to receive more information in a centralized way concerning the condition of the wind turbines and actions taking place at the wind power plant.

4.1.4 *Defining the offering with strategic suppliers and other partners*

Operating as a service integrator required cooperation with group- or country-level strategic suppliers. Each actor had a clearly defined role in providing services. Similarly, the service offerings were formed and delivered in cooperation and were based on each actor's capabilities. Defining the services with the strategic partners required clarifying their future interests.

It has gone so that we first discuss what each party would like to do. Afterwards, we see how much our suggestions overlap and if the partial services fit to each other. When we have common customers, we also need to decide who is going to give up certain offerings and who is eventually going to provide them to the customer. The basic offering is fit together in this way. (Alpha's business area director for wind power)

Figure 2 illustrates the network of actors that influenced Alpha's service portfolio development.

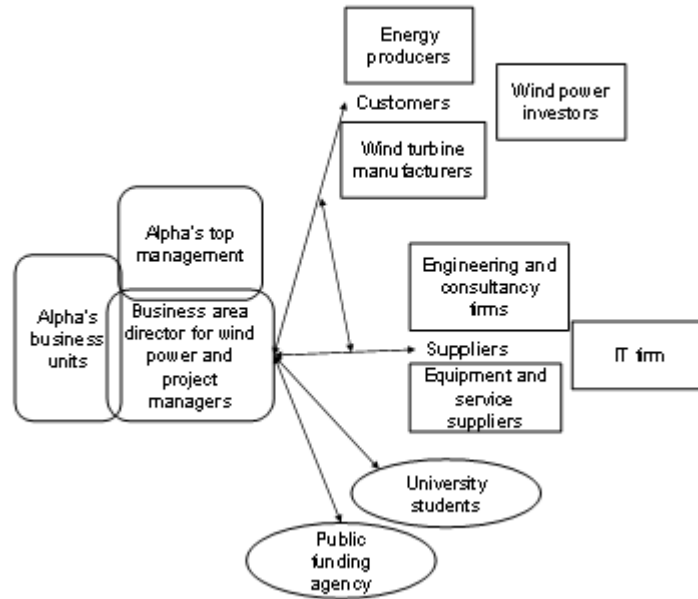

Figure 2. Network for the wind power service portfolio development project.

The nature of the wind power business as a nascent industry impacted the constellation of Alpha’s network; it was under constant change in terms of established relationships. Their formation was dependent on partly unexpected moves of other actors also impacting Alpha’s offering. For example, the ten-year guarantee for wind turbines bound to service agreements excluded Alpha from the business opportunity as the turbine manufacturer chose to use other service providers for new plant maintenance.

The Finnish Funding Agency for Innovation, Tekes, provided funding for the development projects, and therefore Alpha was able to allocate funds for the smaller actors to support their service development. Those firms played the role of suppliers and consultants in the development project.

4.2 Beta’s foundation solution for wind turbine towers

4.2.1 Beta’s business model innovation – new solution for new markets

Beta is a Finnish provider of fastening technology for concrete constructions and composite beams for slim floor structures. The firm had earlier experience from supplying traditional energy companies and in 2009 made a strategic decision to expand its business to wind power. The study of the existing foundations for wind turbines revealed an underdeveloped space of more sophisticated foundations. Beta realized that it could best serve customers by developing a service, a turnkey solution with the design and components that Beta manufactured for the foundation of wind power turbines, as well as offering construction services. The innovative solution opened an avenue for providing remarkable added value, but at the same time it required managing the value chain and its links to a greater extent. “As a starting point, we realized that we are not able to provide added value if we do not manage all the areas in the value chain and provide with each link some added value” (technology director, Beta).

For Beta, the conversion into a service company implied increasing the number of interfaces on the customer side and in the partner companies. Internally, the shift from product orientation toward service orientation created its challenges in terms of a greater focus on customers and the corresponding resources. Beta’s customers included those energy companies that had chosen to manage their own projects, as well as turbine manufacturers, construction companies, and engineering consultants that provided planning and design services. The service integrator Alpha had a dual role as a partner and customer of Beta. The firm approached Beta when they encountered a need to modernize foundation technology as part of their service offering. The technology director of Beta stated: “Our collaboration started because Alpha had a need for a technology partner, and we provided the possibility for that.”

For Beta, defining the business model for the nascent industry of wind power required analyzing the firm’s earlier experience that could contribute to the new business and cooperating with partners that were able to provide expertise in design and understanding the customer needs. With this knowledge Beta was able to evaluate the feasibility of the business and proceed to developing a business model. The original business model developed remained mostly the same with a few modifications over the years.

4.2.2 The network in the development and implementation of the offering

Beta's network was vital for defining the features of its offering and contributing to its development and implementation as the technology director of Beta described: "[The partners] are so important. We could not do without them. It is impossible to develop this kind of multidimensional solution on our own."

Defining the solution was thus based on the interplay between Beta, engineering consultant Delta, the system configurator, service integrator Alpha, and turbine manufacturer Epsilon. The discussions with them defined the path taken by Beta. For the sales and implementation of the wind turbine foundation, Beta cooperated with the engineering consultant Delta in two ways: First, Delta studied if there were business opportunities when new bids were announced. Together the firms then submitted their proposals. Second, Delta provided R&D, planning, and configuration of Beta's offering based on Beta's idea generation; their role was making sure that Beta's ideas could be technically implemented.

Beta's offering, however, had to be modified to fulfill the requirements set by the cooperation between turbine manufacturer Epsilon and the service integrator Alpha. The turbine manufacturer was considered the strongest influencer when the type of foundation was selected and its requirements defined. Alpha's well-functioning relationship to the turbine manufacturer Epsilon also served Beta's purposes as the firm was interested in receiving feedback from this market actor.

Beta's goal was widening the customer base with a mass-tailored solution. For this, it aimed at establishing partnerships and supplier relationships with the turbine manufacturers. The contacts with the new actors were also expected to boost the development of innovative solutions as the talks were likely to enrich the view on the current business. Figure 3 illustrates the network of actors that had influence on the foundation solution development for wind power turbines.

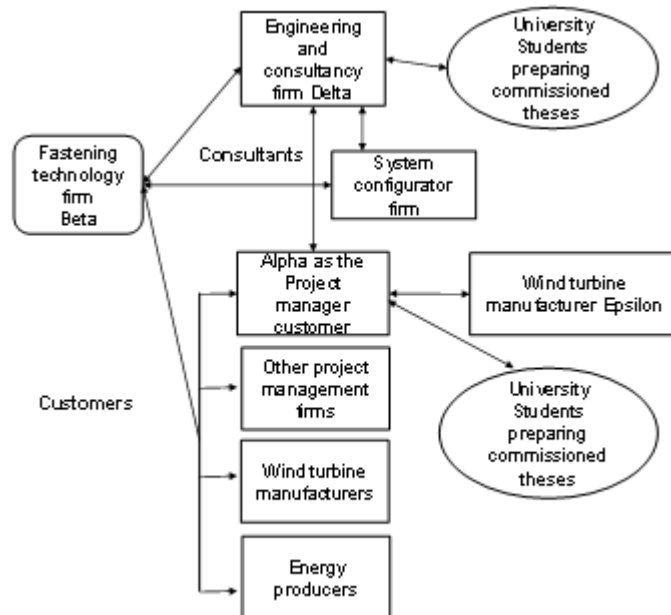

Figure 3. Network for the innovation of the business model for wind turbine foundation solutions.

Involving the customer as a partner to define the offering was different from a passive buyer role. The active joint development of solutions was expected to improve them, but it also increased the risk on each side: "In the development project each actor carries much risk, and this makes the ability to bear and manage that risk perhaps the most important thing. Another side is that the target is seen in the long term, even in years" (technology director, Beta). Accordingly, the time perspective in the relationship was expected to be longer than just the one project in order to pay back the investment in the development.

4.3 Delta's service portfolio for the wind power industry

4.3.1 Delta's business model innovation – total service package

Delta is an engineering company providing design and consultancy services for the energy and manufacturing industries and traffic infrastructure projects. Their business in the wind power industry started when they acquired an engineering firm that had carried out the first environmental impact assessments in Finland and laid the foundations for the field. When the wind turbine projects started to increase, customers increasingly demanded engineering and consultancy services from Delta. Soon Delta became the largest expert in the field in Finland.

In their strategic wind power projects, Delta aimed at combining existing capabilities from different technical fields and business units to provide total service offerings to their customers. In 2010, it established a wind power management group for coordinating the dispersed capabilities between five different technical fields. The company welcomed the new wind power business since one of its main businesses, transportation infrastructure projects, was impacted by the cuts in government budgets.

4.3.2 Model and service offering innovation as a response to customer needs

Delta’s goal was to sell a full set of services to energy companies. Services needed to be modularized for this purpose. The wind power management group then planned a service package from the various modules, which was used for marketing purposes. This also required acquiring new capabilities associated with the new business: “The new wind power expert complements our set in such a way that now we can purchase turbines, too. We have knowledge on how to write quotes to foreign companies, to different turbine manufacturers” (regional unit manager, Delta).

Including new capabilities through recruitment and service innovation in expert groups inside Delta and designing a total service package was a response to customer needs. The energy firms had expressed their interest in wider service entities instead of buying services separately from different consultants. The shift from the latter choice could be traced back to the nature of the wind power business; while it demanded use of different experts, their large number would simultaneously complicate project management. Delta’s customers felt that a large firm was a secure partner. Very small wind power actors did not always have sufficient resources for maintaining and managing several consultant relationships.

Governmental ministries and regional councils seeking environmental impact assessments and urban planning for wind power projects formed another customer group. Simultaneously, Delta provided R&D for infrastructure companies that were suppliers of wind power service integrators and energy companies. When the projects demanded, the company used subcontractors to provide planning services for electrical grids. Delta had given up on this business because their customers mostly performed their own electrical services.

4.3.3 The internal challenge of defining and implementing the offering

Although the new business was based largely on Delta’s existing capabilities, internal coordination of the wide range of different technical fields was challenging. “Wind power is not that complicated. But the whole process has so many different pieces. It reaches from environmental impact assessment to planning the foundations and performing stability analysis for the turbines, and so on” (regional unit manager, Delta).

For Delta, serving the customers with wider service entities required seamless and efficient cooperation between the units. Furthermore, in Finland the firm had offices in several locations, each specializing in a specific technical field. This also challenged coordination of the service offering as each internal unit that in the past had been regarded as a separate “locker” now had to play together in order to combine their know-know. Figure 4 illustrates the network of actors that influenced the service portfolio development at Delta.

Figure 4. Network for the innovation of the business model for Delta’s wind power service portfolio.

Also, the capabilities of the group’s other Nordic firms were examined. The Swedish sister company could contribute to evaluations and Norway to wind turbine acquisitions. The firm in Denmark had a long history of experience in off-shore wind power projects. This knowledge needed to be better utilized in wind power projects, and the sister companies took steps toward closer cooperation.

5 Analysis

The case descriptions show how the business models of the selected case companies evolved in a networked and intertwined manner when new services were developed and how network actors influenced and directed other actors' choices concerning the model elements in each project phase. The following tables contain the key findings regarding each company with the respective business model element and actors influencing its contents. The tables 2, 3 and 4 also show the drivers behind development of the business model element and actions taken in this respect.

Table 2. Network actors participating in defining the business model elements of the Alpha case.

Business model element	Actors influencing element	Drivers for developing the element	Actions taken
Internal structure	Customers	Demand for large service entities because of new customers' small organizations	For the first time, different business units combine their capabilities as they respond to customer feedback
	Business units	Possibility to make use of firm-internal capabilities broadly and grow the business of various business units	Joining the forces for service portfolio development.
	Suppliers	Establishing new relationships to partners with broad capabilities	The service integrator no longer needs certain in-house experts as the suppliers have developed their capabilities in performing the services.
Offering and development process	Customers	Customer requirement	Avoiding overlapping offerings with customers.
		Customer need	Service entities modified in cooperation with customers. Developing flexibility in module composition through ten entities. Creation of innovative services that customers need.
	Business units	Offering together a service package	Developing the services modules in different business units under management team supervision.
	Suppliers	Objective between the partners cooperation instead of competition Good match between partners' resources	Partners provide complimentary service/technology for Alpha.
	Universities	Broadening knowledge and understanding	Students conducting research projects.
The funding agency for innovation	Enhancing innovations in wind power	Funding provided for R&D projects in wind power networks.	

Business model element	Actors influencing element	Drivers for developing the element	Actions taken
Revenue and cost mechanism	Government	Project feasibility	Government decisions on the tariffs ensuring project feasibility
	Customers	Customer requirements	Risk of exceeding/ the planned costs is shared with the customer. Pressure from the customers for more service and lower price leads to looking for cost reductions, e.g., through a resource management system innovation. New revenue models tested among customers, e.g., dependability.
	Suppliers/ Partners	Sharing between the partners	Partners receive a share of the margin in proportion to their added value.
Sales process	Customers	Existing customer-supplier relationships	Actor that has an existing relationship with the customer takes primarily care of the sales process when making joint bids.
	Suppliers	Project "ownership"	Actor that has initiated the project takes primarily care of the sales process when making joint bids.
Value network and channels	Suppliers	Partners jointly forming the network Definition of network roles and positions – Balancing between cooperation and competition	Partners create relationships to third parties. Carefully considering with which actors to act and how.
	Customers	Efficient and effective delivery of services	Building a network that provides possibly much value to the customer.
Delivery and implementation	Suppliers	Separate capabilities	Each actor delivers its services separately in the project but toward the customer as only one entity.
	Business units	Ensuring smooth implementation of projects	Planning jointly delivery processes of various services.

For the service integrator Alpha, the network was crucial in defining the service offering. The needs of Alpha's customers directed the contents of the service modules, which further influenced the formation of the value network in terms of supplier partners. Alpha's customer orientation highly contributed to an innovative IT-based service.

The customer preference of receiving comprehensive service from one service provider required Alpha to establish and maintain a network with the needed resources. With the supplier capabilities, cooperation widened to new areas and markets, e.g., through joint bids. Coordination between the parties shaped the offering and necessitated constant decisions on each actor's role toward the end customer. The relationships with some of the customers and suppliers were characterized with competitive elements as well.

The revenue and cost model was also influenced by the signals received from the network. The customers needed cost effectiveness but also understood the value added in the offering of the specialized service provider. Alpha also participated in sharing the risk and benefits with the customer.

Table 3. Network actors participating in defining the business model elements of the Beta case.

Business model element	Actors influencing element	Drivers for developing the element	Actions taken
Internal structure	Customers	Match to customer needs	Providing service entities requires more internal interfaces.
Offering and development process	Customer/ Partner Engineering and system consultants	Match to the needs Technical feasibility of the offering	Customer/partner (service integrator) participates in defining the contents of the offering and contributes to the development of the foundation. Contributing to the design and technical feasibility.
Revenue and cost mechanism	Customer/Partner	Sharing the cost	Partner is expected to contribute financially in the development of the solution.
Sales process	Customer/Partner	Customer mediation Considerable input of the customer/partner in offering development Various ways to acquire foundations for wind turbines and various actors influencing the acquisition decision	Sales contacts subjected to the customer's contacts Making an agreement on joint bids. Customizing the sales process. Need to consider several actors in a wind turbine project.
Value network and channels	Customer/Partner	Balancing with competition Variation in wind power project organizations	Agreeing in acting together in specific future projects. Building the network and channels to respond to various project organization models.
Delivery and implementation	Customer/Partner Other customers	Beta's solution was part of Alpha's service offering Customer's own scope of services	Service integrator implemented Beta's solution Erection of the foundation an option and implemented by partners.

As with Alpha, the network notably participated in the business model development of Beta when the combination of product and service was defined. The involvement of Beta's customer, the service integrator Alpha, and the turbine supplier influenced Beta's product and service design, which was carried out in cooperation with the engineering consultant. The service integrator also moderated Beta's sales processes and target market selection because of its dual role as a customer and competitor. Delivery and implementation took place by the integrator Alpha, which also facilitated Beta's access to another important value network actor, the turbine manufacturer Epsilon. Epsilon, in turn, can express its possible requirements concerning the offering and willingness to apply it later on.

Table 4. Network actors participating in defining the business model elements of the Delta case.

Business model element	Actors influencing element	Drivers for developing the element	Actions taken
Internal structure	Customers	Increasing demand for large service entities.	Starting cooperation between business units and technical areas.
	Business units	Internal coordination needed to provide turn-key service and increase sales	Different technical areas and business units in different locations coordinated in a new way in order to maintain the customer relationship throughout the project
	Sister companies	Existing capabilities inside the group	Deciding which capabilities needed in-house and which acquired from sister companies.
Offering and development process	Customers	Match to customer needs Small customer organizations preferring one supplier	Designing an optimized combination of services for customers Turn-key service and service package development
	Business units	Offering together a service package	Joint development of the service package.
Sales process	Customers	Match to customer needs Need to keep the customer and grow sales	Coordinated sales processes between the different units according to customer needs Selling services of other business units as well
Value network and channels	Customers	Customer preferences	The partner selection according to the customer budget
	Suppliers	Outsourcing decisions at Delta because of customers' own service organizations.	Sub-contracting of electrical grid planning and design
Delivery and implementation	Business units and sister companies	One entity toward the customer	Coordinating the delivery of each module or service

For Delta, the company's internal network in terms of its various business units and sister companies was extensively used for coordinating the know-how when compiling the wind power services. In line with that, understanding and forming a match to the customer needs directed the compilation of the firm offering. Integration of the internal units is crucial in order to provide a consistent wind power profile for the customers. The customer preference for a comprehensive service package and turn-key service also required turning to the value network, thus outsourcing certain capabilities.

In spite of the slight differences in the way the network influenced business model development and implementation at Alpha, Beta, and Delta, all in all the network actors were involved to a great extent in defining each other's business model elements. These three firms were part of each other's networks. In addition, they were actors that had significantly included end customers, other suppliers, and partners and public institutions in their service portfolio and solutions development. Table 5 below sums up the results of the Alpha, Beta and Delta cases.

Table 5. Summary of network influence on business model development in service firms.

Business model element	Actors influencing element	Drivers for developing the element	Actions taken
Internal structure	Customers Business units Suppliers Sister companies	Size of customer organization More efficient use of in-house capabilities and resources Suppliers' and sister companies' capabilities and resources	Combining the capabilities and resources of different actors in-house Co-development in-house Outsourcing of expertise or hiring new expertise Adding interfaces between actors in-house Starting new kind of project cooperation in-house Learning new ways to coordinate actors and projects in-house
Offering and development process	Customers Business units Suppliers Consultants Universities Government/ The funding agency for innovation	Customer needs and requirements New joint offerings Enhancing cooperation and avoiding competition Matching resources Increase in knowledge New service innovations	Co-development with various actors Modularizing of services Developing service packages and portfolios in cooperation Organizing research projects Applying funding from the agency
Revenue and cost mechanism	Customers Government/ The funding agency Suppliers/Partners	Customer requirements Enabling wind power development High development costs Enabling win-win situation	Sharing risk and costs in new ways Increasing efficiency in performing work, e.g., through process development Added value as the basis for sharing margins
Sales process	Customers Customer/Partner Suppliers	Existing customer-supplier relationships Input in development process Different ways to acquire solutions Project "ownership"	In joint bids, sales process taken care by the actor with existing customer relationship Customization of sales process Making agreements on joint bids to provide compensation for input in development Actor initiating the project takes care of sales process Coordinating sales in-house Cross-selling of services
Value network and channels	Customers Customer/Partner Suppliers	Need for efficient and effective service channel Need to balance with cooperation and competition Structures of wind power project organizations Need to include other actors in network formation	Building a network on the basis of amount of value to the customer and/or different project organization models Carefully considering with which actor to cooperate and how Joint establishment of relationships to third parties Deciding on sub-contracting instead of in-house service production
Delivery and implementation	Business units and sister companies Suppliers Customers Customer/Partner	Smooth implementation of joint projects One entity toward customers Separate capabilities Solution of one actor embedded in the offering of another actor Customer's own scope of services differs	Joint planning of delivery and implementation processes Coordinating the delivery of each service and service module Separate service deliveries by actors Actor implementing the solution varies depending on project organization Erection provided as option performed by partners

Table 5 demonstrates that the network actors influenced on development of various business model elements: (1) internal structure of the focal firm, (2) service development process and offering development, (3) revenue and cost mechanism, (4) sales process, (5) value network and channels, and (6) delivery and implementation of services. *Customers* and *suppliers* had influence on each element. *Business units* had a strong influence when developing the firm's internal structure. They similarly contributed to the service development process and offering development. Delivery and implementation elements of the business model were also influenced by business units. The influence of

the case firm's foreign *sister companies* was remarkable especially on the firms' internal structure, as well as the delivery and implementation of services.

The funding agency for innovation contributed especially to the service development process and offering development. *Government* was involved in defining the revenue and cost mechanism through their decisions on the tariffs ensuring project feasibility. Also Finnish *universities* had a role in the service development process through students, who conducted research as part of the development.

The drivers for the development of the internal structure in the focal firms included customers' internal structure, as well as the capabilities and resources of the various network actors. Customer needs and requirements, increased knowledge, initiation of joint offerings, and the funding provided by the network actors formed the drivers behind the service and offering development. The revenue and cost mechanism development was driven by the customer requirements, high development costs, and a need to share the margins in a fair way with the supply partners.

The sales processes were influenced by the network actor relationships: in each case they were led by those actors with an existing relationship to the customer and in new projects one actor was in charge. Furthermore, sales process of the focal firm was influenced by the partner involvement as the new customers had to be jointly approached. Who actually was the customer or the final decision maker was not always straightforward and created a need for adaptations in the sales process. Value network and channels were developed in response to the customer needs and to balance between cooperation and competition. The need for smooth joint project implementation and separate capabilities of service providers and capabilities of customers affected the service delivery.

The internal structure of the focal firm was developed through a novel type of cooperation and coordination in the network and by creating new combinations of capabilities and resources. Service and offering development was enabled by co-development between network actors, modularizing of services and building packages of them. Revenue and cost mechanism development required sharing of risk and costs as well as margins in new ways between the parties. Similarly, the new means to increase work performance were important. The sales process was developed through joint bids, project customization, coordination of sales between network actors, and cross-selling of services. The value network formed a basis for the value it provided to the customer. Actors carefully considered with whom to cooperate and how to avoid unnecessary competition. The decisions between in-house service production and sub-contracting led to changes in the value network. The service delivery and implementation was planned and managed through joint coordination.

6 Conclusions

This study focused on examining how business models with new services in their core are developed by business-to-business market actors in a networked manner and how these actors influence each other's business logic. Our findings based on wind power industry cases corroborated the view by Palo and Tähtinen (2013) that innovative models develop dynamically as a result of an intensive cooperation between the network actors. This provides grounds to extend the view on business models commonly examined from an individual firm's standpoint and suggests that, due to the high interconnectedness between the firms' models and network actors' mutual influence to the models, the use of a networked business model concept is appropriate.

The case findings also demonstrated that although network involvement was emphasized in the beginning, when the offering was defined the actors also participated in the business model development in other phases of the project (Tuli, et al. 2007). In addition, their contribution also went beyond the focal projects as the firms sought to understand better customers' and partners' future needs and capabilities and to look for new business opportunities.

Network participation was the most intensive in defining the service offering. It was guided by the end customers and suppliers and the customers' and partners' needs, requirements, and preferences. Together with the firms' internal orientation, they formed a main driver for the business logic change that took place when there was a shift from separate product/service offering to comprehensive service entity offerings. This implies that the logic change is not one-sided and evolves as interplay between the supply and the customer sides. This change, which is likely to bring resistance from the traditional industries (Morris, et al. 2005), has on the contrary been embraced by the customers in the nascent industry. It is also suggested that the extensive network involvement in service offering development can be traced back to the new industry, the network characteristics, and actor positions as well as to the nature of the offering.

In the networked environment the boundaries between the different actor roles were partially blurred, and therefore value chain thinking, where one actor would provide a clearly defined product to another actor and add further value, was challenged. As a consequence, a supplier was able to choose, at least in principle, between serving the end customer or the service integrator, who also was its direct competitor. The cooperation with the latter required precise coordination when the offering was developed, highlighting the customer role as a partner (Kindström 2010). On the other hand, the end customer's in-house service production had the power to make the supplier relationship redundant. Therefore, we argue that a firm, regardless of its position in the network, has to consider the business logic of other actors in order to continue operating as part of the network and in relationship with each actor. This requires balancing between the firm offerings and defining clear roles as pre-emption for rivalry.

Service innovation as a core offering was another factor driving network involvement. Creation of service modules and packaging offered flexibility, and the customer/partner could choose a fitting combination. In addition to the existing ones, the actors created new services and bundled them according to the market needs. In addition to the

existing offerings, service innovations in the case companies varied from services that were new to the companies and the markets to service process innovations and even to the paradigm change as the services and technologies that were previously offered separately were now combined into one turn-key service (Bessant; Davies 2007).

Furthermore, the flexibility concerning the service offering responded proactively to the need for modifications in new projects. In contrast to developing new models each time (Kujala, et al. 2010), the model components could be modified “on-demand.” Furthermore, it is suggested that the traditional models of service/product development (e.g., stage-gate) (Ardichvili, et al. 2003) should be complemented with a notion to the dynamic influence of the network actors when the opportunities are evaluated.

The new industry impact was associated with the service offering; the undefined or developing needs of the nascent industry actors required their presence and interaction between them when the offerings were defined. The other model components and their development – internal structure, revenue and cost mechanism, constellation of the value net for the delivery and implementation – were also shaped in cooperation with the network actors and impacted by the new industry. The study findings also suggest that firms’ internal networks involving business units or sister companies based in other countries had much influence on what was offered and how capabilities were leveraged in the wind power industry. Furthermore, new revenue models and cost- and risk-sharing mechanisms were tested and discussed by the network actors. By participating in defining the value offering, the network actors defined their own position and other actors’ positions in the value net.

We also argue that the business model innovation (e.g., change and extension on value creation and/or capture) is driven and preceded by changes in the business logic that the firm adopts and continuously revises. A central area, especially regarding knowledge-intensive professional services, is the creation of new capabilities – here, a firm relying on a networked business model is more likely to combine its capabilities with firms in the same network rather than hiring in-house expertise in each specialized area. When the network is missing a particular capability, inviting new members to join enlarges the network. Altogether, this enables a quick response to changes in market needs; without resorting to networks, firms in knowledge-intensive industries would easily be hindered by excessive learning curves.

The structure of the network determines what new opportunities emerge and are identified. We propose that this leads to a form of path dependence in which networked business models develop through joint iterations by member firms; however, as long as the system remains closed, the development of the networked business model is tied to the capabilities and resources of the members and its boundaries are therefore a result of these capabilities and resources. However, when new firms join, the opportunity space of the networked business model is expanded (given that it introduces new capabilities or resources). The efficient use of this expansion, nevertheless, depends on the firms’ abilities to comprehend the network as a whole and contrast it with external demand stimuli. This highlights the role of the resource integrator.

6.1 Managerial implications

From a practitioner’s perspective, a networked business model becomes particularly relevant when there are many contingencies between the offerings and other model components of firms operating in a certain industry or a nexus of industries. For the managers, recognizing and analyzing the business logic of other firms provides a point of reflection concerning the decisions on the business model.

First, the business models of actors who have or aim at establishing a business relationship can be examined from the standpoint of their model synchronization; are the components compatible in all their parts in an optimal way or can the partner suggest improvements that can benefit the relationship? The same applies to business model innovation; changing one component of the model can bring about changes in others, and the results with regards to other actors and their business logic should always be evaluated. This does not imply that a business should remain static, but an early assessment of the model can reveal the feasibility of the model and assist in finding its deficiencies in time. The assessment is especially important if the model realization is dependent on the critical network resources.

Second, in order to gain an understanding regarding the models and develop them further, firms should continuously seek feedback from their partners and customers. This requires maintaining active communication with customers and partners and to map previously unforeseen business opportunities, such as service expansions and networked offerings. The potential is easily overlooked without periodical status checks focusing on the opportunity horizon.

Above all, managers should consider the network’s value in a strategic sense – a source of resources, ideas, and new business opportunities (but also tension, cooptation, and complexity). The reconciliation of alternative business logic of different firms in the same networked business model requires care and attention, but the outcome is determined by strategic vigilance and the ability to coordinate the business model in the direction of market needs while maintaining a competitive advantage over rival networks.

APPENDIX 1 Interviews conducted in the companies participating in service innovation projects

Innovation project	Company	Interviewee position	Date of interview	Total amount of interviews per project
Service portfolio for the wind power industry at Alpha	Construction, maintenance, and professional services provider (Alpha)	Business area director, wind power	2/19/2010* 11/25/2011* 12/11/2012*	10
	Alpha	Country manager	2/9/2010	
	Alpha	Business development director	2/15/2010	
	Alpha	Business unit director	2/15/2010	
	Alpha	R&D director	2/19/2010	
	Alpha	Sales director	9/4/2012	
	Engineering firm B	Divisional director	1/24/2012	
	Wind power producer	CEO	1/24/2012*	
Foundation solutions for wind turbine towers at Beta	Engineering firm A (Delta)	Project manager	9/26/2010* 12/12/2011*	6
	Technology firm (Beta)	Technology director	1/30/2012	
	Construction, maintenance, and professional services provider (Alpha)	Business area director, wind power	2/19/2010* 11/25/2011* 12/11/2012*	
Service portfolio for the wind power industry at Delta	Engineering firm (Delta)	R&D coordinator	1/28/2010	8
	Delta	R&D director	3/10/2010	
	Delta	Project manager	9/26/2010* 12/12/2011*	
	Delta	Divisional director	1/30/2012	
	Delta	Regional unit manager	2/1/2012	
	Delta	Wind power specialist	9/3/2012	
	Wind power producer	CEO	1/24/2012*	

* Same person interviewed for two projects in a single interview

Customer-based value creation and productivity in service-related business models

Andrea Rößner¹, Jens Neuhüttler¹, Alexander Schletz²

¹University of Stuttgart, ²Fraunhofer Institute for Industrial Engineering IAO

The shift from being mere manufacturers towards so-called producing service providers, also known as “servitization”, affects both the companies’ business models and it challenges their value creating system. This in turn means that service-related business model elements need to be detected and inserted to a comprehensive framework. Moreover, the contribution of those business model elements to the overall productivity of the services provided needs to be measured with the aim of emphasizing on those service elements with a positive ratio of outputs and inputs. Performance externalization and the deployment of new technologies are promising measures, as will be shown by a real-world case from forestry industry.

1 Introduction

In recent times, services take over an increasingly strong part of the modern economic value-added system of most European countries. According to recent studies, the contribution of services to the macroeconomic growth (Dauderstädt, Pfaller 2014) represents a large potential for economic growth. Exemplified by the economic growth of Germany, for example, this means that services account a growing share of GDP of almost 70% today, irrespective of the specific sector that the heterogeneous services are assigned to. Coming from this broad perspective, those macroeconomic results also provide some idea of the particular meaning that services do have for singular companies. “Servitization” can be used as an umbrella term for the increasing importance of services for formerly manufacturing companies that are on the way to transform towards so-called solution providers. Those solutions – or hybrid products – mostly contain a mix of services and products that are bundled together. In modern life, services and the associated use of technology and digitalisation takes over a huge part of the actual value creation processes. This applies to the B2C, and also to the B2B business area. A taxi driver will more frequently use modern communications technologies in order to best fit to his customer’s needs (fast and convenient transport of passengers). And a formerly manufacturing company will shift the portfolio it offers to the customers in a B2B-context more and more towards hybrid products and services that rely to an increasingly large extent on services (supported by digital elements). In the consequence of those game changing developments (Servitization and digitalization), the established business models – especially from manufacturing companies which we emphasize here in this paper – need to undergo incremental changes in order to still fit the customers’ needs, and to redefine the roles, duties and contributions of customers and providers to the service delivery. This again has got a strong influence on what is called service productivity. Questions arise, about what specifically value (and output) of services and hybrid products offered to and co-created by the customers is, and should be. At the same time, “cost-effectiveness” and “productivity“ of a whole business model can be defined by “more than the sum of its parts”. Therefore, effective and efficient measurement systems need to be deployed in order to continuously (re-)define the measures taken within the elements of a business model. Thus, for example, the use of technology as well as the steering of customer interaction can be efficient for enhancing productivity.

2 Particularities of business model framework for Services:

In this chapter, we will introduce what we believe that a service specific approach to business model development should look like. This implies that we will present what elements such a framework should include, and which steps need to be followed in order to realize an efficient and effective (and thus productive) business model.

By providing these insights that result from literature studies about business model development as well as practical case studies (Neuhüttler/Meier/Stadie (2014), Forthcoming.) we want to give appropriate guidance for companies that struggle with the development and/or the integration of service specific aspects in their business model (in the context of “Servitization”). At the end of this paper, we will provide a (partly real-world, partly fictional) case study from a manufacturing company that has successfully integrated those ideas by introducing a) a service specific business model and b) improving service productivity at the same time by setting the focus on the (specific customer groups and their potentials) and integrating technologies in the services offer portfolio.

2.1 Phases for the Development of a service-specific Business Model Framework:

The transformation for a pure manufacturer towards a company that focuses more and more on services needs systematic support. When new business activities in the service sector are increasingly carried out in such companies, this business area should also be systematically developed. Needless to say in that context, that a business model is

always the core of business activities. Also the development of a service specific business model can help to systematically develop services according to the companies' goals, strategies, and customer segments.

In order to develop such an adequate business model that meets the service specific requirements, we first propose a step-by-step-procedure, accompanied with suitable measures and methods that are helpful in each phase. Since we are focusing on customer specific aspects (and the business model element "value proposition" that can be supported by technical features, see also: case in chapter 3), we present an overview of each of the phases that we think are important for developing a service business model, and we will present the phase about the customer centered management aspects in more detail. Second, we will introduce, of which elements such a business model framework consists of.

1. Idea- and Integration Phase

The process for developing a service specific business model starts with the Idea- and Integration Phase. It serves for the definition of what long term goals the company seeks to follow with the service provision on the market. In this phase, the idea of the service business model (BM) should be integrated in the overall corporate mission of the company. The mission of the service BM should answer, which core competences are existing. Those have to fit with the company's values and should be aligned with the future vision of the company. The service specific vision should thus also describe a realistic, and future oriented picture of the company. For example, it should describe, how the future of forthcoming generations will be improved by the utilization of the service offer.

The service strategy development serves to determine the possible customer needs, the competition, the type of strategy which should be focused, and the critical success factors. Methods that are supporting this phase could be: the scenario analysis, the 7-S-Model, the formulation of a BCG-Matrix, and a Product-Marketgrowth-Matrix (according to Ansoff).

The description of the actual value proposition and thus the benefit for the customer in utilizing the service offer should be early described in this phase. It should be focused on potential problems of the customers, which can be solved by the proposed service. Methods in this phase could be the adapted use of the (service) value chain (according to M.Porter), the Blue-, Red Ocean Strategy, and a SWOT analysis.

2. Concept phase

In the conceptual phase, more concrete decisions are made concerning potential customers, an efficient value creation management, and the financial management of the service idea.

a. Customer Management

The future customers are a very crucial part of the service business model and as such, this element should be prepared very thoughtfully.

The future customer segments and their specific needs should show a high accordance with the goals defined in the previous phase. Furthermore, those goals should be reachable (realistic) and the service offer should clearly focus on the goals and customer needs. It can be helpful to undertake a segmentation of customer groups (B2B, B2C) in order to elaborate the specific needs more precisely. Methods that support those activities could be a Target Group- and Data Analysis, and Data-Mining.

The customer relationships are a crucial factor that should describe, how initiation, stabilisation, intensification and the revival of the customer relationships can be analysed, planned, performed and controlled. In this phase, mostly the relationships towards the previously defined customer segments are of great importance, and also measures for acquisition of new customers, for customer loyalty and retention should be defined. Those could possibly be reached by the differentiation from the service proposition of competitors; early setting of service standards and guarantees, price bundling, decisions about individual customer performance, and the way, the customer will be integrated in the service performance. For customer retention, service innovations and value added services could be targeted measures.

Supporting methods in the context of building customer relationships could be the Customer journey, the Service Blueprint, the development of a Customer Contribution Margin, the Share of Wallet, Customer Lifetime Value and the Customer Revenue.

The customer channels again define how the company seeks to reach the previously defined customer groups and which communication channels are used to transmit the value proposition to those customers. Especially in this phase, the service specific characteristics (intangibility, integration of the external factor, etc.) should be taken into account. The communication channels thus need to be congruent with the customer segments, the market and the goal of the company, the information technology that is available for communication with the customers, and the value proposition as such. It is important to make sure that it is able to access the performance components properly. In a service business model those targets should be already defined. For example, demand-based targets such as the presence and accessibility (distance to a local office), the possibilities of access for the external factor (shuttle towards the transportation center), and the time period, preparedness and reliability of delivering the service (pizza service that only delivers a certain region, but guarantees to deliver the full menu and to deliver within a certain

time period after the order). Again, in this period, the Customer journey and the Service Blueprint are helpful methods to describe and to evaluate the goals and measures.

b. Value Creation Management

The value creation management describes basically, which key resources the company would like to use in order to realize the business model and the respective service value proposition. The focus in most service related BM is likely to rely on human capital (personal) resources, however, also diverse material (physical) and nonmaterial resources such as technological competencies and capacities or further service relevant components that should be integrated in the planning of this phase. Again, the definition of Critical Success Factors and of the resources (including already the teams/staff allocation) is necessary.

Also, the core competencies needed to be able to perform the service, for positioning on the market and to build customer relationships should be defined in this phase. A business plan and project management (using a respective tool) brings an overview, and Critical Success Factors on the basis of a BM performance Scorecard can indicate how can indicate how they might be proactively used.

The key partners in the value creation network are now to be determined. This should include the test, which service components can be performed by the provider itself, and which components should be outsourced to a network partner. In the example of a carsharing provider, the energy supply could be performed by a network partner. Methodologically, the screening of suppliers and other key network partners is useful in this phase.

c. Finance management

This part of the BM Development is in charge of all measures starting from the capital procurement until refund. It thus comprises the entire design of relations regarding payment, information, co-determination, control etc. with investors. A capital model should thus be generated to secure liquidity.

The cost structure is a central component of the BM, since the most important costs of the service proposition are defined here. Those can arise for example from the previously explained BM-components (customer- and value creation-related). Since each BM contains individual cost- and value creation structures, the costs may highly vary. Methods that are helpful to identify the arising costs, the financial Key Performance Indicators (KPI) and the Critical Success factors, are: the resource costs analysis, capital requirements calculation, the liquidity planning and the comparative cost analysis.

In order to fulfil the goals of each business activity, the revenue structure must be best described in order to reveal the most possibilities for revenue generation via different ways. Therefore, cost-covering prices have to be fixed in order to substantiate the value proposition, like for example a carsharing utilization fee.

3. Test- and Implementation phase

Pre-tests help in this advanced phase of the Service BM Development to figure out, whether the BM is realistic and ready to be implemented and applied in the market. It is important to test in this context, if the developed value proposition is being clearly explained and will transmit this message to the potential customers. This can be done by using specific infrastructure like the ServLab, a high-end laboratory specifically developed for testing and improving services, which contains a huge methodological toolbox, or by simply using online technologies like Second Life. Activities in this phase could comprise the formulation of the test aims and strategies, the planning and design of the test and the testing itself, and finally the completion and evaluation of the test. In parallel, the testing should be documented (Burger, 2012).

4. Monitoring and Control phase

In this phase, the assumptions, goals and success factors that have been specified mainly in the concept phase (2), have to be contrasted with the defined KPIs to monitor the BM performance. A comprehensive overview of possible KPIs to be used for this can be found in the Productivity toolbox which was developed with the involvement of Fraunhofer IAO and 33 German joint research projects in the course of the meta-project strategic Partnership "Productivity of Services". Another possible method in this context could be the use of the Business Model Scorecard, which was also developed by Fraunhofer IAO.

The previous paragraph is based on: Neuhüttler/Meier/Stadie (2014): "Dienstleistungsorientierte Geschäftsmodelle entwickeln - ein Leitfaden für KMU." 2014, Forthcoming.

2.2 The service-specific Business Model Framework: Elements

When a company that wants to develop a service specific BM has successfully passed through the phases described in the previous chapter, the resulting BM should give a clear overview of what elements are important for the respective service(s). Thus, the most important elements of such a BM are shortly described in the following. An overview of the generic (and adaptable) BM Design Framework can be seen in the following figure:

Figure 1. Business Model Framework for Service Companies (Neuhüttler/Meier/Stadie (2014).

The core of the BM is the value proposition, which is developed in the first process step (1) and permanently re-developed by taking into account the specific requirements of the involved partners and customer groups.

The BM elements like the cost structure, the finance perspective and the revenue perspective are crucial for service performance/productivity, as has been seen in the process description (see: chapter 2.1, phases 3 and 4). Likewise, the internal value creating perspective, including the key resources and activities play an important role for the value creation process. Furthermore, the external value creation perspective, which comprises the analysis of customer segments, customer relations and –channels as well as key business partners play a non-negligible role in service-performance-related considerations (see: chapter 2.1, phase 2). The whole system is impacted by the competitive environment, an external system that can be described by factors such as stakeholders, competitors, politics, or market regulations, etc.

That is one reason, why performance measurement via KPIs plays such a paramount role for each of the BM framework elements. In the following chapter 2, we will describe to what extent companies are ready to use those KPIs and which KPIs are estimated to be critical for companies. Furthermore, we show the current challenges, potentials and future needs for action for the use of KPIs in order to improve service productivity and the respective business models.

The previous paragraph is based on: Neuhüttler/Meier/Stadie (2014): "Dienstleistungsorientierte Geschäftsmodelle entwickeln - ein Leitfaden für KMU." 2014, Forthcoming.

3 Productivity measurement in Research and Practice

As mentioned before, the measurement and steering of service productivity is estimated to be crucial for the success of a service business model framework and thus for the services proposed on the market. Both, activities in performance measurement and business model (re-)development are usually established on a very strategic level in practice. This reaffirms that both, business model development and productivity measurement, are considered critical for success. As such, they are most important issues for the companies' present and future development. Events within the corporate environment that have an influence on the strategic business model development most possibly do also have a strong, significant influence on the corporate performance and the associated performance measurement systems. Nevertheless, only few companies do possess a structured way of dealing with questions arising from those issues. Dealing at the same time with service-specific business model (re-)adjustments and with performance and productivity issues implies the integrative development of overall measures.

This already became apparent in the year 2010 when Fraunhofer IAO conducted a short study among industrial companies about service productivity. The results showed that at that moment about one quarter of the respondents did not use any service productivity measurement. On the other hand, more than half of the respondents would use specific KPIs in order to measure their Service Productivity. The growing share of services in the business model was reported as one reason for productivity measurement. Further reasons mentioned in that context were the increase of competitiveness, innovation and quality (Kicherer et al., 2011).

Those results could be reaffirmed by a short survey that was conducted in 2011 among 61 stakeholders from the service research community. It revealed and again strengthened the assumption, that service productivity is mostly derived from the industrial productivity concept. As such, service productivity is largely understood as the ratio of output to input, under consideration of service-specific characteristics. At that moment in 2011, service productivity research was considered as a very young scientific area (87%). This fact correlates with research about service productivity being considered marginally more disciplinary (57%) than interdisciplinary (43%) and a little more general (56%) than focused on specific industries (44%). However, in view of the increasing number of publications within the service productivity area, it was concluded that the topic is significantly increasing in importance. The consensus among the respondents was that within different areas, the need for action is required. First of all, economy (37%) was considered as in high need for action, but also science (34%) and politics were deemed to have huge needs for more insights about service productivity (Mörschel, Kramer, 2011, whole section).

This requirement for better understanding what service productivity really means was one reason, inter alia, why the funding priority „Productivity of Services“ and the related meta-project “Strategic Partnership Service Productivity” were initiated by the Federal Ministry of Education and Research already in the year 2009. Consisting of more than 32 research projects, the Strategic Partnership applied a structured approach to improve knowledge about Service Productivity and to perform comprehensive cross linking of issues concerning service productivity with key issues of innovation management for services, as well as an advancement of the research policy centered discussion on the productivity of services. Organised as a public-private-partnership, the “Strategic Partnership Service Productivity” aims to enhance networking among all relevant actors from economy, research and politics. The Innovation Office of the Strategic Partnership has made it his task, to take a closer look at the development of service productivity research in recent years. Research activities and key contents, as well as their thematical and regional distribution were analyzed, particularly through publications. Thereby, key issues and research activities have been identified and it could also be determined, which areas have been little explored in current research.

In the next chapter, we will highlight which are the main challenges that companies, which are transforming from traditional manufacturing companies to service companies, have to face concerning service productivity.

3.1 Recent needs and emphasis on Productivity measurement: results of an empirical study

Due to the fact that services play an increasingly paramount role in the market, service providing companies need to focus on improving their service offer (using an adequate business model) and at the same time enhancing the service productivity. Increasing service productivity opens up potentials in many aspects: the (re-)definition of most recent fields of action, the critical analysis of service productivity-related approaches currently applied, or anticipating prospective activities, in short: all those managerial implications of productivity increases again disclose the potentials for service business model innovation of producing services providers.

In order to exploit the huge potential of increased service productivity, tools and concepts for the measurement and assessment of service productivity are required. Although companies from manufacturing industries greatly possess knowledge about productivity management in general, they often lack to transfer those concepts and instruments accordingly to the special characteristics of services (vgl. Janeschek et al., 2013). One challenge remains in the transmission and appropriate use of productivity-related concepts in consideration of the service specific characteristics (vgl. Ganz, Mörschel, 2011).

In order to clarify which current state of knowledge German companies do have about the issue of Service Productivity and which key levers are still needed for implementation of further solutions, an empirical study was performed by the Institute of Human Factors and Technology Management IAT, University of Stuttgart in 2012 in the context of the joint research project “ServUp”. One of the goals within „ServUp“ was to capture service productivity in a systematic way and to combine practical knowledge from the companies involved, and theoretical aspects such as the results of studies etc. Also when asking companies about the extent, that productivity-related issues are integrated in the strategic and operational planning and monitoring activities, interesting results can be found. Productivity seems to play an important strategic role for companies, as it is also described in the business model framework in chapter 2. But when it comes to the effective application of Service Productivity measures, companies still seem to struggle. In the following, selected results from a broad study are presented, that give insights about the current state of knowledge about service productivity and that reveal starting points for service business model implementation. The aim of the study was to mostly reach companies from manufacturing industries, and deliberately extending the scope to companies from other industrial sectors. Therefore, the target group comprised 1000 companies from capital goods industry, industrial goods sector, consumer goods sector, and from other manufacturing industries. The companies were addressed via letter, email, and an additional online version of the standardized questionnaire. Amongst the 103 responses, in total 90 were fully valid and thus included into the study. Those applicable responses came from business representatives at executive positions in business segments like Service Management, Controlling, Information Technology, or the Executive board.

In the following, the survey results about managerial implications of productivity within the manufacturing and service area will be presented. Those give insights about the main challenges and needs for action, the approaches about

managing service productivity that are already applied in business and prospective opportunities and activities in that context.

The majority of the companies confirmed the growing significance of service productivity for the respective area. In doing so, more than two thirds (71%) of the respondents considered service productivity a relevant issue, 39% of them even considered it to be of particularly high importance. This growing relevance of service productivity can be related to the increasing significance of services for the company's portfolio turnover. Responses to another question in this context indicated that the average share of services for the total company turnover grew by 8% between 2007 and 2012, whilst the service turnover grew by 20% within the same five years. This increasing importance of service productivity could allow the conclusion that service business models (frameworks) are of great need and importance for companies that want to systematically develop their service portfolio successfully.

Another interesting fact can be derived from the study, when the respondents were asked about the service dimensions recently focused the most, and where they currently estimate the most need for action. The majority of those cumulated answers showed, that "Quality" (31%) and "Customers" were the most emphasized dimensions. The highest needs for action were identified in the area of process- and customer focused elements like as "Integrating customer requirements into service engineering processes", "Controlling of interaction processes with partners or customers". With reference to the above described, elements of the business model framework, those statements again emphasize the high coincidence to the business model elements. Especially customer related aspects seem to have both a strong influence on service productivity improvements, and play a crucial role for the development of service specific business models.

When being asked about the approaches for managing service productivity that are currently applied, the respondents gave interesting insights about the organisational level, the data about service productivity is collected. Service productivity is mainly scaled on an aggregated level rather than on a level of single employees. From the 57 answers 20 respondents stated, that they measure productivity only on the level of the whole company 17, that they measure in the level of business divisions (13 respondents measure productivity of their services on a team level and only 7 for every employee). This could be interpreted as an indication, that companies have not yet fully exploited the potentials that rely in services and their productivity and maybe, they lack of the respective business models in order to do so.

The relevance of different measuring objectives is evidence that reaffirms this idea. The respondents rated on a five-point Likert scale (1=highly relevant; 5=highly irrelevant) that first the measurement of the profit margin (1.7) and second the "Integration of customer-related aspects" (2.1) and "Organisational aspects" (2.2) as well as "Resource capacity and allocation" (2.2) were the most ranked. "Innovation integration" (2.8) was still ranked rather relevant than irrelevant.

The challenges that arise from the measurement objectives within the context of service productivity proved to be "qualification and controlling of employees" (24%), "service standardization" (15%), and "service modularization" together with "quality assurance" (14% each).

Almost two-thirds of the respondents use the collected data about service productivity mainly to support the decision-making process. Thereby, KPIs support both, decisions on the strategic (29%) as well as on the operational level (26%). This is interesting, in that also the development of a service specific business model should be carried out by integrating those organizational levels. The remaining third of the respondents uses the service KPIs to manage development-related topics, such as "Resource development" (18%) or "Human resource development" (17%).

The majority of the companies use certain KPIs to quantify the productivity of their services. However, it still uncertainty exists about which KPIs should be applied in order to measure the service issue. It could thus be identified that companies rather prefer a dynamic and flexible adaptation of KPIs to the service lifecycle than a static and one-time structured approach. As such, service-related KPIs can be developed by collecting data to meet customer and market requirements. The most relevant KPIs in monetary value turned out to be "turnover / return / profit" and "costs / effort / goodwill". In terms of non-monetary values, the most crucial aspects for service productivity appear to be "utilized capacity", "customer satisfaction", "quality / claims" and "time to react / time needed".

Asking about future needs for action, objectives and application fields for Service KPIs, the respondent emphasized on both, internal and external aspects. Similar to the basic goals of a service business model, also KPI-systems are estimated to be most important for the "Protection of competitive position and innovation ability" (21%), and for "optimising personnel utilisation" (17%).

Also, the answers about the future significance of productivity-oriented management systems (on a five point Likert-scale) were noticeable: more than 93% of the respondents estimated KPI-based service productivity management systems very important (27%) or important (66%). About 7% of the respondents had neutral opinion about this and none of the interviewees had the vision that Service oriented KPI Systems would not be of great importance in the future.

(the whole chapter is based on results of Neuhüttler/Meier/Stadie, 2014)

3.2 Example from practice: development of a service specific business model and simultaneous productivity improvement, viewed as executed by the two framework elements “customer” and “technology” within a case study from the forestry industry

The aim of the preceding statements about service business model development and service productivity is to support the successful transformation of manufacturing to service companies. We believe that this should be promoted by providing insights about necessary changes within the respective service business model elements. In addition, we think it important to conduct productivity increasing measures in companies transforming towards solution providers, such as performance externalization strategies or deploying of new service technologies. That is why in this chapter, the concrete premises and results from customer integration by technology use will be prospected for both, business model innovation and service productivity improvement, using the business case of a producing service provider from the forestry industry. The practical example results from the joint research project ServUp, which is a part of the aforementioned knowledgebase called strategic partnership “Productivity of Services”.

In the previous chapter 2, we learned that the core of the business model, the value proposition of a service a) differs in many aspects from the value proposition referenced to an industrial product. Therefore, it b) needs to ensure, that the service portfolio proposed will meet the specific needs of the customer. In our case, not only the willingness to perform the service to the customer, the so-called service readiness, is crucial but also the resources of the customer are required for service delivery.

Technology integration is one key lever to permanently (re-)developing new or to redefining existing services offered to the customers in order to meet the customer’s needs. In that context, the starting point of this development process is from interest: will technology be used in the very early stage of the development process, while the service business model and as a result the value proposition will be defined from the provider’s point of view? Or will technology be integrated within the already specified and established service offer in order to react to changing customer’s requirements?

In summary, it can be stated that for the (re-)development of a service business model as well as for the efficient and effective, and as such productive, service delivery the customer- and technology integration is an important lever. How the customer-focus and technology can be successfully integrated in a service-related business model, will be shown in the following.

In the following case study, we will describe the above mentioned correlations as clear and practice oriented as possible. The case – partly a real world scenario – originates from one of the 33 joint research projects within the German funding priority “Productivity of Services”, called “ServUp”. The aim of the project “ServUp” was to support the transformation of traditional manufacturing companies to service companies by providing insights about productivity increases which necessarily comes along with changes within their business model elements. As such, productivity increasing measures like performance externalization strategies or the application of new service technologies can be executed successfully.

In the case presented, we will focus on the maintenance and repair services provided by a manufacturer of machines for automated harvest and transport machines in the forestry sector. This very specific sector also being affected by the increasing service orientation (Servitization), the formerly manufacturer is on the way to transform into a solution provider, and service partner for its customers. To put it into another perspective, one could notice that the company is at the same time developing a new service business model in order to react on internal and external changes in the market. The reason: changes in the competitive environment, the technological progress resulting in an increasing similarity of the competing products (machines) on the forestry market, and changes in the customers demand asking for services and products from one single source. In order to ensure its competitive advantages, the forestry manufacturer thus decided to adapt its business model and to set a stronger focus on services.

The initial situation from the provider’s perspective:

both maintenance and repair are services that formerly were additions to the company’s standard product portfolio. Since both are product-related services, they were attached to the sold forestry machines in the past. As such those types of services were provided for free and did not obtain a lot of attention, neither from the manufacturer, nor from the customers. Since the forces on the market for forestry machines became increasingly competitive and the technology within the machines became more or less similar between suppliers, the services became one distinguishing factor for competition.

The initial situation (context) from the customer’s perspective: those machines are highly mobile and they are working in forestry areas (often mountainous, densely forested regions). Considering the case of a machine breakdown, fast access by another vehicle is not always possible. The forestry industry (customers of the machine manufacturer is a) highly capital intensive and b) depending on favourable weather conditions (no storms, no rain, no flooding, etc.) which will actually reduce the harvesting period. A machine breakdown in the best harvesting time means high capital losses for the machine user (customer of the machine manufacturer), since reactive repair and the provision of a replacement machine will take time.

The solution: The use of Information and Communication Technology (short: ICT) can lead to a new service business model, and the associated performance externalization strategy leads to more productivity for both, customers and provider. ICT was in this case used to create new service offers to the customers.

Technological point of view and service externalization: The provider started with transmitter modules that had been integrated within the customer's machines and that would allow to transfer defined data via satellite from the machine of the customer to the provider. Permanent and automated data monitoring and analysis allow the respective service manager or –technician to fastly react when the first signs of a possible breakdown appear. This again allows to the supplier the proposal of a preventive service offer that eliminates risks of standstills. As such, the main input factor for successful service provision is based on the data that the customer allows to transfer from its machines to the analysis systems of the provider. Even if a direct, personal relation only takes part while the Maintenance- or repair service is being performed, the use of customer data requires a good and trusting interaction. Thus due to the focus on technology integration in this example, the entity "customer" can be understood in the sense of (data) resources that need to be integrated in the value proposed by the provider and co-created by technically-enhanced interaction of provider and customer. This is considered under the premise that the emotional and relational customer experiences only do play a secondary role in this case. When some data indicates, that the machine will soon require a proactive service visit, the service coordinator could make an appointment with the customer at a time that fits best for both. Still, the customer is needed to this process since only him has the right and detailed information about the real machine use (machine hours, but beyond that also how often, for how long and under precisely what conditions the machine has been used). Thus, effective and efficient service delivery still depends of the cooperation with the customer, which shows what extent the value co-creation is externalized to the customer. Service provision is thus based on the externalisation of data capturing towards the customer. This again requires a constantly and trustly cooperation in order to co-create the value those services provide.

The Service offer and –value proposition:

The aim for development of the service providers overall service portfolio was to evolve the product-related services from »reactive« services and toward »proactive« services. The innovative use of technology enables the provider to access machines' data. Early, real-time detection of situations and conditions that could lead to the machines' breakdown are made possible, even before the failure those conditions are leading to would occur. Appointments for preventive maintenance can be scheduled after consultation with the customer in order to avoid reactive, "after-the-fact" repairs.

Different types of value are proposed to the customers:

The customers are offered three types of value: restoration of machines' operational readiness following malfunctions/ breakdown (repair), assurance of machines' ongoing operational readiness and full productivity in use (maintenance).

Those types of value are bundled in three different service packages; the scope of services depending on the price, the customer is willing to pay.

For the service provider, these services require the provision of the technological and organizational basis for remote monitoring of the customers machines. This requires a precise data analysis and thus a deep understanding of the data provided by the systems (machines of the customer and data analysing systems). All data transmitted has to be properly examined for abnormalities (or possible signs for pending machine failure) and addressed via suitable measures, which requires expert knowledge. This data monitoring comprises new process steps which were not required when only reactive repair was offered. Since this is costly to the service provider these expenses have to be offset against the earnings the service yields. Thus, the business model of the company grants to pass on some of the costs resulting from the provision of the services (and technological and organizational basis) to the customers. Still those rates are low and attractive to the customers, since, as mentioned before, the reduced periods of unplannable machine breakdowns are more costly to the customers than the price for the proactive service offer.

Since the services »maintenance« and »repair« usually consists of customer-individual combinations of (sub-) services, the packages remain so flexible, that the customer can add sub-service modules or purchase a more comprehensive service package. To give an example of what those services comprise: the data analysis and the proactive maintenance service through the provider for the tasks of checking of engine emissions, checking of crane hydraulic systems and crane maintenance.

In general, the utilization of technologies in order to generate an innovative service value proposition is means a decreasing in the costs of service provision. Both, the customer and the service provider gain benefits. This again brings gains in productivity on both sides, which will be further described in the following..

Productivity gains for the provider – efficient use of resources:

Efficient – and thus productive – allocation of resources is the most important reason for the service provider. The challenges rely in the planning, management and accounting, and in the planning of the actual service provision in the field. Reactive services like repair rarely allow the resource planning in advance. Services like maintenance that are offered within the proactive service packages, allow to the service provider to plan the deployment of resources (Service technician, material, equipment needed).

Through rapid access to the customer data and the additional internal information, a service request can be completed rapidly by suitable measures via the staff of the provider. Standardized, technological infrastructure allows to the service technician (and the hotline agent who will plan the maintenance in coordination with the customer) to figure out which could be the best solution for both sides (provider and customer) in order to avoid a machine breakdown. In doing so, emergencies that require immediate action are markedly reduced. Complexity can be reduced to the staff involved, because less unplanned requests occur and the respective customer- and machine data is available. In this knowledge-intensive work environment also less time-pressure (when a sudden request occurs) leads to more staff satisfaction. And for the management in turn, this leads to better possibilities for personnel planning in advance since scheduling of the service provision as well as routing can be improved. From the providers point of view, in the provision of »maintenance« and »repair«, two roles are involved: service coordinator and the field-service technician.

The workload and availability of the latter depends on customer demand. The service coordinator will traditionally be charged with planning, coordination and management of HR (service technician) resources, and accounting. His work tasks will change slightly when proactive planning is introduced, towards reviewing and analyzing the data of the customer's machines which also means to review the current usage periods (»machine hours«) in light of those data in order to get an overview of what is the current status of the machine and the lifecycle of the components. On the basis of these data, if necessary, possible proactive measures can be derived and proposed to the customer. Finally, the use of technological infrastructure utilizing the data from the customers makes it possible to partly automate and standardize the service-related administrative processes as well as the service offer to the customers.

Productivity gains for the customer – savings in time and less cost-intensive breakdown-periods:

As mentioned before, the customer's requirements in the areas of both repair and maintenance will depend on his specific level of machine use; and maintenance intervals that are defined in terms of hours of operation. Since unexpected machine breakdowns can be very expensive for the machine operator (who is under great time pressure and pressure from his own customers in the value chain), avoiding of those incidents has the first priority for the machine users. The proactive service offer will increase the reliability of the serviced machine, since the service technician can even make some adjustments at the machine while operation via remote control (no on-site visit necessary). And this means a higher possibility of always working machines and thus, huge potentials for increases in the customers productivity. Even more, when a customer owns more than a handful of machines, what makes it difficult to keep on track, to keep the overview of use-periods and the machine data. Another fact that cannot be discounted is that the satellite control can protect the expensive machines against theft. It may happen that in unpopulated regions that are difficult to access, the machines can be stolen when drivers shortly leave them (to have a short lunch break, etc.). Productive work also requires specialized drivers of the machines. The data captured allows them to improve their own productivity. As they can read the actual production data and also alarm from machine part that are not working well, fast reaction is possible. And also the communication, since conventional communication via mobile phone is often not possible in their working environment amidst the forest. Inclusion of ICT within the proactive service offer (standardized interfaces, etc.) thus allows gaining many productivity increases via the automated data transfer on the customers' side. Rapid data access and permanent monitoring enables a fast completion of the service request if necessary. Shorter times of machine breakdown and stillstand are one result. And when an alert occurs, another important factor is travel mileage. Since the machines can be difficult and expensive to transport, the service technician and the driver have to agree on the exact place and time where the service would take place, as well as actual information of the machine use to enable the service technician to bring the necessary equipment (tools and spare parts) to the on site maintenance or repair. In providing his service, the formation of a more personal customer relationship through proactive cooperation is another advantage. The customer (service coordinator or driver of the machine) usually will have one single contact person that knows the machines and their history, and further circumstances that are important about the work if the customer (highly-productive areas and regions, where the driver might happen to work in the moment of an alert).

In conclusion, scheduled service provision reduces unproductive and unplanned machine breakdown times. The respective service appointments are agreed in advance by the service customer and initiated by the service provider. Even if the service provider will externalize some costs (payment per selected package) towards the customer, the latter profits strongly from the opportunity to generate productivity gains. Those rely in less production downtime and reactive repair costs that are comparatively more expensive to the service customer than low rates for proactive maintenance.

(The whole case is based on the description in: Productivity guideline: Productivity of service work, Rößner, Kicherer, Nägele, Quality and Service Management, Processes for improving the productivity of service provisioning)

Life Cycle Business Transition through Sustainability Service Innovation Model

Vesa Salminen¹, Jukka Valkonen², Maria Lindroos³, Pertti Lukkari⁴

¹HAMK University of Applied Sciences, ²Spiral Business Services Oy, ³Sandvik Mining and Construction Corp., ⁴Fastems Corp.

Abstract

In order to sustain competitive advantage, manufacturing companies are expanding their value proposition by concurrently creating new products and co-innovating lifecycle services. They are expanding their value proposition multidimensional by concurrently creating strong potential through developing more sustainable customer-engaging products, co-innovating sustainable services together with their value network partners. Companies today are facing increasing complexity to execute profitably on continuous sustainable business transition. This article introduces a strategic concept, sustainability service innovation model, for utilizing sustainability as a business and innovation driver to facilitate the transition of industrial business towards the new service economy.

1 Introduction

In order to sustain or create competitive advantage, to grow and secure future, manufacturing companies are expanding their product offering to provide lifecycle services, too. By doing so, these leading companies are expanding their value proposition multidimensional by concurrently creating strong potential through developing more customer-engaging products, co-innovating services together with their customers and partners, and collaborating to create integrated new business models. Companies today are facing increasing complexity to execute profitably on continuous business transition. This paper will demonstrate that sustainability is not only the goal but also the means for achieving both tangible and intangible results. Sustainability is the ability to meet the needs of the present without compromising the future's ability to meet its needs. Sustainability services mean all activities (business & industrial) that help customers to be more sustainable.

Technology is enabling sustainability by facilitating compliance while simultaneously providing insights into process improvement and mitigating diverse business risks. Furthermore, forward-thinking business leaders are taking it one step further, deriving multidimensional business value as well as competitive advantage from the opportunities and innovations that sustainability challenges are uncovering.

Most companies do not have a strategy or analysis on aligning business to sustainability. Being green to achieve mitigation, clean to reach up to optimization and smart to manage the transformation is the integrated, evolutionary approach. Sustainability is an opportunity integrator on the path. Integrating novelty with technology brings new opportunities for more sustainable business models. The transformation towards sustainable business takes a long time and that is why it is important to fully understand the strategic concept, identify the key issues and harness the associated opportunities. From initial compliance or carbon footprint thinking, steps can be taken which can concurrently be used to optimise enterprise-wide business processes and perhaps even begin creating strategic differentiation and offering enhancement. When establishing benchmarks or KPIs to measure your progress on the sustainability path, it is good to select those relative to your company's priorities. Their wider context should be considered and integrated into daily decisions. Initial focus could be on internal issues such as energy savings, product life cycle or employee ethics and welfare, followed by focusing on external stakeholders such as the planet, supply chain partners and customers. The starting point is the business today and markets and the world tomorrow.

2 Relationship to Existing Theory

Sustainability is no longer a question of if, but of when, and to what extent it will impact a specific business sector. It is no longer a negative reactionary tactic to moderate environmental climate change, but a positive proactive strategy to accelerate long-term business climate prosperity. It is not just about risk, reductions, and recycling, but an industry-changing paradigm integrating innovation, differentiation and transformation. Antonio Tajani, EU Commission Vice President on Industry & Entrepreneurship stated "there will be no sustainability without competitiveness, and there will be no long-lasting competitiveness without sustainability. And there will be neither of them without a quantum leap in innovation." Eppinger (2010) has discovered that the link between sustainability and innovation is commonly mentioned, but not commonly made. Chesbrough (2003) points out there are a new logic behind open innovation which embraces external ideas and knowledge in conjunction with internal R&D. This offers a novel way of creating value. Miller and Langdon (1999) introduce how to manage disruptive innovation by managing platform, product and process innovation in continuous cycles. Nidumolu, Prahalad and Rangaswami (2009) explain widely why sustainability is now the key driver of innovation. Salminen (2008) has discovered that when new value for the customer is created in the form of a product or service offering and it results in sustainable innovation, it is essential to know whether there is also a transition into a new business model. At the same time the business innovation must be built on the essential business structures (operational systems, contracts, network structures, competence, etc.). Tammela and Salminen (2007)

introduce the interoperability concept through which common innovation of sustainable products and services can be accelerated by an open semantic infrastructure. The open innovation process requires the definition of interoperability in order to achieve a critical level of network dynamics to create new products and services. The Sustainability Service Model is created as an opportunity to build the missing links between sustainability and innovation. Skyttner (2007) introduces new systems theory with self-organization and evolution. Jamshid (1999) introduces that system thinking is the art of simplifying complexity. It is about seeing through chaos, managing interdependency, and understanding choice. Concepts are important to explain chaos. Tang and Salminen (2001) introduced the complexity management approach for the purpose of product and service management in continuous innovation. The key to open innovation is the integration of the customers and consumers' ideas into the process of innovation. This means that the creation of the innovation should come largely from the customer's input, ideas and feelings. This entails that the issue of trust is not uni-lateral, the customer gains trust from the service provider because of the interaction, but the company must first have trust in order to spend the money, time and knowledge on their open strategy (Belz, Peattie, 2010).

3 Research questions and research approach

The role of sustainability as a business driver is growing in industrial service business and has to be carefully taken into account in business transition. The opportunities of sustainability have not been understood in full context and as new service innovation. The main research questions are

- a) What does sustainability mean in industrial service business context?
- b) How to create business insight and business structures to support continuous innovation in sustainability services?
- c) How to manage the growing importance of sustainability in the business transition with a DNA model based on system dynamics?
- d) What type of sustainability service model and implementation process is needed in sustainable growth of business?
- e) How can the life cycle challenges of the customer process be managed in a networked environment?

This article introduces a new concept model for utilizing Sustainability 2.0 as a business and innovation driver to facilitate the transition of industrial business towards the new Service Economy.

This applied research was based on qualitative research approach. The study is based on concept creation according to combined industrial and research knowledge and case studies in real industrial environment at Fastems Corp., the life cycle care provider of industrial and intelligent automation systems and services, at Sandvik Mining and Construction Corp., the equipment and service solutions provider for mining and construction industries and at Tieto Corp, the IT system integrator and life cycle services provider.

The Sustainability Model was developed as a joint initiative between research institute experts and various international companies in Finland and was applied to individual enterprise strategies in order to validate how sustainability can be used to drive business value in the creation of new services. Insight into participant case studies will be provided to substantiate breadth of applicability and ease of use.

This applied research was based on qualitative research approach. The study is based on concept creation according to combined industrial and research knowledge and case studies in real industrial environment. The sustainability service innovation model was developed as a joint initiative between research institute experts and various companies and was applied to individual enterprise strategies in order to validate how it can be used to drive business value and how sustainability influences on business transition and how it can be managed. The intention has been to provide insight into participant case studies to substantiate breadth of applicability and ease of use.

4 Industrial Service Business and Life Cycle Care

The main question for service business strategy is the evolution of the customers' business. This means the changes in the customers' business should be addressed by the new service solutions. There are different market trends (e.g. technology, market and society trends) that are changing business. Companies competing within the industrial service business market should track the potential and business value that the customer may capture with the aid of services. Based on the expected business value, the concept of the service offering should be designed over the life cycle of customer process. Figure 1 illustrates the various types of industrial service business models through which a technology company can grow their business - ranging from product centric towards service and value centric.

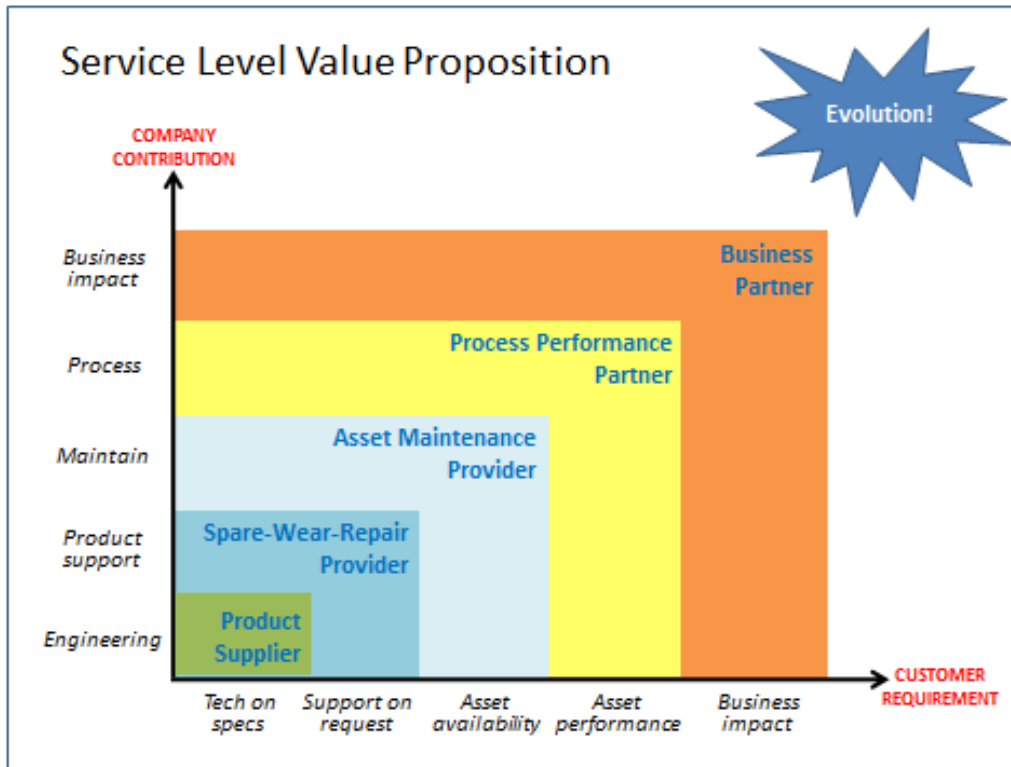

Figure 1. Business model dependence on customer requirements and value creation capability.

Each of these five business models has its own “mindset”. When a supplier (or service provider or partner) aims to proceed from one model to the next, it faces challenges, mostly in terms of getting the customer involved in this and developing its own technical and business competencies in order to achieve the new role. The strategic positioning decision between supplier and customer is important and has to be prepared as thoroughly as any other strategic decision.

The first two models focus on the supplier’s activities to support the customer’s investment and not on supporting the customer’s process. A spare-wear-repair provider needs the ability to understand and interpret the customer’s actual processes. An asset maintenance partner concentrates on professional maintenance management as a continuous process. As the process performance partner, the supplier can have a responsibility for the actual daily performance of the customer process. When the supplier is a business partner, it is involved in the customer’s value generation, e.g. producing optical cable in a cable factory at a given quality and price exactly according to market need estimated. The supplier needs to have competence of the customer’s business. The required level of knowledge and experience is such that it must provide the competence for productive communication between partners in the value network. During this type of business co-evolution the role of sustainability as a business driver in service business is continuously growing. It is important to outline the sustainability path (Figure 2) from supplier values through supplier business value to continuous customer value creation. Succeeding on this co-evolution requires continuous business, social and environmental forecasting and foresight as well as strategic business alignment related to changing requirements and multidisciplinary development activities.

Figure 2. Outlining the sustainability path to customer value

Customer requirements and expectations on business value grow significantly the further we proceed as to the business model. Managing the network of partners involved in the business becomes more demanding and the level of knowledge intensiveness raises, too. In the business model on upper levels the integration of service and product is essential because of continuous analysis and expectations on raising the customer process performance. Type of complexity is changing when customer value is increasing and business model is changing. Dependencies are increasing on upper levels and management of complexity is focusing on dependency management. System engineering and dynamic markets have to be understood better to manage business co- evolution.

As an example, an asset maintenance partner offers maintenance services to support the products and application in its own installed product base. The objective is to provide higher product availability through lowering down time or supporting the application by proactive maintenance. The proactive maintenance is enabled by knowledge of products and application and monitoring globally the same kind of applications over their life cycle. The costs of maintenance can also be lowered in comparison with customer's own maintenance function. On the other hand a process performance partner offers process, energy and environment efficiency by taking care of some parts of the technical processes of the customer and ensuring high performance of these parts. Value is created in collaboration with the customer and thus seamless information exchange and joint processes are needed. The offering includes process availability and sustainability on certain performance level, performance data, forecasts, and decision support aids.

On a more sophisticated level, the industrial service results in increased customer process performance. The service provider is then responsible also of the sustainable innovation. Business partner represents a service centric business model. This is the case when the customer business value is based on the operation of equipment. As an extreme example, the service would mean to provide the desired outcome so that the customer does not even know what systems are used to produce the outcome, or where the outcome is produced.

The offering and sustainability enrichment is usually achieved by providing particular knowledge to other companies down the supply chain, in order to increase the value in the customer processes or products. Figure 3 shows, how the value proposition of sustainability is built on the result of network operations in value network.

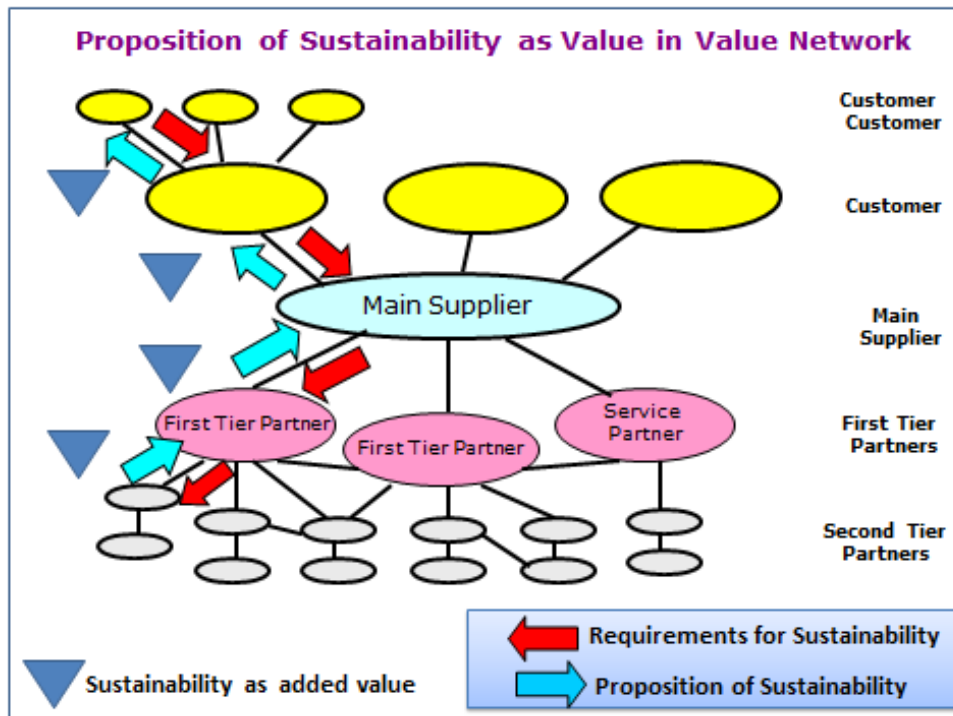

Figure 3. Requirements of Sustainability as Business Value in Value Network.

Competition happens not only between single enterprises but between networks of business. The partners in the value network have common responsibility on final customer process performance and its continuous development. Networked business means new ways for earning logic, too.

The requirements of customers and customers' customers have to be visible and well understood for whole the network to succeed in solution (product and service) development and delivery. As a result, companies are moving closer to or even into the operations of their customers, which requires a different organization approach and "networked thinking". A network in this sense consists of individuals and organizations with the resources they have, taking part in a process and thus interacting. This network perspective should already be implemented in the service development phase.

A well understood business architecture and structure supporting the selected business model is a very important strategic tool when business is evolving according to market requirements. Sustainability innovation needs new approaches and leads to business concept management. In the future, it will be possible and essential to sell business models based on the available architectural structure of a company.

Knowledge intensive business is in continuous evolution. Life cycle challenges can be faced and competitive advantage achieved in knowledge communities (Salminen, 2009). Increasing share of the innovation process is taking place outside the single company. In the global scale the information is available anywhere when there is internet connection available. The community shares the same information at the same time. The question is how to integrate and synchronize knowledge, technology, competences and processes, especially when creating something new in a networked environment over the life cycle of customer's process.

5 Generic findings

The business environment is influenced by a variety of economic and dynamic trends. The associated importance of sustainability is growing exponentially as a key business driver and it is an enterprise integrator to cohesively assess and align various stakeholder perspectives and requirements. Companies are often concurrently impacted by technological innovations, industrial regulations, and market transformation, amongst other factors. All these factors and trends add to the complexity of service and product development and make rapid new offering introductions even more important, and specifically ever more challenging. Sustainability focused companies, those able to manage these challenges and address the opportunities effectively and efficiently, are the ones which have a better position in dynamic markets in which internal and external players execute service development activities.

Business requirements can be integrated into corporate strategy by following a progressive sustainability path from 1) compliance, ethics and corporate responsibility through 2) risk management and process streamlining to 3) business innovation, differentiation and competitive advantage. This journey, from values to value, starts with reactive adherence and progresses through proactive insight and will eventually instill companies with the innovative foresight required to stand apart from their competition. As fewer companies on the Global Leader indices actually make tangible products, we see the majority of companies putting their R&D investments into services and innovating the way they do things,

not just the things themselves. Figure 4 introduces the continuous development cycle of the internal alignment and external positioning in sustainability service innovation. At first, sustainability can be seen as being a sustainable supplier. The focus is on improving internal sustainability in functional processes. Next level represents increasing sustainability in own products and services as new offering when becoming a sustainable solution provider. The leading edge in business is becoming as sustainable co-innovation partner with your customer and providing sustainability as a service.

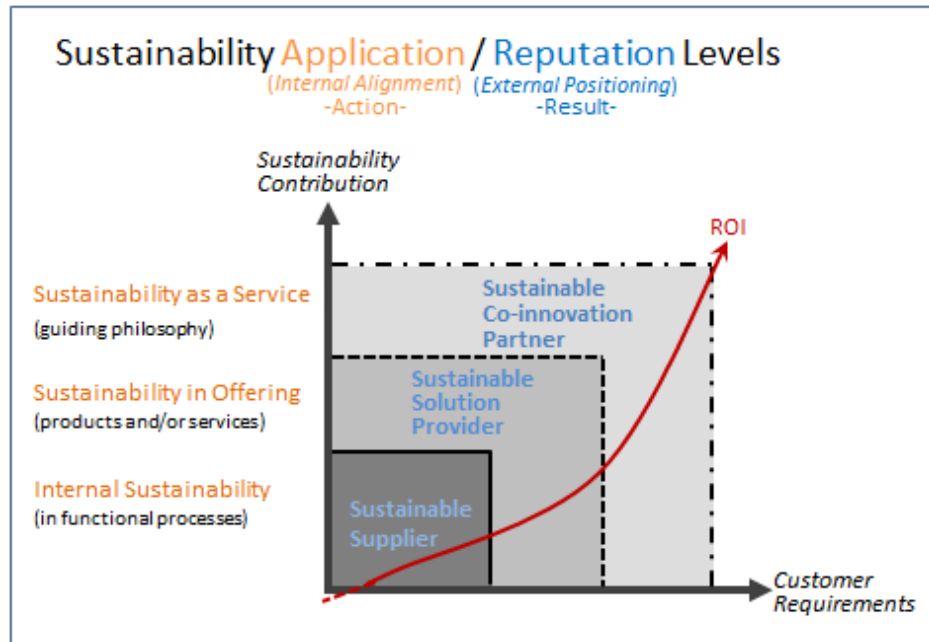

Figure 4. Internal alignment/external positioning in sustainability service innovation.

To be considered innovative, an offering must differ significantly from its predecessor. Figure 5 describes the trifecta approach in sustainability service innovation.

When we take the sustainability trifecta into consideration, economic sustainability factors give way to social sustainability implementation, enablement and engagement activities, and both of them benefit even further when combined with environmental mindfulness. It is possible to end up on process effectiveness (e.g. strategic, production), performance effectiveness (energy, resource use) or business outcome effectiveness (i.e., financial, product/offering, market environment, brand) by this approach.

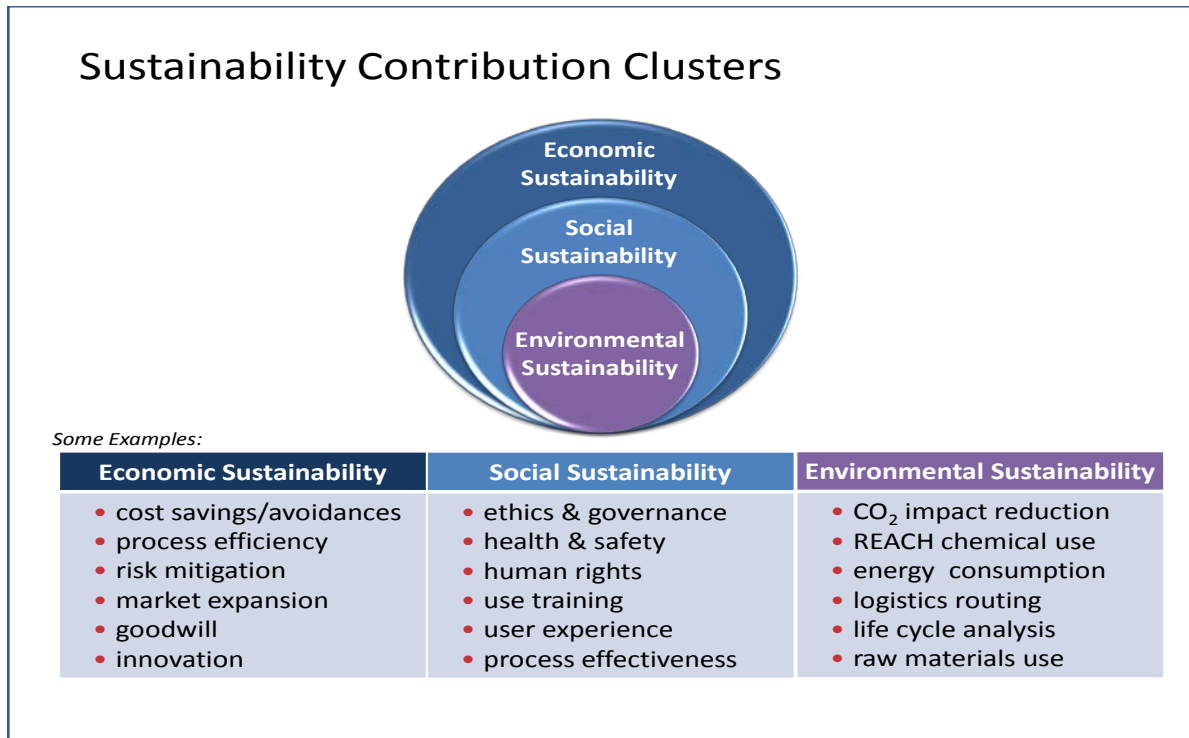

Figure 5. Trifecta approach in sustainability service innovation.

6 Sustainability Service Innovation Model

According to the empirical study of this research and the business knowledge gathered it was recognized that sustainability understanding and innovation in service design and engineering requires more systematics. The research group concentrated on building up an innovative and systematic way to manage the continuous increase of sustainability during business coevolution.

The Sustainability Services Model is the contribution from the research work. It outlines a 6-step systematic approach to integrating sustainability within a business, driving exponential growth and accelerating the path to ROI. The phases of the Sustainability Service Model and implementation process are (Salminen, Valkonen, Lindroos, Lukkari, 2012)

- Step 1: Develop Services Category Lifecycle, Identify Sustainability Subcategories
- Step 2: Brainstorm your Sustainability DNA Molecule by Sustainability Cluster
- Step 3: Highlight the Sustainability Impact of each service category
- Step 4: Plot Sustainability Contributions at the appropriate service level
- Step 5: Identify Sustainability Relevance at each service evolution point
- Step 6: Discover Sustainability driven Opportunities & Business Growth areas

At the **first step** the process starts by looking at the sustainability potential of existing service categories. It helps to highlight the sustainability impact of each service, and then plots the materiality of the sustainability contributions at each service level. Figure 6 describes an example of the categories of services with sustainability linkage.

Figure 6. Categories of lifecycle services and identification of sustainability subcategories.

The listing shows current services delivered to customers today. The categories include elements that are bundled and sold as service to customers. For example, if we analyze service contracts the cost is very different if the number of KPI's followed is either small or high.

The process flow charting normally starts with high-level perspective followed by activity analysis to identify, which activities are really services. Then it is important to verify, what the sustainability related subtasks are in each service category. It is good to specify which are current or future services and which are company offered or customer required services. If the service is company offered and is not yet required by customers, it could be a differentiator in marketing. It might bring some new value for customers and also be worth higher price.

At the **second step**, the 3-way relationship, shown in Figure 4 (trifecta) is built as a system model with dynamic interrelationships. If it is applied conceptually to the business in value network (Figure 3), it shows the relationship map a company has with its employees, partners and customers. It creates a value network of authentic attributes, much like a DNA molecule does for an individual. The continuous evolution of the relationship turns employees into solution providers and customers into co-innovation partners, harmonizing internal alignment with external positioning to match customer requirements with sustainability contributions.

By identifying the sustainability relevance at individual evolution points, a company can discover sustainability-driven opportunities for service innovation. Figure 7 introduces the result in one company case study.

It is essential to identify the leading issues associated with each sustainability cluster element relative to:

1. How your business must respond to sustainability (main challenges, risks, compliance issues)
2. How your business can capitalize on sustainability (main business, growth, market development) opportunities

It is important to understand the relationships between services and how you execute the customer service by internal functionality. It is possible to see whether the created idea will carry further and has got the needed elements to deliver the service. As examples of interdependencies 1) the purpose of cost saving leads to energy cost saving, 2) process effectiveness to optimized logistics routing, 3) REACH chemical use to HAZMAT awareness training, 4) health and safety consideration to accident rate reduction, 5) risk mitigation to insurance cost decreasing or 6) operation permits and life cycle analysis to 35% recyclable. It is possible to use coloring to show current services, services under development, future need areas and highlight trends. It is also possible to show interdependences between services.

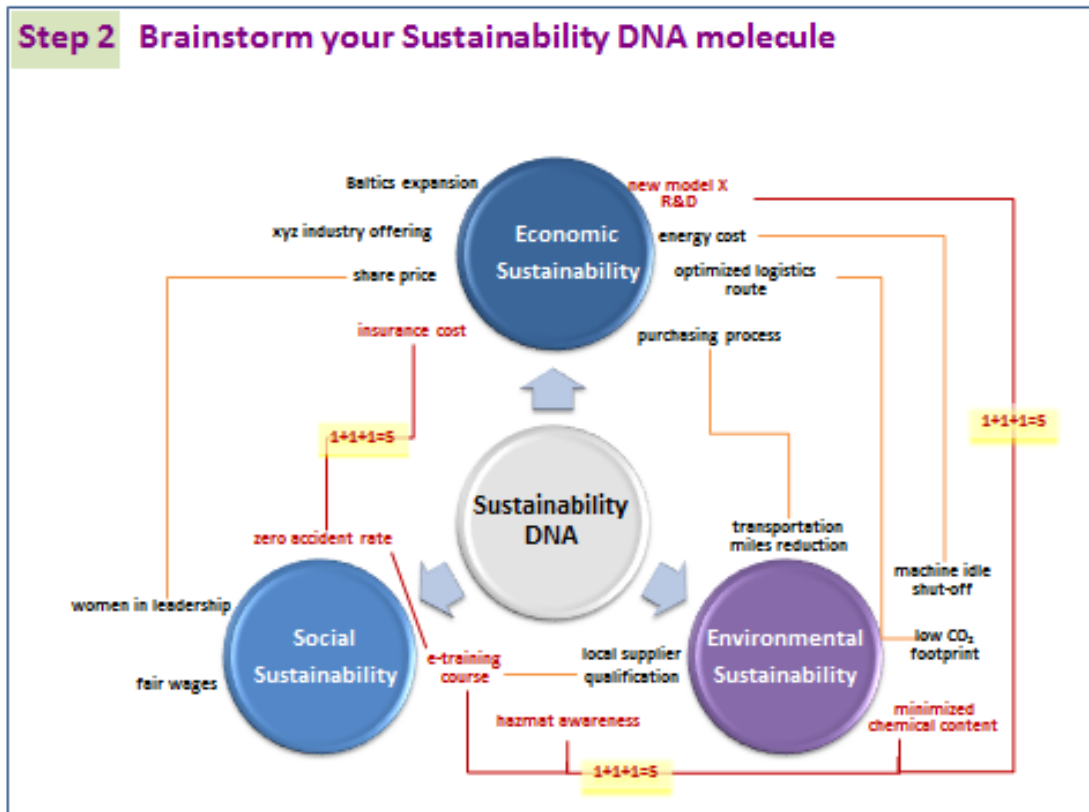

Figure 7. Sustainability DNA molecule for sustainability mapping.

The third step concentrates on highlighting the sustainability impact on service category (Figure 8). It is essential to understand your internal sustainability position on the perspectives of ROI, customer requirement or customer relationship. The position can be analyzed positive (benefits or opportunities) or negative (challenges or risks). The purpose is to take element or inspiration from step 2 and use positive or negative ratings to recognize the impact to business. The purpose is to evaluate existing service with possible opportunity. As to existing service it is essential to analyze if it has been included in marketing and sales material and whether the company has got a business structure to support the improvement of this service or to eliminate the risks.

Step 3 Highlight the Sustainability Impact of each service category

1+1+1=5

Service	Economic	Social	Environmental
1 Pre-sales	+ Cost Savings (for Customer) + Market expansion -	+ Added value (for Customer) + Improved use (effectiveness) - Incumbent is local	+ Added value (for Customer) + Improved efficiencies
2 Customer training			
3 Equipment auditing	+ Based on predictive maintenance + Production efficiency	+ Based on predictive maintenance + Risk understanding	+ Based on predictive maintenance + Environmental efficiency
4 Service contracts	+ Based on business requirements	+ Based on social requirements	+ Based on environmental requirements
5 Process auditing	+ Based on predictive maintenance + Production efficiency	+ Based on predictive maintenance + Risk understanding	
6 Equipment recycling			

Figure 8. Sustainability Impact on each service category

During the **fourth step**, a cluster analysis is made based on materiality level of sustainability contribution on the perspective of value creation to the customer (Figure 9).

Figure 9. Materiality Analysis of Sustainability Contributions.

If we look more closely at case example 6, it shows that some of the equipment in the customer application is at the end of the life cycle and should be recycled. First an analysis is needed as to what to do with the recycled equipment to fulfill the requirements of social environment and environment laws. The new equipment should be more sustainable on the basis of production, energy and environment efficiency addressing filling business, social and new environmental requirements. Customers can use it as brand marketing argument when facing their own customers. Whole this incident chain calls for advance cluster analysis based on materiality level of sustainability and value contribution.

The fifth step starts by identifying the relevance of sustainability at each service evolution point. Figure 10 illustrates the analysis of sustainability on the perspective of economic, social and environment influence.

Figure 10. Company case of sustainability relevance and service value proposition by sustainability cluster element.

During this step it is essential to rise up the following questions as well as to execute the following tasks:

1. Does our service match the approach required by the customers and the market?
2. Evaluate the services according to economic, social, environmental relevance.
3. Analyze services plotting to define overall value proposition and gaps

The sixth and final step discovers and describes the sustainability driven opportunities and business growth areas. The value that leads to competitive differentiation has to be understood as well as the way how the new created service can bring ROI. The company launching the service recognizes how to capitalize on existing strengths. Step 5 creates differentiation strategy based on strengths. The opportunity is to start from DNA molecule (Step2) linkages and innovate new services based on its' analysis (Figure 11).

The sustainability positioning and opportunity matrix (Figure 11) and strategic sustainability path (Figure 2) with its development roadmaps should somehow direct “punctual” innovation over the life cycle of the customer process. Customer requirements change over the life cycle. Technology-related functional requirements change too and constantly bring new opportunities in technology implementation. The benefit, or in a more generic way the value, for the customer and all stakeholders in the value network should be better determined. That understanding helps in decision making and allows for quicker implementation.

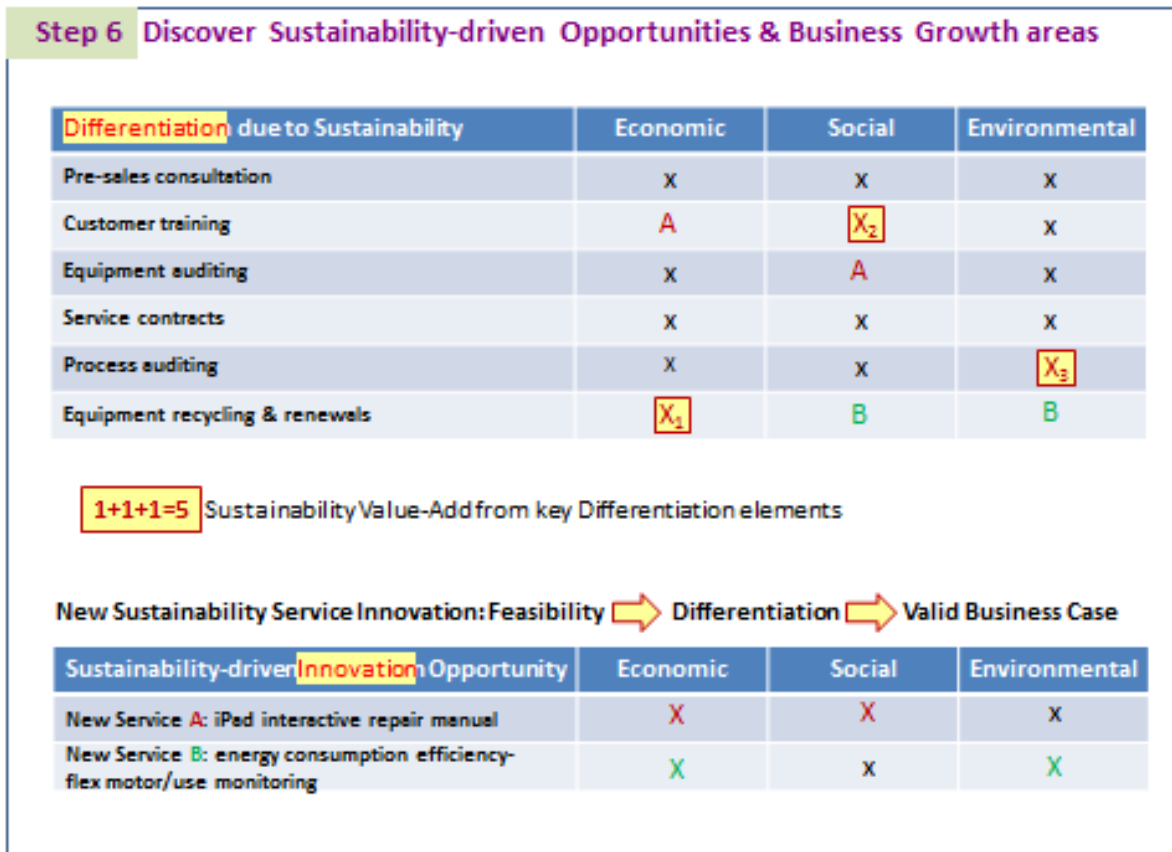

Figure 11. Sustainability Positioning and Opportunity Matrix: Innovation Opportunity

7 Life Cycle Business Transition

Manufacturing companies entering into service business undergo a stepwise transition process from equipment-based to more customer-oriented. Methods and structures supporting the business need to be adapted to a new situation. A company, willing to run profitable business in industrial context, needs to master its business transition at three levels: 1) the strategic level and strategic insights, 2) structural level and 3) operational level. Three levels of management are illustrated in Figure 12. When amount of product and services are increasing, the offering management and the relation between the products and services become more complex. In order to reduce complexity the main focus is to define business structures that are able to handle the products and services. The structural elements are covering product and service life cycle management and support the continuous change of the life cycle business.

Figure 12. Service and Product Development System Enabling Business Transition.

8 Generic Business Model Structures Routing Life Cycle Innovation and Business Transition

Business transition needs some traceability and generic structures to manage continuous change. The main functionalities in business transition are

- Managing continuous value creation and proposition at customer process
- Value creation process in service business
- Management of customership and earning logic
- Making and managing of business change foresight and forecast
- Management of strategic change
- Management of business structures during change
- Service innovation, modelling and productization
- Managing operative processes and measuring
- Mastering metadata of information
- Managing semantic infrastructure and information systems supporting service business
- Mastering international business and working in networks

Business transition needs a generic business model structure (Figure 13) to route the development activities during the change. The interrelation between the elements has to be managed during fluent business transition. Business strategy is adaptive and needs continuous aligning during coevolution. It is important to understand the whole business structure to create value promise with good emotion in delivery. The promise, however, is not enough; it should also follow by proposition of the value and good emotion produced by business structures is even more important. Special attention should be placed on the most difficult changing item is organizational culture.

Figure 13. Generic business system model to support the dynamic transition.

9 Practical implications

The case study companies and value network companies have gained competitive advantage by implementing the created knowledge and sustainability service model via implementation processes in their business environment. It is also a great opportunity for other enterprises and partners in value networks to benefit from the created model in their own business environment to reach sustainable life cycle product and service innovation.

All the participants recognized that when the daily business is growing, and becoming more network oriented, then sustainability in service business is becoming a crucial business driver. All the partners in the value network are dependent on each other's sustainability because the sustainability of the joint offering of the value network is vulnerably dependent on the weakest link in the network. It is also very difficult to offer sustainable products and services to a customer, which is not mature enough to understand the benefits and impacts of sustainability on their business and the business of their customers respectively.

The scope of this research has been very interesting but as well too broad, therefore making the research rather complicated. Narrowing the focus of the research too much in the beginning would have made it difficult to build up a Sustainability Services Model for continuous analysis and innovation in life cycle business co-evolution routing. This work has concentrated on constructing a model based on several sub-systematics. As it would have been difficult to validate the full model in one go, parts of the model and new systematics iteratively developed have been validated in turn. For this reason, first the vision of the full system and then the ideas of the sub-systems were developed according to the constructive research and concept mapping. Sub-systems have been validated independently by various case study companies and value networks with the help of grounded theory. University experts have used the created knowledge and sustainable model in their own following research activities.

Sustainability means embedding a commitment to values while driving bottom-line business value. The first trifecta (People, Profit and Planet) is generally referred to as 'The 3Ps of Sustainability.' These elements establish the internal corporate principles which ensure organizational change is conducted in an ethical and integrated manner while minimizing risks. They set the foundation for what the company is today and what it aspires to be tomorrow. The second action oriented trifecta illustrates the proactive stance a company adopts to be able to respond to both the challenges and the opportunities sustainability considerations create. It means establishing a continuous improvement infrastructure which ensures that the company strategies are reflected in business processes, and that multidimensional profit is derived from improved performance.

Sustainability ties business functions more closely to solving the global agenda of challenges – social, environmental and economical – and simultaneously capturing market wide opportunities. The web, and

especially emerging cloud services, provides the platforms where the actions of individuals and companies can have an impact far beyond your market or industry. In this new age of the 'linked economy,' mobile phones and other smart technologies, sustainability can be used to ensure you are integrated with all your stakeholders anytime and anywhere. Sustainability is creating significant impact and opportunities where business, technology and innovation intersect.

The business positioning and opportunity analysis and strategic development path with its development roadmaps should somehow direct "punctual" innovation over the life cycle of the customer process. Customer requirements change over the life cycle. Technology-related functional requirements change too and constantly bring new opportunities in technology implementation. The benefit, or in a more generic way the value, for the customer and all stakeholders in the value network should be better determined. That understanding helps in decision making and allows for quicker implementation.

The case study companies and value network companies have gained competitive advantage by implementing the created knowledge via implementation processes in their business environment. It is also a great opportunity for other enterprises and partners in value networks to benefit from the created model in their own business environment to reach life cycle product and service innovation.

The scope of this research has been very interesting but as well too broad, therefore making the research rather complicated. Narrowing the focus of the research too much in the beginning would have made it difficult to build up a framework of integrated service and product development for continuous analysis and innovation in life cycle business co-evolution routing. This work has concentrated on constructing a model based on several sub-systematics. As it would have been difficult to validate the full model in one go, parts of the model and new systematics iteratively developed have been validated in turn. For this reason, first the vision of the full system and then the ideas of the sub-systems were developed according to the constructive research and concept mapping. Sub-systems have been validated independently by various case study companies and value networks with the help of grounded theory. University experts have used the created knowledge in their own following research activities.

Outcomes of reflective practice in services

Minna Saunila, Juhani Ukko

Lappeenranta University of Technology, Lahti School of Innovation

This research examines the outcomes of reflective practices in services. The literature on the strategies to foster reflective practices is still early in development and there is a lack of studies addressing the outcomes of reflective practices. The paper contributes to the current understanding of the relationship between reflective practice and outcomes by presenting a description of the internal (i.e. what kind of reflection is required to attain desired outcomes) and external factors (i.e. under what kind of circumstances reflection results desired outcomes) of reflective practices. The results are based on a case study where both quantitative and qualitative methods of data collection are utilised.

1 Introduction

Innovation has been suggested to be one of the most important issues that drive organisational performance. What it comes to services, the traditional forms of developing innovation do not fulfill the needs of rapidly changing environment. New ways of developing organisational innovation are thus needed. Reflective practices, where individuals learn from their own professional experiences, may be the most important source of professional development and improvement (Nakamura; Yorks, 2011), and also innovation and other outcomes. Earlier literature has reported some positive effects of reflective practices (e.g. Page; Meerabeau, 2000). There are some examples in the current literature suggesting that team reflection is driver of both team innovation (Somech, 2006) and product innovation (Lee, 2008). According to Somech (2006), the process of team reflection serves as a vehicle through which the interaction of participative leadership style and functional heterogeneity enhances team innovation. There are also many similar factors behind reflective practice and innovation development. These include for example individual skills and capabilities, collective culture and structural aspects. Clouder (2000) has argued that if reflective practice stops at the individual it will be limited in scope and will serve only to maintain the status quo rather than promoting change. Thus, reflective practice can also be realised also in group and organisational levels (Hildén; Tikkamäki, 2013). The literature on the strategies to foster reflective practices is still early in development and there is a lack of studies addressing the outcomes of reflective practices (Mann et al., 2009) namely organisational level innovation and outcomes.

When focusing on the previous research, it is clear that in-depth empirical studies are needed to achieve a deeper understanding of the mechanisms and arrangements that connect reflective practice and outcomes. The studies that discuss the interphase of reflective practices and outcomes have mainly been theoretical considerations or surveys that lack an in-depth understanding of how the different methods operate in a real life context. This research aims to address this research gap by examining the outcomes of reflective practices in services. This paper argues that reflective practices are a way of boosting outcomes in services. To reach the aim, the paper contains a description of the internal (i.e. what kind of reflection is required to attain desired outcomes) and external factors (i.e. under what kind of circumstances reflection results desired outcomes) of reflective practices.

2 Literature review

2.1 Reflective practice in services

Continuous professional development should not be just attending courses and gaining qualifications, but integration of learning and work, and learning from wider experiences, both on and off the job. Nowadays, developing organisations through utilising human resources should be seen as a combination of structured and unstructured learning and performance-based activities which develop individual and organisational capacity to cope with and successfully manage change. (Simmonds; Pedersen, 2006) In this paper, reflective practice is seen a way to improve the meta skills that can be learned only through experience.

The field of learning from experience illuminates the importance of reflection (Nakamura; Yorks, 2011). It has been suggested that reflection can be an important tool of developing human resources when individuals learn from their own and each other's professional experiences, rather than from formal training. Boud defines reflection as "a generic term for those intellectual and affective activities in which individuals engage to explore their experiences in order to lead to a new understanding and appreciation". (in Mann et al., 2009) Reflection involves thinking about past or ongoing events, situations or actions so as to make sense of them, potentially with a view to informing future choices, decisions or actions (Reynolds, 2011). Reflection thus fulfills several functions, including helping to make sense of complex situations and enabling learning from earlier experience (Mann et al., 2009).

When discussing reflection in organisational development, the term reflective practice has been widely used. According to Schön (1983) reflective practice is "the capacity to reflect on action so as to engage in a process of

continuous learning". Hildén and Tikkamäki (2013) consider reflective practice as the actual ways in which reflection is manifested through individual and collective action within the organisational realm. Reflective practices are tied to learning processes as people interact and effectively share ideas and opinions as well as when they discuss possible solutions (Høystrup, 2004). The ability to reflect seems to be amenable to development over time and with practice and in the presence of group work. Discussing challenging situations or problems with supervisors, mentors, colleagues and other with greater experience seems to be important for reflection. (Mann et al., 2009; Nakamura; Yorks, 2011) Actually, support for planning and reflective practice is essential. This can come true through freedom and possibility to reflect, to make plans, to keep meetings and to get feedback on actions and plans. (Høystrup, 2004)

According to Hildén and Tikkamäki (2013) there is a need to explicitly connect the processes at the levels of individual, group and organisation to holistically understand the reflection process. All three organisational levels are simultaneously present and must be acknowledged in any reflective practice.

2.2 Consequences of reflective practice

Reflection enhances learner awareness of their abilities and promotes independent learning. When learners reflect on their own performances, it promotes metacognitive awareness of performance and the processes behind it, and this awareness is held to be necessary for autonomous learning (c.f., Chen, 2008; Little, 2007). Reflection may also be a useful tool to empower people to initiate change without having that change imposed on them (Page; Meerabeau, 2000).

It has been widely acknowledged that, in its best, reflection can generate variety of outcomes, i.e. job satisfaction (Page; Meerabeau, 2000) and innovation (Somech, 2006; Lee, 2008). There are some examples in the current literature suggesting that team reflection is driver of both team innovation (Somech, 2006) and product innovation (Lee, 2008). According to Somech (2006), the process of team reflection serves as a vehicle through which the interaction of participative leadership style and functional heterogeneity enhances team innovation. Also reflective project leadership, meaning questioning one's own leader behaviour, can be a way for project leader to promote innovativeness (Ollila, 2000).

One criticism of reflective practice is its association with the production of individual knowledge (Clouder, 2000). When investigating consequences of reflective practice, previous research has concentrated on the consequences of individual or group reflection. Organisational level reflection and its consequences have not received attention. In this research, a more holistic view of reflective practice is adopted. Reflective practice can be realised at the levels of individual, group and organisation. Also Ukko et al. (2014) have stated that when reflective practices become more explicit and are targeted through different organisational levels, they will also better foster organisational outcomes.

3 Research methodology

This research utilises case study approach. The organisation that is the subject of this case study is located in southern Finland and operates in service sector. The case organisation consists of two units with a total of 70 workers. The case study was conducted in the organisation during years 2012-2014. The store was established in 2007, and has therefore had the potential for the development of reflective practice. The organisations compares very favorably to its competitors in terms of financial measures. An action oriented development project was conducted after which the outcomes of reflective practice were studied.

Both quantitative and qualitative methods of data collection are utilised in the study. First, a survey was conducted to trace the relationship between reflective practice and outcomes. Second, interviews were conducted to clarify how the mechanisms between reflective practice and outcomes operate.

3.1 Quantitative methods

The survey included 15 items to measure reflective practice (adopted from Hildén; Tikkamäki, 2013). The survey of reflective practice is presented in Table 1. Likert-type scale ranging from strongly disagree to strongly agree was adopted. A neutral response "neither disagree nor agree", was adopted to reduce uninformed responses.

Table 1. The survey for reflective practice.

Level of reflective practice	Items	Description	Alpha value
Reflective practice on individual level	5	Within intuiting and interpreting processes	0,779
Reflective practice on group level	5	Within interpreting and integrating processes	0,747
Reflective practice on organisational level	5	Within integrating and institutionalising processes	0,867

The survey included also 2 items to measure job satisfaction and 2 items to measure service performance (to reflect people-related outcomes of reflective practice). The items of job satisfaction were adopted from Valentine et al. (2011) and the items of service performance were adopted from Chuang and Liao (2010). For each of the 4 items of outcomes, the respondents were asked to indicate their opinion on a scale ranging from 1 (weak) to 4 (excellent). The surveys were sent to all employees of the organisation. This process resulted in a total of 49 responses, and the final response rate accounted for 70 per cent.

3.2 Qualitative methods

In the second part of the study, two group interviews were conducted in the case organisation. To achieve an overall view of the outcomes of reflective practice, representatives of all levels of organisation were interviewed. The interviewees included two top managers and four sales managers of different units and departments. The interviews focused on the same three levels of reflective practice that were utilised in the survey tool. The themes of the interviews included for example the following three issues. First, the prerequisites the reflective practices in work. Second, the factors related to reflective practices that have led to a good financial performance. Third, the mechanisms between reflective practices and outcomes. The questions of the interviews were decided in advance, but the discussions were informal and were facilitated using supporting questions and comments made by the researchers.

4 Results

4.1 What kind of reflection is required to attain desired outcomes

Table 2 presents the intercorrelations of the variables used in this study. It was found that all three levels of reflective practice had significant and positive correlations with job satisfaction. Correlations were not significant with the levels of reflective practice and service performance.

Table 2. Intercorrelations of the variables.

	Individual	Group	Organisation
Job satisfaction	,391 **	,486 ***	,646 ***
Service performance	-,203	-,077	,131

Sign. *** ≤ 0.001 , ** $0.001 < p \leq 0.01$

Based on analyses presented in Table 3, all three levels of reflective practice are significantly and positively connected to job satisfaction. The regression model studying the relationship between reflective practice on individual level and job satisfaction, is significant ($F = 4.854$). The adjusted R^2 is 0.106, meaning that 10.6 per cent of the variance in the dependent variable (job satisfaction) can be explained by individual level reflective practice. Also the regression model of the connection between reflective practice on group level and job satisfaction is significant ($F = 10.134$). 19.1 per cent of the variance in job satisfaction can be explained by group level reflective practice. The model of reflective practice on organisational level is also significant ($F = 32.214$), explaining 44.6 per cent of the variance of job satisfaction. Thus, the results indicate that reflective practice in all three levels tends to be positively related to job satisfaction, which is consistent with the predictions. On the other hand, the models investigating the connection between the three levels of reflective practice and service performance were not significant. It can be concluded from the regression results that all three levels of reflective practice are connected to people related outcomes. However, this applies only job satisfaction, but not service performance.

Table 3. Regression analysis results of the variables.

Independent variable	Reflective practice in		Different levels			
	Individual	Group	Organisation	Individual	Group	Organisation
	Beta	Beta	Beta	Beta	Beta	Beta
Job satisfaction	,325*	,437**	,668***			
Service performance				-,177	-,049	,221
F	4,854*	10,134**	32,214***	1,360	,108	2,362
R	,325	,437	,668	,177	,049	,221
R ²	,106	,191	,446	,031	,002	,049

Sign. *** ≤ 0.001, ** 0.001 < p ≤ 0.01, * 0.01 < p ≤ 0.05

4.2 Under what kind of circumstances reflection results desired outcomes

Based on the interviews the main prerequisites for the reflection are the right capabilities and resources for working. This means the understanding of a job description, having the appropriate skills for a job, as well as the organisational support, up to date tools and enough time for the tasks. This enables the proper focus, time and energy for the reflection and development in an individual level. This encourages breaking the organisational boundaries and discussing about the critical issues enabling at the same time changing the old routines. Further, it is essential to understand that these prerequisites need to be acknowledged also in group and organisational levels associated to the consultative culture and rewarding.

Also the results of the interviews strengthened the notion that reflective practice in an organisational level is crucial for attaining outcomes. Multiple issues were disclosed to foster a connection between reflective practices and the desired outcomes.

- The development subjects/themes that the reflective practices are intended to effect need to be limited to a few key themes and the connection to the performance is needed to be justify and discuss.
- A variety of reflective practices can be utilised to facilitate the selected themes.
- The reflection needs to be target-oriented at individual, group and organisational levels.
- Different organisational levels need their own measures and targets for the selected themes that the reflective practices are believed to have an effect.
- The measures and targets of different organisational levels need to be in line with each other.
- Work satisfaction, work motivation and commitment are important features for the reflective actions.
- The performance management systems have to be considered as a communication and social system to enable reflectiveness and both the individual and organisational learning.

In the case organisation there are a number of organisational level measures that need to be achieved. However, the common perception of the interviewees was that there can be only a couple of themes that the reflective practices can be linked. This means that the utilisation of reflective practices needs to be controlled to a certain point and sent the clear message for the employees what the contemporary development targets are. Otherwise there are too many issues that the employees need to focus, which may lead to unfinished development actions. The managers thus need to filter the right development targets and justify their connection to performance. In a case organisation the key development targets were outlined to be the following: 1) multi-skills (technical & product), 2) active sales approach and willingness to serve, 3) coaching skills, and 4) system skills. These development targets were aimed at result superior customer experience of the service. These development targets were measured in all three levels of reflective practice; individual, group and organisational levels. The connection of these targets to the financial performance was highlighted in all possible situations that allow reflection:

- The managers took a contact to all the employees in every day
 - Managing individuals

- The managers had conversations with all the employees (presence, meeting)
 - Increasing the meaning of work by the interest of managers
- The managers gave problems to solve for the employees (effectiveness)
 - Activating employees
- Regular small group meetings
 - Increasing the openness and facilitating the transmission of tacit knowledge

In all situations above, the development targets and/or measurement information were discussed and highlighted both formally and informally. Those situations were also perceived as good places for the reflection and learning, and considered as reflective practices.

As an example of reflective practices, the interviews resulted factors beyond the good financial performance in a case organisation. In comparison to other stores, the studied units made their own targets and decisions in addition to the efficiency targets that were launched by the chain control. These decisions were made together with the employees by allowing them to ideate the actions towards the desired targets. This allowed the possible to avoid the redundancies and reorganise to tasks, which was perceived as better work atmosphere and a motivational aspect that strengthened the commitment of the employees. This in turn promoted the thinking that the work is something that needs to be developed, which realised as an excellent service, a service culture and positive service experiences (customer satisfaction feedback). The sense about being as excellent sellers was strengthened through the reflective practices.

4.3 Summary

The following Table 4 provides a summary of the results of the quantitative and qualitative parts of the research.

Table 4. Summary of the results.

<i>Outcomes of reflective practice</i>		
	what kind	under what kind of circumstances
Reflective practice on individual level	+	Clear job description Appropriate skills for a job Organisational support Up to date tools Enough time for the tasks
Reflective practice on group level	++	Regular small group meetings Organisational support Up to date tools Enough time for the tasks
Reflective practice on organisational level	+++	Target-oriented Clear and limited key themes Connection to performance justified and discussed Assisted by performance measurement (Facilitating reflective practice as a communication and social system)

5 Conclusions

The paper contains a description of the internal (i.e. what kind of reflection is required to attain desired outcomes) and external factors (i.e. under what kind of circumstances reflection results desired outcomes) of reflective practices. The research contributes to the current research by clarifying the connection between reflective practice and outcomes. According to the results, reflective practices are connected to outcomes. When reflective practices become more explicit and are targeted through different organisational levels, they will better foster outcomes. The role of performance management and measurement is important in connecting the reflective practices with performance. There is a need to have measures in all organisational levels that enable comparison and reflection of the results, and showing the direction of the development at the same time. However, performance management must be consider as a communication and social system that allows the employees to discuss about learning and development process as a part of the results. As a practical contribution, the results of the research may help professionals begin to understand that leveraging reflective practices may aid an organisation in achieving its desired outcomes.

The results of this paper are based on case study in one company, which limits the generalisability of the findings. Thus, it is required to assess its robustness and validate its adequacy. Although the results supported many of the

propositions in prior literature, they also generated a number of open questions for further research. First, it is not clear whether, and to what extent, reflective practice affects financial outcomes (e.g., profitability). This should also be a subject of future studies. Second, it is worth examining more detailed in what types of impacts does it result when utilising reflective practice in other sectors. Third, it seems that the consequences of reflective practice are dependent on many factors, and it is thus important to study how reflective practice should be organised in different business areas and with different types of reflective processes.

Personal health systems technologies: Critical issues in service and system innovations

Doris Schartinger^c, Effie Amanatidou^b, Barbara Heller-Schuh^c, Susanne Giesecke^c, Ian Miles^b, Laura Pompo-Juarez^d, Özcan Saritas^b, Günter Schreier^a

Personal health system (PHS) technologies can enhance public and private health service delivery and provide new business opportunities in Europe and globally. Although plenty of PHS technology has already been developed and is potentially available to technically provide virtually everyone with an access to actively participate in personalized health care, research undertakings driven primarily by a technology push may fail as they do not situate PHS within the wider health and social care service systems they have to form a part of.

This paper captures various aspects of the scattered PHS research and innovation landscape and markets: We deployed several kinds of analyses (bibliometry, patents, SNA, stakeholder workshops and interviews). Our analyses aim at the identification of critical issues in the development and implementation of service systems around PHS technologies.

Introduction

Health care systems face the well-known challenges like rising costs, ageing population, increasing demand and shortage of health care professionals. Personal Health Systems (PHS) assist in the provision of continuous, quality controlled and personalised health services to empowered individuals. PHS provide a horizontal development area across a variety of patient groups, clinical specialties, technology fields and health services. Hence, the development of PHS requires and can mobilize the emergence of novel cross-disciplinary and -sectoral innovation partnerships. Building on the earlier definitions (Codagnone 2009) we have defined the PHS for the purposes of this work to consist of:

- Ambient, wearable and/or in-body devices, which acquire, monitor and communicate physiological and other health-related data
- Intelligent processing of the acquired information (data analytics), and coupling it with expert biomedical knowledge and in some cases, knowledge of social circumstances and living conditions
- Action based on the processing of acquired information, either applied to the individuals being monitored, or to health practice more generally, concerning information provision and/or more active engagement in anything from disease and disability prevention (for example through diet and lifestyle management) to diagnosis, treatment and rehabilitation.

Former research in the area of PHS has often given little account of special patterns of innovation in the PHS sector (Cunningham, C. et al. 2005), as the knowledge and experience about how to implement research results into concrete policy and strategy development in health is still in its infancy, particularly with regard to the specific needs of the European level.

We examined the PHS research, innovation and policy areas with the ultimate goal to attain a deeper understanding of mismatches between the potential of, and need for, PHS, and current policy and innovation initiatives and framework conditions (e.g. in terms of future technological opportunities and societal demands).

The main question of this paper is why PHS technologies do not diffuse readily despite the advantages they offer to a variety of actors in the health and social care system (HSC).

The next section introduces the conceptual approach this research is based on. Section 2 provides insight into the methods of investigation we applied. Section 3 shows the results, section 4 concludes.

1 Conceptual approach: service systems

Services are often thought of as essentially person-to-person interactions, where the service “product” is coproduced in the course of a service relationship. But we have become familiar with technology-to-person services, where instead of interacting with a member of staff of a service organisation, the client interacts with technology – often through online and mobile communications, sometimes through devices based at the premises of service organisations. These are often described as customer self-services, basic considerations are relevant in the area of PHS. For instance do examples of transactional self-services indicate that typically the service is provided within a “service system”, a concept that has gained considerable attraction in the last ten years. As well as the customer/client and the devices (and software) they are using, there is the service organisation which they are reaching through these interfaces, the personnel of this

organisation – some of whom they may interact with (front-office staff) and others who provide unseen support services (back-office staff). Information flows are a universal feature of such systems, in which the organisations (often using technologies) link people ; some other transformations may be effected by specialist people or technologies too (such as surgery and other medical interventions, physical transport, and classic personal services such as hairdressing and help with daily life).

The concept of Service Systems is one that has evolved quite rapidly, with some specialist versions (often coming from the information systems community) being rather elaborate and restrictive. One well-known definition introduces the notion of POTI – Service Systems are “dynamic configurations of resources (people, technologies, organisations and shared information) that can create and deliver value to customers, providers and other stakeholders” (IfM and IBM 2008: 18). Various authors, such as Karni and Kaner (2006) stress the service element of such systems, with customers/clients being much more important parts of the “P” in this framework (as compared to many other Sociotechnical systems) - they are participants who often provide important effort, information, and the like into the service design and provision. They may well place limits upon what the (formal) service provider can do, and set standards for what should be achieved. In many cases, health and social care included, the customers/clients may not be just the recipients of care, but also other stakeholders (such as family members) who may have their own demands upon, and inputs into, the service. Maglio (2010) sees these four key building blocks of service systems as varying on two dimensions: physical versus non-physical, possessing or not possessing rights. This characterises the various four resources of Service Systems as follows: People (physical, with rights); Technologies (physical, without rights); Organisations (non-physical, with rights); and Information (non-physical, without rights).

Karni and Kaner (2006) went beyond the POTI framework, to provide a description of the elements of service systems, noting the role of consumers/clients in these. It is not hard to see how such a framework could be elaborated much further with HSC examples at the fore. People – whether consumers or service suppliers, are complex agents, with highly diverse cognitive frameworks, values and attitudes, physical and emotional needs, and so on. This means that Service Systems can be complex to model and manage – but also that they may be resilient and innovative. People can be empowered to act in non-mechanical ways, responding to unexpected circumstances and collaborating to solve problems. They can be linked together through new information technologies.

The service itself is seen by Maglio and his colleagues as essentially involving a value proposition that is shared with and delivered to the consumer. When we think about the HSC case, we can see that there are many levels of granularity we might need to consider: the immediate service provided at one moment in response to a particular event (e.g. administration of a drug); the set of interactions immediately surrounding this specific service activity (e.g. the visit of the consumer to a surgery or the visit of a HSC professional to the person’s house); the broader treatment of the consumer in question over a series of interactions (“touchpoints”) with the service organisation as the “service pathway” or “service journey” is traversed by the consumer; or the overall service to the community that is provided by a particular HSC organisation (which may be a constellation of many of the specific services discussed above). The level of granularity that is chosen for analysis is rather a practical matter.

1.1 System innovation and transitions

Rotmans (2006) has described system innovations as “organization-transcending innovations that drastically alter the relationship between the companies, organizations and individuals involved in the system”. Such an ambitious type of innovation is required to address many of society’s grand challenges, including those associated with active independent living and the introduction of PHS. It is often related to the need for “transition management”, an approach that enables breaking out of various locked-in heritages and organisational routines; there are costs as well as benefits in such changes, and there are liable to be protracted learning processes and negotiations undertaken.

This sort of perspective is introduced to account for what are often seen as the barriers and obstacles to progress, often encountered when technically effective innovations are introduced into social systems (Schot and Geels 2008). The transitions approach argues for the need to take the interests and perspectives of numerous stakeholders into account (for example, hospital management may not benefit from the reduction of in-patient stays associated with the use of PHS – but hospitals are still an important part of the HSC chain). The approach suggests particular types of experimentation and development of strategic niche markets; of determining “boundary objects” through which stakeholders can gain their own appreciation of the innovation; and to develop transition pathways through which the new service system can be constructed.

The shift to PHS may be understood as a system transition in the sorts of terms established in transition management accounts, and which draw on ideas from the approaches developed in Social Construction of Technology and similar approaches to innovation studies²²⁴.

²²⁴ Broch (2011) provides an example of multilevel analysis of innovation around care services for the elderly.

2 Methodology

Figure 1 gives an overview of the different types of analysis that were applied in our research project. Our first approach was to get a comprehensive overview of the various kinds of PHS projects through web-based research. Apart from the purely technical research projects, PHS projects exist on different levels of aggregation and analysis:

- **Meta level PHS projects:** These are mainly research projects which have made considerable efforts in defining and demarcating the PHS area. They are academic projects which follow an analytical approach in their occupation with the field. They are mostly publicly financed and well documented.
- **Meso level PHS projects:** These projects combine an analytical approach with a strong focus towards application. Typically the project partners involved are from research and consulting organizations, also academic organisations on the one side, and on the other side are based on various case studies distributed over Europe where actors from private, public and third sectors are involved in implementing local personal health systems. These projects are well documented, especially on the single case level.
- **Micro level PHS projects:** These are national/regional local bottom-up projects, primarily focused on application. They are PHS cases according to the definition applied in this paper. Project partners develop out of their eco-systems and receive financing at some points in time. Typically projects and follow-ups develop over at least one decade, it is often difficult to demarcate the start and end of these undertakings. These projects exist in a wide variety on the national and local levels. They are not well documented, in most cases there does not even exist a project website.

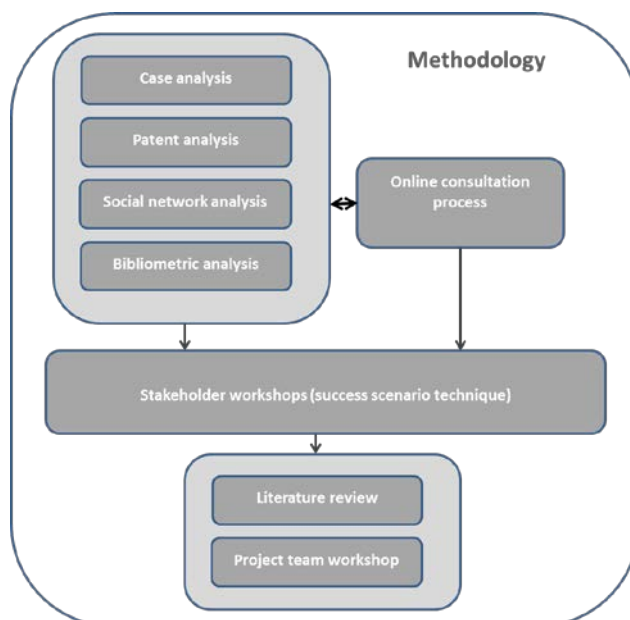

Figure 1. Methodologies applied in the course of the project.

Source: By the authors

At the start of our research we conducted several small analyses in order to get a first overview of the PHS area:

- A **bibliometric analysis** aimed to provide an understanding of present state and future trends on the PHS topic.
- An additional small study was conducted to analyse the **patents** in the field of PHS. Patent information was obtained from “Derwent Innovation Index” and “Patent Citation Index”.
- Tools and concepts of **Social network analysis (SNA)** were used in this study to visualize R&D collaboration networks and central actors in the area of PHS on the European level. A SNA perspective focuses not on the individual social actors, but on the broader interaction contexts within which the actors are embedded.

Furthermore, throughout the project, the project website has been deployed to establish an online platform for launching a structured and systematic **online consultation process** with multiple phases to generate and cluster visions on breakthrough innovations and societal demands.

Two stakeholder workshops were organized in order to explore the pathways for desirable future developments. The method applied was the success scenario technique, which is supported by background research, and organised in a detailed set of procedures. We took a Scenario to be a systematic vision of future possibilities. “Systematic” implied that the scenario had a good measure of internal consistency; and also that it covered developments in a fairly holistic way, it was not just an assembly of a few quantifiable parameters. “Future possibilities” covered two elements of scenarios, with specific studies often emphasising one or the other: Future Histories (outlining events or trend developments so as to describe an evolving, unfolding future), and Images of the Future (focused more on describing

the future state of affairs at a point in future time). "Vision" implies that we were articulating our account of the future into a coherent narrative, rather than just presenting lists of disconnected bullet points. Scenario workshops typically bring together a range of knowledgeable and experienced participants, usually stakeholders of one kind or another, within a structured framework of activities. They represent opportunities for structured strategic conversation. This means careful design. The scenarios should also possess greater legitimacy than those produced by a smaller expert group or visionary guru, at least if the workshop has drawn upon a reasonable range of participants.

Results from all previous analyses, the online consultation process and the stakeholder workshops were then again **cross-checked with existing literature** and discussed and rounded up in a **project team workshop**.

3 Results

The various strands of analysis resulted in a number of critical issues (for an overview and basic definitions see Figure 2) and related governance deficits, which can be the basis for possible policy designs to overcome the variety of thresholds in the adoption and diffusion processes of PHS technologies and the services around them.

3.1 Social acceptance

The general trend towards individualization in healthcare works in favour of a more widespread use of personal health service systems. Highly standardized mass-production of healthcare services may satisfy needs only in a limited number of cases, instead healthcare services have to be heterogeneous and personalised in order to reflect individual needs.

Stakeholders in interviews and discussions during the PHS project as well as the literature on PHS assume that the growing technology affinity works as a driver for PHS diffusion. The global dissemination of sophisticated technologies and mobile phones and consequently the use of these devices (internet applications, smart phones and application (app) development) is a strong trend, and this trend is reinforced as increasingly the senior part of the population will be familiar with advanced ICT as they will have used it already in their professional and private lives (The Capital Region of Denmark and Health Care Innovation Centre 2011: 6).

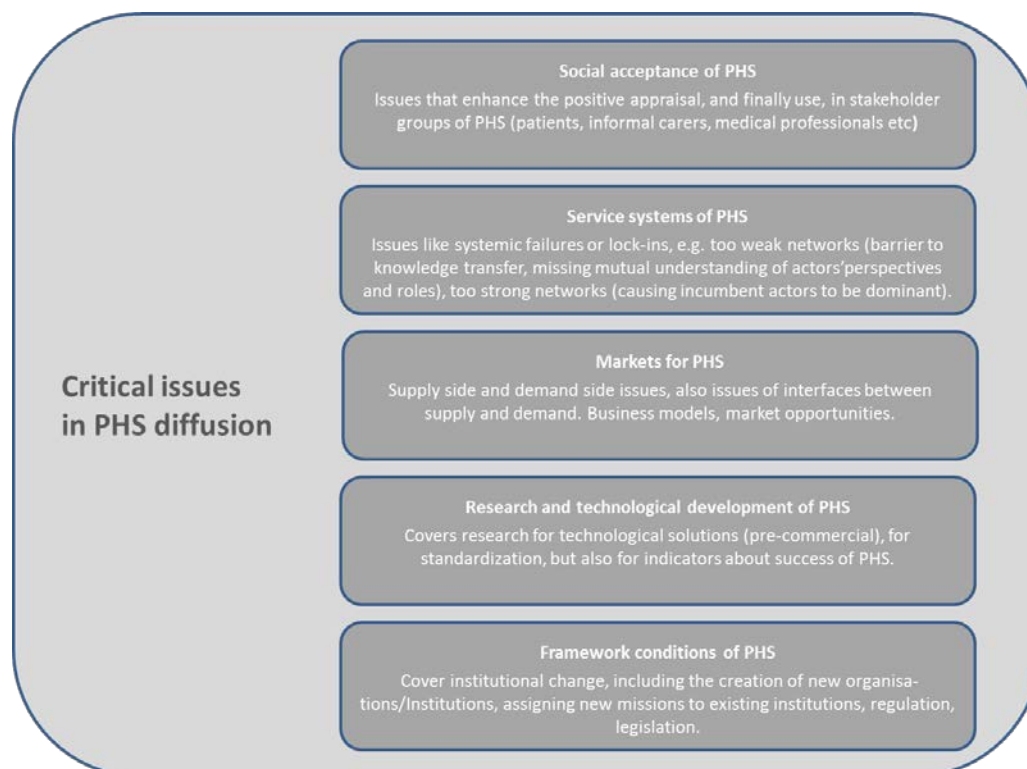

Figure 2. Critical issues in PHS diffusion.

Source: By the authors

At the same time technology skepticism acts as a barrier: Elderly individuals show uncertainties as to new technologies, e.g. they frequently commented that they are unable to use touchscreens. There is lack of trust in technical devices, as such can fail, either due to an operating error or due to a technical defect. Social acceptance of the technology includes also acceptance on behalf of professionals. Innovation-mindedness on a lower management level and a positive attitude of care professionals can be of vital importance for eHealth innovations. If there is a general fear of operating errors or hard to control alarms, this will slow down adoption rates of PH service systems (Gkaitatzi, Bekiaris et al. 2010; van der Plas and van Lieshout 2012). These attitudes depend on several factors, including: levels of digital literacy in society;

alleviation of public and professional concerns about confidentiality of health-related data; approaches to pricing of and payment for PHS use; and strategies concerning the "imposition" of PHS and/or changes in or even the withdrawal of the traditional services they may replace.

Implementation of PHS may entail that actors in health care have to leave their predefined and expected roles, which is always likely to cause resistance. Social insurance funds have a culture of financing health services once the damage is done -providing health care services to prevent further damages is increasingly the role that is expected from them, but has not always been. Physicians may be reluctant to engage in further services and training in order to empower patients and treat them as equals, as experts themselves, which may prevent the implementation and use of personal health system. A further obstacle is the primary mono-disease orientation of medical professionals. On the other hand, patients are often expected to show more commitment, participation and self-management, abandoning the traditional doctor-patient hierarchy.

A point of general concern in the workshops organized during the PHS foresight project was the issue of equity and equality of access to PHS. While it may be possible to seek to apply the equal distribution principle applied in hospitals - i.e. that all people should receive equal attention and treatment - this is less applicable when healthcare is "brought out into society". Inevitably there will be more advantaged social groups (RADs) who may be able to afford more sophisticated services than the less advantaged (REDs). Alongside this issue, which has a strong political component, there is also the possibility of PHS directly contributing to social inclusion, for example by reaching out to remote geographical locations that may have been less well served by centrally managed public health systems (Amanatidou, Miles et al. 2014).

Social acceptance of PHS is of course crucial for the widespread implementation and use of PHS. According to our discussions and analyses during the PHS Foresight workshops and interviews, social acceptance is hinged to several factors: Digital literacy of the population as a whole is vital, as well as concerns about confidentiality, and also the pricing of and payment for PHS use. What is often neglected in discussions about social acceptance is the fear of potential users concerning the "imposition" of PHS, which means that the introduction of new services relating to PHS technologies may cause a withdrawal of traditional services (too early) or the use of PHS technologies may be used as a condition in order to be able to receive other types of services (e.g. insurance), and in the extreme to punishing non-adopters.

Governance issues relating to social acceptance of PHS

- Equality of access: It is important not to increase social inequalities through enabling PHS services only for the more advantaged. This encourages also public financing of certain PHS services.
- Implementation of PHS in new services may naturally involve new roles for practitioners and patients, who may not always accept these easily. This may need matrons (on part of the nurses)/champions (on part of the patients) to advertise new roles.
- An increase of digital literacy is necessary for social acceptance, e.g. education programmes for professionals. This helps overcoming technology scepticism of medical professionals and management. Social acceptance of PHS also depends on digital literacy.
- More broadly, increasing health literacy of population is likely to support social acceptance of PHS, e.g. education about healthier life-style management.

3.2 A systems perspective: Ecosystems of PHS

A **wider systems approach** takes into account the need to design complex architectures relating together people (recipients of care, care-givers, and others), organisational structures and processes (that determine divisions of labour and responsibilities, flow of resources, etc.) and technologies (especially the information technologies, but also other health and social care-related devices and software).

One notion that has increasingly attracted attention in this context is the notion of **ecosystems**. Ecosystems consist of different stakeholders, each with its own goals, perspectives and challenges. Stakeholders on the one hand are part of the science and technology system, like firms, technology developers, the scientific community, and are on the other hand part of the health care delivery system, with actors public and private, practitioners and patients, as well as patients' organisations and relatives. All of these are heavily influenced by regulators, and the institutional framework in general.

In order to introduce innovative ideas in health care successfully, it is often vital to take account of the ecosystem. Especially integrated service solutions often depend on aligning various actors in the ecosystem, and are hinged to the **health care reimbursement and financing models**, regardless of the differences in EU countries' institutional set-ups of public health care. Basically, there are two models of reimbursement in public health care: fee for service (DRG based reimbursement, typical for hospitals), and fee per capita (number of patients treated, regardless of measures taken, typical for general practitioners). Both models for reimbursement applied in public health care seem to run against the implementation of personal health systems and integrated service solutions. Keeping patients out of hospital – through successful implementation of PHS – reduces the fee for services which hospitals receive, and hence their incentives to adopt PHS. On the contrary, general practitioners who receive fees per capita may be unwilling to accept extra (and maybe unpaid) work which is associated with the additional PHS services (Abadie, Codagnone et al. 2011).

These funding silos in residential and hospital care pose substantial difficulties to the introduction of PHS services, which often aim at linking the two or avoiding one for the other.

This puts the focus on introducing additional fees (for PHS services) or other types of remuneration and financing. But it also highlights some of the problems that a transition between service systems can involve – the **challenge of system innovation**. This typically requires more than just excellent technological solutions, but also a multi-stakeholder process of service system design. Another major barrier is the rigid division between health care practices and home care practices. This is typical for many countries and has severe consequences for the widespread introduction and adoption of PHS.

Governance issues relating to the systems perspective and PHS ecosystems

- Organisational and system innovations in public health care are not likely to come on their own, they would have to be a (political) priority. A combination of all different sources of finance and adaptation of current models of remuneration means a system innovation in many European countries.
- Public financing of PHS: Public reimbursement is often hinged to system innovations. Funding silos result in disincentives to invest: Investors cannot enjoy advantages of investment because resulting cost savings often appear in a different budget. Overcoming of funding silos will be necessary to also enable PPPs in funding and providing PHS health care services.

3.3 Markets for PHS

3.3.1 Markets for PHS: Data

Reliable data on the markets for personal health systems seem **hardly available**. There is a variety of market reports by market research companies and consultancy firms that share a common optimistic view on the markets, or particular market segments²²⁵, of PHS (e.g. Frost and Sullivan (Frost&Sullivan 2010) Arthur D. Little (Taga K. et al. 2011), Datamonitor (Datamonitor 2007), Deloitte (Ludwig 2009), and InMedica (Khandelwal 2010), cited from Baum and Abadie (2013: 15; 27; 44). However, these market **reports by market research companies tend to use a technology-driven market segmentation**, and often are methodologically unclear as to what units are actually counted in sales figures. Some of the reports note that ehealthcare investment has generally been proxied by ICT investment rather than healthcare investment (Baum and Abadie 2013: 8; 13). In general it may be noted that the perception of PHS markets by these market reports is skewed by a supply-side view.

3.3.2 Markets for PHS: characteristics of supply

There is an inherent difficulty in surveying the supply-side of the PHS market, as it is likely that **supply is also characterised by individuals or very small companies**. The smart phone approach has lowered significantly the market entrance barriers for new producers who can now rely on an existing smart phone and programme an app at nearly marginal price (Baum and Abadie 2013: 36). E.g. the mHealth supply is dominated by individuals or small companies, with 30% of mobile app developer companies being individuals and 34.3% being small companies (defined as having 2–9 employees) (IDC, cited in European Commission 2014: 7).

The above has to be considered when looking at existing surveys of the PHS supply side: The SIMPHS project surveyed of 115 companies, which supply PHS technologies and solutions and are active in Europe (but may originate elsewhere). Of these 115 PHS companies, almost three quarters (73 per cent) are large and medium-sized firms and around two thirds (66 per cent) are more than 5 years in business (Baum and Abadie 2013: 61). This points to the difficulties of identifying small-scale operations (e.g. individual programmers) and young firms which can be assumed to also populate the supply-side of the PHS markets, especially in the mHealth and fitness realms.

Still, **in terms of markets shares** it seems likely that the markets are **dominated by large incumbent champions** (Baum and Abadie 2013: 26). Purchasing decisions of public health care as customers may be powerful factors of success. However, if the customers are public health care providers, innovation and adoption cycles are extremely long (5–10 years). Firms need certain characteristics to endure such long phases of adoption which mostly incorporate extended processes of adaptation to customer needs. Furthermore, public health care providers as customers need reliable partners over years or decades, which make them more likely to ally with incumbent supply firms that have been successful for a long time already.

²²⁵ Market segments are the remote patient monitoring and treatment (RMT) market, the Telecare market, Telehealth market, mHealth market

Governance issues relating to market supply

Long adoption and innovation cycles in (public) health care have to be accounted for. Left to self-organising mechanisms, this favours large firms and publicly financed organisations and disadvantages SMEs, due to length of the process.

3.4 Markets for PHS: characteristics of demand

Considering all available material and qualitative research carried out in the present research project we assume that that the optimistic market prospects by market research and consultancy firms may fail to take into account the demand side, and in general, a wider systems view, which seems particularly complex considering health technologies like PHS. The wider systems approach we adopted in the PHS project led to the following considerations concerning the demand for PHS:

Who expresses demand? It seems to be a characteristic of demand in PHS markets that clients are on the one hand users and may on the other hand be patients, in which case the client may be a different kind of person/organisation. This depends of course on the type of PHS service solution, and accordingly, the literature on PHS markets is torn between the focus on users (ICT focus) and on patients (health focus). One of the main questions that come up is if demand for PHS will rise substantially on the basis of out-of-pocket money from users/patients or on the basis of private insurances who acquire additional services for their clients. Or if instead there will have to be clear financing and/or spending decisions on the part of public health care bodies. However, there seems to be only anecdotal evidence of PHS market players negotiating agreements with public health care bodies, and these were the results of longstanding, resource-consuming individual efforts (Abadie, Codagnone et al. 2011: 57).

One issue impacting on demand in the PHS area is lack of trust in individual applications. If there is a high number of applications existing, which one should the user/patient as an individual trust. And is it then necessarily the same that his physician trusts? This bears a danger of disoriented markets and consequently leads to the following question: **How then, does a general need for change and efficacy in health care translate into demand for single PHS products and services?** It may have been too readily assumed that the advantages the introduction of PHS solutions can have in terms of efficient and personalized care, rather directly initiate new service systems which channel demand for single PHS solutions.

One reason why this may not be the case is that it often involves a systemic innovation which needs a multi-stakeholder process and takes time (see above). Another reason may be that demand for PHS solutions follows patterns that we have learnt from the scarce research on age-based innovations, see for example Levsen and Herstatt (2014). Demand for age-based innovations shows distinct features depending on the obviousness of the *age-specialisation of the product or service* (Levsen and Herstatt 2014: 19ff). If products or services show a moderate to high age specialization, they face great challenges: **First**, moderate to high age specialization of products and services means they offer substantial benefits in sustaining or restoring individual autonomy, and as a consequence potential users are largely limited to those who have already experienced a markedly age-associated decline in individual autonomy. The main challenge here is that **users are hard to reach** due to their significantly reduced mobility or cognitive abilities. The search for information and processes of choice, which are cornerstones of purchasing decisions, are limited. Distribution via regular consumer channels may be significantly restricted, which results in costly and difficult sales processes. **Second**, if users do not suffer from advanced autonomy decline, products with moderate to high age specialization bear the **risk of stigmatization, or of being non-prestigious at the least**. **Third**, if others, like informal carers, take over the purchasing decision, these products and services bear the **risk of non-acceptance by the targeted users**.

On the other hand, if goods are similar to non-age-based products and services in appearance and functionality, i.e. designed to be used independently of age, this has two direct consequences: First, benefits in enhancing the potential users' autonomy are likely to be less. Therefore, these products and services target clients that still have a relatively high level of autonomy. Second, existing advertising and sales channels may be used, which offers ample possibilities for private business and corporate for-profit innovators.

Moreover, Levsen and Herstatt (2014: 21) point out that when innovative products and services with moderate to high age specialization and the associated challenges in demand also involve substantial and costly R&D efforts, these are of limited attractiveness for purely profit-seeking innovators. The **financial risks here are related to both, technical development and subsequent commercialisation**. Hence, innovators are mainly organisations that are wholly or partly financed by the public (e.g. research institutes, universities, private companies that receive public funding or tax breaks). Their motivation to innovate is guided by the societal challenge of an aging population instead of the aspiration of short-term profit.

Governance issues relating to market demand

- Lack of trust hampers technology transfer - there is a risk of disorientated markets: If there are a million applications out there, which one should a patient/user trust? And is it necessary the same their doctor trusts?
- The age-specialisation of innovations poses particular challenges in expression of demand and sales processes.

3.4.1 How to gain value? PHS and business models

Throughout all contacts and investigations during our project relating us to stakeholders in the PHS area, there has been a constant claim for new business models in the PHS area - the logic behind being that valuable market opportunities for PHS solutions pass because of ill-defined value propositions. This poses the important question of why new business models in the PHS area do not develop readily. **What prevents profit-seeking individuals/ organisations from defining new value propositions and exploiting technological opportunities if they seem obvious?**

Looking at the (small strand of) research on business models in health technologies we found that the **definition of value propositions may indeed be a fraught with difficulties**: Apart from the pharmaceutical industry where there are productive alliances with biotech spin-offs, there is little research on how business models and health technology evolve and interact with each other, one of the few exceptions being Lehoux, Daudelin et al. (2014). According to them, business model innovation is no smooth process and may take time as a number of interacting factors are relevant: The development of a business model results from a “sequential adaptation to new information and possibilities” and articulates an innovation’s value proposition and its market segment, the value chain, the revenue model, the value network and the competitive strategy (Chesbrough and Rosenbloom 2002: cited in Lehoux et al. 2014). It starts with a selection of one value proposition latent in the new technology, out of different latent value propositions in the same technology. The definition of the market segment to which the (health) technology will offer value also has important consequences. Patients and their relatives, physicians, nurses, health care managers, governments, employers and third-party payers are all concerned by the value of a health technology. There is an uneven distribution of benefits among them resulting from the new technology, and they may be unevenly willing to pay for these benefits. Managing the value chain for creating and distributing the value selected and offered involves tradeoffs and may interfere with the different interests by stakeholders (Lehoux, Daudelin et al. 2014: 1028). Hence, the development of a business models faces significant uncertainties regarding an innovation and its market, the uncertainty being even higher if it is a newly founded firm out of non-business spheres (private, academic). Uncertainty may seem less in a newly founded firm out of industrial sphere, but here it is often heavily influenced by the industry’s dominant logic (Sabatier, Craig-Kennard et al. 2012).

Owing to these uncertainties, fleshing out a business model often results in processes of synergistic readjustments or even drastic reconfigurations of the original business model (Lehoux, Daudelin et al. 2014).

PHS technologies and services are associated with **positive externalities**. Positive externalities are benefits which accrue to others than those who pay the price. In case of PHS, informal carers, patients, relatives, health professionals, hospital managers, social insurance, tax payers, employers – they all may benefit from the introduction of a PHS technology. Depending on the business model, however, they may not all be priced. In economic theory, this is one type of market failure, which justifies government action. If left to private producers, the product or service in focus is supplied too little. On the whole, this may contribute to markets in PHS not boosting. Private firms expect investment by public actors, who apart from financial restrictions also would have to engage in a process of system innovation in order to implement PHS service systems efficiently. Instead, public health care providers/ public actors expect investment by private firms. These mutual expectations may result in hesitant investment, or underinvestment on both parts.

Governance issues relating to business models

- More research efforts in business model innovation for health technologies will be necessary. New business models do not seem to develop readily. Slow diffusion is often attributed to lack of business models.
- Hesitant markets: Positive externalities of PHS products and services may result in sluggish investment, or even underinvestment.

3.4.2 New market opportunities

From the above theoretical issues and empirical evidence that we have from the various PHS Foresight investigations we derived four types of stylized markets, which are distinct in their characteristics of supply and demand, and are hence distinct in their particular drivers and barriers (see Table 1).

Table 1. Stylized markets in PHS.

Health status / age Financing	User / younger age	Patient / older age
Public	<p>Public PHS services for prevention</p> <ul style="list-style-type: none"> ▪ Most likely for users with risk factors ▪ In widespread diseases (public health) ▪ Requires health literacy on part of patients ▪ Requires widespread change in public health care systems which now mainly dedicate funding to therapeutic and palliative care, only minor amounts to preventive care ▪ Extremely long innovation cycles (adoption 5–10 years) 	<p>Public PHS services for therapeutic use</p> <ul style="list-style-type: none"> ▪ For the unhealthy, elderly, disabled, mentally declined ▪ Most likely in widespread diseases, (public health) ▪ Demand mediated by public actors, may be difficult in acceptance and require organizational/system innovation ▪ Long-term development and adaptation of technology ▪ Large firm involvement more likely because of long innovation cycles and resulting financial burdens by firms ▪ Extremely long innovation cycles (adoption 5–10 years)
Private	<p>Life-style PHS products/services</p> <ul style="list-style-type: none"> ▪ young, dynamic, stylish, cheap, web-based apps; ▪ demand difficult to foresee, may be viral in adoption and in dropout ▪ Very short innovation cycles ▪ supply by SMEs, or even individuals 	<p>PHS products/services for home care</p> <ul style="list-style-type: none"> ▪ Addressing the unhealthy, elderly, disabled, mentally declined ▪ Relevant users hard to reach through conventional advertising and communication channels ▪ Maybe demand through informal carers, also depends on acceptance by patients ▪ Costly and difficult sales processes ▪ Non-prestigious products ▪ Limited attractiveness for purely profit-seeking innovators

Source: By the authors.

On the basis of these stylized markets we derived **new market opportunities** from the various workshops, discussions and interviews during this research project, which may lead to additional market opportunities in PHS.

- ✓ Rooms for manouvre may be provided by the third sector, charities, NGOs, and private health insurances. They all may generate considerable demand apart from public health care providers and private customers/patients. These may also be services for specialized groups provided by the Third sector.
- ✓ Housing and real estate developers are potential customers as they equip their compounds increasingly with telecare systems and services which are complemented by safety and security services (see also Baum and Abadie 2013: 30).
- ✓ mHealth services can be part of corporate social responsibility (CSR) activities of companies. Firms purchase PHS solutions /services for their employees. CSR initiatives may also promote healthy lifestyles.
- ✓ Conventional and standardized, publicly funded PHS services for REDs; sophisticated, highly personalized services for RADs (e.g. financed through private insurances);
- ✓ Crucial for the self-organisation processes in complex systems is the spread of information about successful applications, but also about failures. The dissemination of good practice and modes of PHS applications through an easy-to access information portal was estimated leverage diffusion.
- ✓ On a more general level, public and public-private measures (in collaboration e.g. with food industry, sports clubs, etc.) are important to promote healthy lifestyles and wellness, as well as general measures to increase health literacy in the population.

Governance issues relating to new market opportunities

- Self-organisation in PHS realm is hampered due to insufficient information about successful applications. Disseminating good practice is vital, e.g. through a data base of PHS projects, containing evaluation. Coordination of PHS activities is important, also a follow-up of pilots.
- Knowledge sharing about applications and successful and unsuccessful PH service systems is seen as crucial. Successful projects as well as failed projects should be available in the data base, in order to enhance learning processes.
- Evidence base for PHS is seen as crucial: How did implementation of PHS technologies improve health outcomes? Reliable data on this are crucial for empirical evidence base and decisions based upon this.

3.5 PHS research, technology development and innovation (RTI)**3.5.1 Technologies and standards**

Today, plenty of technology is potentially available that can be utilized to overarch the “last mile”. But healthcare processes are complex since they potentially comprise of many system players in different organisations. One way of dealing with interfaces and complexity is promoting interoperability, i.e. the capability of systems to exchange data in a plug-and-play like fashion. Interoperability is generally thought to have at least three distinct levels, i.e.:

- Syntactic interoperability (e.g. Bluetooth, USB, ...)
- Semantic interoperability (IEEE X73, HL7 CDA, ...)
- Pragmatic interoperability.

Most standards widely in use today are concerned primarily with the syntactic layer, i.e. they deal with data communication protocols and message composition. Standards for the semantic layer, which are concerned with the “meaning” of the data, are much harder to use and less mature today. Such standards are essential though when it comes to making systems to understand each other, for example if one would like to apply decision support on a multi-modal data basis, taking into account information from clinical documents and data provided by patients directly via PHS.

To achieve pragmatic interoperability, finally, means to be able to orchestrate (the ICT infrastructures of) different healthcare providers into a continuous caring process, spanning the borders of healthcare organisations or even whole healthcare systems in case of cross-border healthcare.

It turns out that standards are often not enough to achieve higher levels of interoperability. This requires initiatives that guide the utilisation of standards in the context of well-defined use cases. Major interoperability initiatives in the field of healthcare are the “Integrating the Healthcare Enterprise” (IHE), and the “Continua Health Alliance” (CHA) initiatives. IHE is an initiative by healthcare professionals and industry to improve the way IT systems in healthcare share information. IHE promotes the coordinated use of established standards to address specific clinical need in support of optimal patient care. CHA’s mission is to “establish an ecosystem of interoperable personal connected health systems that empower individuals and organizations to better manage their health and wellness.” (Carroll, R. et al. 2007). Both organisations do not create standards themselves but promote clearly defined use cases in which existing standards are deployed.

Whereas IHE is primarily healthcare system focused and becomes relevant mostly in the last step while sending healthcare related data to EHR systems, CHA is taking care of systems and devices close to the patient. CHA’s mission is broader and includes not only telehealth in terms of remote monitoring of vital signs but includes systems more dedicated to wellness and fitness as well as to support elderly people in terms of independent living (Ambient Assisted Living) and also those being cared for at home (telecare). As such, CHA is of prime importance to the PHS domain. IHE, however, is also essential in cases where PHS systems are to be linked to healthcare professionals and are not confined just to the patients themselves, informal care or consumer oriented systems (“gadgets”).

As organisations promoting standards, it is of vital importance that these alliances be open and provide access to various types of firms and organisations in partnership, otherwise there could be a danger of limiting market entry. Market entry barriers are a major concern for competition policy.

During the PHS Foresight workshops certification and standardization of hardware, software, devices and systems were estimated as the main role of public policy to ensure quality of services and allow interoperability.

3.2.5 PHS indicators of success

Research on PHS is not only necessary for technologies and standards, but also to analyse the benefits of PHS applications. This is the basis for comparing PHS applications and also for communicating success. The empirical investigation of efficacy and effectiveness of PHS implementation in turn is the basis for the wider diffusion of these technologies and development of new services around these technological solutions. However, it needs further research on criteria for success and indicators, also in order to compare either different service solutions or before-and-after situations.

Questions guiding this kind of research are likely to be:

- What are criteria for the successful implementation of PHS in new services?
- How did PHS solutions impact on health and wellbeing in society?
- Who benefits and how can this be measured best?

Governance issues relating to RTI

- Further technological research concerning features of the technologies, interoperability, userfriendliness, reliability, robustness etc seems necessary.
- There are standards existing, however there is still an issue of interoperability at the seminactics level
- Standardization is seen as a main role of public policy. Open clubs are necessary in standard setting and interoperability issues, otherwise competition may be hampered.
- Research on indicators for benefits of PHS

3.6 Framework conditions

During the PHS workshops and interviews it was often stated that healthcare services will no longer be provided only by traditional caregivers like nurses or physicians. Many other qualifications have entered this sector changing also the social stratification. Policy makers are challenged to assess these developments and take the right decisions in order to maintain a critical workforce of service providers on the one hand and guarantee high quality healthcare for every member of our society on the other hand (see also MovingLife (2012)). With new technologies we will need technically skilled experts able to implement, run, and maintain the systems and at the same time train the users (patients, nurses, doctors, relatives, etc.) for daily usage of such systems. At the same token many care givers who originally are not affiliated with modern technologies are facing new challenges when needing to adapt to their daily usage. Different patients might need different technologies. In every home there might be another technological device to help the patient and in many cases it is actually the care giver and not the patient who is using the technical device. All players in the health sector will need to think how these additional skills can be achieved by the care givers and according to what mode they will need to be reimbursed.

How health care organizations deal with their accumulated digital information (big data) is crucial for the uptake of health ICTs. Sharing sensitive patient data in a large heterogeneous environment complemented by the use of web-based applications raises a number of privacy and security concerns. Case study evidence by OECD (2010) suggests that appropriate privacy protections must be integrated in the design of new health ICT systems from the beginning as these proved to be difficult to be introduced ex-post (OECD 2010: 66f).

According to EHTEL (2008: 6) the implementation of incident reporting procedures would also be welcome – similar to those employed by the pharmaceutical industry. Associated with such incident reporting should be the control that all eHealth information systems have been properly implemented and audit trails managed, which should be the subject of constant monitoring for incorrect operation or abuse. This is a standard for medical products on the basis of the Medical Device Directive (MDD), however apparently there are gaps with respect to service packages based on PHS technologies (Apps as medical products?).

Governance issues relating to framework conditions

- Legislation in different European countries has to be harmonized. This also concerns admission processes of PHS as medical products.
- Legal: Regulatory framing: Who is liable in case of malpractice?
- Ethical: Issues of privacy and data security of data are vital; certification, quality assurance. Apart from being ethical issues and provisions have to be integrated in the institutional framework, issues of privacy and data security also have consequences for social acceptance: Social acceptance also depends on concerns about confidentiality.
- Education and certification of emerging skills is important, e.g. concerning big data.

4 Discussion and conclusion

The concept of PHS is often collapsed into the specific information systems that are constructed to support new HSC services; or even into the specific devices that are employed within these information systems, such as wearable sensors to monitor health conditions and/or behaviour patterns. In this paper we argued that this fails to take into account the importance of a wider systems view, one which situates PHS within HSC service systems. Such a wider approach takes into account the need to design complex architectures relating together people (recipients of care, care-givers, and others), organisational structures and processes (that determine divisions of labour and responsibilities, flow of resources, etc.) and technologies (especially the information technologies, but also other HSC-related devices and

software). But it also highlights some of the problems that a transition between service systems can involve – the challenge of system innovation. This typically requires more than just excellent technological solutions, but also a multi-stakeholder process of service system design.

There is a widespread view that PHS can contribute to improved health outcomes as well as increasing the efficiency of health services. In principle these should be very substantial contributions, though early demonstrator studies are somewhat equivocal in displaying major gains (in particular, cost-savings). This reflects the fact that we are dealing with "wicked problems" involving numerous stakeholders, numerous specialised types of expertise, and indeed a multiplicity of specific problems aggregated together under the healthcare rubric. "Wicked problems" evolve, and PHS are emerging at a time when complex restructuring of health systems - and even of the notion of health itself - is being prompted by demographic, technological and social changes. PHS will be part of this restructuring, and the extent to which the potential gains of PHS are achieved will be affected by the form it takes. Substantial challenges are involved in shaping this restructuring so that it can rapidly capitalise on the potential of PHS, while supporting equity, patient empowerment and moves to more healthy lifestyles.

Numerous stakeholders will be involved in this process, which involves building what participants described as "a PHS Innovation eco-system". It will be important to recognise the very real interests of different stakeholders - for avoiding deterioration in health outcomes, for maintaining and extending the equity and social inclusion elements of health systems, for stimulating the development of innovative and effective health interventions and medical technologies, for maintaining professional competences and social status, for rewarding entrepreneurial behaviour, for protecting and for using personal data. At present the emergence and potential of PHS has not been widely debated beyond expert communities, and much wider processes of consultation, dialogue and vision-creation will be required to ensure that interests can be articulated and - where necessary - challenged in a transparent manner.

Meeting these challenges will require experimentation, dialogue, and monitoring of change. This study indicated some of the major aspects of change that will need to be addressed. They range from the creation of new business models and partnerships between organisations of different kind, through stimulating the acquisition of new skills and the emergence of new professions in health (and related) workforces, to putting regulatory frameworks into place that can allow for informed acceptance of evidence-based solutions. In all of these aspects of change, public attitudes will need to be taken into account, since citizens are crucial stakeholders in these processes. This will need to be the focus of much greater effort in the near future.

The present study is, hopefully, one step in the direction of adopting a holistic and combined approach in understanding PHS and establishing and sharing visions of the desirable futures that can be achieved with the use of PHS, and the problems that may be encountered and the ways in which these may be addressed, in the course of shaping these desirable futures.

5 Acknowledgement

The research leading to these results has received funding from the European Union's Seventh Framework Programme (FP7 2007-2013) under the project "Personal Health Systems Foresight", grant agreement no. 305801.

Software and Services in the Music Industry: A Proposition of a Data Description Standard

Frank Schumacher¹, Stephan Klingner², Ronny Gey², Michael Becker²

¹Institute for Applied Informatics (InfAI) e.V., ²University of Leipzig

This paper presents the results of the research project ART-e-FAKT²²⁶ that investigates the problems and shortcomings of today's music business. Forced into massive changes by the triumphal procession of the internet, business models, accompanying supporting software systems and standardised process models to deal with these changes are lacking. Therefore, we were investigating the most pestering problems and developed a solution from a technical point of view.

1 Introduction

The highly fragmented music industry is characterized by a multitude of small and independent actors operating on an increasingly competitive market. One important challenge is the variety of international distribution (streaming, downloads, physical etc.) and marketing channels (print, online, TV). This results in an increasingly complex market with a strong emphasis on the dissemination and intelligent use of data, for both, describing music and billing purposes. Software solutions supporting these tasks holistically are not available yet. Instead, either non-standardized software or no software at all is used. This results in the lack of interoperability due to heterogeneous data formats, discontinuity of media, inconsistencies between data of different actors and redundant work steps. Due to limited financial resources and diverging requirements of the multitude of actors, advancements like standardized data formats or consistent software support have not been achieved yet.

This paper proposes an ontology as an intermediate schema for business data of the music industry as a possible solution for these challenges. To determine the domain-specific requirements as foundation for an appropriate solution, the first step consisted of various workshops, interviews and a market analysis (Chapter 0). On that basis, the specifics of services in the creative industry are deduced (Chapter 0). The music business ontology (MBO) as the main result of these findings is presented in chapter 0. To show exemplarily the usefulness and applicability of the ontology, various use cases with corresponding tools are introduced in chapter 0.

2 Methodological approach

In order to develop a well-grounded understanding of the music industry, its players, its processes, its technologies in use and derived from that the potential need for services, we approached our field of study in an explorative manner. We conducted a qualitative research approach to ensure openness and objectivity towards our research environment. The entire study is presented in Gey et al. (2014). In the realm of this paper at hand, we focus on the relevant facts for the development of a better understanding towards service and technologies.

We conducted eight qualitative expert interviews from October 2013 to June 2014 based on the suggestions of Liebold and Trinczek (2009). We used a semi-structured questionnaire as a guideline. Our interviewees were employees and owners of labels and publishers, mostly small and medium sized companies (SMEs). Moreover, we could speak to representatives of collecting societies and the organization of independent music organizations (VUT – Verband unabhängiger Tonträgerunternehmen) in Germany. The interviews covered questions about their daily work processes, about their communication patterns, and about their network of clients and suppliers. Further, a loose collection of issues our interviewees are struggling with in their daily work was compiled. The interview questions were closed by topics about software tools and potential services the interviewees felt they were in need of. The material was transcribed using the Open Source transcription software *easytranscript*²²⁷. After interview transcription, we organized two workshops with the interviewees in order to discuss our first results. The workshops were split into a label specific and a publisher specific one. During the workshops, we could further analyse processes and established services in the music industry as well as the tools the actors in the industry are using. Interview transcriptions and the analyses of the workshop were then analysed with a content analysis approach (Krippendorff, 2004) and by using the qualitative data analysis software *Atlas.ti*²²⁸.

Our data analysis showed several results. As mentioned earlier, the complete list of results can be consulted in our study on the music industry (Gey et al., 2014). At this point, we focus on results relevant to the subject service and technology. Our analysis showed, first, labels and publishers nowadays have to deal with a growing amount of possible business models and revenue channels – distribution options of music are manifold: vinyl, tape, CD and various digital download and streaming channels. The growing diversity of distribution channels significantly increases the

²²⁶ <http://artefakt.uni-leipzig.de/start.html>

²²⁷ <http://e-werkzeug.eu/index.php/de/easytranscript>

²²⁸ <http://www.atlasti.com>

administration costs on the label or artist side. This is particularly challenging regarding the stagnating or even declining revenues on the label side. The major challenges for a successful endeavour in the music industry are the efficient handling of the distribution channels or to make purposeful decisions in favour of specific channels. Further, we estimate the aggregated market share of various digital distribution channels continues to increase in the future. Consequently, marketing expenses and efforts increase as well. Online marketing and social media complement and outpace conventional marketing channels. The rising administrative workload of labels and publishers is attended by a multitude of economically smaller distribution channels. This calls for approaches towards service-oriented technologies in order to facilitate the administrative workload.

Moreover, problems with technology were constantly reported throughout the interviews. Data redundancy, missing or error-prone standard software or interface incompatibilities were topics our interviewees are continuously confronted with. Several times, they articulated the need for holistic software covering more than only one specific aspect of the music business, for instance, a customized enterprise resource planning application for the music industry. In the moment, labels and publishers manually control, edit and transfer data from one system to another which signifies a high time consumption. Differing formats and manual data transfer result in a missing reuse of data and consequently increase the administrative burden of the actors in the music industry.

A continuously differentiating market, a lack of technological solutions and missing data standards in the realm of the music industry led us to several conclusions. First, data schemas have to be developed. Second, software tools based on these schemas to support the operational tasks of musicians, labels and publishers must be engineered. Third, based on the tools new services can emerge around these new software tools.

3 Service specifics of music industry

Several aspects that influence the development and provision of services could be identified by means of the conducted interviews. First of all, it was revealed that a wide variety of different partners is involved in a typical value chain of the music business. Though only a few global players dominate the music business, about a quarter of sales are generated in smaller companies²²⁹. Since these companies cannot afford to lose income, it is of special importance for them to make their everyday business as efficient and effective as possible.

Due to the widespread type of companies involved in the music business, up to now, no agreement on standards exists. The absence of standards is an increased challenge due to the growing IT usage. Thus, a multitude of different, company-specific software tools is used. These tools usually cannot communicate with each other due to missing standardised interfaces resulting in the fact that a lot of manual and redundant labour is required.

Most of the services that are accomplished as daily business from companies in the music business are characterised by a high degree of routine work, e.g. registration of a musical work and account costing bringing a new musical work into the market. According to the classification of Verma (2000), these services can be described as *Mass Services* with the following characteristics.

First, the services have a low degree of customer contact and only offer limited support for customisation. This is due to the fact that artists usually do not have any influence on how their labels work internally. Furthermore, most artists are not interested in these facts, since they need to concentrate on creating musical works. Though activities like registering new musical works today are responsible for a great amount of work, they can be easily supported using standardised software tools. In doing so, it is possible to shift the type of these services (*Mass Services*) to *Service Factories*. Besides only limited contact and customisation influence, service factories are also characterised by a low labour intensity (Verma, 2000).

Due to the growing economic pressure and decreasing profit margins, companies of the music industry need to provide their products on different distribution channels, e.g. downloading, streaming, licensing. By using standardised software tools, it is possible to serve all these distribution channels by the means of one single access point. In the music business, special emphasis should be placed on creativity and not on bureaucracy. Thus, simple solutions are necessary especially for artists for allowing them to concentrate on creating musical pieces.

As mentioned above, standardised software applications seem to promise the greatest benefits regarding enhancing performance and simplifying everyday business. However, due to the great diversity of involved companies, it might not be possible to enforce one single application with reasonable effort. Hence, this paper presents approaches for defining an open and interoperable format for communication between different companies. In doing so, every company can use specific software systems providing functionalities the company requires.

4 The music business ontology

Based on our conclusions we were looking for a technology, that would support the specifics of the music business in the best way. Our technology of choice became the Semantic Web (Berners-Lee et al., 2001), more precisely ontologies (Chandrasekaran, 1999). An ontology models a bordered part of reality as a formal representation of knowledge and concepts. It uses a shared vocabulary maintained by the W3C to denote types, properties and interrelationships of those concepts. Every object or instance of concept is represented by an URI that uniquely identifies it. Information about this

²²⁹ www.enrasys.de/schule/material/musik.pdf

object is stored as triples. Triples are in the form of subject, predicate and object. As with natural language, the predicate relates the subject to the object and describes the kind of the relation, see Figure 1. An extensive introduction to ontologies is beyond the scope of this paper so the interested reader is referred to e.g. Chandrasekaran et al (1999), Guarino (2004) or Smith and Welty (2001).

Figure 1. Triple.

An advantage of representing the data as triples is the higher flexibility of the data scheme in comparison with conventional relational databases. As a consequence, it is easy to add data not already designated by the schema and to extend the schema itself. Further, data based on different versions or extensions is still exchangeable. Another advantage is the possibility to link the data with existing data from peripheral contexts, like geographical information. Moreover, the use of ontologies is usually residing in an Open Source Community context, which will alleviate the propagation as an open format.

We started the development of the Music Business Ontology (MBO), which models the field from the perspective of companies from the music business. We researched existing formats dealing with music objects like the Music Ontology (Raimond 2008), or the community driven portal musicbrainz.org²³⁰, that collects data about music. Its structure to represent the data was incorporated in the development of the MBO. Further, we had a look at existing proprietary formats from the music business like Phononet²³¹, DDEX²³² and Gracenote²³³.

The main difference of the MBO to other formats from outside the music business that deal with musical objects is that the MBO focusses on those objects as products that can somehow be traded with, where the other formats focus on depicting information mainly about the music itself. This information is important to the MBO as well, but is arranged around the business objects. To these business objects, we relate information about their use in business transactions. For example, you can store information about the authors and their share of a work and the royalty statements of distributors and copyright societies.

As one specific goal, we want to propagate the MBO as an intermediate format. Approaches like the Global Repertoire Database have shown that the enforcement of a generally accepted data standard throughout the business is a bold task that even the bigger companies were unable to establish. With the use of the MBO as an intermediate format, there is no need to instantly restructure the whole IT-infrastructure of the entire music business. The only necessity is to develop converters that translate a given proprietary format to the MBO format and vice versa. This way, the data transport can be made more fluent and the daily business of the players in the music business is simplified. On top of that, a set of tools supporting very specific tasks can be established. As more and more software will support or be able to work with data in the MBO format and more tools are available, it will be easier to propagate the MBO as a quasi-standard. In Figure 2, we show the potential of the MBO as an intermediate format for the music business.

How the MBO can improve data transfer in the music business

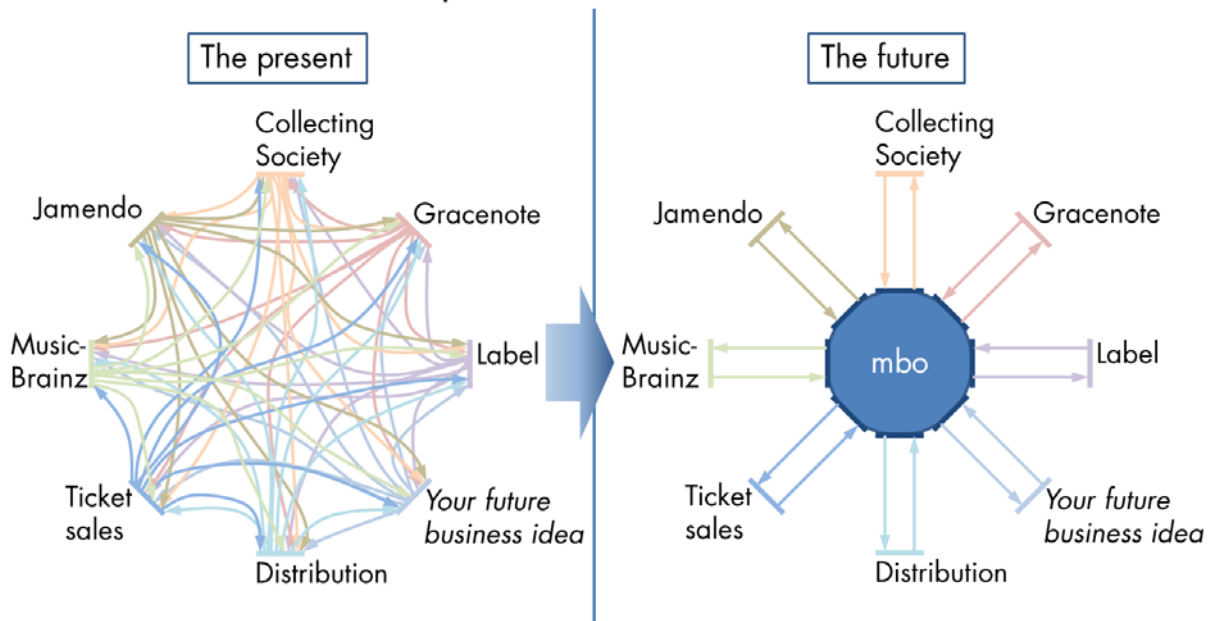

Figure 2. The MBO as intermediate format.

The first goal when developing the MBO was to represent the products which are dealt with in the music business. We identified *releases*, *recordings* and *musical works* as the main products that the music business is selling. We then created the relations between them. Then we added other crucial concepts relevant for the business processes like the performing *artist* and the *authors* of a *musical work*. This can be considered as the basis of the MBO. To this basis, we add business concepts like *royalty statement*, which describe the revenue the artists and labels get for sold products, the *creation involvement*, which describes the portion each author contributed to the creation of a musical work. Figure 3 describes the main concepts and relations between them of the MBO. As the development of the MBO continues, more business concepts like live performances or merchandise will be added in the future.

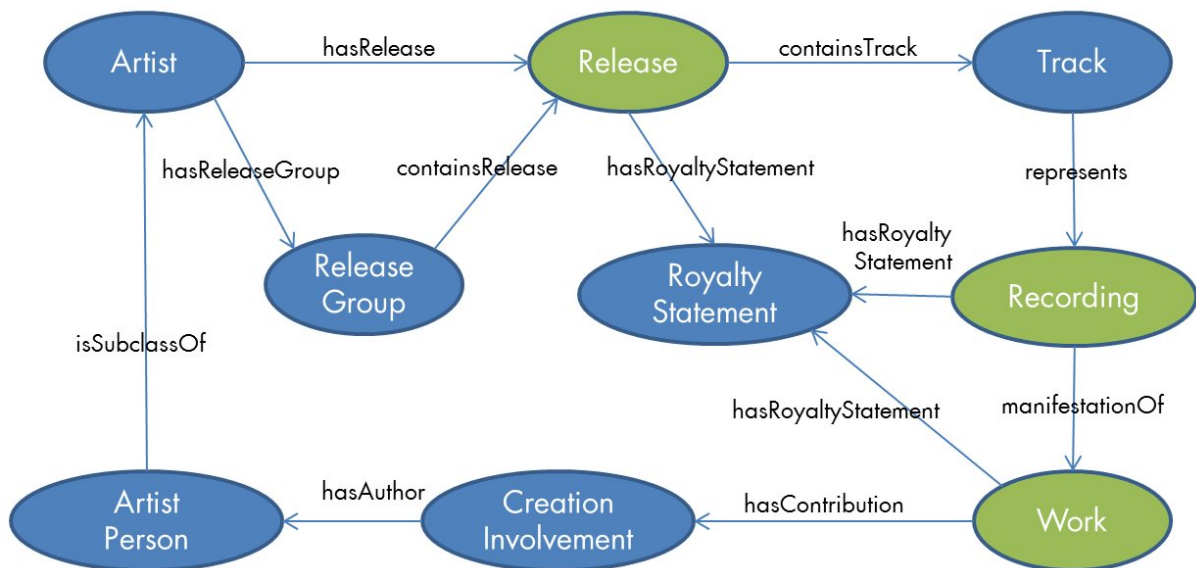

Figure 3. Main class structure of the mbo.

This structure serves as a schema for the information stored in the database. As mentioned before, the data is stored in the form of triples (subject, predicate and object) where subject and object resembles an occurrence of a concept and the predicate depicts the relation between those occurrences.

An example would be to store an artist and a release and the connection between both. The connection is that the artist created the release, which is resembled by the property *hasRelease*. At first we need to create an identifier (URI)

for the artist and add the name of the artist to the URI. For our example, we use the turtle notation²³⁴, which is commonly used when writing triples. First, the necessary namespaces are established using the following PREFIX identifiers.

```
PREFIX mbo: <http://creativeartefact.org/ontology/>
PREFIX res: <http://creativeartefact.org/resource/>
PREFIX rdfs: <http://www.w3.org/2000/01/rdf-schema#>
```

Using these prefixes, it is possible to define the respective artist:

```
res:myArtistURI a mbo:Artist.
res:myArtistURI rdfs:label "mollust"@de .
```

Then we create the URI for the release in an analogue way:

```
res:myReleaseURI a mbo:Release.
res:myReleaseURI rdfs:label "Schuld"@de .
```

Now we can create a relation between the two entities, thereby depicting, that the artist "mollust" has created the release "Schuld".

```
res:myArtistURI mbo:hasRelease res:myReleaseURI.
```

In this way, we can store any information about the objects, e.g. the members of a band or the tracks that are part of a release. The MBO offers a set of concepts and properties. In the future, we can add more of these, when the need arises or another, more specific ontology that is based on the MBO may be created. This way, we are very flexible regarding future changes and developments of the music business. If a new way of exploiting music is invented, the regarding concepts and properties can be simply added to the MBO.

5 Use cases

To spread the use of a schema like the MBO, it is mandatory to provide tools, that benefit from the MBO and that add a significant value to the daily work of the players of the music business. Moreover, the introduction of the new tools has to be as smooth as possible, requiring as less manual work as possible from the user side.

Nowadays, the data of the music business companies is spread over a wide range of formats, tables, stores, files etc. that can only be used by the application that stored it. The MBO enables the application to share the data amongst each other. This enables the user to reuse data already stored and avoid the need to manually re-enter this data for different applications or uses. Thereby redundancy and error-prone, multiple manual input of data is minimized.

Figure 4. Reflected data in the musicbrainz importer.

One Use Case is there for the import of already existing data into the new format. To showcase this, we developed a tool, which reads all information about an artist stored at the musicbrainz website. This includes information about the artist itself, about the releases he or she published including the recorded songs, about the songs the artist contributed to and so on. The user can choose which of this data to import and if he wants to change data in order to avoid the adoption of incorrect data. We used reflection to create a hierarchical structure of the data, so the user can choose or change each single data, see Figure 4. This data is then converted to triples and can be written to a Semantic Web data store like the freely available *Virtuoso* server²³⁵ using a standard sparql-endpoint. A sparql-endpoint is a standardised way to access triple stores, with the sql-like language sparql²³⁶. In this process, we query for other data that might be used for our new objects. For example, we query *dbpedia*²³⁷ for URIs about places. The artist ‘mollust’ from our example comes from Germany, so we store the URI for Germany from *dbpedia* <<http://dbpedia.org/resources/Germany>>. This way we can link the information about the origin of the band to information that is stored about Germany in any other knowledge base.

In the same manner, it is possible to create tools that import data from any other data source that stores information about artists and their works. Everybody can contribute writing converters and offer this service to players in the music business.

Another tool we want to present is a tool that checks the statements for live activities from the German copyright society GEMA for completeness. Nowadays, labels or publishers that want to check these statements have to compare the data from the GEMA manually with their records of reported live performances of their artists. This can take days or weeks, depending on the number of represented artists and their live activity. Many labels omit this check for the huge amount of effort it takes; thereby forgo a significant amount of revenues for them and their artists.

Figure 5. Checker for GEMA statements.

The tool, which is depicted in Figure 3, reads the statements sent from the GEMA and the data about the reported performances from the artists. Today, this data comes from excel sheets administered by the label or publishers, but within a fully supported MBO-environment, this data could be simply extracted from a triple store. As a side effect, the data from the GEMA can be converted to triples and stored in the company's triple store the same time, giving access to it to other tools or applications. For example, there could be a tool that calculates the artists' share of the statements.

With the available data, the tool checks the GEMA statement and creates lists for performances that are completely missing in the payoff, also giving suggestions for payoffs that might not be assigned due to data errors, as well as a list for incomplete playlists and performances accounted in the wrong category. These results can be written to a csv-format file, which can be sent as a complaint to the GEMA. The time saving is huge and it is less error-prone than a manual check.

There are other tools prototyped like the import of distributor statements and the export of those statements into an enterprise resource planning system. With a handful of tools that use the MBO as a shared database, the need to manually copy data in the music business, as it is nowadays, could be reduced significantly. This would result in better data quality and time saving on the administrative side, which can be invested in the promotion and support of the artists.

6 Conclusion

In this paper, we presented a pre-study with the aim of analyzing the demand of the music industry towards tools and services. As a basis for new services and tools, we developed the MBO - a first conceptual draft of a semantic data description standard. The MBO as an open and freely accessible framework is a lightweight yet powerful approach for structuring music business metadata. Structured metadata is an essential requirement for reliable, redundancy free and efficient interfaces and communication between software systems of the various players of the music industry.

Hence, the results of the paper were twofold. First, we highlighted actual problems in the music industry and outlined the specifics of the music industry collected in workshops and interviews. Based on these findings the MBO was developed as a possible solution. Correspondingly, the concepts and properties of the MBO were introduced.

As the resulting ontology can be used for future developments of integrated software and services, various tools addressing the specific challenges of the music industry were described in different use cases. In that way, the applicability of the MBO could be illustrated exemplarily.

The future work consists mainly of two major aspects. First, the development of the MBO has to be extended to a broader range of players of the music industry. Thereby, the concepts and properties of the MBO can be evaluated, completed and possibly corrected. Second, an institutional construct needs to be established to give the MBO a frame in form and content. This would allow for a controlled and directed development and professional dissemination of the ontology.

The presented results and principles are easily extendible to other parts of the creative industry like literature or film as they also deal with virtual assets and have to keep track of the use of their individual properties. The same issues and technology that arise from virtualization of the works can be observed for example at the book market, where eBooks compete with traditional hard- or softcover books. And the idea of streaming music also emerges in the eBook market²³⁸ nowadays.

Examining ingredients for new business models in public service networks

Laura Seppänen

Finnish Institute of Occupational Health

Abstract. *Both service-dominant logic and cultural-historical activity theory see the relation between services and customers as foundational. This paper proposes that different types of service-client relations in public services could be seen as relevant characteristics, or ingredients, for building efficient and effective business models for public service networks. Three types of relations are depicted, based on Vygoda's (2002) and author's previous studies: responsiveness, collaboration, and justice. Ordinary service situations in two public service networks, the social services for divorced families, and the supervised probationary freedom, are then empirically examined with these relation types.*

1 Introduction

The core of a service is the support provided by one party for another party's practices and processes. Public services refer to services that are created through the public policy process and regulated by government but which can be provided by a range of public, third and private organizations (Osborne; Strokosh, 2013, 32). The political and policy context is essential in public services which imply that the interests and outcome expectations are multiple and even contested. Moreover, the public service users can be, contrary to private ones, unwilling or coerced (Osborne; Strokosh, 2013, 37). Actual pressures of public services ask for renewal in the business models public service organizations (Osborne et al., 2014) and in the relation between public administration and citizens (Vigoda, 2002). This paper attempts to enrich the discussion about business models with an activity theoretical systemic approach, applied in the study of public service networks.

The aim of the paper is, first, to interpret and enrich the notion of a business model with an 'activity concept' in order to shed light to how business models are carried out in practice. Traditionally, business models are used for analysing and developing strategies. Here I take another perspective where ordinary service practices are analysed as manifesting strategic ingredients of business models. *Possibly, this may help in strengthening the theoretical underpinning of the business model concept.* The second aim to investigate a supposed change in public service - client relation, and articulate three types of relation – responsive, collaborative, and justice. Based on a recent study on public service networks (Seppänen et al., 2013; Seppänen et al. 2014), these types seem developmentally relevant. Third, the aim is to empirically analyse, how these types of client-service relations are acted out in ordinary situations of networking services. In order to develop services and service business models, practitioners and managers alike need to see how the logics or principles of different business models translate in practical services. Therefore, their contextual and practical identification and interpretation is important.

The investigation of ingredients of business models will be based on literature review and on findings from a recent study on service networks (Seppänen et al. 2014). The empirical material comes from two different service networks: supervised probationary freedom (SPF) from state-level criminal sanctions, and social services for divorced families (SSDF) from municipal social work that both deal with complex social and societal questions. The data consist of transcribed discussions from developmental workshops where the professionals of SPF and SSDF networks, correspondingly, discussed about the trajectories of their common clients.

The findings illustrate in what ways responsive, collaborative and justice relations between clients and public services, understood as ingredients designing business models, are contextualized and concretized in the ordinary service situations of public service networks. They also reveal some of the organizational, cultural and legal conditions that either enable or hinder working according to these types of relations. These findings may contribute to business model design also by helping to elaborate concepts and methods for learning with which service actors may better understand and develop the services.

With these aims, this paper is an attempt to make a contribution towards depicting ingredients for types of networked business models in public services in which the relation between service providers and service users is taken as the starting point. The paper is a preliminary investigation into these themes.

2 Business models, service-dominant logic and activity concepts of networks

2.1 What are business models?

Business models provide a set of generic level descriptors of how a firm organises itself to create and distribute value in a profitable manner (Baden-Fuller; Morgan, 2010, 157). It is defined in many ways, such as 'the set of which activities a firm performs, how it performs them, and when it performs them (Afuah, 2004), 'the logic of the firm, the way it operates and how it creates value for its stakeholders' (Casadesus; Ricart, 2010), and 'a system of interdependent

activities that transcends the focal firm and spans its boundaries' (Zott; Amit, 2010). It addresses the 'how' of providing customers and end-users with products and services (Mitchell; Cole ref. in Zott; Amit, 2010), or is a 'cross roads for competence and consumer needs' (Sabatier et al. 2010). Business models have a long history, ranging from guild and craft systems to mass production and further to new emerging technology- and network based or cost-innovative models.

Business models operate at an intermediate level between the real world of firms and theories of firm behaviour: they are neither so general that they fail to distinguish firms' main relevant differences, nor are they too particular and detailed (Baden-Fuller; Morgan, 2010, 159). There are no fixed number of business models as labelled boxes, because the characteristics, or ingredients, based on which business models are formed change over time as things in the world develop. Each different way of sorting may reveal different aspects to be of importance. Business models can be constructed both by observation and empirical work (taxonomy) and conceptual and theoretical work (typology), their combination yielding Weberian 'ideal types' such as business models. (Baden-Fuller; Morgan 2010, 159-161).

Conceptualizing the multi-level changes taking place at work is necessary for promoting well-being (Launis et al. 2007). Experiences from developmental interventions suggest that creating and using representations of activity theoretically informed business models may help practitioners better cope with the changes and fare better overall (Seppänen et al. 2009). This is especially important in contexts of complex inter-organizational collaborations. The aim of this paper is, both theoretically and empirically, to examine some ingredients, or characteristics, for conceptualizing business models. These ingredients may give means of expression for describing and building new business models.

2.2 Service-customer relation as fundamental in service dominant logic and activity concepts

2.2.1 Service-Dominant (SD) logic

S-D logic says that the application of competences (that is, the service) for the benefit of another party is the foundation of all economic exchange (Vargo; Lusch, 2008,4). It is basically about co-creation. It happens when people specialize through developing competences, and exchange services for services based on these specialized competences (Lusch; Vargo, 2006, 406-407). The marketplace, with its fundamentals of money, goods, organization and networks, mediate this basic exchange. Simultaneously, this mediation blurs, or masks, the fundamental principle of service exchange (Lusch; Vargo, 2006, 410), which in turn gives rise to division of labour, organizations, and learning. Not only services, but also values, dialogue, processes and networks are co-created. S-D logic views marketing as the process in society and organizations that facilitates voluntary exchange through collaborative relationships that create reciprocal value through the application of complementary resources (Lusch; Vargo, 2006, 408).

For the interest of this paper, three points are interesting in S-D-logic. The first of them is the the exchange of services as the foundation of economic activities. We will come back to this later. Second, it sees that customers are always co-creators of value. Value is created in customers' processes as value-in-use, which implies that service is inherently customer-oriented: it is a a mediating factor in the process of value creation. Third, value is experientially (phenomenologically) determined by the beneficiary of the service, which emphasizes the *relational* nature of services.

2.2.2 Activity concepts and networks

Activity concepts refer to a notion, idea or logic according to which a certain entirety is built, functions and develops (Virkkunen et al., 2010). Two basic dimensions are essential in an activity concept: the relation of exchange between producer and user, and the relation between use value and exchange value (Virkkunen 2007). In all productive activities in the market economy there is a fundamental inner contradiction between the use value of the product or service and its exchange value in the markets (Virkkunen 2007). Use value means the benefit for the service users in their activities. Exchange value means the general value, mostly understood as money and price.

(Virkkunen et. Al, 2010, 45)

Activity concepts are materialized into ‘recurring patterns of purposeful activity that are distributed over people and technologies in work practice’ (Hall & Horn, 2012, p. 241). Smagorinsky (2012) proposes a notion of a practical concept, consisting of fragmented understandings that are inherently compromised by attention to contradictory means of mediation in their contexts. We need to pay attention to the practicality of the activity concepts, that is, ‘a good enough’ concept, responding sufficiently to many needs. Both production and use are human activities which are, crucially, processes of transforming an object into an outcome. Analytically it is possible (and perhaps necessary) to distinguish two sides or levels of the object in public services: the societal needs (referring to service practitioners’ understandings of the general overall goal) and the concrete, particular client.

Business models and activity concepts share an interest in the logics or principles of how value is created. Both of them may function as models, by providing means for description and classification, by operating as sites for research, and by acting as recipes for managers and practitioners (Baden-Fuller; Morgan, 2010, 156). The notion of an activity concept may enrich insights into business models in at least three ways:

1) An activity concept always *exists in the practice of work*, regardless of its degree of explicitness or articulation. In this sense, it differs from an organization concept, defined by Heusinkveld et al. (2013, p 9), which is a more or less coherent prescriptive vision, that includes guidelines for managers and other organizational members regarding how to deal with specific organizational issues, and is known by a particular label. As activity concepts ‘live’ within work and collaboration, they are never totally fixed and stable and thus, rather than trying to make a clear definition, characterizing phenomena is more convenient than trying to completely describe it (Marková 2000).

2) Activity concepts focus on and depict qualitative changes in forms of work activities and include activity’s societal purpose. One point of reference in the examination of activity concepts involves historical types of work such as craft, or standardized or flexible mass production (Victor & Boynton 1998; Pihlaja 2005; Launis & Pihlaja 2007).

3) The process of analysis of activity concepts, mediated by a developmental methodology in activity theoretical research, often includes, in one way or another, the perspective and intentionality of the actors/subjects. This has at least two implications. First, universal concepts of high level of abstraction, such as historical types of work or activity concepts created by researchers only, are not necessarily the best ones in understanding and promoting change in the practices of a particular domain (Seppänen 2004, 40). Second, the notion of an activity concept has potential for understanding meaningfulness and well-being at work, and in particular, their relation to changes at work. Talking about, and in particular experimenting with activity concept reveals and may articulate an activity’s quality which in turn has implications for reflection and learning on the one hand, and for branding and commodification on the other. An activity concepts’s capability to reveal new qualities of work activities has resemblance to the notion of a transpersonal dimension of activity (Clot & Kostulski 2011, 685), which concerns the historical memory of the profession that contribute to making the work “doable”.

Based on understanding of objects in cultural-historical activity theory (Engeström, 1987), it is their many-sidedness, complexity and multi-faceted nature that makes a need for *network collaboration*, because different service activities or functional units, as a result of specialization and division of tasks, are unable alone to deal with such objects (Seppänen et al., 2012). Service networks make new relationships and new configurations of elements possible and in this way increase positional value (Norman 2001, p 114). It is expected that network collaboration is increasingly part of any work in the future (Alasoini et al., 2012). Network concepts are more complex than activity concepts in terms of mediations, social relations and objects. So far, there is very little research done on network concepts. The networks increases the complexity of tasks of individual practitioners but is also a potential for expanding the object and thus increasing motivation and better seeing developmental possibilities. The notion of an ‘offering’ (Norman 2001, 118) also makes a need to depict activity concepts or business models for service networks. The activity system perspective to business models (Zott; Amit, 2010), and open business models using the growing division of innovation

labor (Chesbrough, 2006, 2), come close to the idea of a service network of this paper. Public services need to be outward-focused on external effectiveness for service users and on creating sustainable public value for local communities. Sustainable public services are dependent upon building long-term relationships across service systems rather than seeking short-term discrete and transactional value. (Osborne et al. 2014, 170).

S-D logic brings not only the customer to the process of co-creation of value, but also the organization's partners throughout the value creation network. Lusch; Vargo, 2006, 408). This is because S-D logic views knowledge as the fundamental source of competitive advantage, and collaboration is needed to take into use the knowledge that is dispersed in the marketing system and society.

2.2.3 Types of public service-client -relations

If, as suggested by both S-D-logic and activity theory, the relation between service providers and service users is crucial in order to understand and develop services' business models, we need a typology for empirically investigating this relation in service. Therefore, we turn to notions of responsiveness and collaboration as elaborated by Vigoda (2002).

Vigoda (2002) depicts an evolutionary continuum of public administration-citizen interaction. While the question of public services and service users is narrower than this, the proposed historical phases might anyway help us understand the nature of co-production or co-creation between public services and users. The oldest type of public administration-citizen-interaction is *coercive* which existed until mid-or late eighteenth century. Services were limited and citizens had very little power and control over services. The installation of the voter electoral system changed the interaction into *delegation*: citizens were given an option of voice, but only through representatives and intervals of time. Simple delegation type of relationship between rulers and citizens was not enough, which gave a need for change efforts through the NPM (new Public Management) movement (Vigoda 2002, 532).

A major belief among NPM advocates views citizens as clients and customers of the public sector. A major goal of government is to show high responsiveness to the public by satisfying their demands. *Responsiveness* as a type of interaction (or relation), in short, means that public service organizations and their actors respond to needs and exigencies of their clients and customers. Responsiveness follows a market logic and, basically, is promoted by New Public Management. According to Vigoda 2002, there are two approaches for understanding public administration's responsiveness. First, it may be viewed as a necessary evil that contradicts the value of public service professionalism and runs counter to public interests required by the society and policy. The second approach to responsiveness suggests that democracy requires administrators who are responsive to popular will, and only by creating a market-driven environment can public services adopt necessary reforms to improve their performance, effectiveness and efficiency (Vigoda, 2002, 528). A responsive professional is reactive, sympathetic, sensitive, and capable of feeling customers' needs.

Moreover, Vigoda (2002) distinguishes *collaboration* (partnership) from *responsiveness* in the relationship between citizens and the public sector. Collaboration is necessary because, according to Vigoda, responsiveness, with its terms *customer* or *client*, gives only passive role to service users and does not encourage their participation or contribution to society or to citizenry actions. The actual evolution of public administration-citizen interaction should go towards rational and applicable levels of integration among all social players, and collaboration is a way to do that (Vigoda, 2002, 535). Contrary to responsiveness, the nature of collaboration is negotiation, participation, cooperation, free and unlimited flow of information, innovation, agreements based on compromises and mutual understanding, and a more equitable distribution of power and resources. This goes counter to Weberian legacy of clear hierarchical order, which is still strong in public services (Vigoda 2002, 529). For service users, the collaborative approach asks for extensive responsibilities and involvement on the part of the public (Vigoda, 2002, 535).

My understanding of the collaborative type of relation between service providers and users is informed by relational agency as theorized by Anne Edwards. Put simply, it means that the resources or perspectives that others bring to problems can enhance understandings and can enrich service responses (Edwards, 2010, 13). Therefore, the relational turn

... "brings with it demands for new configurations of practices which require organizations to focus more on revealing the complexity of problems and on supporting and developing the expertise of practitioners, than offering either the comfort of routines or the tight prescriptions of targets" (Edwards, 2010, 13).

Osborne et al. (2014, 170) propose that the key resource and route to effectiveness for public service organizations is knowledge (both of professionals and of service users) and the key tools for its transformation into successful public services are relational rather than discrete and transactional comes. Relational agency (Edwards 2010) may well be a necessary mechanism to enhance knowledge-based effectiveness in public services.

The distinction between responsiveness and collaboration fits very well to our investigations of client understanding public service networks (Seppänen et al., 2013, Seppänen et al., 2014). However, they are not enough because also bureaucratic hierarchy and juridical issues seem to affect a lot the relation between public services and users. Juridical issues in public services is typical to Nordic welfare states where the role of public control/regulation is considerable. Moreover, social services are seen to become increasingly judicialized, which

means that issues or phenomena become juridical, are increasingly controlled by regulations or become objects for judicial settlement. It also has positive effects, such as transparency through registering and justification, and by protecting clients' rights. But mostly, judicialization is considered negative because the emphasis on juridical concerns may pass issues of ethics, care and interaction. A legalistic social work does not necessarily provide help for families or protection for children. Moreover, it may lead to a situation where societal problems are argued about as judicial. (Sinko, 2004).

The similarity of S-D logic and activity theory is that the microlevel activities in the client-service relation is the fundamental base of services, and changing this relation implies transforming the division of labor and organization through strategies. Also Osborne et al. (2014, 170) suggest that co-production is at the heart of public service delivery and is the source both of effective performance and of innovation in public services. They both, as I understand, support bottom-up approach to renewing business models.

As S-D logic and activity theory suggest, the exchange relation between service provider and the customer/service user is foundational, this has at least two implications. First, this relation, in all its aspects, is also central to business models of services. Second, then we need a typology with which we can distinguish between different types of exchange relations. The conceptualization of Vigoda (2002) above seems promising for this purpose. Before empirically testing these types, we take a look at the public service networks.

3 Supervised probationary freedom (SPF) and Social services for divorced families (SSDF)

The interest of this paper is the operational and dynamic client-service relation in two public service networks. Social services for divorced families with children (SSDF) have lately emerged as activities that should rather be developed together in their entirety, than each of them separately. The purpose of these services are to increase families' well-being and to protect the children. The central partners in SSDF are family counseling, family law issues and child protection. When parents divorce, often municipal family law issues helps parents make and verifies an agreement between parents on the different matters concerning the children. If parents are not able to agree, the issues are solved in the magistrate's court. Child protection gets involved when concern for the child arises, caused by, for example difficulties in care and upbringing, violence, drug use or other crises. Divorced families can turn to family counseling, which helps in questions related to the upbringing of children and adolescents, and in problematic or crisis family situations. Family counseling collaborates closely with child psychiatry clinics. These three specialized social services combine, in different ways, the legal and aid systems: Family law issues often performs assignments for the magistrate's court in legal issues, while family counseling is voluntary. Child protection works on both voluntary and legal levels.

The SSDF network of this study deals particularly the services around prolonged divorce cases where the families use many services. Often, the customers experience these services as fragmented (Schaupp et al., 2013). The divorced parents have ownership to their matters, except when they (voluntarily) take their case to magistrate's court.

Supervised probationary freedom (SPF) means that, if certain prerequisites are met, prisoners are released from prison up to six months prior to the time they would otherwise have been released. One of the main objectives of SPF, which became law in 2006, is to decrease the use of prisons by emphasizing sanctions that both cost less and are more effective in preventing crimes. During SPF, prisoners are required to take part in activities such as working, studying or rehabilitation. Based on the aims designed individually for each prisoner at the start of the sentence, the content of SPF, written in an enforcement plan, is drawn up so that it promotes these aims. SPF may help a person return to normal society by softening the boundary between life inside and outside prison.

The way in which SPF is designed enables prisoners' participation in it. Participation is directional because SPF is a purposeful and normative project that aims to promote prisoners' redirection towards a crimeless and normal life in society. The degree of prisoners' participation and agency vary and depend on the interactions during the design and implementation of SPF.

The SPF network is established and institutionalized as a network. The SSDF network is not institutionalized, and mostly functions occasionally, although its separate functions are institutionalized. Both SSDF and SPF services are free of charge for clients. The funding (exchange value) for SSDF is municipal. In SPF, Criminal Sanctions Agency is funded by government, but a municipality (where the prisoner comes from) has to pay certain services during SPF such as housing, education or rehabilitation. These services can be provided by public, private, or third sector organizations. From the point of the crucial relation between use and exchange values, the ways and indicators of how these services are evaluated are very significant and need to be considered in designing business models. Table 1 condenses the main features of SPF and SSDF customers and networks.

Table 1. Features of SPF and SSDF networks.

Feature	SPF	SSDF
Client	Selected prisoners at the end of their prison sentence.	Divorced families with children who have long-term relations with various social and legal services.
Clients' agency	Conditioned by the prison and SPF rules. Prisoners participate in SPF design and their agency increases stepwise in the sentence trajectory.	Parents have ownership of their own matters throughout the trajectory, except when they take a matter to court.
Use value for clients	Helping return to society from the prison, enhancing conditions for crimeless life.	Advice, help and support during divorces.
Use value for society	Overall security, diminishing crimes.	Overall well-being of families, children's rights.
Funding (Exchange value)	Mainly state funded. Municipalities are responsible for funding services outside Criminal Sanctions Agency (CSA) during SPF.	Funded by municipalities.
Service actors in the network	In Criminal Sanctions Agency: Prisons, assessment center, surveillance patrols controlling during SPF and community sanctions offices. Outside CSA: municipal social care, workplaces, rehabilitation centers, residential or other NGOs, schools, police etc.	In municipal social services: Family legal issues, child protection and family counseling. Child psychiatry clinics, magistrate's courts, schools, health care, police etc.
Network features	More hierarchical (CSA is responsible).	Flatter (no clear hierarchy between the three municipal social services).

While SPF as part of criminal sanctions is coercive, prisoners still can be called clients because the strategic goal of Criminal Sanctions Agency, enhancing returning to crimeless life, is not possible in the long term without prisoners' own motivation and agency. Also SSDF has some coercive elements.

4 Data and methods: multi-voiced workshop discussions

The data consist of two 3-hour workshop meetings, one from SSDF, one from SPF, in which data regarding the processes of clients, a prisoner 'Steve' and a family T, were jointly discussed and analysed among professionals of these services. Part of the participants had been involved in the services of these clients. This kind of data offers an intermediary perspective to client-service relations in between face-to-face interaction and strategic level. First, 127 microepisodes including professionals' talk about both customers' matters and network relations were identified. The main focus of analysis was the customer-service activities and events taking place outside the meeting. Originally the microepisodes were identified and analysed for the purpose of examining *mismatches* between services and clients (Seppänen, Cerf & Toiviainen, 2013 where data and method are described more in detail: see also Seppänen; Kloetzer, in press).

Here I analyze the relational categories of responsiveness, collaboration and justice in these microepisodes with a following method. First, only those episodes showing practical service situations were selected (consisting of 63% in SPF, and 60% in SSDF, of the total episode data). Episodes about abstract features or future desires were thus omitted. Each episode was named according to the situation it was about - one single situation could be discussed in many episodes. After this, episodes were interpreted and categorized into responsive, collaborative or justice type of relation between service providers and clients.

The situations are complex and interpreting the type of relation in them is not easy. The data is from a discussion where multiple networking service providers together reflect on the service trajectories of their common clients and thus there are many perspectives and voices concerning one situation. In the data the situations are often expressed narratively. A perspective, or voice, towards a situation has analogy with a story: a situation is one and shared, but there can be many stories about it. The relational categorization, therefore, is based on both content analysis and the way how professionals talk about the situations. One situation may include many types of relations. 22 and 17 situations were found in SPF and SSDF data correspondingly.

Situation as a unit of analysis helps us examine the complex context in the practical, ordinary service activities. As a result of this complexity, it was necessary to form new categories of 'unresponsiveness' and 'anti-collaboration'. The most interesting is the contextual quality of the relation types. I introduce the findings below.

5 Responsive, collaborative and justice relations in SSDF and SPF networks

Tables 2 and 3 show the situations according to the relational categories.

Table 2. Situations in social services for divorced families manifesting different kinds of service-client -relations.

Relation types	Situations
Responsive relation	5 Examining alternatives for custody from clients' own social networks 9 Obtaining information and support from the network 11 Making way and space between the child and parents' quarrel 13 Getting a reliable adult contact for the child 16 Leading the service network
Unresponsive relation	1 Rules of getting psychiatric therapy to a child 6 A social worker's visit to a child's home
Collaborative relation	3 A network meeting with parents 5 Discussing alternatives with clients' own social networks
Anticollabo-rative relation	17 A school is involved in the family's quarrel 3 A network meeting with parents
Justice relation	1 Rules of getting psychiatric therapy to a child 7 Hearing of the 12-year-old's opinion 8 Parents' agreement about meeting the child does not come true 9 Parents' fight yields in a park a child welfare announcement 10 Hard measures are needed for maintaining child-father contacts

A relation of a situation is *responsive* is when service providers, in one way or another, make an effort to help a client. More specifically, a service shows responsiveness when clients' particularities and own situations are considered. For instance, professionals in SSDF may have experimented with new methods of working and learned something from them (Table 2, situations 5,11 and 13). Or, as expressed in many SPF situations of this category, responsiveness is already embedded in the concept and instructions for designing supervised probationary freedom. Besides immediate relations, I have classified as responsive also 'back office' type of operations if they aim at improving service quality for clients. Quantitatively, this category is common in both service networks but it is proportionally more prevalent in SSDF than in SPF.

Analysis of data reveals also that some basically responsive service situations do not reach, for some reason or another, the needs of the client, or clients experience these services uncomfortable or unsuitable. I call this a category (or possibly a subcategory) of '*unresponsive relations*'. For instance, in social services for the divorced, the client may find there a standard practice of a social worker visiting a child in his/her home as threatening (situation 6, in Table 2).

Table 3. Situations in supervised probationary freedom manifesting different kinds of service-client -relations.

Relation types	Situations
Responsive relation	8 Deciding about the length of SPF 12 Prisoners' friends being present in SPF activities 13 Designing peer support in an NGO 18 Sharing client information in the service network 21 Support for being a parent
Unresponsive relation	3 Prisoner's escape and return 6 Prisoner's mates as risks for offenses 9 Many SPF activities as a problem for the prisoner
Collaborative relation	7 Prisoner wakes up the SPF process 14 Negotiation during SPF control visit to the prison 16 Prisoners' impact on the SPF contents
Anticollabo-rative relation	10 Prisoner freezes completely in a network meeting of authorities

Relation types	Situations
Justice relation	1 SPF is cancelled (due to offences) before starting 2 Finding out information about the prisoner for deciding about SFP 4 Prisoner’s permission before talking about his/her issues 5 Revoking SPF due to an offense 8 Deciding about the length of SPF 9 Designing SPF activities 11 SPF control visit interrupts prisoner’s school lesson 15 Isolating the prisoner during SPF 17 Giving SPF enforcement plan to his service providers

Situations in the category of *collaborative* relation include either negotiation between service professionals and clients, or show that clients’ agency is positively needed or considered in providing the services. As an example, family counselling and child psychiatrist, together with other service providers, organized a network meeting together with the parents to discuss the matters of their child. This situation occurred out of the child’s need and is not a standard practice in the local social work. Collaborative situations of SSDF are occasional while the collaborative nature of SPF situations is coded in the standard practices of probationary freedom. We thus see that strategic guidelines are a powerful way to enable (but not guarantee) collaboration.

Similar to unresponsive relations, some collaborative situations seem to work against good attempts of the services. In the situations of ‘*anti-collaborative relations*’, collaboration takes place, but their outcome is negative for a particular client, or even negative for the common, societal purpose of the services. For instance, revealed by a small story of a social worker, a school became so involved in the parents’ dispute that it became impossible for their child to attend that school anymore. Anti-collaborative and unresponsive relations show the delicate nature of service- client relations in these public services. Responsiveness or collaboration as such do not guarantee the success of the services.

The juridical elements SSDF and SPF service networks can be seen in the ‘justice relation’ -category. Naturally, this category is more prevalent in SPF than in SSDF.

The justice relation –situations reveal some of the legal and institutional constraints that restrict possibilities for responsiveness or collaboration. For instance, there is a rule that a prisoner must remain sober during SPF preparation time. If s/he breaks this rule then the preparation, with all its collaboration, is interrupted. This is a problem for service providers because a lot of work done becomes wasted. Some of these situations show principles that affect services a lot. In SSDF, the main official principle, in divorces where both parents share the custody, is to try to maintain the relationship between children and the parent with whom the children do not live, which is often the father. Sometimes this may go counter to responsiveness in terms of what children want. The principles and legal issues behind justice relations –situations can also be seen as frames within which professionals do have professional contentual autonomy to act (Sinko, 2004; Rostila; Vinnurva 2013, 198). Standardized procedures and formalization contribute to efficient and effective services (Walsh; Dewar 1987) and also support service professionals in their work.

Many of the justice-relation type of situations show that the legal or formalized procedures are immediately negative for clients, but in the long term they may support clients’ acting according to what is societally good. Also, sometimes procedures can be based on assumptions that do not correspond to clients’ lives. For instance, psychotherapy, according to experts, is not suitable for children where circumstances in the family are not stable. This is based on an assumption that an unstable phase for children is short, and does not go on for years as sometimes is the case. In these cases, being responsive requires finding innovative solutions, as our studies have been able to show (Seppänen et al., 2013; Seppänen et al., 2014).

Many of the situations of this category show that the formalized procedures also protect clients’ rights. For instance, for privacy protection reasons, only the prisoner has a right to share his/her SPF enforcement plan, approved and largely made by prison authorities, to those actors outside Criminal Sanctions Agency that provide services or activities to him/her during SPF.

Justice relations not only hinder responsiveness and collaboration, they also may offer places for acting responsively or collaboratively. For instance, in SSDF, when a child becomes 12 years old, s/he may decide not to meet the father. This decision is respected despite the general norm of supporting child-parent relations of social services. This legal principle thus opens up a new avenue for responsiveness and negotiation between the client and public services.

6 Discussion and conclusion

If we take seriously the message of SDL, then new vocabularies for better understanding different service-customer – relations are needed. Many initiatives and projects, in social and health services or the services for the unemployed for instance, are enhancing clients’ activeness. Customer orientation is central in the developmental rhetoric of both private and public sectors. Virtanen et al. (2011) distinguish client centric from client-oriented way of developing services. The former means that clients’ needs are considered, but the client is not able to influence on how the service is provided. This roughly corresponds to responsiveness. In the latter client orientation, the client participates to both design and

realization of services, where the actor moves from the service provider to 'we', including both client and service provider. This roughly corresponds to Vigoda's collaboration. But the notion of collaboration, to me, much better informs the relevant characteristic of what Virtanen et al. (2011) call customer-orientedness. The distinction between responsiveness and collaboration (Vigoda 2002) seems important for opening up some crucial distinctions of client-service relation, and for developing business models for public services. If clients' activeness is a strategically important, then the difference between responsive and collaborative relations need to be distinguished in all levels and activities of the services. The purpose for identifying responsive and collaborative relations in service practices is to try to find relevant ingredients for building business models or activity concepts that potentially would contribute to making public services more efficient and effective. This paper is a preliminary examination in the operative level of two public service networks.

The analysis shows that identifying responsiveness from collaboration is not easy. Based on the findings in SSDF and SPF networks, they both are needed when modelling activities in public service networks. Responsive, collaborative and justice relations are also intertwined and condition each other, which makes their identification even more important. For instance, turning to clients' own social networks is a responsive way of looking for good solutions for a particular client, but when put into practice, collaborative relation is needed. The justice type of relations show that the challenge for learning and business model building for public services is not only to move from responsiveness to collaboration, but can sometimes be moving to responsiveness. Maybe the justice type, rather than a service-client relation, should be considered more as a characteristic of the public service context which enables and restricts responsiveness and collaboration in different ways.

The findings concerning collaborative and anti-collaborative types of relation show that collaboration and partnership require specific capabilities and skills to be successful. Learning collaboration, in the case of enhancing clients' activeness and participation in providing and developing public services, seems to be a major long-term educational effort for all parties.

Institutional pluralism as a driver for innovation

Jaakko Siltaloppi¹, Kaisa Koskela-Huotari², Stephen L. Vargo³

¹Aalto University, Helsinki, Finland; ²VTT Technical Research Centre of Finland, Oulu, Finland; ³University of Hawaii at Manoa, Honolulu, USA

Recent research points to a service-based and systemic understanding of innovation in which focus is on the shared value co-creation practices shaped collaboratively by many actors. This research seeks to understand where and how new value co-creation practices emerge. Institutional pluralism, or the diversity of rules, norms and schemas that constrain and guide human action, offers the basis for answering this question. Actors encounter contradictory situations when multiple prescriptions for action are activated in a specific situation. This elevates their conscious problem solving which allows them to develop new solutions to resolve issues at hand, these solutions carrying the potential for institutionalization across a broader system. This view has implications for studying innovation at both micro and macro levels.

1 Introduction

Since Schumpeter's (1934 / 1983) seminal work, innovation studies have provided a number of insights into the emergence of new solutions. One of the more recent developments in the innovation literature is the integration of products and services within a single framework for studying innovations (e.g., Drejer, 2004). Coombs and Miles (2000), for example, suggest that the value of physical products derives from the services they deliver, portraying service as the more foundational aspect for understanding innovation. Similarly, but more extensively, Vargo and Lusch (2004, 2008) suggest that service (singular) is the fundamental basis for exchange. They define service as the application of competences for the benefit of other actors (and the actor itself), proposing that innovation is not concerned primarily with the creation of new material artifacts or technologies, but the creation of new service practices (which may or may not make use of various artifacts) that offer solutions to human problems (Vargo et al., forthcoming).

In this context, innovation is not a lone effort of one actor, but shaped by multiple actors interacting in various networks (Coombs; Miles, 2000). Vargo and Lusch (2011) promote a networked view of value creation and innovation, in which all actors are resource integrators and service providers participating in collaborative value creation (value co-creation) processes in service ecosystems (see also Lusch; Vargo, 2014). Similarly, innovation literature illustrates the networked processes through which many actors integrate their resources to develop new solutions in specific systems (e.g., de Vries, 2006; Windrum; García-Goñi, 2008). As many actors interact in shared systems, over time they develop shared practices for value co-creation. Taking an institutional lens, these practices are both constrained and enabled by the shared rules, norms and schemas actors develop (Scott, 2014). In this context, innovation is not only concerned with the initial and local emergence of novel solutions, but their institutionalization across a broader system (Vargo et al., forthcoming), that is, the development of patterned problem-solving behaviors and shared meanings associated with these behaviors that persist over time (Berger; Luckman, 1966; Tolbert; Zucker, 1996; Zucker, 1977).

While existing research on innovation at the systems level has begun to elaborate the complex processes through which shared, institutionalized practices change and evolve (e.g., Coriat; Weinstein, 2002; Geels, 2004), this research offers only limited insights into the initial emergence of new solutions within the broader institutional contexts. Furthermore, micro level research often ignores the institutional dimension, focusing solely on the actions of a specific entrepreneur or organization as if they were unconstrained by the rules, norms and habits of surrounding contexts. Thus, the question for our research is: Where and how do new solutions – new value co-creation practices – emerge?

Building on recent advances in marketing, particularly service-dominant logic, and organizational institutional theory, our purpose is to develop a more complete view of the emergence of innovation. In particular, our aim is to describe how individual actors, in and through local interactions, are able to endogenously set in motion changes in the systems of which they are part. Our key argument is that due to the pluralism and diversity of constraining and enabling institutions inherent to human life, contradictions surface in the day-to-day conduct of actors providing opportunities for reforming and reframing existing solutions. To fully elaborate this argument, we proceed in three stages. First, we offer an overview of the service-based view to innovation, laying the foundation for more detailed analysis. Second, our paper expands the systemic and networked dimension of innovation by introducing the concepts of service ecosystems and institutions in the analysis. The third section leverages recent advances in organizational institutional theory to focus on the emergence of contradictions at the intersections of different institutions, and how they enable the creation of new solutions by individual actors. We conclude with a discussion of the implications of this view for theorizing and studying innovation.

ILLUSTRATION: A case study of the Finnish residential sector

Throughout the article, we will illustrate our conceptual arguments with examples from an empirical case study in the Finnish residential sector. These examples draw from over 70 interviews conducted with various actors in the field seeking to understand the institutional diversity in the residential field, as well as the innovation efforts of individuals and organizations operating in the nexus of multiple institutions. Thus, these examples offer an illustration of the intersection between micro-level actions of individual organizations aimed at innovation, and the field-level institutional forces shaping, and being shaped by, these actions. Before moving on in the institutional dimension, however, we will start with an overview into the service-based notion of innovation, as it constitutes the conceptual basis for the remainder of the article.

2 Service-based view to innovation

Recent developments in innovation research emphasize service as the foundational basis for studying innovation, allowing researchers to transcend the classic dichotomy between products and services as separate entities. The essence of this view is that the value of physical products derives from the service they render. This has important implications for research on innovation (Coombs; Miles, 2000: 101): First, it portrays innovation as a result of intertwined and complex material and immaterial changes (cf. Gallouj; Weinstein, 1997), as opposed to occurring solely in the product (output), or process. Second, the locus of innovation shifts from intra-organizational R&D processes to networked processes among many actors within and between organizations contributing to the shaping of new solutions. Third, these shifts imply that the overall notion of innovation expands from the production of novel material or immaterial outputs to entrepreneurial acts which change existing (social and) market relationships and may, or may not, involve material novelties.

Vargo and Lusch (e.g., 2004, 2008, 2011) echo, extend, and elaborate this further by viewing service, and not tangible goods, as the fundamental basis of exchange. Service-dominant (S-D) logic defines *service* (singular) as the application of competences for the benefit of other actors or the actor itself (Lusch; Vargo, 2014), distinguishing the singular notion of service from services (plural) understood as immaterial outputs of firm-driven production processes. S-D logic perceives all actors (e.g., “producers” and “consumers”) as resource integrators who use their competences and other resources to integrate them with resources acquired from others to solve specific problems (i.e., create value), for others and for themselves. This implies that no actor creates value alone; instead, value is always co-created in the ongoing resource integration and reciprocal service provision among many actors (Lusch; Vargo, 2014; Vargo; Lusch, 2004). The service-based view, therefore, portrays innovation both resulting in, and being driven by, the ongoing value co-creation practices by many actors integrating and exchanging their (specialized) resources with those of others for specific purposes (cf. Vargo et al., forthcoming).

By reframing innovation as change in the value co-creation practices shared by many actors, S-D logic offers an overarching and integrative view of innovation across all economic and social contexts. As mentioned, such view is not completely new to innovation studies. In addition to Coombs and Miles (2000), Gallouj and Weinstein (1997) offer a synthesizing view to innovation by describing innovations as novel combinations of technical and competence characteristics that jointly contribute to the formation of new final characteristics. In align with S-D logic, the characteristics-based model highlights innovations as new combinations of operand (technical) and operant (competence) resources that allow actors to co-create value in novel ways, resulting in new experiences of value-in-context (final characteristics) for specific beneficiaries (e.g., Lusch; Vargo, 2014). More recent evolutions of the characteristics-based model suggest that these novel combinations are not crafted by individual actors, but emerge as a result of networks of actors contributing their technologies and competences to the creation of the novel solution (de Vries, 2006). Furthermore, actors’ preferences in such networks determine how available artifacts and competences are integrated into novel solutions, pointing towards an increasingly systemic view of innovation (Windrum; García-Goñi, 2008).

This systemic view is further elaborated by S-D logic in its focus on resources as interconnected and dynamically evolving: As new resources are created by integrating existing resources in novel ways, their utilization in value co-creation processes requires the adaptation of other resources with which the new resources are integrated (Lusch; Vargo, 2014; Penrose, 1959/1995). Thus, resources are not inherently ‘valuable’, but become more or less valuable depending on the context of their integration (Chandler; Vargo, 2011). Examples of such dynamics are present in early studies of technological and organizational innovation (e.g., Abernathy; Clark, 1985; Damanpour; Evan, 1984), in which technological renewals were considered destroying existing organizational competences and requiring reorganization to leverage the potential of new technologies for value creation. More generally, the fact that resources configure other resources means that value creation, and innovation, inherently intertwines with the surrounding system, requiring the consideration of systems of many actors acting in concert to co-create value in new ways.

CASE STUDY, PART 1: Dominant logics in the residential sector

The context of the case study, residential sector, can be characterized as following a ‘goods-dominant’ logic in the way it perceives its primary purpose and core functions. The development and maintenance of residential properties, tangible assets, lies at the heart of most organizations in the field, from funding agencies to developers, investors, and various organizations responsible for the maintenance of the buildings. In recent years, however, actors are increasingly framing their operations in the field as serving the residents, questioning some of the long-held assumptions and core values of the traditionally production-centered field. This emerging shift aligns with the distinction between goods- and service-dominant logics: the former emphasizes the production and exchange of tangible assets, buildings, whereas the latter draws into limelight the value co-created with the residents inhabiting the buildings and using them as one of the critical resources in constructing their everyday lives. Thus, the notion of value also changes as organizations move from a goods- to service-based interpretation of their purpose and action: In the former approach, apartments are considered as investment assets (valuable on their own), while the latter approach perceives value as co-created with the residents, emerging only when the apartments are integrated with other necessary resources in the residents’ environment and daily life. The emerging divide between goods- and service-dominant interpretations also entails differing emphasis on resources and resource integration: the goods-dominant interpretation of the residential field emphasizes efficient supply chains, sourcing strategies, and marketing channels, while the service-dominant interpretation more closely considers the integration of various applied resources (i.e. service) – including the apartments – from various sources for the benefit of the residents.

3 Ecosystems and institutions

The emerging systemic view of innovation emphasizes the networked and distributed character of value creation. As Vargo and Lusch (2004, 2008) state, no actor alone creates value. More specifically, this view portrays all actors, whether individuals or organizations, as resource integrators (Vargo; Lusch, 2011) intertwined in a complex web of service-for-service exchange relationships unfolding over time and space (Lusch; Vargo, 2014). As discussed in the previous section, the networked resource integration by many actors continually shapes the contexts for subsequent resource integration and service provision, transposing the networks into dynamically evolving systems (Vargo; Lusch, 2011). This dynamic systems view is encapsulated in the concept of *service ecosystems*, defined as relatively self-contained, self-adjusting systems of resource-integrating actors that are connected by shared institutional logics and mutual value creation through service exchange (Lusch; Vargo, 2014: 24). In other words, the service ecosystems perspective describes dynamically evolving systems of actors interrelated through the activities of resource integration and service provision, and characterized by the formation of shared *institutions* with distinct logics of action that allow actors to interact and co-create value efficiently.

Institutions describe the enduring aspects of social systems and human life (cf. Giddens, 1984). Scott (2014: 56) defines institutions as the “*regulative, normative and cultural-cognitive elements that, together with associated activities and resources, provide stability and meaning to social life*”. In other words, institutions consist of formalized rules such as laws, less formalized norms including social expectations and values that define legitimate behavior, as well as cultural assumptions and cognitive frames or schemas that encapsulate the taken-for-granted assumptions and beliefs concerning social action in specific situations. Institutions are not objective and immutable, but constantly created and re-created by value co-creating actors (Lusch; Vargo, 2014). The service ecosystems view thus adopts the structuration view by Giddens (1984), who perceives institutions as both the medium and outcome of human practices. Thus, actors simultaneously draw from and produce the social structures – institutions – that guide them. In this view, institutions only exist in the instantiations of human practice, as well as in the memory traces of human actors, without having any objective existence (ibid.).

In this sense, institutions can be considered as the structuring properties of service ecosystems; they are the constraining and enabling structures (Sewell, 1992) which lend ecosystems their systemic ‘form’ by shaping resource integration and value creation among actors (Lusch; Vargo, 2014). The perspective for innovation thus expands beyond the discovery of a novel artifact to the unfolding of change in the institutionalized value co-creating practices of a service ecosystem (Vargo et al., forthcoming). In other words, the focus expands from the emergence of new solutions to their *institutionalization* across the ecosystem (ibid.). Here, institutionalization is understood as the development of patterned problem-solving behaviors (habitualization), the development of shared meanings associated with these behaviors (objectification), as well as the sedimentation of these behaviors into the social fabric (Berger; Luckman, 1966; Tolbert; Zucker, 1996; Zucker, 1977). The implication of this view is that, as opposed to perceiving innovations as created by unconstrained individual actors (usually firms), innovations are seen as constantly unfolding sequences of dynamic interactions among human actors, material artifacts and the governing institutions (Geels, 2004) that shape the search for, and formation of, new or better solutions to identified problems.

CASE STUDY, PART 2: Institutions in the residential sector

The residential sector draws attention to various institutions at the regulative, normative, and cultural-cognitive levels. In addition to general legislation, national building codes as well as regional and municipal zoning regulations provide the regulative contexts for organizations operating in the residential sector. Industry norms, such as common contracting practices, establish normative guidelines for legitimate action. Finally, the taken-for-granted cultural assumptions and schemas involve specific ideas of how, for example, the construction process, property management practice, or provision of maintenance services should proceed, constituting the core of the industry practices among the organizations. These include more general frames such as ideas or principles of technical and economic performing in the field, or more specific templates for specialized tasks such as contracting suppliers, performing specific maintenance tasks, or pouring concrete. From the residents' perspective, the meanings associated with what housing is and should be, how homes function and are organized, as well as how they relate to the broader environment also derive from institutionalized notions of the role of housing in the society. In addition to these cultural-cognitive institutions, shared norms on how to behave with neighbors, for example, and the legislation that governs housing from the residents' perspective, represent other aspects of institutions enacted by the residents. Finally, interactions between different organizations and residents are also constrained and enabled by various institutions. Legislation on rental agreements is an example of a regulatory institution that dictates the roles and responsibilities of the tenant and landlord. Norms associated with property transactions and real estate brokerage offer another example of the institutions that influence exchanges between the "producers" and "consumers".

4 Institutional pluralism as the driver for innovation

The service ecosystems view broadens the basis for understanding value creation and innovation in human systems. On the one hand, it portrays actors' resources as configured by other available resources, implying that value co-creation opportunities depend on, and are configured by context(s) actors themselves shape (Vargo; Lusch, 2011). On the other hand, it also draws attention to the institutions that govern resource integration and service provision in ecosystems, suggesting that human actors are not unconstrained agents, but constrained and guided by the existing rules, norms and schemas according to which they reproduce large parts of their daily life to preserve the stability and order in their day-to-day interactions (Lusch; Vargo, 2014). However, while the structuration view explains institutions as constantly produced and reproduced by actors in their social practices (Giddens, 1984), it does not offer a detailed view of how actors simultaneously reproduce institutions, that is, repeat institutionalized patterns of behavior, and consciously create novel solutions from available resources that diverge from the preexisting patterns of social action. For our attempt to understand the emergence of innovations, the question is: How actors are able to change the very institutions that govern them (e.g., Garud et al., 2007)?

One answer to this question is rooted in the fact that actors in service ecosystems are simultaneously governed by, or draw from, many institutions each with a distinct logic (Lusch; Vargo, 2014). These *institutional logics* are defined as "the socially constructed, historical patterns of cultural symbols and material practices, including assumptions, values and beliefs, by which individuals and organizations provide meaning to their daily activity, organize time and space, and reproduce their lives and experiences" (Thornton et al., 2012: 2). The existence of multiple institutional logics – *institutional pluralism* (e.g., Kraatz; Block, 2008) – means that institutions do not exist in isolation. Instead, institutions need to be understood through the mutually dependent yet contradictory relationships between multiple institutional logics (Friedland; Alford, 1991), each applying to specific spheres or situations in the diversity of human life (Ostrom, 2005). In this sense, institutional pluralism is constitutive to human systems, social action, and innovation.

The consequence of institutional pluralism is that actors often encounter situations in which many institutional logics offer contradicting and conflicting interpretations of, and prescriptions for, action (Friedland; Alford, 1991; Greenwood et al., 2011). In the context of service ecosystems, for example, the intersecting and overlapping institutional logics can create conflicting views on what value is, and how resources should be integrated for value co-creation (Vargo et al., forthcoming). In our view, these conflicts lie at the heart of innovation: When actors encounter situations with contradictory prescriptions from multiple institutional logics, the taken-for-grantedness of institutionalized practices breaks down and elevates conscious attention to resolving the conflict (Seo; Creed, 2002). Conflicts between logics thus activate praxis, that is, the free and creative reconstruction of social patterns based on reasoned analysis, that allows actors to envision and enact novel solutions in the complex situation (ibid., see also Thornton et al., 2012).

This means that conflicts between prescriptions from multiple institutional logics – *institutional complexity* (Greenwood et al., 2011) – can be seen as the potential locus for innovation. It is only potential in the sense that actors are not forced to find a novel solution, but can resort to preserving existing solutions and avoiding or defying the conflicts deriving from institutional complexity (e.g., Kraatz; Block, 2008; Lawrence; Suddaby, 2006; Oliver, 1991). In addition to activating actors' conscious attention to finding a resolution, multiple institutional logics also offer actors the tools with which new solutions to complex situations can be developed. In align with S-D logic, actors do not develop new resources and meanings associated with them 'out of thin air', but access the existing practices and symbols from the ecosystems, and the associated institutional logics, in which they are currently embedded (Thornton et al., 2012).

Institutional pluralism thus provides actors with multiple available ‘cultural toolkits’ or strategies of action, with which new solutions to complex situations can be developed, including both material practices and symbolic resources for meaning (re-) construction (Greenwood; Suddaby, 2006; Swidler, 1986).

Taking a more detailed view to institutional complexity, conflicts between logics can unfold on at least two distinct levels, goals and means (Pache; Santos, 2010). When multiple means (i.e., specific practices prescribed by an institutional logic for achieving a particular goal) run into conflict, the reconciliation may more likely focus on the reorganization or recombining of material tasks and associated competences. As an example, changes in the hiring routines in the Danish Learning Lab were driven by conflicts with the governing state organization, leading to a trial-and-error process of the organization seeking a routine that would satisfy the demands behind both the bureaucratic (state) and innovative (Danish Learning Lab) means for hiring professionals (Rerup; Feldman, 2011). Conflicts over goals, or deeper meanings associated with specific situations, may create more profound and severe conflicts that can lead to political contestation and the amplification of the conflict across broader ecosystems. Such conflicts derive from completely different interpretations of the situation, and differing views of legitimate goals, implying very different grounds for action and evaluating what is right or just (cf. Boltanski; Thevenot, 2006; Thornton et al., 2012). Empirical studies in institutional literature offer a number examples of contested change processes unfolding in the nexus of conflicting “world views”, including those between market and professional logics (e.g., Suddaby; Greenwood, 2005; Thornton; Ocasio, 1999), or between environmentalism and industrial logics (e.g., Hoffman, 1999; Zietsma; Lawrence, 2010).

This view of the innovation process, emphasizing conflicts and their resolution, takes a *dialectical* perspective in which the contradiction between thesis and antithesis – here, incompatible aspects (e.g., identities, goals or practices) of different institutional logics – are reconciled in synthesis (e.g., Hargrave; Van de Ven, 2009; Seo; Creed, 2002). Dialectical view fits well with the notion of pluralism central to the current argument, since conflicts between different institutional logics are viewed as the driving force for improvement. Smith and Lewis (2011) offer a detailed view of the dialectical process. They start with the notion of latent paradoxes or conflicts which permeate human systems characterized by pluralism. In certain situations, some aspects of these latent conflicts become salient, activating action towards reconciliation. While the system can deteriorate under complex pressures if actors are unable to develop new courses of action, actors can also build acceptance to embrace the tensions (‘truce’), and eventually, seek to develop transcending solutions that integrate the conflicting sides in a manner that resolves the tensions more permanently (‘synthesis’). Central to the dialectical view is its cyclical nature: synthesis of one conflict constitutes the thesis for another conflict, offering a view of system-level evolution based on recurring dialectical cycles that drive innovation (see also Van de Ven; Poole, 1995).

Finally, our previous consideration offers an endogenous view of the micro-foundations of innovation, drawing attention to emerging contradictions, and dialectical processes that reconcile them, at the heart of innovation (Bledow et al., 2009). This means that despite their institutional embeddedness, actors are capable of performing *institutional work*, defined as the purposive action of individuals and organizations aimed at creating, maintaining and disrupting institutions (Lawrence; Suddaby, 2006). The resulting view of innovation is therefore one in which multiple actors, driven by different goals and possessing different means, perform different types of institutional work thus contributing to the emergence and institutionalization of novel solutions through distributed and networked processes. This view blurs the traditional boundary between discovery and diffusion (e.g., Rogers, 1995 / 1962), as all actors are considered, in the least, as adopters of novel solutions to their unique contexts. In this sense, all actors perform translations through which actors identify problems or problematize situations, develop bridges between conflicting views by manipulating resources, and mobilize actors (including themselves) behind new solutions and roles that associate with them (e.g., Callon, 1986). In this sense, translations drive the (ongoing) institutionalization of novel solutions (Vargo et al., forthcoming).

CASE STUDY, PART 3: Institutional complexities as the drivers for innovation

Building on the descriptions of goods- and service-dominant logics in the Finnish residential sector presented in part 1, we identified two institutional logics offering contradictory frames or interpretive schemas for organizations making sense of their purpose and practices in the sector. The goods-oriented frame portrays buildings as the key assets to be developed and maintained, emphasizing technical and investment practices at the heart of operations. Although residents are considered important, they are perceived as the ‘buyers’ (or renters) of standard products, with whom the organizations interact at an arm’s length. The service-based frame, on the other hand, emphasizes the value co-created with residents through multiple channels, platforms or offerings, only some of which the particular organization provides. In this frame, the role of the organization is to facilitate these processes and offer means for residents to integrate various elements for consistent experiences that fit their context and need. Thus, the field is characterized by an emerging conflict between the frames deriving from the dominant, building-based logic, and the emerging, resident-centered logic, providing platforms for developing new solutions.

The emergence of the resident-centered logic is central to the increase of conscious attention in the field towards fitting these two logics together for more sustainable business. In our case study, different organizations dealt with this complexity in different ways: Some, including many building investors, denied the legitimacy of the resident-centered

logic as viable and feasible basis for operations. Others attempted to incorporate both frames in their operations by combining the existing, building-centered practices with the resident-centered service practices in their organization. Finally, some organizations even provided overarching solutions that reconciled the conflicts between the logics more durably by developing novel organization forms and practices rooted in ‘hybrid’ frames that created the basis for new value creating practices between the organization and residents.

In addition to developing different ‘ranges’ of solutions to the complex pressures, the case study also illustrates both types of conflicts, over goals and means, and different types of solutions envisioned in response to these conflicts. The introduction of a home renovation service by a property investor offers one example of reconciling a conflict over means, in which the incompatible practices between managing a mass of properties and serving individual households were fitted inside the organization by compartmentalizing different practices into different organizational subunits. Conflicts over goals were present in a publicly owned investor organization whose owner, a municipality, required the organization to simultaneously seek efficient operations around the building-based logic to provide low-cost housing, and seek to improve resident welfare through various support-oriented means. The development of a hybrid frame that legitimized both goals inside the organization created the basis for the ability of the organization to simultaneously address diverse needs of their residents.

The examples above illustrate institutional complexities as the locus and driver for the creation of novel practices and frames. These practices and frames offer other actors in the field templates for resolving similar problems with conflicting institutional logics, their adoption facilitated by interactions with other organizations in shared forums (e.g., industry associations), and by observing how others use the solutions. Examples in the case study show that these templates are not often adopted in full, but as parts of broader toolkits ‘tailored’ to the idiosyncratic context of the adopting organization.

5 Discussion

The central argument of this paper is that innovations stem from contradictions between multiple institutional logics that impose pressures on actors by prescribing different courses of action, or different goals and interpretations of the situation at hand. Contradictory pressures elevate actors’ conscious and creative problem solving, and allow them to recombine available resources for new purposes. In other words, institutional complexities ‘loosen’ the taken-for-grantedness of the ways resources are applied to specific purposes, and allow actors to envision and experiment with new uses and solutions. As this unfolds over time and place, novel solutions that initially emerge in one context may institutionalize as more and more actors adopt, or translate, these solutions in their contexts by reconfiguring their resources. This view is rooted in a dialectical view of change (Van de Ven; Poole, 1995), in which recurring cycles elevate and address conflicts, producing gradually evolving solutions that characterize specific service ecosystems. This view differs radically from the classic linear models of innovation, drawing attention to non-linear, dynamic, iterative, distributed and experimental processes at the heart of innovation (e.g., Cheng; van de Ven, 1996; Garud; Karnøe, 2003; Moonman; Miner, 1998; Toivonen; Tuominen, 2009; Van de Ven et al., 1999).

For macro-level studies on innovation, this paper proposes an endogenous mechanism for system-level change, according to which actors adapt and recombine existing resources to resolve contradictions between institutional logics. This view expands current literature, which, for the most part, emphasizes the role of exogenous shocks as the source of change in socio-technical systems (e.g., Geels, 2004; Sine; David, 2003). In this sense, our conceptualization of ecosystems differs from the punctuated equilibrium models of innovation which consider systems as inherently stable, occasionally disturbed by shocks that cause discontinuous shifts in the value co-creation practices. On the contrary, our dialectical view portrays ecosystems as structured by multiple institutional logics, the overlaps and contradictions of which shape the ongoing dynamic processes through which actors shape, produce and reproduce, the systems (Friedland; Alford, 1991). This view can provide valuable new insights for studies of innovation systems, especially the multi-level perspectives that map changes in technological regimes in the nexus of institutional rules and socio-technical practices (e.g., Coriat; Weinstein, 2002; Geels, 2002; Geels, 2004). Fuenfschilling and Truffer (2014) offer one interesting avenue for future research by elaborating on institutional pluralism as the basis for understanding technological regimes, as opposed to uniform institutions changed by exogenous shocks. Another interesting avenue for future research may unfold around the recurring dialectical processes that reinforce path-dependent trajectories of ecosystems (cf. Garud; Karnøe, 2003).

In the context of micro-level studies of innovation, our contribution lies in elaborating the institutional embeddedness of individual actors. Traditionally, innovation research has considered individual actors, whether entrepreneurs or firms, as somewhat heroic individuals as the creators of novel solutions, unbound by existing structures. Our thinking, on the contrary, roots agency that transforms solutions and ecosystems in actors’ simultaneous embeddedness in multiple institutions with distinct logics of action, which provide both the loci and resources for the creative reconstruction activated by conflicting institutional prescriptions. Thus, rather than rising above the constraints, the institutional entrepreneurs “hop and bridge from one social world to another” in constructing change (Thornton; Ocasio, 2008: 117). In align with our view, the concept of bricolage (Levi-Strauss, 1966) offers a view of innovators as

entrepreneurs making do with resources at hand, refusing to enact the limitations of resources as they recombine available resources for new purposes (Baker; Nelson, 2005). Building on this notion, future research on the micro level could benefit from more detailed accounts of how novel recombinations of resources (i.e., new solutions) emerge, and especially how the innovators or entrepreneurs give meaning to these solution so as to legitimize them and facilitate their institutionalization (e.g., Christiansen; Lounsbury, 2013; Garud et al., 2014; Suddaby; Greenwood, 2005). In addition, future research could benefit from explicit attention to the multiple institutional logics that guide the behavior of individual actors during different stages of the innovation process, and how these logics blend or reform as a result of actors' purposive work.

Finally, our systemic and dialectical view of innovation also has implications to strategy as a part of innovation. The traditional notion of strategy places strong emphasis on prediction, that is, developing explicit goals for action by collecting and analyzing data from the environment. However, the dynamic systems view draws attention to distributed processes laden with discontinuities and unintended consequences. This means that the more rapidly an ecosystem changes, the less effective are predictive strategies. Sarasvathy (2001) proposes the logic of *effectuation* as an alternative to prediction, which, like bricolage, emphasizes the means available to actors, and the ends attainable to those means, as the basis of action and innovation. Selecting between the various possible ends attainable using the means at hand unfolds in recurring cycles in which the entrepreneur seeks commitments from new stakeholders (e.g., partners, investors, suppliers, customers) to gain new resources necessary for improving and expanding the possible solutions. At the same time, however, new stakeholders impose their constraints on the new solution, leading to the convergence of goals around specific solutions (Sarasvathy; Dew, 2005). Thus, innovation strategy in effectuation is of an emergent kind, developed in networks of actors, emphasizing control over emerging futures rather than prediction of inherently uncertain futures (Wiltbank et al., 2006). An interesting question for future studies on innovation is to what extent, and how, effectual processes apply to, and unfold in, established organizations and highly institutionalized contexts with more constraining structures in place.

6 Conclusions

The service-based conceptualization of social and economic activity makes visible the underlying basis of innovation rooted in service, that is, the application of competences for the benefit of others (Vargo; Lusch, 2004). This view expands to a systemic understanding of value creation and innovation, in which no actor is able to create value alone, or change the shared value co-creation practices. Instead, actors collaboratively integrate resources in service ecosystems governed by shared institutional logics. In this context, the notion of innovation expands from the local development of novel technologies to the institutionalization of novel value creating practices (Vargo et al., forthcoming), requiring an explanation for how the actors become able to change the very institutional structures that govern their value co-creation. Institutional pluralism offers the basis for a conceptual solution in which conflicts between multiple institutional logics elevate actors' attention to problem solving, and allow them to creatively combine resources from multiple sources for new purposes. This view radically expands the scope of innovation studies, not only offering an alternative to the traditional dichotomy between produces and services, but also linking the micro and macro levels of analysis into a systemic understanding of innovation. In this sense, service-based conceptualization of innovation appears increasingly central to the formulation of future agenda for innovation research.

The impact of service characteristics on trade: evidence from Belgian enterprises

Peter M. Smith

KU Leuven

The paper examines empirically the link between service characteristics, cross-border trade and sales of foreign affiliates using micro data held by the National Bank of Belgium over the period 1997-2005. Service characteristics related to tangibility exercise a particularly strong influence on exports and imports, while characteristics relating to search-experience-credence, proximity and border location particularly affect the choice of entry mode for trade in services. For foreign affiliates, service characteristics seldom affect the value of sales. Firms which operate in less competitive markets domestically have less incentive to trade cross-border, while lack of competition on the Belgian market attracts foreign investors.

1 Introduction

The low level of cross-border trade in services lacks as yet a fully satisfactory explanation in spite of their growing tradability through the application of information technology. A number of barriers to trade have been identified, many of which relate to the inherent characteristics of services (Canoy; Smith, 2008). These characteristics apply equally to domestic markets and an issue to be explained is why these attributes affect the sale of services cross-border so much more than domestic ones.

This paper innovates first in exploring the different ways in which service characteristics affect trade. Second it looks at how these characteristics should affect the amount of and choice between cross-border trade and permanent presence. Third it tests whether observed characteristics do in fact affect the value of trade in services in the way predicted and which of the different characteristics are most significant in explaining the value of trade. In order to do so the paper uses a unique set of panel data on nearly all individual enterprises for the period 1997-2005 held by the National Bank of Belgium²³⁹. The choice of Belgium has both advantages and disadvantages. The country can be considered representative of the small open services-oriented economies of north west Europe and we would expect to see more trade in services from this type of economy than for the larger developed economies or the smaller less service oriented ones. The disadvantage is that the need to specialise inherent in small economies may mean that trade in services is biased towards those services in which the country has a comparative advantage.

Section two provides a literature review of the characteristics of services and how they can affect trade – whether cross-border or through the establishment of a permanent presence. Section three sets out the hypotheses to be tested and section four develops the methodology to be applied. Section five describes the data used to apply the methodology. Section six presents the results. Section seven examines some implications of the results for policy. Section eight concludes.

2 Literature review

One strand of the literature from economics looks at how characteristics of goods and services influence the functioning of markets and provides a theoretical foundation for these interactions. Another strand of the literature from marketing takes the theoretical categories developed in economics and tests them empirically against observed outcomes. The two strands are therefore complementary. The literature on international trade and investment remains very general when making the connection between characteristics and trade.

2.1 Characteristics of Services

Gadrey (2000), building on Hill (1977), examines different approaches to defining services. The earliest, or classical approach, applies various technical criteria to either the output or the process. The first and most obvious characteristic of services relates to intangibility. To be more precise: “The final output of the activity is material if it takes the form of tangible things that have an existence in time and space that is independent from that of their producers, their consumers and the production processes that led to their creation.”(Gadrey, 2000) The second relates to the interaction between producer and consumer in achieving the desired outcome. The third concerns the fact that goods are both storable and transportable.

None of these criteria provide a hard and fast way of distinguishing between goods and services. It may indeed be more useful to consider goods and services as a continuum along different dimensions rather than as two separate

²³⁹ The author wishes to thank the National Bank of Belgium for providing access to their data for this research and in particular to Catherine Fuss and Philippe De Coninck.

entities (Araujo; Spring, 2006). The relative impact of different characteristics can then be evaluated through their variation across services. To the extent that goods also display differences across the same dimensions, this allows a confirmation of the results obtained from the study of services.

The literature on marketing has indeed exploited technical characteristics of services to examine their impact on consumer behaviour (Gabbott; Hogg, 1994). This approach derives from the economic literature on consumer behaviour and in particular the observation that goods are valued for the attributes they possess and that differentiated products are essentially different packages of attributes (Auld, 1972; Ratchford, 1975). The development of electronic commerce has given a new impulsion to the study of the relationship between service characteristics and purchasing behaviour. Because purchases over the internet can easily be supplied also cross-border, differences between internet and bricks-and-mortar behaviour may also provide some insights into the reasons behind and potential for cross-border trade in services.

Fundamental for consumers is how to obtain information about the service, comparing alternative providers and evaluating the service encounter (Ostrom; Iacobucci, 1995). The first two elements apply equally to goods. The early services literature placed the major emphasis on issues of intangibility and explored different implications of this dimension (Levitt, 1981). Because intangible products are more difficult to evaluate they increase the level of uncertainty and perceived risk of consumers.

Laroche et al. look at intangibility as a construct rather than as a way of distinguishing goods from services (Laroche; Bergeron; Goutland, 2001). Intangibility is usually defined negatively as something that cannot be touched, smelled or seen. This first dimension concerns physical intangibility. However there are other dimensions to the construct. Generality refers to the degree to which a consumer can define or describe a particular product. A third dimension, mental intangibility refers to the degree to which a product is capable of clear mental representation even where it is physically tangible. It is a step beyond generality. Mental intangibility is identified as the most important dimension of intangibility by Laroche et al. They find that some services are rated as significantly more tangible than some goods.

The three dimensions of intangibility are linked to the perceived difficulty of evaluation. They are also linked to perceived risk of purchase both directly and indirectly through the difficulty of evaluation. Contrary to received wisdom, physical intangibility should yield an easier evaluation process since it relies on prior experience rather than an assessment based on physical attribute. Online purchasing is found to reduce evaluation difficulty. However the link between evaluation difficulty and perceived risk is observed as stronger in the online compared to the offline situation, leading to overall greater perceived risk for online purchasing (Laroche; Yang; McDougall; Bergeron, 2005).

The economics literature on search, experience and credence goods (S-E-C) has proved a rich source of understanding for the functioning of markets for services as well as for goods. Nelson developed the categories of search and experience goods in his article on information and consumer behaviour to which Darby and Karni added that of credence goods (Nelson, 1970; Darby; Karni, 1973). Search goods are those for which it is possible to accurately predict quality before purchase while the quality of experience goods can only be determined by use and experience after purchase. With credence goods the consumer can ex post only observe but may not be able to assess quality even after purchase (Dulleck; Kerschbamer, 2006).

In his study of automobile insurance as an experience good, Israel shows that not all experience goods are alike and that experience with a service can be described as a learning process which depends on the characteristics of the service and that initial expectations about quality may be far from that actually provided (Israel, 2005). Villas-Boas points out when purchasing a product, a consumer learns about its valuation. As a result that product has an informational advantage over products that have not been tried in future periods (Villas-Boas, 2006). Since experience goods must be purchased in order to assess quality, there is path dependency according to which product has been purchased first.

Even in the case of credence goods there can be a search element in the form of a second opinion (Wolinsky, 1993). This form of search is costly and the ability of the customer to accurately choose the best offer among those contacted not guaranteed. The alternative is reputation where the seller invests in maintaining reputation in order in order to keep repeat customers or to attract new ones.

Ford et al. make the important point that a good or service may contain aspects of different attributes so that it is difficult to categorise a product as exclusively search, experience or credence in nature (Ford; Smith; Swasy, 1988). In practice, this difficulty can be circumvented by rating products on the different dimensions so that they contain in a certain sense a bundle of attributes. A second important point is that characteristics may change over time. Thus credence goods may become search goods if unverifiable claims such as those for environmental sustainability are backed up by credible controls on, for example, eco-labelling (Grolleau; BenAbid, 2001).

A number of studies apply the S-E-C framework to online purchasing (Girard; Silverblatt; Korgaonkar, 2002; 2006). Verhagen et al. use the S-E-C framework as a control for the effect of the attributes of intangibility. (Verhagen; Boter; Adelaar, 2010). Girard et al. examine the extent to which the willingness to shop on the internet differs according to the product category. Overall they conclude that products that are costly and difficult to evaluate are the least likely to succeed on the Internet. Huang et al find that significant differences in consumers' perceived ability to evaluate product quality before purchase between search and experience goods in traditional retail environments become blurred in online ones (Huang; Lurie; Mitra, 2009). The presence of product reviews from other consumers and multimedia that enable consumers to interact with products before purchase has a greater effect on consumer behaviour for experience than for search goods.

It should be remarked that both the studies relating to intangibility and those using the S-E-C framework explicitly or implicitly deal with the issue of information and how it affects the purchase decision. They should be related to the economics literature on information and markets and in particular to that on asymmetric information (Grossman; Stiglitz, 1980). Imperfect competition is one consequence for markets with asymmetric information. Nevertheless markets exist and function so that mechanisms have developed to overcome the imperfect information problem among which one can cite reputation, certification, guarantees and prices themselves (Stiglitz, 1989; Huck; Tyran, 2004; McDevitt, 2011). Vernon Smith points out that there is no imperfection in a market possessing incomplete information if it would not be remunerative to acquire complete knowledge (Smith, 2008). He goes further in stating that even markets with imperfect information work remarkably well. Support for Vernon's position comes from a paper on executive search by Clark, who found that in the face of information asymmetries market based solutions such as contingent fees and familiarity gained from past transactions with clients served to generate trust between search consultancies and clients (Clark, 2001).

Inseparability of the production and consumption aspects of the transaction has also been identified as crucial (Lovelock, 1983). The degree of customisation varies widely from one service to another. Some are quite standardised (public transport, fast food); others require customisation. Even there, the contact with personnel may be quite limited to for example taking an order while in other cases it is extensive (professional services, household repairs). There is therefore a relational as well as a spatial dimension to the interactions between customers and suppliers.

The burden of proximity takes on different values according to whether and the extent to which the customer needs to be either physically or mentally present. For example, automated teller machines do not require the customer and the supplier both be present but the location of the service provision is constrained. Telephone banking does not require physical colocation but involves a mental exchange between the two parties. Internet banking requires neither a physical nor a mental exchange to take place.

2.2 Trade and characteristics of services

While the literature, both theoretical and empirical, on the relationship between characteristics of goods and services and markets is quite rich, that on the impact of characteristics on trade is sparse. In line with the accepted definition of trade in the World Trade Organisation and the European Union, trade in services comprises both cross-border trade and permanent presence. Therefore, the way in which characteristics of services affect sales of foreign affiliates as well as cross-border trade and the choice between exports and establishment abroad needs to be examined.

At the highest level of abstraction transaction costs are incurred when trading either goods and services, whether cross-border or through a commercial presence. It is the nature and amount of these costs compared to those incurred by domestic suppliers that determines to a large degree the amount of trade (Anderson; van Wincoop, 2004). Trade costs indeed are as applicable to services as they are to goods (Miroudot; Sauvage; Shepherd, 2013). A second, less apparent way in which services become tradable is when they can be embedded in a good or another service which is traded, even though no financial flow may be associated with it. This is typically the case for a service that is part of a joint product with a good, such as after-sales service.

Hirsch provides a theoretical justification for the importance of distance for trade in services based on the inherent characteristics of services (Hirsch, 1989). His analysis of trade in services turns around the degree and forms of interaction between producer and user, which is formalised as the fraction of the total costs of service to the user incurred during that interaction. To the extent that cost and time of travel depends on distance, one would expect that services requiring proximity would be most likely to be affected by distance and therefore depress cross-border trade. But, interaction between producer and user no longer needs to take place at the same location. Technology obviously facilitates such interaction. For example Skype allows anyone with an internet connection to engage in such interaction for a modest cost. We can expect that technology will increasingly weaken the effect of proximity on trade as it has already for services that can be supplied over the internet. In the end it may be that rather few services will be constrained by the need for proximity.

The second issue to be addressed is how service characteristics affect the choice between cross-border trade and commercial presence. The literature on foreign direct investment (FDI) for goods is vast but much more limited for services. Dunning examined why foreign direct investment has been the preferred route for organizing cross-border activities involving services (Dunning, 1989). To produce and market services more successfully than their competitors, multi-national enterprises (MNE) need to possess specific ownership advantages which they can exploit by choosing where to engage in production (locational choice advantages). Thus in terms of the impact on internationalisation of services, there must be both an advantage to produce locally rather than export cross-border and for the MNE to possess specific advantages over domestic competitors. Services for which much of the knowledge is proprietary, those that rely on brand name or image to protect quality and trade-related service affiliates like Japanese trading companies are likely to trade through foreign affiliates. Papers by Christen and Francois (2009) and Fillat-Castejón, Francois and Wörz (2009) both look at permanent presence and cross-border trade in services as alternative or complementary ways in which firms internationalise their service operations Neither look specifically at service characteristics as determinants of FDI.

Blomstermo et al. examine foreign market entry mode for hard and soft services (Blomstermo; Sharma; Sallis, 2006). Hard services are those where production and consumption can be decoupled and are therefore tradable cross-

border. They expect hard services with a relatively high degree of tangibility and low demand for physical interaction between producer and customer to be exported or licensed. With soft services, where production and consumption occur simultaneously, decoupling is not viable. Highly personalised services requiring much personal contact are more likely to be offered through either a high control mode such as a local subsidiary or a low control mode such as licensing or franchising a local supplier rather than exported.

Examining the impact of service characteristics on trade should be subject to two important caveats. Service characteristics can have the effect of limiting competition on the domestic market and diminishing the incentives for companies to go abroad. In that case there will be a spurious association between service characteristics and absence of trade. It will therefore be necessary to control for domestic market characteristics. Second, and linked to the first, much service specific regulation is based on the need to protect customers against the possible negative effects of service characteristics particularly when such effects are serious in nature or long lasting. Regulation of services often takes the form of an entry barrier and even when non-discriminatory in nature can act to reduce trade again giving rise to a spurious association between service characteristics and absence of trade.

3 Research questions and Hypotheses

This paper explores the extent to which the characteristics of goods and services affect the amount of trade for both cross-border trade and sales of foreign affiliates and the choice of entry mode for foreign firms. In line with the previous discussion, a number of hypotheses can be advanced for subsequent testing (Table 1).

With regard to physical intangibility the impact can operate either through evaluation difficulty and perceived risk of foreign clients or from that of making a service more transportable and storable. Services that can be stored in digital form and transmitted over the internet at close to zero marginal cost can be considered as more rather than less tradable than goods. Speed to market for downloadable services is also practically instantaneous compared to the time it takes to physically transport goods from point of production to point of sale. To the extent that physical tangibility facilitates evaluation and makes a service more transportable and more storable, it is expected to have a positive effect on cross-border trade. Because cross-border trade is less costly for firms than entry by permanent presence, a characteristic that stimulates such trade is likely to be preferred to sales of foreign affiliates (H1 a,b,c).

Even when a service is not physically tangible, it may be easy for the user to grasp its nature and therefore to make an assessment on the basis of objective criteria. Generality measures this dimension and is expected to have a positive influence on cross-border trade. Whether this would also stimulate provision through a permanent presence cannot be deduced a priori and therefore is left indeterminate (H2 a,b,c).

Mental intangibility affects the possibility of evaluation and perceived risk negatively, which in turn increase the importance of trust. Trust and culture are closely linked and consumers tend to prefer services from their own country, from countries with a similar culture to their own and from economically advanced countries (Javalgi; White, 2002). Mental intangibility therefore is likely to depress cross-border trade and is expected to stimulate sales of foreign affiliates because such sales would be considered as less risky by the customer (H3 a,b,c).

Similar considerations apply to the search-experience-credence framework. That is search products provide the greatest incentive to purchase cross-border since this widens the available offer and the attributes are most easy to assess, particularly on price, and therefore bring least risk. The effect on both cross-border trade and share in total trade should be positive while that on sales of foreign affiliates is indeterminate (H4 a,b,c).

Experience and particularly credence goods tend to be less price elastic than search goods and the advantage of purchasing cross-border, for instance over the internet, will be less. Certain experience goods and services, such as air transport, are nevertheless supplied cross-border and the impact on sales of foreign affiliates is expected to be weaker than for credence ones (H5 a,b,c). For the latter, issues related to how to mitigate risk will be more important and these are likely to militate in favour of providing such services through a local presence rather than cross-border (H6 a,b,c).

Table 1. Hypotheses relating to trade and characteristics of services.

Characteristic	Hypothesis	Cross-border trade	Sales of Foreign Affiliates	Share of Cross-border trade in Total trade
Physical Tangibility	H1 (a, b, c)	Positive	Negative	Positive
Generality	H2 (a, b, c)	Positive	Indeterminate	Indeterminate
Mental Intangibility	H3 (a, b, c)	Negative	Positive	Negative
Search	H4 (a, b, c)	Positive	Indeterminate	Positive
Experience	H5 (a, b, c)	Negative	Indeterminate	Indeterminate
Credence	H6 (a, b, c)	Negative	Positive	Negative
Proximity	H7 (a,b,c)	Negative	Positive	Negative
Border	H8 (a,b,c)	Positive	Negative	Positive

The need for physical proximity between supplier and customer constitutes an additional cost for those services over services that can be stored and transmitted in digital form. Cost of transport of both goods and people have been falling but it remains nevertheless more costly to transport persons than goods and services that require either the supplier or the customer to physically move to provide the service cross border is expected to depress cross-border trade in services and encourage supply through sales of foreign affiliates (H7 a,b,c).

The choice between exporting and a permanent presence is likely to be affected also by the physical location of the provider. Just under half (47%) of the population of Belgium lives in an area directly adjacent to an internal border and a similar percentage (48%) of Belgian firms have their headquarters located there as well.²⁴⁰ Very large firms tend to be headquartered in Brussels however. Services that require proximity can be served locally in border regions and with no physical border to impede movement and a common currency it should be feasible to provide very local services in border regions, which should favour both cross-border provision over permanent presence and smaller firms (H8 a,b,c)).

4 Methodology

The effect of service characteristics on trade has been tested empirically by regressing trade in services on different characteristics of 24 services covered by the Extended Balance of Payments Services Classification (EBOPS). Similar regressions were run on trade in 97 categories of goods using level two of the combined nomenclature (CN2) in order to provide a comparison with services. The source of the data in each case is the National Bank of Belgium (see following section).

A first series of service characteristics based on the categories identified by Verhagen et al. cover intangibility and the search-experience-credence framework (Table 2). Each of the dimensions relating to intangibility is covered by responses to three different questions on a seven point Likert scale. Similarly the responses to five different questions on a seven point scale of semantic differentials covers the search-experience-credence framework, three of which relate to search.

It is important to note the way that the responses to these questions are scaled with regard to the hypotheses in the previous section. According to these, the values on physical tangibility and generality should be positively associated with cross-border trade and that for mental intangibility negatively associated. All of the search-experience-credence values should be positively associated with cross-border trade by the way they have been coded because experience and credence questions are coded so that those that are easy to know are coded high.

Table 2. Characteristics of Services.

Physical Intangibility			Generality			Mental Intangibility		
7-point Likert scale from strongly disagree to strongly agree								
This product is very easy to see and touch	I can physically grasp this product	This product is very tangible	I could easily explain many features associated with this product	It is not difficult to give a precise description of this product	It is easy to describe many features related to this product	I need more information about this product in order to form a clear idea of what it is	This is a difficult product to think about	This is not the sort of product that is easy to picture
Touch	Grasp	Tangible	Features	Description	Explain	Information	Think	Picture

Search		Experience		Credence	
7-point semantic differentials					
hard to evaluate before purchasing	easy to evaluate before purchasing	hard to inspect before purchasing	easy to inspect before purchasing	difficult to know without experiencing it	easy to know without experiencing it
Evaluate	Portray	Handle	Experience	Experience	Credence

Source: Verhagen et al.

Responses to each question for each of the goods or services were coded by three different coders at a Belgian university²⁴¹. Since the constructs to be measured as well as the variables to measure these constructs have been developed in previous studies, confirmatory factor analysis was employed to ensure that the latent variables of interest were being satisfactorily described by the variables as coded for trade in services. The use of seven point Likert or

²⁴⁰ The basis of attribution was the arrondissement which is smaller than the Belgian province. The Belgian province is roughly equivalent in area to the French department or the English county.

²⁴¹ One was a recent PhD in business economics, a second a teaching assistant with a master's degree in business economics and the third an undergraduate in an unrelated discipline. Using an indicator of similarity of the responses of the different coders compared to the average, a high degree of consistency was found in coding by the different coders. As a result a simple average of the responses was used for the values of the different variables.

semantic differentials scales is potentially problematic because they are not continuous variables. Instead they are generally considered to be ordinal and their distribution tends to be non-normal, which poses a problem for maximum likelihood factor analysis. The asymptotic distribution free method does not require multivariate normality and so was preferred to maximum likelihood estimation.

While each of the three dimensions of intangibility has three different indicators, only the search criteria in the S-E-C framework is being measured by three different indicators and while confirmatory factor analysis could be applied jointly to the different indicators for intangibility, only search could be analysed using a single factor. In subsequent analysis the three dimensions of intangibility and the search criteria are measured using the factor scores from the confirmatory factor analysis while for the experience and credence variables only the coding of the relevant questions could be used. The basic structure of the two confirmatory factor analysis along with the standardised values of the coefficients and error terms (**p<.001) are set out in the path diagrams below.

Figure 1. Confirmatory Factor Analysis.

Each of the indicators loads strongly and positively on the relevant construct. Only the indicator portray among the search indicators has a somewhat weaker coefficient. Goodness of fit can only be measured for the intangibility model. In terms of the standard criteria for goodness of fit, four are within minimum accepted levels (Chi-square/df<3, p value >.05, Comparative Fit Index (CFI)>.90, Root Mean Square Error of Approximation (RMSEA) between .05 and .10) while the value of one, the Standardized Root Mean Square Residual (SRMR), is clearly outside the accepted range (>0.9). Overall goodness of fit can be considered as acceptable.

Reliability of the results of the factor analysis was confirmed with a Composite Reliability indicator (CR) above 0.7 and convergent validity with both a CR above Average Variance Extracted (AVE) and a value of AVE above 0.5. Finally, a value of Average Shared Variance (ASV) lower than AVE was used to establish discriminant validity (Table 3). Mental intangibility and generality shared the highest variance without compromising discriminant validity while physical intangibility and search also share some common variance.

Table 3. Validity and Reliability.

Variable	CR	AVE	ASV	ASV	ASV
			Physical Intangibility	Generality	Mental Intangibility
Physical Intangibility	0.964868	0.901663			
Generality	0.931271	0.818755	0.270088		
Mental Intangibility	0.937597	0.727362	0.33074	0.668633	
Search	0.866251	0.691737	0.625523	0.20286	0.209489

Since the need for proximity between provider and customer has been identified as an important influence on trade, it was necessary to add a variable that captures this aspect. When physical proximity is required either the customer must move to the supplier (mode 2 under the GATS) or the supplier must move to the customer (mode 4 under the GATS). For certain services for which either the necessity to move is inherent in the service (construction services must be supplied in situ) or where it is the overwhelmingly dominant way to provide a service (the customer moving physically to the provider in the case of travel), a simple identification of the mode by which the service is supplied should be sufficient to take in the proximity requirement.

However certain services can be supplied in multiple ways and this creates a problem of identification because the data on cross-border trade do not distinguish between the different modes. As indicated previously physical proximity is not always required for interaction to occur and physical proximity is becoming less and less necessary for certain services so that any identification of modes 2 and 4 is likely to change over time. Based on work in the World Trade Organisation (WTO) an identification was made of the principle mode by which different services are traded at that point in time (WTO, 2008; 2009). A dummy variable was then created taking the value of one for services for which the principle mode requires either the supplier or the customer to move physically across a border.

After testing the results of regressing trade on these characteristics with cross-section data for three different years, few differences in the results were found over time. To simplify the presentation of results, pooled OLS regressions were run on the panel data of Belgian enterprises over the years 1997 to 2005 (details of the data are provided in the next section). Because in a pooled regression there is considerable continuity in trade for each enterprise, robust standard errors were clustered at the firm level.

The general form of the structural model to be estimated is as follows:

$$\ln(\text{trade}) = \beta_0 + \beta_1 \text{service characteristics} + \beta_2 \text{firm characteristics} + \beta_3 \text{sector} + \beta_4 \text{related trade} + \beta_5 \text{time dummies} + \epsilon$$

The dependent variable *trade* takes on one of three values: cross-border trade (exports or imports), sales of foreign affiliates and share of cross-border in total trade. Trade for the 24 categories of services and 97 categories of goods is the value of trade world-wide per firm measured in euros. The first two variables are expressed in logs, while share is a percentage. They are measured separately for exports or sales of foreign affiliates of Belgian companies and for imports and sales of affiliates of foreign firms in Belgium. Thus there are in all six different dependent variables. In addition the regressions are run separately for trade in services and trade in goods making twelve different types of trade regression. Because the emphasis is on measuring the effect of individual characteristics of services and goods, for firms that trade in more than one product there can be multiple observations for the same year. The unit of observation is therefore *Firm*Year*Category* (good or service).

The set of *service characteristics* is composed of the variables relating to characteristics of services and also goods. They include the factor scores for physical and mental intangibility, generality and search with the responses to the individual questions for the experience and credence variables plus for services only the dummy variable for mode of supply of the service.

The set of *firm characteristics* is composed of a dummy variable for whether the firm is situated immediately on the border with a neighbouring country (*border*) plus a number of control variables relating to the individual firm. The log of turnover (value added for sales of affiliates of foreign firms in Belgium) is a size variable which is always present along with the log of the date of creation of the firm (*age*). Other similar variables which vary according to the

regression specification relate to the log of labour costs, the log of labour productivity, profitability and the markup, included as a control variable for the level of competition.

The set of variables related to *sector* is composed of a series of dummy variables of the sector of activity of the firm. In the simple specification this is limited to dummies for manufacturing and services (the reference group is composed of firms categorised as either in agriculture and extractive industries or non-market services). In the extended specification, dummies are included for individual types of services or, in the case of goods, for manufacturing at the two digit NACE level.

The set of *related trade* variables covers a series of associated trade variables for each firm which also vary with the regression specification but are always present in the relevant form. This allows to control for complementarity or substitution between different forms of trade. Trade variables cover the log of the value of complementary trade of the same service or good either cross-border or through foreign affiliates. The extent to which service traders also trade goods or goods traders also trade services is controlled for by the log of the total value of imports and exports of goods or services.

The set of *time dummies* controls for developments over time in the dependent variable and ϵ is an error term.

5 The data

Panel data on individual firms for the period 1997 to 2005 held by the National Bank of Belgium is drawn from five different sets linked by the basic business repertoire. One data set holds balance sheet data, another holds data on cross-border trade in services, another on cross-border trade in goods, one on outwards foreign direct investment and the fifth on inwards foreign direct investment. From these different data sets the relevant variables identified in the previous section are extracted and combined.

All firms in Belgium with a limited liability legal form are obliged to file balance sheet data with the National Bank of Belgium (NBB). Most economically active firms in Belgium choose to incorporate in order to benefit from limited liability. The exception are some of the self-employed who may choose to incorporate or not. The balance sheet data used here does not cover the financial sector for which a different type of balance sheet is used. Small firms are only obliged to file limited balance sheet data, while large firms must file an extended version. Since most firms in services are small, only items available in the short version of the balance sheet were selected. A few firms that export or import are not present in the balance sheet data and these have been dropped from the data set.

There are two major problems with the balance sheet data. Small firms are not required to file data on turnover in their balance sheets. In fact only 40% did so in 1997 declining to 25% in 2005. Since turnover is the variable required to calculate various indices for the study, it was imperative to solve this problem by combining data from the VAT authorities with that from the National Bank. In this way it was possible to achieve an overall coverage of turnover of 84.2% of all firms for which there is balance sheet data. These firms however represent 97.5% of value added, 98.4% of employees, 99.1% of imports of services, 98.7% of exports of services and all imports and exports of goods. The economic representativity of the data is therefore very high.

The second major problem encountered is that only employees are covered in the balance sheet data while 52% of all firms in the NBB balance sheet data had no employees, which falls to 48% if only those firms for which there is data on turnover are considered. On the one hand this makes the coverage of the data very interesting because it covers service firms that are excluded in most data sets, including micro enterprises. On the other hand the absence of any employment data for these firms makes any calculation of labour productivity problematic because we lack a suitable denominator. In practice, productivity can only be calculated realistically for those firms with twenty or more employees, since below this threshold the figures are quite biased by the self-employed. Even the proxy of labour cost is only available for those firms with one or more employee. Because labour costs enter into the calculation of the markup, this variable is also only available for those firms with employees²⁴². Including only those firms with one or more employee reduces the number of observations for exports of services by 16% and by 62% if only those with twenty or more employees are included. The equivalent figures for foreign affiliates of Belgian firms are 11% and 42%. Small and even micro firms with no employees therefore do not engage in trade and it is worth including them in any analysis.

Another important issue concerns the coverage of the data on cross-border trade in services. Data on cross-border trade in services is collected by the National Bank of Belgium as part of the statistics on balance of payments. They are the source for data published nationally and also by Eurostat as well as those published by international organisations such as the OECD and the IMF. During the period covered here, financial intermediaries had to report payments made or received by their clients when the payer or the payee was a non-resident. This source of information was completed by returns from some direct reporters (i.e. big companies). Thresholds for reporting increased in 2002 creating a small break in series. More serious is the fact that it has not proved possible to attribute the items covered under "travel" to individual enterprises in Belgium. The NBB data also excludes data on merchanting from their data base on trade in services since it is considered to be part of the trade in goods. For those services for which it was possible to attribute the EBOPS post to an individual enterprise, coverage compared to the total trade reported by Eurostat for Belgium in

²⁴² The markup is measured by an approximation of the Lerner Index as: $markup = \frac{turnover}{labourcost+capitalcosts}$ (Griffith; Harrison, 2004)

2005 varies considerably (Fig. 2). In the case of computer services the value of individual firm data even exceeds the reported ones. For fifteen of the twenty-four services the total value of both imports and exports at firm level represents more than 60% of the total reported.

Figure 2. Coverage of NBB data on trade in services.

Issues relating to cross-border trade in goods are different in nature. Most trade in goods can be attributed to an individual enterprise. However, so called “carry along” trade comprises a large share of Belgian trade in goods. Goods enter the country and leave without transformation in the Belgian economy. It is not possible from the data used for this paper to distinguish trade in goods destined for the Belgian economy from that which is through trade. A second major issue concerns the thresholds for reporting and the effect of the 2004 enlargement of the EU. Thresholds for reporting changed more frequently and more significantly for goods than for services. For third countries data is collected at the frontier but for intra-EU trade it is collected via surveys of enterprise with a higher threshold. The result is that on enlargement trade that was previously registered is no longer unless the new threshold is exceeded. Overall therefore the trade in services data is much more stable over time than that in goods but coverage is lower and varies from service to service.

Cross-border trade by firms in the goods and services sectors displays some interesting differences. Goods are traded either by the manufacturing sector or by the distribution sector which accounted for a third of exports and over half of imports in 2005 (Table 4). While exports of services are concentrated in firms in the transport, information and communication and professional and scientific sectors, imports of services are traded much more widely in conformity with their role as key inputs to the economy as a whole. Thus shares of imports are lower than exports for the major service exporting sectors and manufacturing and distribution become major importers as well as non-negligible exporters. At a more detailed level it is possible to identify courier services, computer services, architectural and engineering services, services to agriculture and industry, waste management, other business services and leasing as ones for which the majority of exports are provided by firms whose main activity is outside that of the service being provided. This ability to track cross-border trade in services irrespective of the principal activity of the firm doing the trading is an important advantage of the data set.

Table 4. Cross-border trade by sector of activity, 2005.

<i>Sector of Activity</i>	<i>Total Exports of Services</i>	<i>Total Imports of Services</i>	<i>Total Exports of Goods</i>	<i>Total Imports of Goods</i>
Manufacturing	6.0%	17.9%	65.2%	44.9%
Utilities	0.8%	0.8%	0.0%	0.1%
Construction	4.1%	1.6%	0.2%	0.5%
Distribution	3.9%	10.0%	32.8%	51.2%
HORECA	0.1%	0.2%	0.0%	0.0%
Transport	41.6%	34.1%	0.2%	0.7%
Information & Communication	10.7%	9.0%	0.1%	0.5%
Real Estate	0.3%	0.2%	0.0%	0.0%
Leasing	0.7%	0.5%	0.1%	0.2%
Professional & scientific	19.6%	15.8%	1.1%	1.3%
Administrative services	2.1%	0.9%	0.1%	0.1%
Waste management	0.2%	0.1%	0.0%	0.0%
Audiovisual & recreational	1.5%	1.7%	0.0%	0.0%
Other	8.3%	7.2%	0.1%	0.3%
Total	100.0%	100.0%	100.0%	100.0%

Unfortunately, this advantage does not carry over to the data on foreign direct investment. The data on outward foreign direct investment contains data on the foreign turnover of affiliates of Belgian firms and by matching the data on inward foreign direct investment with that of the balance sheet it is also possible to establish the turnover of affiliates of foreign firms in Belgium. However in both cases there is no breakdown of turnover by type of service or good so that this data cannot be directly matched with that on cross-border trade. The FDI data codes commercial presence by the principal NACE activity of the affiliate. Correspondence tables from Eurostat then permit to match the principal activity with one of the categories of EBOPS for services or CN2 for goods. Attributing all of the turnover of the affiliate to one category of cross-border trade is implicit in this procedure, which on the basis of the data in Table 4 is unlikely to be the case. No work around for this problem exists. The value of the procedure lies in the ability to produce a coherent set of data covering the different forms of trade in services at a disaggregated level.

6 Results

The main results of the pooled OLS regressions are set out in Table 5 for trade in services and in Table 6 for trade in goods. For reasons of space, year dummies have been omitted from the tables as well as other control variables from panel two. Since this paper looks at the structural effect of characteristics on trade, developments over time have not been examined. Overall trade in both goods and services has been increasing but particularly for goods changes in thresholds make time series analysis problematic. Likert and Semantic Differential scales are ordinal and not cardinal making the values of the coefficients of limited usefulness. Only the sign and the significance of the coefficients will be considered here.

Physical tangibility (Tangibility) strongly promotes both exports and imports of services. While the sign for both outward and inward FDI are negative and that for the share of cross-border trade positive as expected none of them are significant. H1a is therefore strongly supported while H1b and H1c are at best weakly supported.

Generality was expected to exert a positive influence on cross-border trade but for both exports and imports the results are significant and negative. They are also negative without being significant for sales of foreign affiliates and positive and significant for the share of cross-border trade in total sales. It would seem that the positive impact of this construct is exercised therefore on the way a service is traded rather than the amount of trade, rejecting hypotheses H2a,b and c.

Mental intangibility (Conceptibility) reduces both exports and imports of services highly significantly as expected. Instead of promoting sales by foreign affiliates, it reduces them, although the coefficient is only significant for inward FDI. Equally mental intangibility tends to promote cross-border provision in the place of a permanent presence. Thus while H3a is strongly supported, both H3b and H3c are rejected. It appears that the difficulty to grasp the nature of a service depresses both cross-border trade and sales of foreign affiliates so that permanent presence does not reassure customers more than when they purchase directly from a supplier located in a different country.

As expected, a positive value on search characteristics increases both imports and exports highly significantly, thereby supporting H4a. The generally non-significant and differently signed impact on sales of foreign affiliates between outward and inward FDI tends weakly to support the indeterminacy of H4b. Since the choice of cross-border trade over permanent presence varies significantly between outward and inward trade, H4c cannot be supported.

On the basis of the literature review, the effect of the experience and credence variables could be expected to be at least as strong as those for search characteristics but this does not prove to be the case. Because of the way that experience and credence variables have been coded, coefficients on these variables should be positive to support hypothesis H5a and H6a that these characteristics depress cross-border trade. Instead we find that coefficients on the experience criteria for both exports and imports of services are non-significant but negative so that services that are difficult to know without experiencing it are more likely to be traded cross-border than those that are easy to know without experiencing it. Hypotheses H5b and c expect indeterminacy of the impact of the experience criteria on the amount of sales of foreign affiliates or the choice of one mode of trade over the other. Instead, the experience variable affects significantly the choice of mode in the direction that services that are difficult to know without experiencing it are more likely to be traded cross-border, contrary to expectation. Thus neither hypothesis H5a nor hypothesis H5c are supported.

The credence characteristic impacts exports and imports of services highly significantly but in opposing directions. Credence actually promotes exports of services while it depresses imports. Coefficients for the sales by foreign affiliates are not significant and with different signs for outward and inward FDI. Contrary to expectation the credence variable promotes a higher share of cross-border in total trade for both exports and imports, significantly so for imports but not for exports. Therefore we have support for H6a only for imports, indeterminacy for H6b instead of a positive impact and no support for H6c.

Overall the impact of the search-experience-credence framework is much less strong than would be expected from the literature. It goes rather in supporting the findings for the tangibility construct since the search characteristic is most strongly related to physical tangibility.

The proximity variable (mode) reduces exports of services highly significantly as expected and also depresses the share of both exports and imports in total trade. The effect on sales of foreign affiliates is non-significant for both outward and inward foreign direct investment but signed differently. The biggest surprise comes from the positive and highly significant value of the coefficient for imports. Imports of professional services, which usually require some interaction between supplier and customer, are relatively more important than for exports and this may help to explain the result. Hypothesis H7a is supported only for exports, while H7b is not supported and only H7c strongly supported.

The impact of a border location is to promote exports but depress imports, to depress sales of foreign affiliates and promote a higher share of exports and imports. The negative impact on imports of services can perhaps be explained by the fact that many very large firms, including holding companies that are major traders in services, are situated in Brussels. Hypothesis H8a can therefore only be supported for exports, while H8b has only weak support contrary to stronger support for H8c.

In conclusion, service characteristics related to tangibility exercise a particularly strong influence on exports and imports, while characteristics relating to search-experience-credence, proximity and border location particularly affect the choice of type of entry mode for trade. Service characteristics seldom affect the value of sales by affiliates.

Larger firms trade more both cross-border and through foreign affiliates and because it requires more resources to enter through commercial presence, smaller firms prefer to trade cross-border rather than through foreign affiliates. Younger firms tend to trade more cross-border (the log of date of establishment of the firm is positive), but age does not have a significant effect on sales of foreign affiliates.

Both exports and imports follow a similar pattern with regards to the corresponding complementary forms of trade. Exporters of services import the same service very significantly and vice versa. There is also a strong relationship between sales of foreign affiliates and cross-border trade both outwards and inwards, indicating complementarity rather than substitution between the two forms. The coefficients on the value of exports and imports of goods are in both cases close to zero. These complementarities are not significant for the sales of the foreign affiliates of Belgian firms. The affiliates of foreign companies in Belgium also import significant amounts of the same service and are very active importers and exporters of goods. When it is remembered that foreign firms are strongly present in the distribution sector, which accounts for more than half of imports of goods and a third of exports, this result becomes less surprising.

The effect of the markup is to depress both exports and imports of services, indicating that firms which operate in less competitive markets have less incentive to trade cross-border. The effect on sales of foreign affiliates by Belgian companies is negative but not significant while that on sales of foreign companies in Belgium is both positive and highly significant. Lack of competition on the Belgian market therefore attracts foreign investors.

Coding the characteristics of goods in the same way as services can help to establish the extent to which trade depends on characteristics that are common to both and to highlight differences between the way in which goods are traded from those of services (Table 7). Since goods are much more homogeneous than services, differences in characteristics for goods are less than those for services so we should expect a weaker impact on trade. The effect of physical tangibility, generality and mental intangibility on imports and exports of goods is also highly significant and in the same direction as for services. Contrary to services, the search variable is not significant for either imports or exports of goods and signed differently for exports than for imports, while the experience and credence variables are in the same direction as for services, but more significant in the case of experience. A border location stimulates exports of

goods but depresses imports just as for services. Of note also the lack of importance of the characteristics of goods on sales of foreign affiliates, similar to services. Overall therefore the results for goods support those for services with partial exception of the search construct.

7 Policy Implications

Service characteristics affect the tradability of services. Tradability is important because it conditions the possibilities for market integration within and outside Europe and market integration is expected to lead to more competition. Service characteristics should therefore have implications for policy development. Service characteristics are not immutable and change under the impact of technology. As a result, forward looking policy on market integration needs

to take into consideration the dynamics that are unleashed by technology which provide new opportunities for trade but may make the current regulatory structure ill-adapted, out-of-date or redundant.

While we have good theoretical foundations for the relationship between technology and market structure for goods (Sutton, 1998; Scherer, 2000), the same cannot be said for services, and even less for the relationship between technology and trade in services (Miozzi; Soete, 2001). Both the way and the degree to which technology modifies service characteristics appears to vary with the construct. Tangibility, both physical and mental, appears one area where there is at least potential for making services more tangible. Clearly technology is modifying the burden of proximity by promoting interaction of persons at a distance (Skype) or even abolishing it altogether where a service can be provided without interaction at all (on-line banking as opposed to a visit to the local branch). It is less clear how technology modifies the need to experience a service or the credence characteristic. As we have seen, the latter can be modified by credible forms of commitment on behalf of suppliers, forms which however have little to do with technology choices.

Miozzi and Soete remark that technological transformations have eroded barriers between industries, resulting, in some areas, in pressures for deregulation. Further the extent to which firms are allowed to enter markets depends on the extent to which domestic regulation constraints can be relaxed. The nub of the problem therefore concerns the fit between current regulatory structures and changing possibilities to offer services, particularly the possibility to offer services cross-border.

These issues are currently brought to the fore by the proliferation of internet applications such as Uber or Lyft for car sharing and Airbnb for room rentals. These applications represent disruptive technology for established providers such as licensed taxis and hotels. Both of these industries are currently regulated in such a way as to create barriers to entry. Through bypassing these regulations the new entrants provide more choice to consumers and erode the rents that the traditional providers have been able to build up on the basis of entry barriers. They therefore have the potential to substantially increase consumer welfare²⁴³. Not surprisingly reaction by incumbents has been furious everywhere with protests by taxi drivers in London, Paris, Milan Berlin and a ban on the supply of such services in Brussels.

The substantially new way in which these services operate is by using the Internet to create a cross-border service from one that was previously very local. It can credibly overcome the information asymmetry between supplier and customer by its capacity first to control the quality of supply. Second the possibilities of feedback to the application firm allow that firm on an independent basis to filter both suppliers and clients. Both bad suppliers and bad customers can be eliminated from the system in such a way as to improve the overall quality of the service. This is a much more powerful tool than usual customer complaints procedures either direct to the supplier or to some third party such as a consumer organisation or public complaints procedure.

Because the services supplied over the Internet with the help of sharing applications are cross-border, it should provide a justification for intervention by a supra-national body such as the European Commission which has the mission to build a Single Market for services. Up until now efforts to liberalise local taxi services have largely foundered on the protests of incumbents. This applies equally to national initiatives such as the Attali report in France (Attali, 2008) or the 2012 Monti decree in Italy and to those mandated by international institutions as a condition for the Greek bailout. It applies in general to structural reforms in Member States regularly recommended under the Lisbon and follow up Europe 2020 programmes. Clearly local regulation to ban or restrict vehicle or room rental services undermines the proper functioning of the internal market for services and presents a test of the willingness of the European Commission to effectively force these markets to open up to competition.

The lack of clear evidence that experience or credence characteristics of services are limiting cross-border purchases of services combined with the new possibilities opened up by technology for controlling quality of services supplied via the Internet would seem to indicate that market solutions to problems of asymmetric information are working better than expected. Since the characteristics of services have served as a prime reason for regulation to protect consumers it is time to review existing regulation of services with regard to who is being protected against which risk by which means. The possibility that market solutions may work better than public regulation in meeting the objectives of regulation should be acknowledged and, where appropriate, acted upon. This should not be taken as a plea for systematic deregulation of services but of a proper calibration of the objectives of public regulation with needs in the context of a rapidly changing environment for the provision of services cross-border.

8 Conclusions and future work

This paper has demonstrated an association between several but not all types of characteristics of services with regard to cross-border trade and the choice of entry mode for the provision of services internationally. On the contrary, sales based on a permanent presence seem to be little affected by service specific characteristics. Most of these findings also apply to trade in goods indicating that we are dealing with inherent characteristics that are not specific to services.

While the main findings with regard to characteristics of service remain valid after controlling for the degree of competition on the domestic market, we cannot be sure that certain characteristics of services are not themselves the cause of a lack of competition on domestic markets. This carries over in particular with regard to regulation, which can

²⁴³ In Ireland, specifically Dublin, starting in 2000 any suitably qualified person could obtain a license, which led to a significant reduction in waiting times for a taxi, from 11.5 minutes in 1997 to 6.2 minutes in 2008, resulting in an estimated value of time savings of more than \$400 million annually for Irish consumers.

affect both entry and conduct on the markets for services, and which is often justified by the need to protect consumers because of the inherent characteristics of services. In order to explore this issue further, future work will concentrate on how regulation in the origin country (Belgium) and partner countries affects trade in services. Because regulation and characteristics are not independent, controlling for the effect of each individually requires that there are services with similar characteristics but different regulatory regimes (or vice versa). This would seem to be the case for example for management consultancy, which is a largely unregulated profession with similar characteristics to heavily regulated professions such as legal or accountancy services.

An Exploration of the Applicability of Service Dominant Logic in Mental Healthcare:

A case study of Care Programme Approach documentation in a UK Learning Disability Trust.

Mark Spurrell¹, Nathan Proudlove²

¹Calderstones Partnership NHS Trust, ^{1,2}Manchester Business School

Recent literature has suggested that Service Dominant Logic (SDL) can usefully be applied to healthcare, but further refinement and empirical work is needed. In the UK, 'Care Programme Approach' (CPA) case management is an interesting object of study. A Networked Service Dominant Logic (NSDL) model is proposed and used as a practical starting template for a qualitative exploration of a series of 8 CPA case reviews within a UK Learning Disability healthcare provider. It was found that the NSDL perspective was useful in capturing the CPA review process and in making suggestions for service improvement. The need for more research to confirm findings and to further develop the applicability of the model is subsequently discussed.

Introduction

There has been a marked development in thinking in recent years about services, service innovation and service marketing (Moussa; Touzani, 2010; Ballantyne; Williams; Aitken, 2011b; Perks; Gruber; Edvardsson, 2012). These developments follow the emergence of Service Dominant Logic (SDL) as a potential theoretical paradigm, most closely associated with Vargo and Lusch (2004; 2007).

In proposing SDL, Vargo and Lusch argued exchange was all 'Service', where 'Service' is the application of knowledge and skills for benefit. The authors adopted 'Value Co-Creation', associated for example with Ramaswamy and Gouillart (2010), as the central part of exchange. Knowledge and skills from relevant sources were produced *with* customers in appropriate combinations to form 'operant resources' which can be integrated by customers to create value for themselves, and co-create value for other participants. 'Value' was deemed as experienced uniquely by the customer, with 'benefit' being potential source of value. It was implicit, and later confirmed by subsequent theorists (Ballantyne; Frow; Varey; Payne, 2011a), that the transaction could be viewed as having a reciprocal dimension: i.e. so long as the customer is able to create value, "the service provider should be able to create value for themselves" (Grönroos; Ravald, 2011). In this context, there has been a significant influence on traditional views of marketing (Olivia, 2012) and a shift in focus from transactions to relationships (Hadjikani; LaPlaca, 2013), which has subsequently been taken up in the B2B literature (cf. "it's all B2B...and beyond", Vargo; Lusch, 2011).

From the interplay with the B2B literature therefore it is now argued that SDL should be viewed as embedded in its relationship network context (Vargo; Lusch, 2007; Edvardsson; Tronvoll; Gruber, 2010). Interestingly, from there it has been a natural development to consider the applicability of SDL to public sector services (Vargo; Lusch, 2011; Hadjikani; LaPlaca, 2013; Hardyman; Daunt; Kitchener, 2014). Healthcare in particular has been proposed as a potentially useful field to consider (Alves, 2012; Radnor; Osbourne, 2013; McColl-Kennedy; Vargo; Dagger; Sweeney; Kasteren, 2012), although more empirical investigation is required. The need for further empirical work is a more general issue for the applicability of SDL in practice (Brown, 2007; Winklhofer; Palmer; Brodie, 2007; Baron; Harris, 2008; Korkman; Storbacka; Harald, 2010; Warnaby, 2011). In essence, the cardinal elements of service exchange emerging from the literature involve the interplay between 'the network context', 'operant resource', 'co-creation processes' and 'value'. It is proposed to label this embedded perspective as 'networked service dominant logic' (NSDL). Further empirical work is required to explore the application of 'NSDL' in practice.

Currently, there is criticism of the concept clarity (Grönroos; Volma, 2012) and practical real world applicability of the cardinal elements of SDL (Winklhofer *et al.*, 2007). As Korkman *et al* (2010) state, there have been few attempts "to understand the actual practical process of resource integration, and how value stems from integration". Moreover, such efforts should focus on studying all the components of SDL in practice together (Winklhofer *et al.*, 2007). This is in contrast for example to Baron and Harris (2008) and Baron and Warnaby (2011) or McColl-Kennedy *et al* (2012) who have empirically explored aspect of SDL such as operant resource and co-creation in isolation. Therefore, there is a shortfall in the service research literature to empirically explore the applicability of SDL in a network context, where all the cardinal elements are included. There is a further issue of extending empirical work, as appropriate, across a wide range of service sectors including the public sector.

Recognising the need for structured empirical work, Spohrer (2011) argues for an integration of SDL with a service science based approach and a supporting model had been proposed (Spohrer; Maglio, 2010). In practice, the model has not been widely adopted, and in a limited exploration of a public library system (Lyons; Tracy, 2013) the model did not represent the individual service user experience. Further, it might be argued that the model was over-complicated and the elements not so clearly distinct in practice. Nevertheless, the study does support the deployment of an ecologically

grounded framework for investigating service phenomenon applied to a defined entity in context. It is proposed that a simpler model that captures the cardinal elements of service dominant logic embedded in a network context would make a useful contribution to the investigation of service entities. A proposed model, ‘the NSDL model’, is set out below.

The Networked SDL Model (NSDL)

Derived from the foundational principles proposed by Vargo and Lusch (2004; 2007) in the context of a wider literature review (Spurrell, 2013), in keeping with the theoretical work of Grönroos (2008; 2011) and Grönroos and Ravald (2011), it is proposed that the cardinal elements for clarification in applying NSDL in the real world would be a practical understanding of ‘operant resource’, ‘co-creation’, ‘value’ and the nature of ‘context’ to the exchange. Drawing on the groundwork of the systems science perspective outlined above (Spohrer, 2011; Spohrer; Maglio, 2010; Lyons; Tracy, 2013) these elements acquire ecological integrity when combined in a suitable framework where care is taken to specify the entity of interest.

The NSDL model (Figure 1), it is proposed, captures these cardinal elements. It is proposed that the model would be applied to a defined service entity in context of a relationship network perspective. The model would provide a framework for mapping the inter-relationship between assembled operant resources, a platform whereby participants engage for the co-creation of value and the value changes represented as reported outcomes. The constituent elements need further explanation.

Figure 1. Diagram representing the elements of service dominant logic as applied to a service entity within a network: ‘The NSDL model’.

The Entity:

It is envisaged that an object of study within the proposed NSDL approach would need to be a ‘service entity’, which can be defined as any service system or sub-system of interest which can be deemed as able to make and keep promises (Freund; Spohrer, 2013). This would be fundamental to drawing conclusions and inferences that have ecological viability within service systems.

The Network Context:

Some would argue that capturing the network perspective is too complex, and that continuing the conventional dyadic perspective of exchange is more practically useful (Winklhofer *et al.*, 2007). However, capturing the perspective of multiple actors is seen as crucial by others (Storbacka; Nenonen, 2011; Spencer; Cova, 2012). This tension is discussed by Zolkiewski; Turnbull (2002). In essence Zolkiewski and Turnbull recognised the need to study customer relations management theory in a network context. Based on earlier work in UK healthcare commissioning (Zolkiewski, 1999) they proposed a triad, applying a portfolio analysis to each of the perspectives as a means of capturing the network context. The advantage brought was the ability to model a practical focus on the contact between customer and supplier, whilst also being able to represent the perspective of other relevant ‘indirect participants’ (Figure 2). A more detailed perspective on triads has been provided by Vedel, Geersbro and Ritter (2012), and is consistent with adopting the Zolkiewski and Zolkiewski and Turnbull’s structured triad approach. In Zolkiewski’s (1999) model (Figure 2), the entity in question (focal organisation) is the service provider organisation, with a portfolio analysis framework applied to each of the perspectives of the customer network, supplier network and an ‘indirect’ network which captured other interested perspectives as regulatory bodies, government, competitors etc.. In conceptualising the NSDL model it is proposed to similarly adopt this triadic structure, though using the service theory lens to examine the participating network perspective. In terms of the nature of that lens, Vargo and Lusch (2011) advocate adopting Gidden’s (1984) ‘structuration’ perspective for capturing service context.

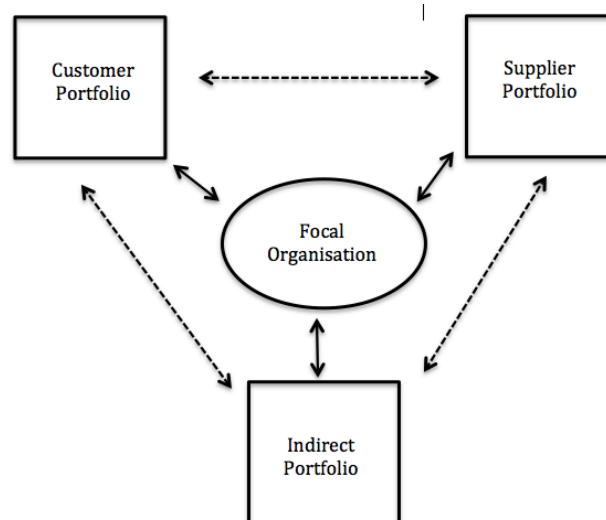

Figure 2. A Network Perspective of Portfolio Analysis. Reproduced and adapted from *Purchaser Provider Relationships in the UK National Health Service: A Marketing Perspective*. (Zolkiewski, 1999, p195).

Operant Resources:

‘Operant resources’ are defined in SDL as complex combinations of knowledge and skill made available by participants for integration in service exchange (Vargo; Lusch, 2004; 2007). ‘Operant Resources’ are distinguished from ‘Operand Resources’, which represent simpler, more fundamental resources such as raw materials. There are already a number of different views on Operant Resource within the literature. Ballantyne *et al* (2011a) studied the phenomenon of ‘practices’ (a kind of operant resource from the definition) as exhibited by both supplier and customer, for example. A similar perspective can be seen in work by Alter (2008). Meanwhile Freund and Spohrer (2013) point out that regulatory structures can act as complex, operant resources. Moreover, there is an untested assumption that all complex resource can be satisfactorily combined to form an adequate account of what is required for exchange to take place. The complexity as to what might be considered operant resource emerges in the Lyons and Tracy (2013) library study. Baron and Warnaby (2011) adopt a practical framework from Arnould, Price and Malsche (2006), which they had previously explored (Baron and Harris, 2008). The framework characterises ‘Physical Resources’ (including physical and emotional strengths), ‘Social Resources’ (including relationships and communities) and ‘Cultural Resources’ (including specialist technical knowledge and skills and historical qualities). It is proposed that pragmatically the Arnould, Price and Malsche (2006) framework should be adopted.

Co-creation Platform:

There has been perhaps less commentary on operant resource and rather more on Co-creation. Vargo and Lusch (2004) built on Ramaswamy and Gouillart (2010) earlier development of the concept of co-creation. Ramaswamy (2011), consistent with Vargo and Lusch (2008), considers value in terms of “human experience facilitated by networks”, but argues for the necessity of “an emergent platform” that bridges the gap from concepts to practice. Similarly, Grönroos (2011) explores the process of co-creation in some detail, presenting a two stage process of co-production of operant resource and a structuring between participants that enables exchange and value co-creation to occur. In fact, the idea of a platform or a structure between participants that captures exchange is widespread in the literature. Alter (2008) proposes such a model with his ‘Service Value Chain Framework’ and Glushko (2013) provides a brief overview and classification of available normative frameworks in service research before adding in a ‘naturalistic perspective’. Glushko’s point is that people naturally gravitate towards an instinctive ‘touch point’ topology when seeking to structure service processes, which can also be valid. Glushko supports a mixed approach to identifying supporting structures. In the context of co-creation therefore, the emergence of touch points that are seen as structuring the value co-creation process in a hybrid approach to structure are one way of capturing and characterising ‘co-creation’ in line with the Ramaswamy’s (2011) ‘emergent platform’ at the heart of exchange within Service Dominant Logic.

Value and Outcomes:

The notion of ‘value’ is clearly a key concept, and contributing to the ongoing debate as to the applicability of SDL in practice, Grönroos (2011) cites previous work to pronounce “Value for customers means that they, after having been assisted by the provision of resource or interactive process, are or feel better off than before” (Grönroos, 2008). For Edvardsson *et al* (2010) Value is a social construction, which therefore requires understanding as “in context”, though that does not contradict Grönroos (2011) definition. Notwithstanding the contextual relevance, however, there is a risk of confusion between what might be ‘value’ as externally apparent benefit: the “better off than before” defined by Grönroos (2011) and ‘value’ as a private experience. Therefore in contrast, Helkkula, Kelleher and Pihlstrom (2012)

are concerned with “the lived experience of value” as the core construct, emphasising the individual phenomenological dimension that Vargo and Lusch proposed. Similarly Hardyman *et al* (2014) for healthcare advocate detailed ethnographic exploration of the individual patient experience. However, this construction leaves ‘Value’ as somewhat inaccessible to the observer and lacks practicality for day to day management purposes. Spohrer and colleagues (Spohrer; Maglio, 2010; Spohrer, 2011) apply a systems science lens to the core concepts of SDL and in that context ‘Value’ is rather represented as ‘Outcome’, where outcomes are “value changes”. They propose that value change can be categorised as one of a range of win/lose outcome combinations for participants. Therefore, the notion of ‘value’ as ‘better off than before’ will be implicit in this model and will be encompassed by a study of ‘outcome’ for participants, where outcome would consist of categorical (‘winning’ or ‘not winning’) progress towards objectives valued by participants.

Positioning and integration of elements of the NSDL Model:

As noted above, Winklhofer *et al* (2007) make the point that the elements of SDL need to be investigated together, and that the practical applicability in the real world is key to the ongoing value of SDL (see also Brown, 2007). In this context, the proposed NSDL model integrates the cardinal elements of SDL in a practical format. In combining a number of elements it should be noted that the model is not intended to relate to ‘a general theory of the market’, or something such as per Vargo and Lusch (2011), although it retains their eco-system perspective. Möller (2013) examines the difficulties of combining theoretical perspectives in this field and argues for a more pragmatic approach rather than relying on a general integrating theory. The approach proposed is consistent with that taken by Zolkiewski and Turnbull in combining network context and customer relation theory (2002). Thus, the model combines ‘network’ as an “articulated contextual aspect” (Möller, 2013) with a structured form consistent with those proposed by for example Grönroos (2011). Therefore the model is not designed as a primary network analysis tool, but rather to explore “what are efficient forms of managing and organising value production in different contexts?” (Möller, 2013). It is proposed that empirical evidence of the practical usefulness of the model would be the means for its justification.

In summary, it is argued that further empirical work on the applicability of SDL in practice would be useful. It is proposed to adopt ‘NSDL’ as a term to represent the necessity for the application of SDL in a network context. There is space for a suitably configured model that captures the cardinal elements of NSDL and which is accessible to practical application in the investigation of a service entity. The NSDL model has been proposed as a pragmatic tool derived from the literature, though requiring further justification in terms of its empirical usefulness in a real world setting. It can be envisaged that an exploration of the NSDL model in practice could usefully form a first stage in a process of theory building as outlined by Christensen (2006), progressing subsequently perhaps to more normative investigation.

Health care

In terms of exploring an area of real world study, as indicated above there is a trend to see SDL as applicable to public sector services such as healthcare (Alves, 2012; Radnor; Osbourne, 2013; McColl Kennedy *et al.*, 2012). However, it is important to arrive not just at a sense of fit of theory, but also at a potential sense of impact for service improvement. In this context there is topical literature that reports a real difficulty with the status of mental health services within UK healthcare (Oyebode; Humphreys, 2011) as well as a lack of “parity of esteem” (Bailey, 2013) for mental health compared with other specialties. Mental health service ought to have a leadership advantage in fact with its traditional focus on patient centred complex case management, particularly in the Learning Disability sub-specialty. However, recent efforts to develop patient centred care models based on ideas such as ‘Recovery’ have been hampered by the difficulty with modeling such concepts in practice Meehan; King; Beavis; Robinson, 2008).

Since 1991 (and revised in 2008) it has been health policy in the UK for all patients with complex case management needs (including Learning Disability) to be managed through a case management system called ‘The Care Programme Approach’ (CPA). The position of CPA within case management approaches has previously been described (Simpson; Miller; Bowers, 2003a; Simpson; Miller; Bowers, 2003b). In principle CPA provides for a person centred process for the holistic assessment of complex patients, to integrate the necessary resources and to work collaboratively with patients, carers and stakeholders to best effect (Department of Health, 1990; 2008). Progress is reviewed through a series of ‘CPA review meetings’ held at intervals. The comprehensive coverage of CPA within UK mental healthcare makes it an ideal phenomenon to study for gaining insights into the configuration of care in mental health services. It would therefore be instructive to employ the NSDL model lens to explore complex case management within a UK Learning Disability service.

Case Study

The process of care within a UK Learning Disability Trust was selected as a convenient area for a first study of the applicability of the proposed NSDL model. The investigation sits within the theory building phase of research, as described by Christensen (2006), and a qualitative exploratory investigation was undertaken of themes derived from the NSDL model on a series of clinical case management reviews (known as ‘CPA’ reviews).

The selected Trust provides in-patient mental healthcare to patients with complex needs associated with Learning Disability and Autism and services are structured into four service areas that focus on the combination of learning

disability with the need for care in a medium secure setting, care in a low secure setting, a women's service and an 'enhanced care', or rehabilitation service. Patients within the services were all subject to the CPA care review approach and the Trust operates a protocol to describe the process of care, underpinned by patient centred values.

It is helpful to understand something more of how a patient CPA review meeting is configured in a network. The key participants in the CPA review process are the individual patient with their network of relatives and carers, and the clinical team. In addition, within the policy, there is an indirect stakeholder perspective included to provide for the accountability for example of the organisations responsible for commissioning service and the accountability of the provider NHS Trust for the regulatory perspective and the wider care system management. Thus, the network triad (Figure 2) adopted by Zolkiewski (1999) and Zoliewski and Turnbull (2002) provides a suitable template for describing network configuration, as discussed above. In Zolkiewski's model the 'focal organisation' (the service exchange in question) sits as an entity between the customer network portfolio of interests, the supplier portfolio of interests and a portfolio formed by the indirect stakeholders (for example regulators etc.).

Similarly, the CPA review meeting itself is an entity: an organisational structure which is able to make and keep promises (Freund; Spohrer, 2013). It is proposed that CPA sits (Figure 3) between the patient network perspective and the clinical team perspective with, similarly, a range of indirect interests to be engaged such as commissioners and regulators, as indicated below.

Figure 3. A triadic network perspective of stakeholder perspective applied to CPA review meetings in a mental health service, adapted from Zolkiewski, 1999, p195.

Local protocols may vary, but in this Trust a CPA review meeting is held usually at 6 monthly intervals over the course of an episode of care. At reviews progress reports are tabled, discussions take place and formal minutes taken and an agreed forward care plan issued. Therefore, each CPA review occurs in a very specific stakeholder context. The triadic network perspective, adapted from Zolkiewski (1999) is therefore a useful tool to be able to represent and position the CPA case review in its participant network context. As such a service entity, it is proposed that the individual patient CPA case review is a suitable unit of analysis for the application of the NSDL model.

In summary, it is proposed that the real test of the value of SDL in context is demonstration of its applicability in practice. Moreover, such testing should encompass all the various conceptual elements that go to form the process of service exchange as described in the literature. The aim of this case study is to explore the applicability of a proposed 'NSDL model' in a real world setting. Specifically, CPA case management reviews within a UK Learning Disability Trust provide an opportunity to explore the model's usefulness in capturing and representing service exchange. The ecological advantage of CPA as a phenomenon common across all UK complex mental healthcare further offers opportunities to identify areas for service and clinical practice improvement for consideration.

Method

Approval was obtained from the Trust Research Committee to undertake the study. No direct patient contact was required for the study and the investigation was structured as a service evaluation project and not a clinical study. All records remained confidential and no identifiable information was included. Within the case study literature it is quite legitimate for the focus of investigation to be a defined entity or phenomenon within an organisation, such as the CPA review (Yin, 2009; Woodside; Baxter, 2011). The project was conducted using a multiple case study design, where 'a case' was defined as an individual patient CPA review within one of the four service areas operated by the Trust: the medium secure service, the low secure service, the women's service and the enhanced care (rehabilitation) service. A systemic sample of cases was obtained by selecting two consecutive cases prospectively from the date of research approval being granted for each of the 4 service areas.

A CPA review takes place for each patient every 6 months at which reports are tabled and the attendance and the minutes of the meeting are recorded.

The data obtained for study consisted of all the relevant documentation filed in the electronic case record for the most recent CPA care review for the selected cases. The documentation in essence consisted of the minuted record of the CPA care review and any reports that may have been specifically tabled, typically professional progress reports for example. Some structured risk evaluations were included, as were in some cases the Health of the Nation Outcome Scale (Wing *et al.*, 1998) and 'the Recovery Star' (MacKeith; Burns, 2010). It was viewed that the designated CPA file constituted the official record. This was a study of documentation as distinct from oral information. In line with Atkinson and Coffey (2010, 80): "documentary materials should be considered as evidence in their own right". Further, they argue that the construction and conventions associated with documents, in this case these being the official record of the CPA review, are also part of the document's reality. Atkinson and Coffey (2010, 90) are clear in their view that the document in itself is not 'reality', rather that the interplay between selected documents provide 'a version of reality'. Therefore the study of the official CPA record is argued to be a valid basis for a study within an interpretive paradigm, supported by the between case triangulation of data to establish inter-textual consistency.

All cases were of adults of working age from within the North West Region of the UK, however as a service process study, apart from gender and service area, more specific demographic data on patients themselves was not included. The approach to data investigation was based on a thematic template analysis of the available documentation, as described by King (2012). As discussed above, the key themes suggested by the NSDL model were the networked context of the CPA review, where the CPA review forms the entity of interest, the assembling of operant resource, a platform to structure the engagement of participants in co-creation of value and valued outcomes. Therefore in the first instance, in keeping with the described methodology (King, 2012) the starting template was derived from the proposed NSDL model and an initial review of the data was undertaken. As a result, as permitted within this methodology, a further cross cutting theme of 'integration' was identified for inclusion in the template. This theme was to reflect the process of reconciling different perspectives within CPA case reviews. Meanwhile, in addition to providing a theme in its own right, the 'network perspective' was also structured as a cross cutting theme interacting with 'Operant Resource', 'Platform' and 'Outcome' respectively within the template. Consistent with the triadic network adapted from Zolkiewski (1999) as outlined above, the stakeholder network perspective was defined as being the patient network, the clinician perspective and the indirect perspective (representing commissioning, the Trust, regulatory oversight and other indirect stakeholders). Table 1 summarises the template and further outlines subthemes that indicate the criteria for assigning data to themes.

The data for each case was reviewed and a commentary was developed on the basis of the template. As an exploratory investigation data analysis was undertaken using pattern matching, consistent with the Cross-Case Synthesis approach to Case Study analysis described by Yin (2009, 156). Here, using between case triangulation, a picture was developed from the documentary data of the consistency and extent to which the NSDL model was able to represent the CPA care review process. Further, potential areas for improvement in service configuration were identified, as suggested through the lens of the NSDL perspective. The evaluation criteria consisted of:

- The elements of the CPA review meeting were plausibly and consistently captured by the NSDL model.
- The elements of the model lent themselves to practical general usage in understanding services.
- The NSDL model application showed consistency with previous theoretical and empirical research.
- The application of the model had the potential for impact on service improvement.
- The findings supported the possibility of progress towards a normative theory.

The implications for the applicability of an SDL networked model are discussed against the evaluation criteria outlined above.

Table 1. Template employed in the exploration of CPA case review documentation. Themes from the NSDL model with supporting references are indicated.

Template Theme	Nature of Evidence and Emergent Subthemes	Supporting Reference

Results

A sample of 8 cases of patient care planning meetings was obtained. The patients involved consisted of 5 men and 3 women, distributed across 6 Responsible Clinician Teams. All the meetings were held in 2013. The cases formed the basis for thematic template analysis, adopting the model developed from the literature as the starting template. The amount of documentation tabled varied from 1 item (the meeting minutes only) to 8 items, encompassing a range of professional and patient related documents. The key findings are reported below.

The applicability of the model to a clinical service

a) Network Perspectives

In all cases there was a strong and distinct representation of participant networks, as evidenced from attendance at meetings, structured space in the agenda, passive and active structuration within reports etc. (cf. Table 1). In this context, the multi-disciplinary clinical perspective tended to remain fairly uniform across cases. As well as family, it was usual for individual patients to have support from at least one of a network of supporters (patient advocate, 6/8 cases; legal agent, 4/8; Social Worker or similar, 7/8). Four cases had no family or friend present. In one case patient peers might be thought of as part of the patient network. The possibility of important distinctions between the patient view and the family view was noted and representation could have been more pro-active for patients. The indirect perspective was more complex. The most prominent feature was the subdivision of perspective between that of commissioning (with responsibility ultimately for resourcing the care pathway) and that of legal and regulatory considerations. With regard to the commissioning perspective, in this investigation there appeared to be a dis-connect with the CPA process, with very limited representation in reviews. Meanwhile, beyond formal legal considerations, there appeared to be little representation of other regulatory or policy considerations such as may interest Trust governance (e.g. practice

guidelines). Therefore there would appear to be evidence of a problem of configuration of mental health service as seen through the lens of CPA review with indirect stakeholder perspectives.

b) Operant Resources

The consideration of operant resource as reflected in the documentation remained narrow rather than systematic. Also, it was not always clear what should be deemed an 'operant resource'. This might suggest a service specific structured model for mapping potential available resource would be an advantage. In other words, there was not a comprehensive review of relevant resource that might be available from participants and their networks. With that limitation however, overall there was evidence of *some* consideration of operant resource relating to each perspective. This included attitude and skills available to patients, contribution of family and carers and clinical care options available. Again, the contribution of indirect stakeholders was notably less prominent. This included an apparent lack of consideration of complex resources bound up in best practice guidelines such as those proposed by NICE (the UK 'National Institute for Health and Care Excellence'). There was also a lack of consideration of relevant supply network resources (community care options) within the purview of commissioners.

c) Platform

These cases encompassed a notable multiplicity of structural forms that served in varying ways as platforms to support engagement and exchange, loosely framed by the CPA review process. There was some limited convergence between patient and clinical participants in some cases. An overarching, inclusive framework to structure these diverse forms would have been an advantage. The most prominent platform consisted of the theme that patients should attend an activity programme, that patients would 'move on' (transfer to another unit or leave hospital) and that the mental health act would be adhered to. For two patients an alternative structure was represented, which consisted of more passive attendance of activities with the apparent purpose to maintain the status quo and not move on, at odds with the more usual clinical purpose. Again, a commissioner perspective was not clearly structured into proceedings.

d) Outcome

There was not a sharp focus on outcome evident in terms of service objectives being categorically met or otherwise, rather the emphasis was on 'making progress' as it was deemed for each case. Outcomes were principally assessed by qualitative evaluation, with varying degrees of structure. There was only a minor level of empirical measurement. It may have been that accomplishment of tasks (process outcomes) or compliance with legislation (regulatory outcome) rather than service outcomes were more the focus of the CPA review. Overall, there were two levels of valued outcomes, against which progress was qualitatively reported. The top level of valued outcome was readiness to move on. The next level consisted of a range of subsidiary valued goals such as improving engagement, improving function and community participation and reducing or preventing risk (including unwanted patterns of behaviour). A more holistic perspective on what 'getting better' might mean for patients was not apparent.

e) Integration

A further process of integration was apparent whereby a sense check of information was made by the collective participants of the review meeting, differing perspectives were reconciled. This issue was most apparent above in terms of the multiple platforms that appear to influence the participants in their view of the care process. From specifically assessing this theme, it was apparent that there were mechanisms for resolving the issue of integration however. Predominantly the structured discussion within the CPA review meeting addressed this issue. In one case a special 'best interest' discussion was referred to whereby a particularly complex resolution to different views could be established. In some cases the integration was structurally supported through the way that documentation was employed to incorporate perspectives (4/8 cases). In some cases (2/8) the clinical and patient perspectives were at cross purposes, but the fact of this was integrated into discussion for further consideration. The issue of integrating the commissioner perspective however has appeared as a general theme within these cases, and of particular emphasis for 3 out of the 8 cases from this aspect of the analysis.

The internal validity of the Cross Case Analysis studying Cases as outliers

A key validity check within this investigation was to study the consistency of findings, against outlier effects that might arise if there were distortions introduced by individual cases. For example findings might be influenced through systematic differences of practices between clinical teams. Alternatively, variation in access to documentation might account for differences in finding. Therefore to study this, sub themes were identified that could only be attributed to 1 or 2 cases. These were mapped against the four service areas, the individual Cases, the clinical team as denoted by the Responsible Clinician or Consultant (RC) and the number of documents available for the analysis. Overall, there were no identifiable patterns attributable to effects of different service areas or the particular Responsible Clinician and associated teams. Therefore the case sample has allowed a rich picture to be developed with a low likelihood of confounding effects from clearly atypical cases.

Discussion

This study has investigated the applicability of a networked model of SDL (NSDL) to the phenomenon of the CPA case management function in a specific UK mental health service. The study of documentation of a sample of CPA review meetings has been adopted as a means of obtaining a view on the CPA care process. The implications of the findings will be discussed against the applicability criteria outlined above, followed by a discussion of areas for further work.

1. The elements of the CPA review meeting were plausibly and consistently captured by the NSDL model. For a researcher familiar with the process of CPA review the template developed from networked model of SDL proposed was very helpful in capturing the elements of the CPA review process. It was reassuring to observe the consistency with which themes were reflected across cases, supporting the inter-textual validity that Atkinson and Coffey (2010) associate with good documentary research. The only theme that was not clearly evident from the SDL approach was that of integration. This theme referred to the process of reconciling different stakeholder perspectives, leading to actionable conclusions.

It is the case however that this was a relatively small sample of cases and it would have been ideal to triangulate these findings with other sources. The documentation of CPA review reflects a reality that is a subset of the CPA review process as a whole, which in turn is a subset of the sum total of service practices involved in patient care. In particular, given the prominence of the findings relating to commissioners, some further specific study of that perspective would be in order to confirm whether these cases typically represent how commissioners relate to the CPA process and to understand whether there might be other meetings or systems of relating to patient care that can be judged as adequate and appropriate alternatives. Other issues to acknowledge are that there may well have been sources of variation in the process of recording and production of documents that were not detected. Further, having selected a systemic sample to ensure coverage of the diverse service areas, the potential contribution of difference in practice between service areas could usefully be studied in more depth with a larger sample.

Therefore, this study has provided a degree of support for the applicability of the NSDL model in capturing elements of mental health service process, as revealed by the CPA case review. Further research is required to confirm this finding, and the addition of a further theme of integration would be consistent with some limitation in fact to the scope of the model, to be further explored in theory development.

2. The elements of the model lent themselves to practical general usage in understanding service ideas. It was encouraging that the constellation of ideas that go to make up SDL in context could be found to have applicability in such a complex service area as mental healthcare. In other words if it can work in this challenging service environment it should work anywhere. As discussed above, the applicability did have some limitations. Each element required a degree of interpretation in the investigation. The network perspective in particular could have benefitted from a more sophisticated assessment. This would suggest the need to further clarify and standardise the concepts and for work to develop suitable measures for capturing these concepts more objectively in further research.

Also, in practice, in many respects these elements were interdependent, and that interdependency was crucial to their meaning. In other words it did not make sense to think of operant resource except in the context of the network, nor to think about outcomes except in the context of platform and operant resources. This supports the holistic investigatory approach advocated by Winklhofer *et al* (2007) and the ecological perspective intrinsic to the Spohrer and Maglio approach (Spohrer; Maglio, 2010; Lyons; Tracy, 2013). Hence although there is literature that for example specifically studies 'co-creation' as a distinct phenomenon (such as McColl-Kennedy *et al.*, 2012), this investigation would suggest caution in interpreting those that do not include a perspective on the wider elements of the system. There is an issue that the model combines concepts from different theoretical roots however, an issue discussed by Möller (2013). The pragmatic route would be to allow the NSDL model integrity only in so far as it was able to have practical real world utility. In the first instance the investigation is encouraging in this respect.

3. The NSDL model application shows consistency with previous theoretical and empirical research. These findings demonstrated consistency with other literature. For example, Grönroos' (2011) conceptualisation of a staged process of co-producing operant resource, followed by joint value co-creation was supported by these findings. Here, the process was akin to assembling elements of operant resource, which in different cases to different degrees had achieved a level of integration in the co-creation process at the point of the CPA case review. The reflection on Grönroos (2011) model however is that this data captured some integration and co-creation of value in some areas prior to the point of review, whereas in other areas the CPA review itself became part of the mechanism for integration. Further, in other areas the opportunities for integrating resource were overlooked (suggesting areas for service improvement). It might be that Grönroos (2011) two stage process is too simplistic, particularly for complex multiple stakeholder service exchange. In other words the flow of service might be better thought of in terms of a multi-stage series of minor assemblages of operant resource elements, with an incremental process of episodes of integration and value co-creation building to an overarching experience of value over time. In this context, the additional theme identified of 'integration' could be thought of as 'overarching integration' as a necessary extension of Grönroos' model in order to accommodate complex service exchange.

Meanwhile, in more empirical terms, there is an interesting parallel to McColl-Kennedy *et al*'s (2012) study of co-creation style in healthcare. The striking feature of their study was the variability of co-creation style within healthcare, linking to variability in clinical outcome. Similarly, in this study there was variation to how different individuals engaged, even being at cross purposes with the clinical team in some cases. In some cases there was clearer pro-active integration of patient and professional perspectives compared with others. This resonates with other literature that argues 'the customer' represents a complex agent and might not want the properties others attribute to them. For example, some criticise the simplistic assumption that all customers engage with 'choice' (Rust and Thomson, 2006; Winklhofer *et al.*, 2007; Nijssen; Hillebrand; de Jong; Kemp, 2012; Porter; Lee, 2013). Some authors argue for the idea of a sub-group of 'Lead Customers' who perhaps can engage more pro-actively and more influentially, but for others that expectation might be counter-productive (Von Hippel, 2005; Nijssen, *et al* 2012). Therefore, a more sophisticated conceptualisation of the participant actors in the NSDL model may be further required. Illustrating this point, the variability to the patient perspective has already been discussed above. The engagement and connectivity of commissioners with the CPA process was also a key question to emerge from this study.

4. The application of the model had the potential for impact on service improvement.

In healthcare improvement, there is a call for methodology development to better understand "practice based evidence" (Green, 2006) and better understanding from the individual case (Baker, 2011). This investigation makes a useful contribution in this respect by illustrating the use of a simple ecological model to structure critical reflection on care processes in the individual case. From the rich picture developed a series of areas for potential service improvement were identified. These areas included for example the need for a fresh perspective on the engagement of commissioners in CPA; ideas for better integrating the perspective of patients and other stakeholders; the value of a structured, overarching framework or platform of care; the prompting of key questions as to how to understand valued outcomes.

Consideration needs to be given to the extent to which the findings of a small selection of cases might be transferable to other healthcare settings. First the sample was selected to represent a broad spread of practice within only one Healthcare Trust and therefore findings need to be interpreted with caution. The consistency of findings across cases supports at least local transferability within the organisation, though. There is only limited previous research in this area, as indicated above. However, reports of better configuration and engagement in CPA being valued by patients (Rose, 2003; Carpenter, 2004) are consistent with the idea of the NSDL model as a helpful structure to guide the participants towards that. Although the CPA case management system is common to all care settings, nevertheless more research is required to establish the wider usefulness of the NSDL model in other healthcare settings.

5. The findings supported the possibility of progress towards a normative theory.

Putting the arguments together, this investigation has explored the applicability of a networked model of SDL, from which there is evidence of the interdependent relationship between the constituent elements. Further work is needed to improve the clarity of the constituent elements, and to develop suitable measures. Adopting Christensen's (2006) approach to theory building, there is in fact an opportunity to move to a normative model approach. Following McColl Kennedy *et al* (2012), outcomes might well be a function of configuration service elements (eg choice of co-creation style). Therefore, if suitable measures could be identified for the constituent elements of the NSDL model, a testable normative theory might be proposed and a causal relationships investigated between network connectivity, the assemblage of operant resource from all quarters and the quality of a platform to structure care, with valued outcomes as the dependent variable.

Conclusion

This small study has provided confirmation that a proposed, simplified networked Service Dominant Logic (NSDL) model can form a useful tool in representing service exchange in the complex mental healthcare setting of a Learning Disability Trust. Further confirmation from a larger case series and in different organisational settings would be indicated. The interdependency between the constructs forming the model was a notable feature and further work is indicated to refine the model. It would also be interesting to explore the applicability of the model further to consider whether the model could be operationalised for use in a more normative paradigm. A number of practical areas for service improvement were suggested. It might be that further development of this methodology within mental healthcare would be of assistance in finding ways to improve the configuration and impact of services for people.

Multilatinas and the growing service economy in Latin America: A Challenge for EU-Latin American business relations

Patrik Ström¹, Claes Alvstam¹, Andrew Jones²

¹University of Gothenburg, ²City University, London

This paper studies the development of the growth of service industries in Latin America and their connection and integration with regional and global value chains, and the development of integration of service economies in Latin America. Relating to ongoing or concluded negotiations of free trade agreements as well as trade and investment partnerships between the EU and separate Latin American countries, e.g. Mexico, Colombia and Chile, with ambitions to in the future also to comprise Mercosur. Also the initiated TTIP negotiations between EU and USA will have an indirect impact to Latin America in general and Mexico in particular, due to the NAFTA connection.

1 Introduction

The service industry has for a long time been the biggest part of the most advanced economies in the world. This development is rapidly also transforming many of the world's emerging markets in Eastern Europe, Asia and Latin America. The value-added within global production chains is becoming to a larger degree determined by knowledge and service content (WIR, 2013). Services also play an important role for manufacturing firms, where a large part of the offer to customers today is a combination of goods and services. This paper studies the development of the growth of service industries in Latin America and their connection and integration with regional and global value chains, and the development of integration of service economies in Latin America. In the perspective of the ongoing or concluded negotiations of free trade agreements as well as trade and investment partnerships between the EU and separate Latin American countries, e.g. Mexico, Colombia and Chile, with ambitions to in the future also to comprise Mercosur. Also the initiated TTIP negotiations between EU and USA will have an indirect impact to Latin America in general and Mexico in particular, due to the NAFTA connection. Europe was in the early decades after WW II a key economic partner to Latin America, but has gradually lost this position to first North America, and thereafter to Pacific Asia. It is therefore a challenge for European business to, at least partly, recapture its previous role, although now as an equal partner rather than as a postcolonial master. Cooperation within the field of service industries may provide a better platform for mutual benefit than the old relation of exploitation of raw material resources and cheap industrial labour.

The regional economic characteristics and fundamentals play a vital role in the development of the service industry. For many emerging markets the growing service industry is also a way to reduce the risk of getting stuck in the so-called middle income trap, where the cost advantage is diminishing and the ability to compete with the advanced economies is limited.

Additionally, a growing service industry can facilitate the shift from informal to formal economic activities. In turn it enables a bigger tax base to be used for welfare creation. The economic development in Asia has attracted much attention and there is also an increasing interest in the development of the regional service industries (ADB, 2012). The economic transformation has been driven by the establishment of complex regional production networks and the willingness among policy makers to create regional service or knowledge hubs in capital and metropolitan regions. Studies of the growing service industry in Latin America are less frequent particularly due to structural connection to global value-chains. The service industries will, however, be a similar positive force for future economic development among the emerging markets in the region. The challenge is connected with the issue of how to make use of regional economic integration, up-grading existing value-chains and develop the knowledge intensive service industry, which is a vital intermediary actor in terms of productivity, innovation and restructuring in advanced economies.

The underlying opportunities with mostly common language, similar cultural structures and trade collaboration such as Mercosur and the impact of a concluded trade and investment pact with the EU, can form a platform for further development. Examples of internationalization among firms in the region, so-called Multilatinas, are often found in relation to the service industry, such as banking and finance, insurance, retail, telecom and business services. These firms can take advantage of the expansion possibilities that exist and rapidly expand beyond their closest geographical context. This conceptual challenge to traditional theories of internationalization has gained strength in studies of emerging market multinationals (Mathews, 2009; Ström & Ernkvist, 2012). Forerunners in this development have been a number of Chilean and Brazilian companies expanding across the continent. These firms might also use their advantages to expand further out on the global market and become competitors to established multinational companies in the advanced economies in Europe and North America.

2 Latin America and the world economy

There has during the long process of globalization of economic activities been a continuous scholarly debate within the fields of international business, economics and international political economy on why firms emanating from Latin

American countries have not taken part in this dramatic transition to the extent one could expect, considering the economic size of the region, as well as its abundance of natural resources within almost all sectors of industry. Half a century ago, in 1963, the share of Latin America in world trade of goods amounted to roughly 7 per cent, compared to 6 per cent in 2013.²⁴⁴ Southeast Asia on the other hand²⁴⁵, a region that in many respects can be compared to Latin America, when it comes to population size, resource endowment, and a history of political and economic dependence on superpowers in Europe and North America, accounted for 3 per cent of world trade in 1963 and 7 per cent in 2013. The EU trade relations with Latin America have stagnated during the last fifteen years at about 2–2.5 per cent of its total foreign trade in goods (or about 8–10 per cent of EU external trade). It is also a remarkable fact that the intraregional trade in Latin America has not grown during the past decades. Its share of total trade is still below 20 per cent, the same share as in the 1960s, despite numerous concluded free trade agreements, customs unions and common market treaties in various constellations. This figure can again be compared with Southeast Asia, where the intraregional trade within ASEAN10 has grown from about 15 per cent to 30 per cent since the mid 1960s.

Also in terms of foreign direct investment, the Latin American countries are underrepresented, even though there is a slow, but continuous increase of the shares of total FDI stocks and flows over time. This notion is particularly valid when it comes to the service industry. The share of IFDI stock in manufacturing and service industries in 2012 amounted to a little less than 8 per cent of the world total, compared to 5 per cent in 1990, while the share of OFDI stock was only about 2.6 per cent both in 1990 and 2012.²⁴⁶ The entire OFDI stock from Latin America – 608 bUSD in 2012 – can in this context be compared to the one of Sweden, which amounted to 408 bUSD in the same year.

Accordingly, outward FDI from Latin American companies can in the best of interpretations be seen to be in an initial stage of development, and that the potential for further growth is huge. The aggregate figure of 608 bUSD is furthermore concentrated to a few geographic origins, in which firms from three countries – Brazil, Mexico and Chile – account for almost 80 per cent of the total OFDI stock. In addition, firms originating from Argentina and Colombia account for about 5 per cent each. Looking at the outflows from these five countries, the development has rather been stagnant or even negative in Brazil, Argentina and Colombia during the last years, with only about 3.5 per cent of the world total in 2012, so the only positive remaining examples of any significance can be observed in Chile and Mexico.

It has been pointed out that the modest volumes of OFDI do not properly reflect the dynamism of Latin American TNCs' productive activity abroad as revealed by the increase of cross-border acquisitions (UNCTAD 2013:59) where there has been a growing trend recently to acquire companies both in the developed economies in Europe and North America and in neighbouring countries. The largest single cases in 2012 within the service sector were the 3.4 bUSD acquisition of the Brazilian airlines *TAM* by *LAN Chile* and the Chilean retailer *Cencosud*, which acquired an affiliate of French *Carrefour* in Colombia for 2.6 bUSD, and the *Prezunic* grocery store in Brazil for 0.5 bUSD (ibid: 59 and 88). Another example was the Chilean bank *CorpBanca*, which acquired a stake in its Colombian unit from Spanish *Banco Santander* (ibid.).

3 Global networks of production of goods and services in the Latin American context

There are a number of crucial issues to take into account when assessing the emergence of new transnational companies with Latin American origin. In this context the focus will be on emerging service TNCs.

- Upgrading in the global value chain within the framework of new industrial policy measures;
- Transformation of the economic structure in the domestic markets;
- Nearsourcing;
- The trade political context at the regional and global level.

Upgrading in the global value chain

The abundance of natural resources in a region can be seen as a rich opportunity to create economic growth and welfare also in advanced manufacturing and services, but has in many cases turned out to keep the resource-rich country in the 'raw material trap'. The potential for upgrading to capital- and knowledge based elements in the GVC, i.e. in the mineral-, energy-, forest- and agricultural industries, was during a long time admittedly held back by foreign MNEs, wishing to benefit from more profitable value-adding activities elsewhere. But the extensive schemes of nationalization and domestic privatization of resource-based companies that have taken place in almost all Latin American countries during the last 3-4 decades contradict the widespread statements that foreign-inflicted resistance should still constitute a barrier towards domestic industrial and service-based upgrading. Rather, lack of capital, local access to technological knowledge and entrepreneurial tradition may be main hurdles to an emerging internationally competitive service industry, e.g. in industrial maintenance, research & development, technical consultancy, consumer product branding etc.

²⁴⁴ All statistical figures in this section are from IMF, Direction of Trade Statistics Database, visited March-April 2014, and UNCTAD, World Investment Report, various issues.

²⁴⁵ Defined here as the ten members of ASEAN.

²⁴⁶ Latin America and the Caribbean, excluding the largest offshore financial centres, British Virgin Islands and Cayman Islands (UNCTAD, 2013).

Since services to an increasing extent are embedded in the competitive performance of the large manufacturing MNE, the absence of internationally successful manufacturing enterprises built on indigenous resources, may also constitute a setback for the rise of global service firms from Latin America.

Transformation of the economic structure

Typical for the economic transformation process of the Latin American countries has been the relatively modest level of the secondary (manufacturing) sector. In the majority of advanced as well as of Southeast Asian emerging economies, the share of manufacturing related to the primary and tertiary sectors reached during the process of industrialization a peak at about 30-40 per cent of the total employment, after which it has declined, due to the continuous rise of the service sector. In Latin America, on the other hand, the peak of manufacturing reached seldom above the 30 per cent level. There was instead a direct transformation from the primary to the tertiary sector in Latin America, where today the share of total employment in most countries exceeds 60 per cent, with the highest level among the largest economies is recorded in Chile with more than 66 per cent of the working employment in the service sector (2010 figures).²⁴⁷ The direct shift from agriculture to services has to some extent led to a situation where a competitive edge in manufacturing has not been built up to the same extent as in e.g. Southeast Asia, and subsequently a relative lack of manufacturing-based service production activities.

Nearsourcing

It is usually argued in the scholarly debate around the emergence and development of global value chains that the phenomena of outsourcing and offshoring have played an instrumental role when it comes to further fragmentation and specialization of manufacturing production. Arguably, there is a 'Janus face' of outsourcing and offshoring, meaning that these activities can on one hand be seen in the perspective of exploiting differences in factor costs between centre and periphery, and in that respect also being an important explanation behind the origin of asymmetric dependencies between rich and poor countries; on the other hand may the hosting of outsourced and offshored activities be seen as a deliberate strategy among emerging economies to attract foreign capital and to subsequently build up indigenous capabilities to manage upgrading in the value chain and in that respect to support future growth of domestic consumer demand. The 'dependency' debate during the 1970s, which was particularly marked in Latin America, represented very much the first face, and may in the long run prevented the widespread use of outsourcing and offshoring activities that became a main tool of industrial transformation in emerging economies in East and Southeast Asia. However, the inbuilt dynamics of outsourcing and offshoring is, if successfully applied, their contribution to the levelling out of production costs or at least diminishing of the gaps between centre and periphery – i.e. the logic of outsourcing and offshoring is a high degree of geographical mobility. There is also the intricate balance between supply-chain costs and production costs, that has during a long time been kept by a continuous decrease of the share of total transport costs in the final consumer product. The trend of 'nearsourcing' - the recapturing of outsourced and offshored activities to the home market itself or to its vicinity - that has been seen recently is still a marginal phenomenon, but may play a larger role in the future when it comes to the reconfiguration of global value chains, and can result in a larger gap between production locations that will benefit from proximity to the large consumer markets, and those which could be even more peripherally located. In the Latin American context, Mexico and parts of the Caribbean region may belong to the first category, while the rest of the Western hemisphere could suffer from the 'tyranny of distance'. Within the field of service industry the phenomenon of nearsourcing will still be closely related to manufacturing, particularly in the case of research & development, maintenance and distribution, but less likely in banking/finance and retailing.

The trade political framework

Trade in services are generally regulated at the multilateral level within the framework of the General Agreement of Trade in Services (GATS). In the absence of a completion of the multilateral Doha Development Agenda, within which the GATS and the ongoing Trade in Services talks, also is to be extended and revised, almost all member states have to different degrees made efforts to seek other routes to further liberalization of trade in both goods and services, particularly through regional preferential trade agreements. The main current endeavours in this respect under negotiation - the *Trans-Pacific Partnership* (TPP), and the *Transatlantic Trade and Investment Partnership* (TTIP) – will, in case of successful completion, have a large impact of MNEs in Latin America, both in terms of trade in goods and services, as regarding investment. The TPP talks involve directly three Latin American countries, Chile, Mexico and Peru, who, together with Colombia, also have taken steps to form an own trade pact, The *Pacific Alliance*. Mexico is furthermore an integrated member of the *NAFTA* bloc. The Pacific Alliance can be seen as a main competitor to the other main trade bloc in the continent, *Mercosur*, consisting of Argentina, Brazil, Paraguay, Uruguay and Venezuela, which was created in the early 1990s, but which has so far failed to meet the early high expectations of successful implementation. Thus Latin America is at present rather disintegrating than integrating, and the aims to forge deeper trade and investment relations with other continents – Asia-Pacific, North America and Europe – are more articulated and active than the visions of a comprehensive *Community of Latin American and Caribbean States* (CELAC).

²⁴⁷ World Bank, 2013, table 3, p. 352f.

4 The European Union and Latin America²⁴⁸

The EU has, like all other advanced economies, initiated talks regarding free trade with different regions in the world. The largest effort directed to Latin America has been the EU-Mercosur talks with five South American economies, re-initiated 2010 after a six year pause. These negotiations aim at resulting in a comprehensive trade agreement, covering, apart from the usual trade in goods, also services, public procurement, intellectual property rights, trade facilitation schemes and technical barriers to trade. The results have been insignificant so far, and very little progress was made in 2013, among other explanations due to the political and economic situation in Venezuela and the suspension of Paraguay. From the Mercosur side, the EU is an important partner, comprising about 20% of its external trade, and also a key investment partner, but only about 3 per cent of EU's total trade. Furthermore, EU has also closed various bilateral comprehensive free trade agreements with Latin American countries, comprising both goods and services, notably Mexico, Chile, Colombia and Peru, an Association Agreement with six Central American states, and Economic Partnership Agreements with fifteen Caribbean states (CARIFORUM). The combined result so far of all these efforts is rather a hub-and-spoke structure of trade and investment relations between EU on one hand and different constellations of Latin American states on the other, even though there has been an explicit ambition to forge separate agreements together to a comprehensive regional structure, or, at least, to work for converging separate agreements in order to pave the way for increased intra-regional cooperation at the firm level.

5 Literature review and theoretical framework

The service sector is large and growing extremely rapidly. It is also becoming much more complicated as radical technological solutions are developed to support the provision of many service functions. Services used to be considered to be local activities that were produced and consumed at the same time and in the same place (Hill, 1977). Technological developments have transformed services by challenging the relationship between place of production and consumption. Many business services involve the creation of high-value added customized services. Recent developments, however, have led to pressures coming from larger client companies to strip costs and profits from suppliers of advanced business services. Technology and especially the ability to create teams that draw upon experts located in low-cost economies have led to an on-going commoditization of some business service functions. This is especially the case in relation to accountancy, consultancy and law. Technology including new knowledge management systems combined with intranets is transforming the production of these services.

A good can be sold without any direct relationship between the manufacturer and consumer. Many services can also be consumed in a similar way. Nevertheless, the importance of face-to-face contact involved in the simultaneous production and consumption of a range of services plays an important role in differentiating the new world of service work from that of manufacturing. At the centre of interactive service relationships are three important elements: the quality of the client interaction, an individual's or firm's reputation and embodied knowledge. The importance of reputation cannot be under-emphasized for the consumption of services.

Producing any product or service involves service expertise to be embedded in different parts of the production process – pre-production, during production and post-production or consumption. Pre-production involves understanding the design process, including market research and the ability to innovate. This may involve the design of a production process or of an actual product or service (Bryson and Rusten, 2011).

The dearth of empirical research on services and internationalization reflects the absence of official statistics on the service sector in general and on service trade in particular. Available datasets are limited by industry, geography and time series. Due to the difficulties of classification, conceptualization and measurement problems, research on service internationalization research is complicated. Traditional international trade theories such as the Heckscher-Ohlin have been used as a frame of reference for exploring service internationalization. But this analysis concluded that trade theory developed to explore trade in good does not help to explain trade in services (Daniels, 1993; Bryson *et al.*, 2004; Dicken, 2011). Government regulations, cultural differences and language differences are extremely important for service internationalization (Beyers, 2012). The debate about service sector FDI has become important since it is a preferred way for companies to move abroad and is specifically determined by locational factors (Rusten and Bryson, 2010).

Studies of internationalization and services have focused on more specific sub-sectors and have often explored internationalization strategies (e.g. Jones, 2002; Bryson 2007; Schultz, 2005; Ström and Mattsson, 2006; Faulconbridge *et al.*, 2008). Firms located in major metropolitan areas, are more likely to be confronted with various internationalization opportunities. Firms in more peripheral areas also show an interest in working internationally, but activity is more limited.

There are major differences between trade in goods and trade in services (Daniels; 1993; Bryson *et al.*, 2004; Dicken, 2003). Firstly, even though information technology has helped to bring parts of the world closer together, much of the activities within the service industry must take place simultaneously and maybe even at the same location. It is often important to have direct contact between producer and buyer. Secondly, the service industry is still heavily regulated in many countries, which affects the possibilities to trade. In some counties the import of services from

²⁴⁸ Main source: European Commission, Memo/13/1080, December 3, 2013.

foreign providers has been prevented through regulation. Finally, there are many obstacles to trade with services such as non-tariff-barriers. These can be of a very different character, such as licenses for legal advisors, medical doctors, accountants, qualifications, language etc. These play an important role as barriers in preventing international service trade. Cultural problems are evident for any kind of international transaction, but in the case of service industries they may be an absolute barrier (Jones, 2002, 2005; Ström, 2005). These barriers have their greatest impact on verbal and media-based services, but standardized and highly technological services may be exceptions to this general rule.

Another important issue for the internationalization of service production is the complexity of value-added in relation to manufactured goods (Daniels, 2000; Daniels and Bryson, 2002). The question of value-added is both valid in relation to where this is produced but also how the value added is traded in relation to the indirect contribution made by services in the exports of goods. In relation to the classification and conceptual difficulties associated with service trade, empirical findings show that the direct contribution of services to national exports is growing slowly and the pattern of trade is highly concentrated. Instead it might be useful to acknowledge and nurture the indirect contribution of services to overall national export activity. Service firms provide functions that support the export of many manufacturing sectors and this enhances total export competitiveness. Specialized services may become embodied in goods leading to the production of goods/service bundles for export (Daniels and Bryson, 2002). These bundles may provide firms with a source of inimitability – a source of competitiveness that provides differentiation in global markets (Bryson, 2009).

The lack of service research in Asia and other emerging markets such as Eastern Europe and Latin America has attracted increased attention (O'Connor and Hutton, 1998; Ström and Yoshino, 2009; Harrington and Daniels, 2006; Daniels et al., 2012; Di Meglio et al., 2012; ADB, 2012). The interconnectedness of mature economics in Europe and emerging markets in East and Southeast Asia has created a complex economic network of production and knowledge networks where services are playing an increasingly important role. It resembles to some degree the economic geographical transformation in Europe where the new members states of the European union have been connected through market widening and increased FDI, but where the economic integration of the service economy has yet to materialize in Asia (Alvstam et al. 2009; Ström and Yoshino, 2009; ADB, 2012). It is noteworthy that China is developing policies to enhance the effectiveness of Chinese business services and this might lead to the development of Chinese service competitors that may challenge European and American service providers.

Service Offshore and Different Types of Service Internationalisation

Service offshoring occurs when firms shift production to foreign locations. The objective may be to reduce costs, to service a foreign market, to reduce exposure to country risk, or to access skilled labour. An additional factor influencing the location of offshore service centres is the requirement to provide a 24-hour service to customers or an extended service beyond standard working hours. The cost of providing such services can be high as late shift workers must be attracted by higher wages or extended holidays. Advanced call-routing and networking technologies enables companies to get around this by implementing a 'follow-the-sun' geographical policy. Companies can link two or more call centres together with each open from between 8 to 12 hours per day. Country risk is removed when a company is able to shift the provision of a function between facilities located in different countries.

Service offshoring is not easily analysed because service tasks can be traded in four ways (United Nations 2002: 1):

Mode 1: *cross-border supply* occurs when suppliers of services in one country supply services to consumers in another country without either supplier or consumer moving into the territory of the other.

Mode 2: *consumption abroad* refers to the process by which a consumer resident in one country moves to another country to obtain a service.

Mode 3: *commercial presence* occurs when enterprises in an economy supply services internationally through the activities of foreign affiliates.

Mode 4: *presence of natural persons* describes the process by which an individual moves to the consumer's country to provide a service, whether on his or her own behalf or on behalf of his or her employer.

Three of these modes are concerned primarily with service transactions between residents and non-residents. Mode 1 involves the provision of services that require no direct contact with customers but procedures must be developed to overcome cultural and language barriers that exist between countries. Recently, there has been a particular interest in Mode 3, whereby enterprises supply services internationally through the activities of foreign affiliates (Bryson et al. 2004). For services, the Mode 3 'method of serving foreign markets is particularly important because it is often the only method that permits the close and continuing contact between service providers and their customers necessary to compete effectively with indigenous firms' (United Nations 2002: 54). In this instance the provision of services through foreign direct investment represents a type of *captive offshoring* or offshoring without outsourcing. Captive offshoring enables a firm to retain control over its assets, intellectual property and core business processes (Bryson, 2007). But captive offshoring creates value for the home of the service provider, but not necessarily local employment. The implications for Europe would be that service FDI by European firms will create employment opportunities in host economies and not in Europe. Europe would provide by FDI being undertaking foreign service providers. It is noteworthy that the development of the internal market for services will create new employment opportunities within Europe.

Trade in services must address cultural differences between countries that restrict the ability of service providers to export standardized services. Modes 3 and 4 enable service providers to localize provision to take into consideration

local cultures and client expectations. Modes 1, 3 and 4 involve what is commonly termed ‘service offshoring’ or more correctly ‘service global sourcing’. This is encapsulated by the concept of a ‘second global shift’ (Bryson 2007). The first global shift involved the relocation of manufacturing employment to low-cost production locations while the second implicates services in this process. There have been three distinct phases to the second global shift. First, during the early 1990s IT programming, testing and network support activities were outsourced and then globally sourced. Second, during the late 1990s global sourcing diversified into the provision of back office and call centre functions and also the development of computer applications. Third, during the early years of this century full service centres emerged that provide a wide range of administration, process, contact and support functions.

The development of service offshoring represents a new type of international division of labour, but with a difference. It is various forms of service activity, ranging from call-centre-based work to back-office administration that is being relocated to low-cost locations rather than manufacturing or assembly activities. A number of factors influence the decision to send a particular service activity offshore. First, it must be capable of some degree of standardization that does not require face-to-face interaction with consumers or clients. Secondly, the inputs and outputs required to deliver the service must be capable of being traded or transmitted with the assistance of ICT. Thirdly, some service activities are not fixed in space and can be provided either as a form of foreign trade or by the temporary relocation of a service worker to a client’s premises, for example, management consultancy or various forms of auditing. Fourthly, specialist services can be provided from central locations with consumers travelling to avail themselves of the service. In many cases such services would be provided within the confines of a nation-state, but some of these services are being consumed by a form of service-based travel, for example education (secondary and tertiary), plastic surgery and a whole range of other surgical procedures.

Outsourcing services to companies located in other countries comes with a number of risks attached to language, culture and the quality of the provided service. Unlike the first ‘global shift’, the geography of the second global shift is determined by the educational and language abilities of service workers located in foreign locations that may also perhaps, but not always, be lower-cost locations (Bryson 2007).

6 Multilatinas and the service industry

The Latin American service industry has seen steady increase during the last decades. Primarily the larger economies such as Mexico, Brazil, Argentina and Chile have been at the core of this development. The manufacturing industry and the raw material based economy is however substantial in many regions. Mexico is one example of where inflows of FDIs are taking advantage of the NAFTA agreement and the proximity to the US market, along with a very favourable cost level. The positive economic development has also pushed for increased economic integration within the region through Mercosur, and other multilateral and bilateral initiatives. The industrial base has generated a number of companies working across the Latin American region, but also becoming increasingly active on the world market. Several of the most important emerging market multinational originates from Latin America, such as Vale, Embraer and CEMEX, to mention a few. However, other companies have pushed forward to take advantage of the economic possibilities on the more regional level. During the last decade, smaller countries (in economic terms) in the region have also seen growth being generated through the service economy.

Apart from the growth in Latin America that has been driven by increased demand of raw material, the increasing consumption has also pushed growth ahead. Another important driver of the Latin American service economy is the increased outsourcing and offshoring of service activities that have taken place. The phenomenon has been driven out of demand from North American based firms, but increasingly from other part of the world where multinationals are looking for a location strategy that covers areas where they are active. According to Stark et al (2014), the firms are mainly using four alterations to take advantage of different location advantages in the service value chain; (1) *product upgrading*, trying to achieve a higher value, (2) *process upgrading*, which refers to improvements in the efficiency of production systems, (3) *functional upgrading*, which refers to the movement to higher-value stages in the chain that require additional skills and lastly, (4) *chain or intersectoral upgrading*, which focuses on entry into a new value chain by leveraging the knowledge and skills. The different stages of the economies in the region have enabled service providers to take part in different stages of the value chain. This can be done through handling functions within larger multinational through off-shoring, but also through independent firms. According to a recent ECLAC study the service industry has successfully created thousands of jobs in countries like Chile, Costa Rica, the Dominican Republic, Colombia and Uruguay (Ibid.). The development shows that it is not only the larger economies in the region that could benefit from increasing the share of the service economy. Countries in the Caribbean have also seen the importance of attracting service jobs, through tourism, but also in related business service industries (CNSC, 2014). The small open economy of Costa Rica has also attracted a substantial inflow of service FDI during the last decade, particularly due to a series of bilateral free trade agreements (FTAs) with key trading partners. FDI inflows increased significantly in the early 2000s, mainly in technologically intensive fields such as electronic components, medical devices and global services. The country has actively sought to attract FDI from companies in a diverse set of services such as contact centres, shared services, back office; entertainment and digital technologies, design and engineering, and software (Flores Sáenz, 2014).

Apart from sectors in the region that grows through service FDI and global value chains, there are also sectors that have taken advantage of the rise in income and economic and political stability throughout the region. This includes

firms within retail, finance, insurance and business services. These firms are more of regional Multilatinas at this stage that are utilizing their regional knowledge to expand business. Studies also show that the countries in the region work with different policies for attracting service FDI and developing the domestic industry. Chile has been one of the most active countries in this respect. All ready in 2000 a program was launched to attract investments in high-tech sectors and business services (López et al., 2014). Similar schemes have also been introduced in smaller economies such as Colombia. Here infrastructural investments to support the usage of English, tax reduction for international experts and the implementation of international financial and accounting standards are all important measures to support the growing service economy. The main aim is to create a service industry in relation to outsourcing and offshoring that is globally competitive (Kshetri et al.,2014).

The growth of the Chilean service economy has been driven by a set of factors. First, there is an increasing demand of services in a growing economy where productivity and competitiveness is on the increase. In relation the public sectors has also been in a need of digitalization. Second, the government has launched a number of incentive programs to support the IT industry, through education, facilitate international competition and public-private partnerships. Finally, the infrastructure through broadband has been expanded. All in all, these schemes have been introduced to strengthen the competitiveness and ability of Chilean firms domestically and abroad.

In a study by Hagen et al., (2014) the internationalization and intra-regional trade is evident for Chilean IT service providers. In the survey presented of these business services the Latin American market is very important, but a number of vital export relations with Europe are also visible. See Figure 1 below.

Figure 1. Chilean IT service export.
Source: Hagen, Marinao, Mulder, 2014.

Figure 2 below also shows the result from the same survey of the main barriers to further enhance the export of these business services. The lack of access to networks is seen to be the most important barrier apart from marketing and financing. The result shows how important networks are within the service industry in order to facilitate growth and trade. Further economic integration in Latin America is dependent upon expanding business networks and financing possibilities. The combination of service FDI through offshoring and domestic development is vital for creating sustained growth on the service sector.

Figure 2. Perceived barriers for Chilean IT service export.
Source: Hagen, Marinao, Mulder, 2014.

Companies from the retail sector have been utilizing the increased income in many countries in the region for expansion. This is an example of regionally expanding firms. These firms could be seen as regional Multilatinas. They use the potential of economic growth and the similarities that exist, such as languages. Companies from Chile have been particularly active in expanding their regional presence. See figure 3 below. According to analysts following the sector it shows signs of growth in many countries. This locational spread indicates that there are regional transformations that would help to increase the development of the service industry. In a recent deal Cencosud finalized the takeover of Carrefour’s stores in the Colombia, whereas the competitors have chosen more of an organic growth. This part of the service economy is less driven by FDI from Europe and North America, but rather the domestic development in the respective country. In relation to the retail operation, these firms are also developing their financial service offers to customers, and further services of more advanced character could be added in later stages. In this sense the sectors is complementing the growth of business services through domestic growth and offshoring in IT and other sub-sectors.

Chilean Retailers – Store presence overview (as of 1Q13)

7 Conclusions

The paper shows the complexity of the service industry development in Latin America. There are several connections to the global market through various forms of offshoring activities of services operations. This has helped to enhance the competitiveness and economic growth in several of the countries in the region. There are numerous examples of how governments have actively worked with developing incentive structures for both attracting inward FDI, but also for supporting the domestic growth of services. The paper also shows the differences that exist among the different countries in term of service industry development. In several countries the manufacturing and raw material based economy have created hurdles for further expansion into services. The volatility on the world market for raw materials has also created a situation where the macroeconomic structures have been changing rapidly, making it more difficult to create sustainable structures for the service industry. The service development can broadly be classified into two different areas. One is driven by the connection to the world market through offshoring and back-office functions. The other area is the regional market where Multilatinas are operating in business services and the retail sectors. These firms try to take advantage of the regional economic growth, but with limited prospects in the short run to venture outside the Latin American continent. In this respect the intra-regional Multilatinas will be interesting to follow in the future. The main question is whether these firms can establish enough competitive advantage for long term competitiveness.

The social and economic disparities generate a complex development for the service industry. There are parts of the population that has seen their purchasing power increase and thus generated a base for service industry development. However, due to problematic political circumstances and social unrest, there are also examples of the reverse. This development is also intertwined with the difficulties of getting trade structures working better in the region. Mercosur has not been at all as successful as was hoped from the beginning. This connects to the problems of Latin America in the world economy, where the share has shrunk compared to the situation about half a century ago. Regional political differences and external relations to the EU have not helped to reverse this trend. External influence in the form of Chinese investment is also a highly important aspect in relation to the economic development in the region. With increased trade and investment focus across the Pacific and with the creation of new trading schemes such as the TPP, the role of the EU might be diminishing despite, historical, cultural and language relations. The EU exhibits itself many different priorities among its member states when it comes to perform the common external trade and investment policy according to the stipulations in the Lisbon Treaty. Even though the supranational authority to carry out a coherent and persistent 'one-voice' policy is strong in theory, the reality looks different. The coordination procedure is shared between the Council within its Trade Policy Committee, and the European Parliament, mainly within its Committee on International Trade (INTA). In addition, the preparation as well as the implementation of policies rest within the DG Trade in the Commission. The difference in geographical priorities regarding EU's external trade relations is unsurprisingly closely correlated with the geography of member states, where the Southern-Southwestern MS have been more likely to push for deeper relations with Latin America, and less enthusiastic regarding e.g. the Eastern Partnership or Asia. The aim of ours is to follow up the identification of a number of promising future areas of cooperation within the field of service industries, in order to contribute to a more solid and sustainable platform at mutual benefit between the EU multinational enterprises and the emerging Latin American firms than hitherto has been the case.

Measurement of service innovation project success²⁴⁹: A practical tool and theoretical implications

Jon Sundbo

Roskilde University, Denmark

ABSTRACT

This paper presents a first attempt to develop measurements at a micro or firm level of the input to and outcome of service innovation processes. This is not easy because many factors are involved of which several cannot be measured with any precision, and definitely not in money terms. The aim is to develop a tool that can be used by service firms. It is not sufficient to develop a theoretical instrument; service firms should also use the measure if we shall get a valid measure and service firms shall get a useable decision tool. The paper refers research that theoretically develops an appropriate measurement instrument and tests whether service firms would likely to use it. The test is carried out in two steps: First a long-term discussion in a group of service innovation managers, then explorative experiments in two service firms. In the conclusion is a suggestion for a measurement model presented.

1 Introduction

Economic and management science has an interest in understanding the economics of innovation, i.e. how innovation contributes to the economy and how that contribution can be measured. One line of thinking, often based on Schumpeter's (1934, 1939) theories, is that innovation creates economic growth. This idea has almost become a dogma within evolutionary economic theory (e.g. Freeman and Soete, 1997; Fagerberg et al., 2005; Andersen, 2008). It may be true that economic growth can be explained by innovations, but that does not mean that every attempt to innovate leads to economic growth. Indeed this is far from being the case, many, or maybe most, attempts, or projects, lead to losses. We do not know how big the losses generally are, they might be as large as the growth effect of the successful innovations. One hypothesis might be that innovation can be both good and bad and that the losses incurred in attempts to innovate may be of the same magnitude as the growth effect, at least for a period of time. These periods of loss could, theoretically, be assumed to be periods of depression. The problem with ascertaining the veracity of these claims is that we currently lack a way of measuring the losses and gains. Despite all the attempts to measure innovation input and output (i.e. CIS, 2009; InnoMetrics, 2007; European Innovation Barometer (EU, 2013) etc.), we do not have a full picture of the value of innovation because the unsuccessful innovation projects that are stopped halfway through the development process and are not measured or included in the statistics. The losses are therefore under-estimated. To get a more correct picture of the economic effect of innovation behaviour for both society and individual firms, we need to count the input and outcome of *all* innovation attempts, not only the successful ones. This requires tools that can measure the total input and outcome of each innovation project that firms or individual entrepreneurs attempt to carry out. To specify and implement such instruments is difficult, both theoretically and practically, particularly within more complex innovation activities such as service innovation (cf. Gallouj and Djellal, 2010), experience innovation (Fuglsang et al., 2011) and open innovation (Chesbrough, 2006).

Far from all innovation projects and processes lead to outcomes that exceed the input: the market may reject the innovation, development costs can be too high, or organisational barriers and other obstacles may appear in the process (cf. Sundbo, 2013). Firms also have a need for tools that can guide them in assessing which ideas or projects have the largest probability of success, i.e. that the output exceeds the input. This is more difficult in services than in traditional manufacturing innovation because a service is an immaterial product in which employee and customer behaviour and state of mind play a larger role. Thus the market acceptance of the innovation may be more difficult to predict because of these subjective factors in addition to the ever present insecurity about market reactions.

Further, the innovation process is more complex in services because many employees are involved for only part of the time, users are often involved and the innovation activities are spread throughout the organization (Sundbo, 1998; den Hertog et al., 2006). Such inputs are therefore more difficult to calculate. Thus a research aim would be to develop measurements at a micro or firm level which can measure, or at least provide indications of, the input and outcome of service innovation processes. This is not easy because many factors are involved of which several cannot be measured with any precision, and definitely not in money terms.

This article presents a first attempt to develop such measures. Since the aim is to develop tools that can be used by service firms, it is not sufficient to develop a theoretical instrument. If service firms will not use the measure because it is difficult, or impossible, to use in practice or because the service firms do not find it appropriate – despite its

²⁴⁹ Acknowledgement: My colleagues Associate Professor Flemming Sørensen and senior researcher Jens Friis Jensen at Roskilde University have participated in the empirical collection and analysis of data. They have contributed to discussions of the measures.

theoretical eminence – we will neither get a valid measure nor will service firms get a useable decision tool. The research referred to in this article is therefore an attempt to theoretically develop an appropriate measurement instrument and a test of whether service firms would likely to use it. If we can not make laboratory experiments, which we can not in economics, we are dependent on economic actors' willingness to provide the necessary empirical data. This may not, sometimes, lead to the most perfect measures, but to optimal ones (a compromise between the theoretically desirable and the practical possible). However, we do not even know what the practical possible is. Therefore the investigation into which factors service firms are willing and motivated to measure is crucial for establishing a scientific measure and for developing measurement tools that firms can use.

Such an investigation has not been done before. Theoretical models of service innovation (e.g. Gallouj, 2002; Sundbo and Gallouj, 2000) and prescriptions for organization of service innovation activities exist (e.g. Cooper and Edget, 1999), but no concrete measurement tools that can tell about the outcome related to the input have been developed. Measurement instruments for innovative capability (Teece and Pisano, 1994) have been introduced (Forsknings og Innovationsstyrelsen, 2008; Damvad, 2011, 2013). However, they do not emphasize concrete inputs and outcomes at the project level, only a general firm capability. There is a lack of such measurement instruments at the project-level. The research referred to in this article will fill a gap in the scientific knowledge concerning which input and outcome factors are really important to service firms and which factors are crucial for success in service innovation processes.

The article discusses the theoretical foundation for a service innovation project measurement tool and, based on this, a suggestion for a practical tool is put forward. The tool has been tested with a group of service innovation managers (a kind of longitudinal focus group, Puchta and Potter, 2006.) and thereafter in two service firms in an exploratory study. The results are discussed in the conclusion.

2 Overall aim and approach of the article

This article is based on research that aims at developing instruments to measure social and economic inputs into and outcomes of service innovation processes. The research investigates areas where service innovations may be valuable and the innovation processes lead to positive outcomes. Furthermore, the article will attempt to develop relevant measurement instruments.

Thus, the article's focus is on the micro (firm or organisational) level; however the knowledge and measurement instruments created during the research will be useable in macro level analyses as well. The ambition is to see how far research can come in developing one simple, overall measure that can show whether an investment in a service innovation process is beneficial and still measure all the important aspects that service innovation theory refers to. Knowing that this is difficult and an ambition that can probably never be fulfilled, this measurement instrument aims at being as systematic and quantitative as possible, which may result in indexing or a compound measure. This is to be investigated in the project.

The research questions are:

1. Which factors should be included in a service innovation project measurement tool if we look at the service innovation theories and earlier attempts to measure service innovation activities at a macro or firm level?
2. Which factors are meaningful for service firms (both because the firms believe in them and because they can be measured by a reasonable resource investment in the measurement procedure)?

3 State-of-the-art of innovation measurement in services

Although there has been much research on service innovation processes over the last two decades (e.g. Gallouj and Djellal, 2010), the field is often in articles (e.g. Drejer, 2004; Howells, 2010) accused of not having one, unified, theory. In other words, no complete and generally accepted framework for sufficient and satisfactory measurement of service innovation exists. Attempts have generally focused on measuring innovation inputs or innovation capabilities (Teece and Pisano, 1994; Damvad, 2011; Janssen et al., 2012). Although this may be seen as a first step in measuring service innovation, it does not suffice. The measurement of innovation output has been confined to the general questions in the CIS (Community Innovation Survey) (Sundbo, 1998; Eurostat, 2004; den Hertog, 2010; Janssen et al., 2012) and the effects of innovation are rarely described (Sveiby 2011). Thus, many scholars call for indicators of service innovation (Abreu et al., 2010; Hipp and Grupp, 2005; Miles, 2009; Schmoch and Gauch, 2009; Steiner, 2001).

The measurement of service innovation and attempts to formulate a theory based on it may thus be an extremely important area of new research over the coming years as measurement instruments are in great demand from managers.

The issue of measuring inputs into and outcomes of innovation processes has been emphasized for a long time, examples being the Frascati manual and Eurostat's CIS surveys. The Frascati manual was created in 1963 and defined innovation and which indicators should be used to measure inputs to and outputs of innovation processes (OECD, 2002). It was a quite narrow instrument that measured economic factors and was based on R&D as the leading innovation activity. In 1992 it was extended to include the Oslo manual with more organisational input indicators and more output indicators than just growth and profit (OECD and Eurostat, 2005). The Oslo manual is the basis for the CIS surveys that Eurostat carries out regularly (Eurostat, 2004).

Many other research based models and instruments to guide innovation processes and innovation investment in firms have been offered (e.g. Cooper, 1988; Burgelman et al., 2004; Lundvall and Nielsen, 2007 based on a knowledge economy approach, or Foss (2003) based on the Resourced Based View). These instruments are primarily grounded on the R&D approach and are generally oriented towards manufacturing (although some of them such as Cooper and Edget (1999) have been applied to services).

We may conclude that existing instruments for measuring innovation inputs and outputs are incomplete and not oriented towards service innovations. An increasing amount of international research carried out in the last two decades shows that innovation in services has characteristics in common with innovation in manufacturing, but also some differences (e.g. Boden and Miles, 2000; van den Aa and Elfring, 2002; Drejer, 2004; Sundbo, 1998; SIC, 1999; Gallouj, 2002; Tidd and Hull, 2005; Edvardsson et al., 2000; Gallouj and Djellal, 2010): Service innovation is very often incremental (Abernathy and Utterback, 1978) and based on practical experiences; very few service firms have R&D departments, service innovation processes have always been open innovation processes (cf. Chesbrough, 2006, 2011). Furthermore, employees, managers and users are involved in the innovation process and act as organizational entrepreneurs. External partners may also be involved (Boden and Miles, 2000; Pinchot, 1985; Kanter, 1983; Kristensson et al., 2004; Tether, 2005; Tether and Tajar, 2008; Sundbo, 1998, 2011; Sundbo and Toivonen, 2011). Often there is no specific budget or formal responsibility for innovation activities, which are carried out as an activity in addition to employees' and managers' normal tasks (Sundbo 2013). The outcome of innovation is economic (increased turnover or profit), but also derived social effects.

The theoretical problems of the measurement of service innovation have been discussed (Drejer, 2004), as have the methodological aspects of measurement itself (Djellal and Gallouj, 2001). Some attempts have been made to measure input and innovation capabilities in service companies (SIC, 1999; Djellal and Gallouj, 2001; INNO-Studies, 2004). New contributions have identified and measured some dimensions of dynamic capabilities in service innovation (den Hertog, 2010; Damvad, 2011; Janssen et al., 2012). Other contributions have developed insights on employee innovation (Sundbo, 1998; ICE, 2010) and the soft (social, organisational) side of service innovation (den Hertog et al., 2006) and involvement of users and other external actors in innovation networks (Sundbo and Toivonen, 2011; Kristensson et al., 2008; Fuglsang, 2010), however, these are rarely based on quantitative measures. Suggestions for indexes that include employees' corporate entrepreneurship and management capability exist (e.g. Sundbo, Fuglsang and Larsen, 2001; Bryson, Rubalcaba and Strom, 2012), however these are few and not very well developed. This has led to the inclusion of new indicators in CIS to capture specific characteristics of service innovation. However, all these attempts are still insufficient to measure all aspects of service innovations and innovation processes.

One may conclude that most measurement instruments and indicators are dedicated to measuring innovation inputs: service firms' innovation organisation, management and general investment in R&D activities (with the latter as a dubious measure of innovation effort in services) or what can be called innovation capability (cf. Teece and Pisano, 1994). A review of measurement instruments (Damvad, 2011) shows a series of such indicators. The measurement of output and of the innovation processes is rare and incomplete.

Further, the measures generally emphasize the macro level. They are attempts to find inputs and outputs at a national level. This is for example the aim of the CIS. Such macro level measures, despite their utility for policy makers, have little relevance for enterprises. They can use them for benchmarking themselves to other enterprises, which can be of some value. Recently suggestions for the most relevant macro or industry benchmark indicators for services have been published (Damvad, 2011, 2013). Enterprises not only need benchmarking instruments, though of course they are useful in a competition perspective. They also need instruments that can help them in their innovation management by sorting out which innovation ideas would be the best in the sense they have the highest probability for successful development, market success and producing an economic surplus. The selection process of service innovation ideas has been described as a funnel in which the management, in successive steps, selects ideas that should be developed (Sundbo, 1998). This demands measures that can inform us about the economic (i.e. resources) inputs and the outputs, which can both be some that can be measured in hard economic terms and some that can not (e.g. increased employee motivation and increased customer loyalty). Such micro measures hardly exist within services.

There has been a focus on customer involvement in service innovation processes, called co-creation (e.g. Prahalad and Ramaswamy, 2004; Kristensson et al., 2004; Kristensson et al., 2008) or co-innovation (Sundbo et al. 2013). This aspect is valuable for creating successful innovations, but also costly because it requires time where employees or managers interact with customers or analyses customer data. Much literature has praised the outcome of co-creation activities and some literature also refers to its measurement (Li et al., 2009; Perks et al., 2012; Gustafsson et al., 2012; Edvardsson et al., 2012). However, such measures are of customer satisfaction with the delivery of existing services. Very little literature has attempted to measure the outcome in terms of innovations, in particular there have been few attempts to establish quantitative measures (some of the rare examples are Li et al., 2009; Perks et al., 2012). This is also true of required input in relation to customer co-innovation (Sundbo, Sundbo and Henten, 2014).

4 What to measure?

Since no appropriate measure that firms can use to assess different innovation projects exists, one may turn to what the service innovation research says about the drivers of innovation processes and the useful outcomes of such processes for service firms. This can be basis for an ideal model of a measure of service innovation efficiency. A review of the

service innovation research (e.g. Sundbo, 1998; Evangelista, R and Sirilli, G. 1998; Gallouj, 2002; Sundbo and Gallouj, 2000; van den Aa and Elfring, 2002; Drejer, 2004; Kristensson et al., 2004; Tidd and Hull, 2005; Hipp and Grupp, 2005; Edvardsson et al., 2006; Gallouj and Savona, 2009; Gallouj and Djellal, 2010; particularly Howells, 2010; Sundbo and Toivonen, 2011; Rubalcaba et al., 2012; Perks et al., 2012) suggests that a broad measure is desirable including both quantitative indicators and qualitative factors that are difficult to quantify. This also suggests that it will be extremely difficult to create one index that contains all input or all output factors. How to characterize the result of the innovation process has been discussed (Damvad, 2011) – whether it should be in terms of output or outcome. The first is considered a more quantitative, narrow income or profit measure, which may usually be expressed in money terms. The latter is a wider measure that includes more than the narrow economic income. Outcome will therefore be chosen here.

A summary of the above mentioned service innovation research literature that has been carried out by the present author suggests the following factors are relevant input and outcome factors:

INPUT FACTORS

These are investments in either money or time (the latter can in principle be converted into money terms).

- *Working hours within the firm* (at all levels and including all activities such as interacting with customers in co-creation activities (Prahalad and Ramaswamy ,2004; Payne et al., 2008; Wittell et al., 2011) converted into money terms)
- *External advice and knowledge procurement* (which can be both expenses, for example consultancy or paid research)
- *Expenses for technology and other materials*
- *Public support* (an income, for example public grants or researchers giving free advice)
- *Network benefits* (e.g. competitors who are also collaborators, representatives from the value chain and others from networks; the input from network activities are normally free, however the firm's time use in network activities should be deducted from that) (cf. Hakonsson and Snehota, 1989; Pyka and Küppers, 2002).

OUTCOME FACTORS

Four types of outcome factors are seen as important in the literature: Income and growth (including productivity), employee factors (such as motivation, competence), customer/market factors (such as branding, experienced customer quality) and strategic/business model (cf. Osterwalder and Pigneur, 2010) changes.

Income and growth

- *Turnover* (more sales – increased turnover)
- *Profit* (either positive or negative)

Employee factors

- *More employees* (an indicator of growth – may be a power factor for departmental managers)
- *Productivity*
- *Employee motivation and competence* (more satisfied and efficient employees)
- *Employee entrepreneurship* (employees more engaged in innovation activities)

Customer/market factors

- *Increased service quality and customer satisfaction* (which in the theories are supposed to be connected, cf. Edvardsson et al., 1994; Grönroos, 2000)
- *Branding and PR* (the firm becomes better known by the market because of the innovation)
- *Penetration on new markets* (a new product launched on a new market can result in firms being able to sell other services in that market)

Business model factors

- *Organisational learning* (the firm learns how to innovate better and more efficiently next time)
- *Changed strategy* (the firm may change to a more appropriate strategy because of the innovation)
- *New networks* (if the innovation required a relation to new external actors, these can be an innovation resource in the future)

5 Practical usability

This theoretical model was tested for its practical usability in a group of 11 innovation managers (of which some were the managing directors) from different service industries and size of service firms²⁵⁰. Three researchers held discussions with this group for a period of one year. The aim of the discussion was to find which input and outcome factors were meaningful to the innovation managers in their business activities, and which measures were appropriate, i.e. some that they would carry out in their firm as tools to assess and choose between different innovation ideas. Thus these measures are also tools in organisational learning (cf. Senge, 1990; Argyris, 1992).

The researchers made notes during the meetings to collect information. These notes were analysed and systematised by the researchers and the results of this analysis were discussed with the group.

One general result was that none of the firms made an exact economic calculation of the total cost-benefit of the innovation processes. Some of the larger ones, and the consultancy firms, registered the number of man-hours used; they could easily find these data and some of them used them. However they rarely learned from them, i.e. they rarely compared them with the outcome and did not compare different innovation projects. They all, in general, expressed that more comprehensive and exact measurements, possibly converted into money terms, were not very interesting to them – they considered this theoretical, desktop, research. They would prefer to use their sparse resources on developing and improving the organisational processes, customer interaction and market knowledge instead of using them on measurement exercises. This may be an effect of a particular national corporate culture. Danish corporate culture is characterised by little formality and an emphasis on practice-based entrepreneurial behaviour, not a big planning approach (cf. Hofstede, 1991; see also Sundbo, 1998 on Danish service firms). The results may be different in for example the USA, France or Germany, which are more dominated by a systematic planning approach (cf. Hofstede, 1991).

Having said that, the managers found all the above factors interesting, however, the outcome factors remained more interesting than the input ones. The managers agreed with what the literature says (e.g. Djellal and Gallouj, 2008), namely that the exact economic effect of innovation attempts is difficult to measure. This is because the effect on profit in particular, but also turnover, can be difficult to isolate from other factors' effects, for example business cycles. Measurement is also difficult and resource demanding in an individual firm thus the advantages of such a measure often does not match the costs of measuring. Those were two arguments given by the managers for not being very interested in the wide range of factors included in the list above. The managers were interested in all the factors, though to different degrees in different firms.

6 Explorative experiments in two service firms

The next step was to make experiments in two selected knowledge service organisations (so-called KIBS). One was a large public organisation (here called 'Tax' – a Danish tax authority), the other a small consultancy firm (here called 'Consult'). The public organization considers itself a service organisation and wants to be innovative hence its relevant for the current purpose. The experiments were explorative as they should investigate the research questions in practice, i.e. which measures are meaningful to the firms and which measures are practicable. The experiments much depended on what the firms, in their actual situation, wanted to do. The answer to that was established and not necessarily very much. This was, from a scientific point of view, not very satisfactory because it did not lend itself to a perfect test of the hypotheses. On the other hand it was an empirical-inductive test of service firms' interest in investing resources in measuring innovation input-output, which also is an aim of this research.

6.1 Method

In each firm we started with a meeting with the innovation managers (who in Consult's case was the owner). We suggested our plan for an ideal measurement and they responded by saying what they thought was practicable and what they wanted to measure, which was not the whole range of factors in the above list. Thereafter they collected data concerning existing innovation activities or developed new measurement activities for a period of six months. The data was connected to a few concrete innovations that were under development at the time. The researchers met the innovation managers and other employees regularly during the data collection period. At the end of the period the researchers and the innovation managers met for a final evaluation of the experiment. The agenda of these meetings was: 1. How did the measurement experiment go – was it carried out as planned, and if not, why not? 2. What was the result, i.e. which values of the input and output were measured? 3. Is it possible to make a quantitative or mixed quantitative-qualitative calculation of the innovation result, i.e. output minus input) (ideally an index)? 4. How do the innovation managers assess the experiment and the results, i.e. are the results useful to the firm and will the firms use them in the future? The next two sections briefly explain the innovations and the measurement activities in each firm and discusses the answers to the above four questions discussed.

²⁵⁰ Members of the group were innovation managers from: A building society, a film producer, a post company, a tax authority organisation, a bank, two small consultancy firms, a film distributor, a large manual service firm providing cleaning, catering, building facilities management etc., a hotel, and a financial IT-advising organisation.

6.2 Tax

One innovation was selected, namely the development of a service letter to entrepreneurs who had abandoned their business and who should be reminded of declaring their income over the last year of the firm's existence. This was a new service. The letter was developed and a test distribution was made before it was finally sent.

At the first meeting an agreement was made about measures of innovation in- and output variables. The outcome variables were to measure how much this particular innovation contributed to outcomes that were considered important by Tax. The variables were:

INPUT

Working hours (salary costs) for development of the activities
 External consultant
 Letter prototypes – expenses for printing, working hours
 Telephone calls (reminders)

OUTCOME

Direct effect ("income" defined as the number of self-declarations)
 Saved costs (fewer cases where Tax should calculate the debt– hours with saved salaries)
 Branding (the clients found the innovation a good idea – measured in a survey)
 Clients' satisfaction with the innovation (the reminder letter) (measured in a survey)
 Clients' general satisfaction with Tax (measured in a survey)
 Employee satisfaction (interviews, survey)

1. How did the measurement experiment go?

All the agreed measurements were carried out except the interviews and survey output measure of employee satisfaction. In the final evaluation meeting, the innovation manager still found this a very important factor, but Tax had not made the interviews (except a couple of test interviews) and the survey. This was because answering a survey would require some work by several employees and the time needed would be taken from their normal work. This was not so popular, neither among the employees nor the managers in different departments, particularly since Tax was undergoing budget cuts and employees were being sacked. We might conclude that employee satisfaction is considered an important output variable, but measurement can be very sensitive. The service firm may, as in this case, prioritise productivity and internal peace over innovation aims.

2. What was the result?

Tax could measure all the input variables in money terms (for example by measuring hours used on the specified activities). A total measure in money terms of the investment in the innovation could be established (which in this case was 12,000 €). Of the output variables only the direct effect and saved costs could be measured in money terms (which was 13,700 €).

3. Can we make a quantitative or mixed quantitative-qualitative calculation of the innovation result?

Already, based on the above two variables, we can establish that the innovation resulted in a surplus. The branding and clients' satisfaction was measured in a survey. There were no significant effects of this innovation. The total result – excluding the effect on employee satisfaction, which was not measured, was the surplus of 1,700 € though of course there was much uncertainty about the result. The innovation manager emphasized that the costs of measuring the variables were not calculated. If they were, it would probably lead to a deficit, particularly if the employee satisfaction measurement had been effectuated.

4. How did the innovation manager assess the experiment and the results?

The manager thought that it was an interesting exercise that could be used in her actual and future jobs. She wrote an article and made speeches about this experiment and the model. However, she was soon sacked and the innovation department closed down in a rationalization round. Thus to Tax the experiment and the results were not that important, or at least they did not want to invest in a specific innovation department.

6.3 Consult

Three innovations were selected. One was "Competencies on i-pad", a service system which provides information about labour force competencies, which can be used by firms, unions and public employers. Another was "Employment Indicators", which is an information system about the degree of employment and unemployment in different industries and geographical areas; customers are the municipalities, unions, employers' associations and analyse bureaus. The third innovation was "My Doctor Friend", a system to find disease diagnoses on the Internet; customers would be all citizens.

The innovations were already in progress when we, the researchers, became involved. At the first meeting we agreed on the following measurement variables which the firm should attempt to collect:

INPUT

Investment in the innovations (man hours where a total price could be estimated)

OUTCOME

Income and surplus (in money terms)

PR

Improved network relations to customers

Increased service quality

Increased personnel motivation

Increased personnel competencies

1. How did the measurement experiment go?

The counting of investment in working hours in money terms was quite easy because of a system in which all employees register their hours. The outcome was difficult to measure. The firm did not have any quantitative measures and had no interest in developing and using such ones. The owner explained that it would be expensive and saw no need for doing this. It is a small firm and he knows the employees and the customers. Thus, the measurement of the outcome was achieved by calculating the income in money terms from these innovations and interviewing the owner and two of the employees.

2. What was the result?

The financial investment was calculated. The economic outcome was partly calculated, and partly qualitatively assessed by the owner. The researchers made interviews with the owner and two employees, which were the basis for a qualitative assessment of customer and employee effects of the innovations.

3. Can we make a kind of quantitative or mixed quantitative-qualitative calculation of the innovation result?

The investments were 13,400 € in “Competencies on i-pad”, 47,000 € in “Employment Indicators” and 8,700 € in “My Doctor Friend” (all during working hours). The economic benefit of “Competencies on i-pad” was estimated to be small as the turnover of this product was small; no exact figures could be found. The outcome of “Employment Indicators” was quite high; the innovation led to an increased turnover of about 1.2 mio € and it was basis for a public development grant of 2 mio €. Although the exact profit could not be measured, the owner saw it as a clear surplus. “My Doctor Friend” was not sold at all thus all investments resulted in a deficit.

The interviewees expressed that the firm had benefitted from the innovations in the following ways: Strengthen their network with customers, increased employee competencies and a clearer customer interface in IT-base service deliveries. These were positively assessed but no monetary value could be placed on them.

4. How did the innovation manager assess the experiment and the results?

He thought the experiment was interesting, but he was not sure of how useful it really was. As an entrepreneur, he was more occupied by creating job and customer satisfaction than in performing comprehensive calculation systems.

7 Conclusion and discussion

From this research we can conclude:

- It is possible to construct reasonable measurement instruments based on theoretical and empirical scientific knowledge. However, they become compound and can not reasonably be combined into an index.
- Service firms can measure the relevant factors although a few of the factors would be difficult and expensive to measure and they have not been part of this measurement attempts (e.g. network benefits, productivity, branding and PR, and organisational learning)
- The service firms were not extremely interested in developing and using the – seen from a theoretical perspective – “perfect measure”. They assessed that the utility of many measures does not always justify the use of the resources necessary to measure them.
- The most important factors for the firms (which interested them and which demanded limited resources to measure) were:

INPUT FACTORS:

- Working hours within the firm
- Expenses to technology and other materials
- Public support

OUTCOME FACTORS:

Income and growth

- Turnover

Employee factors

- Employee motivation and competence
- Employee entrepreneurship

Customer/market factors

- Increased service quality and customer satisfaction

Business model factors

- Changed strategy
- New networks

It was quite surprising that the service firms were not more interested in using quantitative measurement instruments (and not more intensively focused on profit measurement). Some of them, particularly those in the financial services sector, used measures (particularly of man-hour input), but not very detailed ones. They were more interested in directly creating customer satisfaction and employee engagement than in technicalities in quantitative measurement. This preliminary piece of research shows that at least some service firms are more dominated by entrepreneurial trial-and-error than of a systematic quantitative scientific approach. This may be suggested as a general hypothesis for the service sector.

The issue of quantitative service innovation measurement requires more research to conclude about service firms' attitude and which factors should be included in a measurement. The firms may also accept measurement instruments if researchers present a fully developed use and which they find relevant for their way of handling their businesses. one based on what is fairly easy, which demands few resources, for service firms to

For the evolutionary economic science, this research demonstrates two things. First that the validity of the positive innovation dogma – that innovation leads to economic growth and thus the more innovation, the better – may be more dubious than often assumed, particularly in the large stream of recent literature that focuses, often one-sidedly, on the successful innovations. If we extend the innovation concept to include more than formal R&D – for example service innovation, which normally is not R&D based, open innovation etc. – we know much less about the total innovation input and outcome in the society than assumed. Second, it is difficult to create a reliable and valid measurement of all innovation activities. Theoretically we should therefore have a more balanced discussion of whether, or at least in which situations, innovation is good for the economy, firms and the society. A few attempts at such a discussion can be found in the literature (Fuglsang, 2008; Daly, Sætre and Brun, 2012; Alvesson and Spicer, 2012), but this is only a start.

For firms this research can provide a suggestion for a quite simple measurement instrument that both is research based and practically useable. This should be further investigated in practical experiments in firms.

The Role of Design in Service-dominant Logic

Pia Tamminen, Katriina Järvi

Aalto University, School of Science

This conceptual paper presents the main differences in design and engineering –originated design thinking discourses. Based on the foundational premises of service-dominant logic, a common value creation network and a reciprocal role of a customer can be distinguished in both of the design thinking discourses. The findings widen the theoretical aspects of service-dominant logic into the design thinking area while contributing to the timely discussion of the use of design thinking in value-creation networks.

1 Introduction

This conceptual paper examines engineers' and designers' different perceptions to design thinking based on their cognitive style, and social and cultural interests through the perceptual lens of service-dominant logic. The purpose of this study is to present the differences in two design thinking discourses, engineering and design based, and show how service-dominant logic can bridge the two in a way that benefits them both. Engineers' approach and mind-set are in sciences and the natural world (Cross, 2008), and they perceive design thinking differently from designers, whose approach is based on being empathetic, intuitive, imaginative and idealistic (Neumeier, 2009). As a compliment of being 'scientific' or 'artistic', perception of a service includes one or many human experiences, which are subjective and can mean different things to different people. In today's complex and dynamic markets, it is important to have a mutual understanding of the mode of operation and goals in any collaborative work, for co-creation is largely about communicating with stakeholders, including customers, in order to understand their current and future needs (Gustafsson et al., 2012).

Service-dominant logic views social and economic exchange phenomena (Vargo and Lusch, 2008). It interprets and presents them so they can potentially be understood more clearly. This paper aims to find answers to the following questions: How does engineering design thinking differ from design thinking cultivated by designers, and how could service-dominant logic bridge and clarify the two schools of thinking?

The desire to "scientise" design started in the 1920's in conjunction with technological development (Cross, 2001). Design thinking research, based on design research from the 1960's, approaches designers mode of operation with a positivist view (Schön, 1983), yet acknowledging that design is a highly complex and sophisticated skill (Lawson, 1980). Herbert Simon's work "the science of the artificial" (1969) is even today referenced by many researchers as Simon started the development of "a science of design" in the universities (Cross, 2001). The design research has shed light to the understanding of design ability, which is currently more mature, informed and enlightened (Cross, 2011); even non-designers are able to understand the nature of design ability. Design thinking has been defined many times due partly to its over thirty years long history and researchers various interests. The research has mainly focused on either design -oriented (e.g. Cross, 2001; Norman, 2007) or management –oriented (e.g. Buchanan, 1992; Kelley, 2001; Dunne and Martin, 2006; Dorst, 2011) discourses (Boland and Collopy, 2004). Design thinking has also been viewed from innovation, customer experience and brand value (e.g. Lockwood, 2010) and information technology (e.g. Brooks, 2010) perspectives.

Design thinking is a reflective conversation (Schön, 1983). It has become a new paradigm for dealing with problems in many professions. Although the current research has "scientised" design and interpreted the design thinking from many angles, it has not tried to shed light to how designers and engineers perceive the design thinking concept nor how to align designers' and engineers' design thinking. This paper proposes that the two design thinking discourses, despite of their different perspectives, are complementary and can together create better and more feasible end-results based on the premises of service-dominant logic, which state that value is context specific, uniquely and phenomenologically determined by the beneficiary, i.e. customer experiences.

2 Service-dominant Logic as a Paradigm

Service-dominant logic is an organizing framework created to understand economic phenomena with a wide perspective. Service-dominant logic defines service as an application of operant resources, i.e. knowledge and skills (Vargo and Lusch, 2010). The logic implies that all social and economic actors, such as companies and stakeholders, are service-providing and value-creating enterprises. From design thinking perspective, the most relevant foundational premises (FP) of service dominant logic (Vargo and Lusch, 2008) are presented below.

Operant resources are the fundamental source for competitive advantage (FP4). Operant resources, i.e. people's knowledge and skills, create desired changes which drive competition.

The customer is always a co-creator of value (FP6). Creation of value is done in interaction with others.

The enterprise cannot deliver value, but only offer value propositions (FP7). Companies do not create and deliver value independently, but they offer the competences for value creation, which is done in collaboration with the customers using the value propositions of the company.

All social and economic actors are resource integrators (FP9). Value creation is done in different levels of dynamic networks.

Value is always uniquely and phenomenologically determined by the beneficiary (FP10). Value is context-specific and experimental, and it includes a meaning to a customer.

3 Design Thinking as a Paradigm

In this paper, design is defined as “the optimum solution to the sum of the true needs of a particular set of circumstances” (Matchett, 1968), and design thinking as a mind-set, a methodology and an innovation process which “applies a designer’s sensibility and methods to problem solving, no matter what the problem is” (Lockwood, 2010). The basic assumption is that everyone is capable of designing (Papanek, 1972), and design thinking is inherent within human cognition as part of what makes us human (Cross, 2011).

3.1 Engineering Design Thinking

Engineers deal with “hard” knowledge of science, and roots of their mode of thinking lay in the Technical Rationality which is the heritage of positivism (Schön, 1983). According to positivism, propositions need to be either analytically or empirically testable, otherwise they are meaningless. “Rational behaviour” includes guidelines that outline a systematic procedure of first analysing the problem, then breaking it into sub-problems, finding suitable sub-solutions, evaluating them, and selecting a suitable combination of the sub-solutions as the overall solution (Cross, 2011). In design thinking, engineers stress what is necessary considering materials, mechanisms, structures and systems (Buchanan, 1992).

3.2 Design Thinking Originated by Designers

Designers’ work has a starting point in the “soft” knowledge of artistry and unvarnished opinions (Schön, 1983). They explore and generate solutions, and for them an understanding of a problem is tightly integrated with the synthesis of the design process whereas a scientist’s, a non-designer’s, approach analyses first the problem, and creates only after that the synthesis (Lawson, 1980). Design concepts can be designers’ personal insights, which emergence as a result of some considerable cognitive effort (Cross, 2011). In design thinking, designers stress what is possible in the conception and planning of the artefacts (Buchanan, 1992).

In the next chapter, the two design thinking discourses, engineers’ and designers’ legacies, are interpreted through a lens of service-dominant logic. The arguments are exaggerated in order to pinpoint the different perspectives the discourses have although the characteristics are more mixed in reality.

4 Design Thinking through the Lens of Service-dominant Logic

Service-dominant logic and design thinking are not theories but mind-sets (e.g. Kowalkowski, 2010; Dunne and Martin, 2006). They both have an objective to involve people in an integrative and collaborative process, and bring products, services, and experiences to the market (e.g. Lockwood, 2010; Vargo and Lusch, 2008).

Figure 1 illustrates the common nominators of engineers’ and designers’ design thinking discourses from the perspective of service-dominant logic. Human-centricity is a corner stone in design thinking, and the emphasis is on observation, collaboration, fast learning, visualization of ideas, rapid concept of prototyping and concurrent business analysis (Lockwood, 2010). According to Gilbert Ryle (2009 [1949]), designers aim to “know how” phenomena and activities take place. Data in the engineering design process can be presented in the form of propositions as “know that” (ibid.). The design culture views the world through practicality, ingenuity and recognition of emotions experienced by other people while concentrating on “appropriateness” whereas the culture of science values objectivity, rationality and neutrality while aiming at being the “truth” (Cross, 2008).

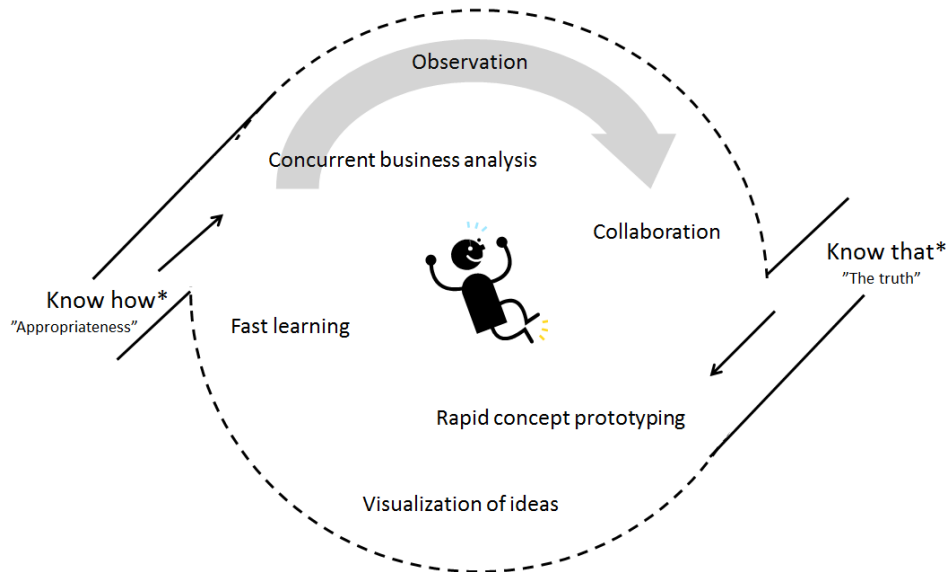

Figure 1. Design thinking is a human-centered methodology and innovation process. The concepts “know how” and “know that” are adopted from Gilbert Ryle (2009 [1949]).

In the following sub-chapters the main differences related to value, mode of thinking, focus, customer understanding, perception of time, scope, quality, and expectation management, of the two design thinking discourses are presented, and the lens of service-dominant logic is used to bridge the discourses together.

4.1 Value

Engineering design thinking is cultivated by multiple engineering disciplines where the natural world and sciences with logical thinking and mathematical facts are seen as the foundation. Engineering design thinking values objectivity, facts and sense making (Cross, 2008, 2011). Designers do not forget science, technology and art but keep them in the background (Lawson, 1980) while concentrating on subjectivity and understanding of the social and emotional aspects of the customer (Cross, 2008). The solutions designers provide do not have right or wrong answers.

According to service-dominant logic, the value is phenomenologically determined by the beneficiary, i.e. customer, in a social context of networks, and the operant resources (knowledge and skills) create the fundamental basis of it (Vargo and Lusch, 2008). The created value is unique to a certain situation and context (Vargo and Lusch, 2010).

4.2 Mode of Thinking

Design thinking can be inductive, deductive and abductive; abductive thinking being the necessary logic of design (Cross, 2011). Engineers apply the design thinking methodology to problem solving from a starting point in the scientific theory and technique. Mode of thinking is mostly inductive and deductive, and each step in the process is a logical continuation of the earlier acquired knowledge and experience based on available facts (ibid.). Designers’ mode of thinking is inductive, deductive and abductive. Dorst (2011) divides abductive thinking into two forms; abduction-1, problem solving, refers to a process where an object that will give definition to both the problem and a solution space is missing. Abduction-2 refers to a more complex process where only the aspired end value is known. Engineers and designers use abduction-1 (ibid.). Abduction-2 is used in latent problems that are not apparent, and it is closely associated with design (Roozenburg and Eekels, 1995). The use of intuition, a leap of faith (Martin, 2009), is difficult to justify for an engineer without facts and evidence (Cross, 2011).

According to service-dominant logic, companies can only offer value propositions, and value is determined by the beneficiary (Vargo and Lusch, 2008), so the value of customer experienced could be a sufficient evidence for an acceptable proposition instead of pinpointing complex mathematical formulas or possible discontinuations in the thinking process. Realization of value requires that an input from a single provider needs to be integrated with other resource (ibid.).

4.3 Focus

Engineering design thinking focuses on solving problems (Lawson, 1980). A general rule of thumb in the engineering organizations is “do not fix it, if it is not broken”. Engineers divide a problem into smaller entities and focus on solving a sub-problem piece by piece (Cross, 2011). Designers focus on finding solutions to problems that might not even exist (Lawson, 1980). Finding a solution to an undefined problem forces designers to focus on the problem setting, too (Schön, 1983). For designers, the problem and the solution are intertwined and developed together. During a design

process, relevant features can emerge in tentative solution concepts and by being recognized, they can have properties that are used in solution-concept or problem-concept or both (Cross, 2011).

According to service-dominant logic, a customer is always a co-creator of value (Vargo and Lusch, 2008), so the focus of design thinking could be shifted to the perspective of service exchange and collaboration of relevant actors since the operant resources are the fundamental source of competitive advantage.

4.4 Customer Understanding

Engineers' approach to solving a problem is technology –oriented and customers' needs are fulfilled with advanced technical applications. A new technological artefact or service is delivered with a thick manual, and the customer is expected to read the manual before using or experiencing the new solution. Designers approach customers ethnographically; they prioritize a customer, and the outcome of the work is based on meanings (Lockwood, 2010). Customers should feel a pleasure when using an artefact or experiencing a service. Designers can also jump to a conclusion already in the early phases of the process (Cross, 2011), rather than being more objective and generating and evaluating many possible options for the solution.

Based on service-dominant logic customers are resources with whom value is co-created reciprocally by using the operant resources (one's competences) for the benefit of another party (Vargo and Lusch, 2004, 2008). Service is the fundamental basis of exchange (ibid.), so the company needs to understand the customer as well as the customer needs to understand the company in a certain context.

4.5 Perception of Time

Engineers split their work into logical entities based on e.g. a project plan or an operational process. The units of time, such as an hour or a week, create a rhythm to the work; e.g. scheduling of a project is done based on the given dead live for the project launch, which "dictates" reserved time slots for each activity in the project. Perception of time is more challenging to the designers since their approach to possibly even invisible problems and understanding of the problem settings is not necessarily logical or bound to a clock. Therefore there has to be allowance for free-flowing activities within the overall schedule (Cross, 2011). Designers are used to live with ambiguous design proposals, leaving many options open for as long as possible (Cross, 2011). It is quite usual that designers seem not to have enough time to complete their work and they need to be "forced" to the solution.

Service-dominant logic is built on long-term relationships and timeless value-creation networks. It emphasises lifetime value and balanced centrality in the network (Gummesson et al., 2010).

4.6 Scope

Since the Industrial Revolution generous two hundred years ago, engineering thinking has been focusing on mass production. Designer's heritage lays in craftsmanship which has even a longer history. A craft was a profession that required particular kind of skills in designing and making artefacts, which were tailor-made to last for a long time. The different perspectives are reflected in how engineering and design –originated design thinking discourses approach the concept of scope even today; increasing competition in global and local markets, and economies of scale and scope have been included in the engineering thinking whereas designers settle for uniqueness and fit-for purpose approaches.

Service-dominant logic suggests that the value creation takes place within and between networks consisting of economic and social actors who interact with each other and exchange services across and through the networks (Vargo and Lusch, 2008). The scope of the value-creation network constitute of the society and the market.

4.7 Quality

Quality systems and standards have been developed to align and integrate the production of goods and services. Correct level of quality, e.g. right dimension, feature or functionality, is an essential factor in company offerings, and it is based on engineering thinking. Designers approach the quality from solution-finding perspective and perceive quality to be embedded in the solution.

Value has taken over the importance of quality in service-dominant logic (Gummesson et al.,2010). Since customers are co-creating the value, the aim of the companies could be in effectiveness, situational "cleverness", not making efficiency the primary target.

4.8 Expectation Management

Traditional engineering mode of operation has been to execute when a plan is ready and end-result known (Cooper, 1990). Currently the agile working methods as well as focus on radical innovation with fast prototyping (e.g. Lockwood, 2010) are popular in engineering discipline, too. Customer expectations are easily missed in the process due to various reasons, the main one being that customers are not enough involved in the process. Designers are opportunistic; they plan their activities at the same time as they work so the end-result is un-known when the work starts (Cross, 2008). Collaboration is embedded in designers' work (e.g. Cross, 2011) so the involvement of

stakeholders, including customers, is as natural for them as the use of logic steps is for engineers. Designers also challenge norms for example by being roughly ready (Lockwood, 2010), or behave opportunistically for example by deviating from a plan when a good idea comes along (Cross, 2011), which can cause difficulty in the interaction process and create misunderstandings of a customer.

According to service-dominant logic, the value creation is inherently relational and since customers are co-creators of the value, the value creation process is transparent for them. This indicates that the co-creation transactions come with social (and sometimes even legal) contracts with implied warranties which are statements that the exchange relationship yields valuable service provision for an extended period of time Vargo and Lusch, 2008).

5 Conclusion

The importance of customer understanding is indisputable in any company but the notion of customer understanding can vary; an engineer builds technology-oriented solutions based on facts and figures whereas a designer focuses on the customer sentiments and situational setting. Through the perceptual lens of service-dominant logic, the differences of designer –originated design thinking and engineering design thinking can intersect and complement each other (table 1). The wider angle in the common value-creation process and the reciprocal role of customers could give a new meaning to both discourses and that way create richer and more feasible results, where the integration of “know how” and “know that” is more than the discourses put together as independent proposals.

Table 1. Service –dominant logic (SDL) can complement the discourses of engineering-originated design thinking (EDT) and design-originated design thinking (DT).

Main differences	EDT	DT	The bridge created by SDL
Value	Fact-based and logical “truth”, objectivity	Context and situation dependent “appropriateness”	Beneficiary determines the value based on his/her experience
Mode of thinking	Inductive, deductive and abductive (abduction-1) thinking	Inductive, deductive and abductive (abduction-1 and abduction 2) thinking	Companies offer value propositions, and value is created in collaboration with all actors
Focus	Piece-focused sub-solutions to sub-problems	Holistic approach; seeing things in terms of how they relate to each other in producing a result	Service is exchanged for a service in collaboration, operant resources are the source of competitive advantage
Customer understanding	Technology-focused	Ethnographic approach, providing a pleasure to customers	Value is co-created reciprocally with customers by using the operant resources for the benefit of another party
Perception of time	Work is split into time slots based on a plan or mode of operation	There is never enough time	Relational and timeless value creation
Scope	Mass production	Uniqueness	Value creation is done in networks of actors
Quality	Verified by an external party, e.g. standardization	Embedded in the design	Value is more important than design
Expectation management	Customers do not think they are enough involved in the work process	Opportunistic working methods are challenging in collaborative processes	Value creation is inherently relational and customers are co-creators of it

In this paper we focus on the main differences between engineering-originated and design-originated design thinking discourses. The similarities between the discourses, e.g. high levels of concentration and engagement as well as the aim to understand various angles and layers of the problem (e.g. Cross, 2000, 2011; Neumeier, 2009) support the design thinking mind-set and common goal setting. Nevertheless, it would be interesting to study how to “trim” the two discourses in addition to “prune” the factors that prevent successful design thinking from happening. This is a conceptual paper so empirical data are needed to verify, deepen and possibly enhance our preliminary conclusions.

Acknowledgement

The first author of this paper wants to thank the research program REBUS, "Towards relational business practices", for the discursive support for this study. The design perspective of this paper contributes to the research activities of P3 (R&D networks) track of REBUS program, which is one of the research programs of the Finnish Metals and Engineering Competence Cluster, FIMECC.

Regional economic performance discrepancies, spatial distribution of services, and rural development in Romania

Laurențiu Tăchiciu¹, Gheorghe Săvoiu², Vasile Dinu¹

¹Bucharest University of Economic Studies, ²Pitești University, Romania

The present paper reports the results of the first phase of a project which final aim is to design service driven rural development policies directed especially toward protected, intermediate and remote rural areas of Romania. The main objective of this phase is to provide a characterization of NUTS 3 regions in terms of (1) economic performance, and (2) presence, structure and localization (concentration) of service activities. Additionally, it is expected that researchers draw some preliminary conclusions regarding specific policy measures, differentiated in correspondence with the local endowment with economic factors and the prospects for economic diversification and market integration of rural areas.

1 Introduction

Romania is divided into 41 NUTS 3 administrative regions regrouped into 8 NUTS 2 regions for statistical and support for development policies purposes, and four NUTS 1 regions. There are 320 towns (out of which 103 larger and better endowed, called „municipiu”) and 2861 rural administrative units called ”commune”. Apart from the municipality of Bucharest and its surrounding areas, the entire territory and population of Romania should be characterized as rural when the analysis regards NUTS 3 or NUTS 2 regions. Six of the NUTS 2 regions of Romania rank amongst the 10 less developed regions of the European Union. However, when looking into more detail, the degree of urbanization, industrialization, the economic performance and growth prospects vary significantly from a region to another, from areas close to cities to intermediate or remote areas. There are important differences regarding the endowment with basic infrastructure, human capital and natural resources. Most of the Romanian rural economy consisting of small agricultural households relies on auto-consumption, barter, and small informal sales. Especially because of this, service driven rural development policies should be designed with the main aim to stimulate, assist and support the marketization, monetization and formalization of the rural economy. Current policies promoting standardized, un-differentiated projects under EU funding are frequently unfitted to local conditions, and so they fail to achieve a spill over effect. The development of an economic typology of Romanian rural areas, which is presented by this paper, provides the grounds for designing a set of differentiated policies.

The paper includes a synthetic presentation of the main lessons from the research in the fields of economic geography and regional economics with a specific focus on services location and local economic impact. A specific section analyses from a spatial perspective the correlation between economic performance, the presence and structure of service activities. Next, in defining and characterizing types of rural areas, the main challenge is the preparation of a consistent data set, from several main sources (National Institute for Statistics, Regional Statistics Offices and Regional Development Strategies, a comprehensive and very detailed database with data at locality level managed by the Ministry of Interior). This work is on-going.

2 Overview of regional disparities in Romania

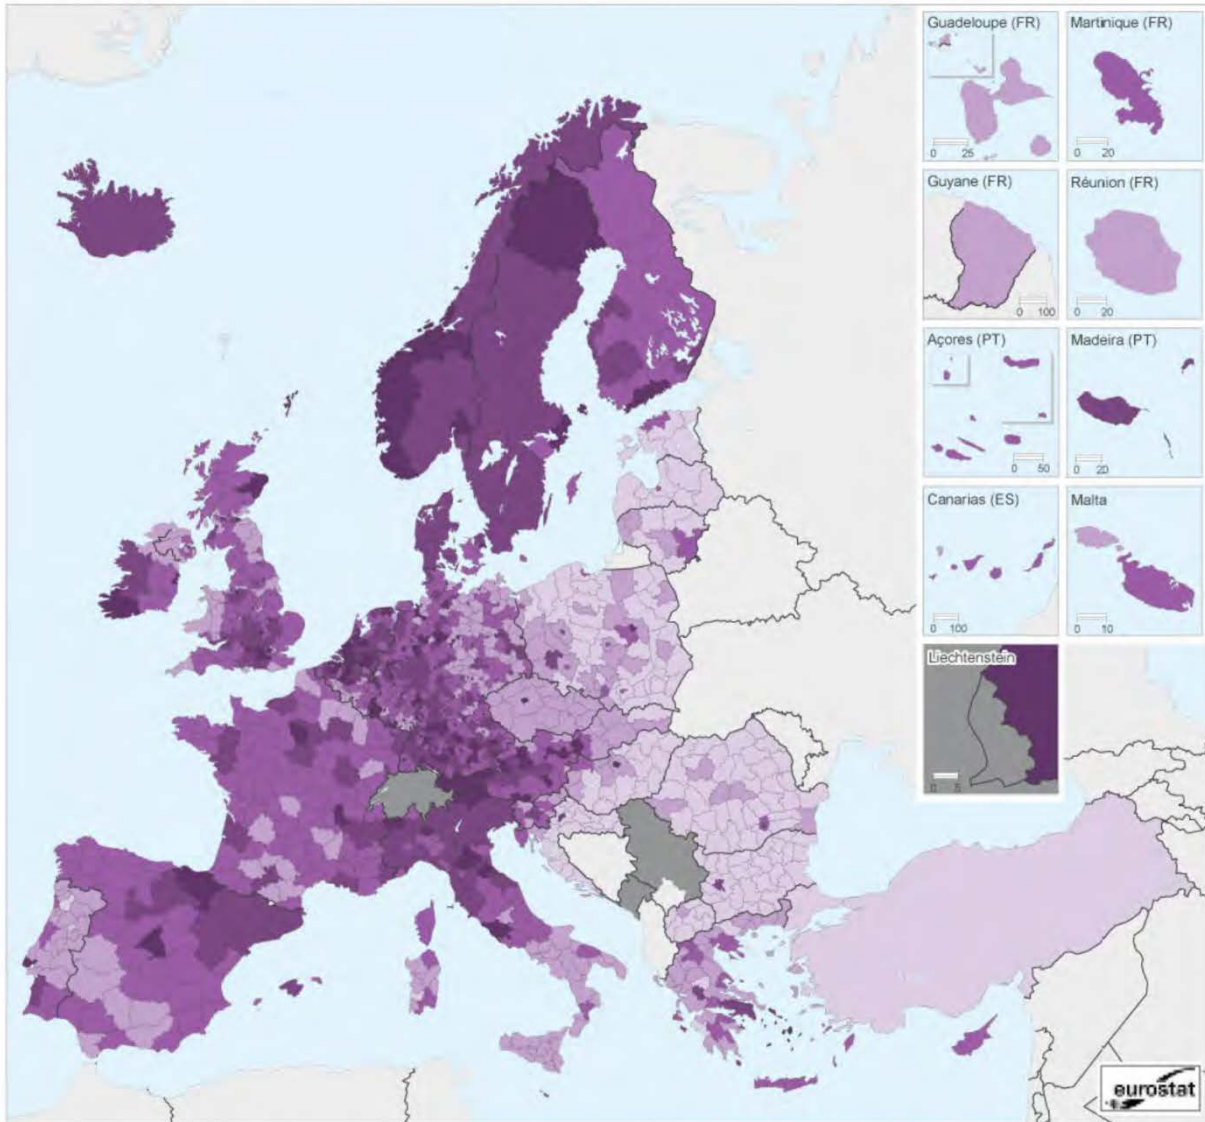

The study of regional disparities is well covered in the literature. The aim of this section is just to familiarize the audience with the specific situation of Romanian regions.

In terms of GDP per capita, Romanian regions rank among the poorest of Europe. As one may see in Figure 1 (next page), out of 42 NUTS 3 regions, Bucharest and its surrounding area (Bucharest-Ilfov) is the only region with a level higher than 75% of EU average. Four regions match EU average, and these are, from west to east: Timiș (J40)²⁵¹, Cluj (J3), Sibiu (J12), Brașov (J8) and Constanța (J21). Four Romanian regions are mentioned among the five that recorded the highest rate of change of GDP in the last decade (2000-2010), as compared with the EU average (the fifth being Sofia region in Bulgaria) (Eurostat 2013, 26). Interestingly, two of these most dynamic regions are from the top of the Romanian regional hierarchy, while the other two rank still below the Romanian average GDP per capita. This finding it is worth to be noted because it contradicts two positions that are frequently taken by analysts, one saying that growth is easier to achieve when starting from a low initial development level, the other saying that richer regions are better equipped to achieve economic growth. On the other hand, it is a consensus that economic growth is not the same with economic development, and even lesser corresponds with the concept of sustainable development. We do not intend to discuss these distinctions within the present paper, but we need to mention that our approach regarding rural development is primarily focused on achieving cohesion in the functioning of the economy. We intend to bring into light the need for modernizing the rural economy, achieving implicitly sustainable development economic structures.

²⁵¹ J1... J40 are conventional notations used in the present document in order to improve readability for readers who are not familiar with Romanian denominations. Correspondence is provided in Appendix 1.

Seen from EU level Romania appears to be almost homogenously (under-) developed. Two other arguments support this idea:

- Romania is a rural country. Leaving Bucharest aside, Eurostat classifies 23 Romanian regions as predominantly rural (with over 50% of population living in rural communities) and 17 regions as intermediate (20-50% rural population). When looking closer, we see that among the „intermediate regions” eight have a share of rural population higher than 40% and only two a share lower than 30%;
- The average monthly income of the population varies roughly between regions from 22000 lei to 27000 lei, which is considered to be relatively low imbalance.

Figure 1. GDP per inhabitant in PPS by NUTS 3 regions in 2010 (% of the EU average)
source: EUROSTAT (2013).

In reality, once we narrow the analysis the regional discrepancies become significant.

In Figure 2 we present the relative position of Romanian NUTS 3 regions compared with the country average. We have eliminated Bucharest and Ilfov (both from analysis and from the average). From this perspective, we put into evidence that GDP per capita is almost double in Timiș than the country average, while for Vaslui the same indicator is with 50% below the national average.

Figure 2. Per capita GDP - % above(+)/below(-) the national average by NUTS 3 regions, 2011, Romania (source: authors calculations, NIS²⁵² data).

The question is if there is any relation between relative levels of economic development as expressed by the GDP per capita on one side and (a) the share of rural population or (b) the contribution of services to the regional Gross added value, on the other.

From the graph in Figure 3 we see immediately the tendency of predominantly rural regions to record a lower economic performance. There are also interesting cases. For instance:

- Hunedoara (J39) is the region with the lowest share of rural population, but has a GDP per capita which is slightly lower than the national average (Hunedoara is characterised by the presence of declining industries);
- Timis (J40) has the highest GDP per capita, but a near average share of rural population. It means that within a modernised economic structure, the predominantly rural character may not be a restriction for economic performance. This is also confirmed by the cases of Dimbovita (J27) and Giurgiu (J28) that are eminently rural but achieve an average economic performance²⁵³.

²⁵² National Institute for Statistics

²⁵³ It is worth to be noted that Timis and Giurgiu are among the most dynamic regions of Europe between 2000-2010

Figure 3. Distribution of Romanian NUTS 3 regions relative to per capita GDP and the share of rural population (source: authors calculations, NIS data).

Quite differently, the distribution of regions according to the economic performance and the contribution of services to GAV (Figure 4) do not show the same linear trend line. Taking the national average as reference, we can indeed identify four clusters of regions:

- NW quadrant, high share of services - low economic performance;
- NE quadrant, high share of services - high economic performance;
- SW quadrant, low share of services - low economic performance;
- SE quadrant, low share of services - high economic performance;

Figure 4. Distribution of Romanian NUTS 3 regions relative to per capita GDP and the contribution of the services sector to GAV (source: authors calculations, NIS data).

Striking, the regions are evenly distributed between North and south quadrants. There are also interesting cases to be considered:

- J18 (Vaslui) is the poorest region according to the per capita GDP, but records one of the highest contribution of the services sector. In fact the highest contribution is made by public services and commerce, while the other economic sectors have a very low output
- J30 (Prahova) is a region with GDP significantly above the national average but with the lowest contribution of services, despite the fact that it is one of the Romanian regions with a well-developed infrastructure for tourism. On the other hand Prahova is also a region with strong industry and construction sectors. This raises, nevertheless a question about the relationship between manufacturing and the business services sector. It suggests that either the manufacturing sector is organised traditionally or it acquires services from elsewhere, in particular from Bucharest given the proximity.
- J3 (Cluj), considered as a centre (core) of the historical region of Transilvania has one of the best equilibrated economies among Romanian regions. Among others it has a strong multicultural university and a well-developed network of education institutions, the most successful industrial park (it was the location of Nokia in Romania but there are many other multinationals still active). It is one of the leading regions in the production of key services as ITC, financial intermediation, professional and other business services, and – not least – cultural activities.

With this brief overview we can draw two main conclusions: first, an important share of rural population is compatible with high economic performance, and second, the contribution of services to the economic performance depends not only on the share of services in the economic output but also on the nature of the services that are produced and their interaction with the other components of the economy.

3 The role of services in the rural economy of Romania

The rural economy continues to be a subject of high interest for researchers, policy makers and other stakeholders. While in developing economies the focus is on enhancing the capacity of agriculture and other traditional activities to provide an economic support for the subsistence of the population, in more advanced economies the focus switches on some other priority themes: acquiring competitiveness, protecting the environment, preserving the cultural heritage, ensuring food security and high living standards for the population. As rural areas exhibit a large variety of particular situations requiring adapted policies scholars are concerned with improving the rural work typology in order to better

address the priorities of different types of rural areas. A very good example in this respect is the work of JRC-IPTS on reviewing EU rural typologies in connection with the territorial impact assessment of policies (Copus, A. & al., 2008). Authors propose a refinement of OECD rural typology by adding a „peripherality” characteristic. It ”reflects potential interaction with all economic centres across Europe, taking account of both their size and their relative proximity” and it ”is seen as a key aspect of the overall business environment, with a theoretical basis in the concept of agglomerative advantage, (external economies to scale), and affecting both prospects for growth and levels of innovation.” (Copus, A. & al., 2008, 72-73). The value of this work also value of this work lies in providing a comprehensive inventory of methodologies and models that can be used in order to combine rural typologies with territorial impact assessment.

Rural development is a major concern for Romania, a country with 40% of population living in rural areas, with large lagging behind in the endowment of rural communities with basic services and were rural life is in many cases associated with poverty, or self-subsistence in the better cases. A Romanian scientist, Dumitru Sandu has extensively studied both the rural economy and the poverty in Romania. In one of his articles he describes the situation of the Romanian villages in the following way: „ Human capital is the most important component of village development or poverty. An explanation of village poverty is given in terms of poverty cycles and regression models. The poorest villages are peripheral villages within communes, located in plain areas, far from large cities and modernized roads, in low developed judets.” (Sandu, 1999, 138). He has also found that besides the consistent classification of poor and traditionalist villages or modern developed villages, another dimension of cultural nature is present. It defines villages that are relatively poor but which population embraced a modern stile of living in the rural context. Dumitru Sandu also developed a composite index of villages’ development (based on 17 indicators) providing an estimate of the average village development index for each region (NUTS 3) of Romania (Sandu, Voineagu & Panduru, 2009). We are using this index for our work. There are many other researches that address the socio-economic development of Romanian rural areas none of which, to the extent of our knowledge, is focusing on the role – actual or potential – of services.

The only data available at this moment for estimating the service activity in rural areas is the number of employees in services. We took into account all kinds of services, except commerce.

We found an almost perfect correlation between the village development index and the number of employees in services per 1000 inhabitants of rural areas (Figure 5).

Figure 5. Distribution of Romanian NUTS 3 regions relative to the number of employees in services per 1000 inhabitants and the village development index (source: authors calculations, village development index from Sandu, Voineagu & Panduru, 2009, NIS data for service employes in services).

This correlation is in contrast with the distribution in Figure 4, and the main explanation is that the village development index is substantially different from per capita GDP. It is build taking into account a large number of indicators including housing infrastructure, public finance, household individual capital and human capital at locality level. Therefore, it reflects better a number of qualitative aspects of development.

Once we found evidence that rural development is correlated with the development of services, the issue is that we do not know if revenue from agriculture and other activities provide the grounds for services development, or the presence of services (as a result of either private or public initiatives, or both, induced by cultural patterns) was the factor that supported the development of rural communities.

We had interviews with a number of rural community leaders (mayors). They all suggest, even if in different ways, that it is a problem of perspective. People from communities with a certain level of development, can see an opportunity to improve their own lives. They enter the formal economy to get more, they invest, pay taxes and demand services. Poor communities lack basic services (water, sewage, roads, secondary and sometimes even primary education, health services). This is not an option for people that aspire to a modern life; they are leaving, and those who remain are those who are satisfied with their living, or who do not have the capacity or the means to change anything. Sometimes many people that find a job abroad send money to their families, or come back with their savings and a new perspective. When such a phenomenon rich a critical mass in a particular community, the prospects of that community are improving as well. Maybe this is a partial answer to what Dumitru Sandu identified as a difficult to explain modern culture in poor communities.

Another interesting case is that of a rural locality where public investments were done for water distribution, swage and gaz. Because people had no money, in the first phase few were able to pay the individual branching and the recurrent charges. But others have struggled to get a monetary income and in three years the utility operators were close to their breakeven point. Access to services generates the needed perspective and initiates a virtuous circle that leads to the modernisation of the rural economy. This does not happen in every case, there are also communities in extreme situation where most of the population lives at the level of pure subsistence from social assistance and other public transfers, and their situation will not change soon. It is a totally different subject, which is not related to economic development, but to our responsibility for ensuring that human rights and constitutional provision are respected.

Services are not only a driving force for the modernisation of the economy in poor rural areas. In more advanced rural areas, business services can also contribute at better valorising local resources. People from a locality in the south of the country are seeking to find a distributor to collect their production of tomatoes. In a locality of Sibiu County guesthouses owners are paying for training in foreign languages, marketing and web design services, most of the productive activities need implementation of quality systems and certification, legal advice or technical expertise.

4 Conclusions

The rural specificity is given by the relatively low density of population, wealth of the ecosystem, the horizontal development of infrastructure, the preponderance of occupations related to agriculture, fisheries, timber harvesting and traditional crafts. The vision we propose is that economic activity has diversified to include the features and mechanisms of the modern economy, developing small-scale and clean services and manufactures, ensuring comfort and safety of residents in levels of modern life, but retaining the other characteristics of rural areas.

Compared to the situation in other countries, the villages of Romania retain many characteristics of rurality. Romanian villages are a national asset that must be cherished, preserved and properly exploited in a sustainable manner.

Romanian rural space is not homogeneous. There are a wide variety of situations in terms of demographic, climate and natural resources, and economic potential. There are communes in which the process of urbanization cannot be prevented, as is the case especially near large cities, where many satellite villages have already been functionally integrated into the city. For this type of localities the solution of metropolitan development should be followed with wisdom so that the locality in question does not turn in a poor suburb. Similarly, there are several villages experiencing a resort-type irreversible development; that fact must be recognized and development solutions must reflect this status. However, for isolated communities, deprived of resources, located in areas affected by adverse demographic or climate trends, which bear the consequences of irresponsible human activity in the past, or are seriously affected by poverty, long term support programs should be adopted deliberately, under the principles of solidarity and social cohesion.

Communities have different aspirations and economic changes cause social changes that must be known and deliberately assumed by the members of each community through democratic participation and good governance based on local autonomy.

Co-designing a collaborative idea-generation model with stakeholders

Päivi J. Tossavainen, Virpi Kaartti, Leena Alakoski

Laurea University of Applied Sciences

Business practices are changing when firms are adopting service business approach as a basis for the operations. Customer centricity and resource integration are among those initiatives requiring new ways of working. This paper reports a case study of an industrial service with a strong strategic implementation supporting service business approach. The empirical data of service development process comes from 13 stakeholding organizations and was collected in various methods. The paper explores the co-design process of a collaborative idea-generation model. The suggested model is based on the Double Diamond model. The novelty of the paper is the stakeholder engagement, which is extended from dyadic two counterpart activity to simultaneous many-to-many collaboration within idea generation phase in service development. The study suggests an approach that may reveal new insights into customer centricity and resource integration research.

1 Introduction

Collaboration during the service development process simultaneously with various stakeholding actors requires attention. Despite the popularity of co-creation, studies focus often on one-to-one collaboration and customer, client or user involvement is common (see Alam 2002, Bessant and Maher 2009, Marasco et al. 2011). There might be other stakeholding actors related to the service, who could be involved in collaboration. This wider stakeholder engagement is still less addressed especially in B2B setting. This paper addresses this shortcoming and extends the discussion to multiple stakeholder collaboration. Further, the paper addresses the influence of multiple stakeholders and the role they also have in developing the collaborative idea-generation model. The paper offers a deeper view on how the model was co-designed.

In service research, studies providing deep empirical evidence is lacking behind the extensive conceptual research. Therefore, this paper illustrates a study, which aimed to focus on concrete real-time activities and empirical evidence for the benefit of the academics and business practitioners.

The purpose of this paper is to focus on contribution of engaging widely both internal and external stakeholders into the idea-generation part of the service development process. Building on empirical evidence, this paper contributes the understanding of stakeholder integration.

Some limitations apply to this paper. It investigates whether the process could be designed by applying service design approach. Following this approach, the paper explores and describes the case and explains how the co-designing of the collaborative idea-generation model took place. The model facilitates and mediates the integration of stakeholders into service development. Although internet and communication technologies (ICT), interactive technologies, and social media provide huge opportunities to engage stakeholders (Ramaswamy and Gouillart, 2010; Russo-Spena and Mele, 2012; Ind and Coates, 2013; Hatch and Schultz, 2010) this case study focused on face-to-face engagement.

The whole service development process needs to be followed through in order to have beneficial value propositions. However, in order to limit the focus of this paper, we elaborate and explore only the idea generation part in this paper. Empirically the paper provides a rich data by studying how participant activities are planned, facilitated, carried out, and analyzed.

2 Framing the joint idea generation approach in service development

The idea generation is studied from the perspective of service dominant logic (SDL) of marketing (Vargo and Lusch 2004). **Customer centricity** and **resource integration** are integral part of the logic and of the SDL literature. In SDL research, one of the main changes has been the question of the ownership of resources leading to resource integration paradigm (Vargo and Lusch 2004, 2008). There is little evidence of resource integration and customer centricity approaches. Yet, truly customer-centric models and multiple stakeholder-driven approaches are yet to be taken into businesses. In B2B context, resource integration has been discussed between one customer and one supplier relationship (den Hertog 2000). Customer centricity is hindered in firms due to the organizational culture, structures, processes, and financial metrics of the focal firm (Shah et al. 2006). In B2B context, and especially in the larger firms, the customer relationship interaction is commonly organized through the key account management system. (McDonald, Millman & Rogers 1997) Hence, direct connections between various positions, roles or professionals may be neglected. This in turn may lead to the situation in which issues, challenges or ideas for improvement are unlikely brought into the attention of the management responsible for the service development.

Literature (Frow and Payne, 2011; Han, 2010; Payne et al., 2008; Sanders and Stappers, 2008; Segelström, 2013; Vargo, 2008) suggests that if a service is considered as a **joint value creation** with wide array of stakeholding partners

such as employees, customers, users, fans, intermediaries, hobbyists, artists, designers, service design professionals, suppliers, authorities, and researchers, it also adds the network perspective into the discussion (Russo-Spena and Mele, 2012). Intrinsically, the terms joint value creation and co-creation emphasize this wider view of “all stakeholders” involved in the value co-creation (Prahalad and Ramaswamy 2004, Ramaswamy and Guillard 2010). Yet, the discussion is typically limited only to customers and users, and dyadic interactions. In their recent review of co-creation, Ind and Coates (2013) found that literature seems to focus on the aspect of “creation” more than the “co”, i.e. the togetherness aspect. Ramaswamy and Guillard (2010) found that the ideas, suggestions, or contributions thus get a “short shrift.” This paper acknowledges the importance to focus on the “co” aspect and extends the discussion on how it can be supported.

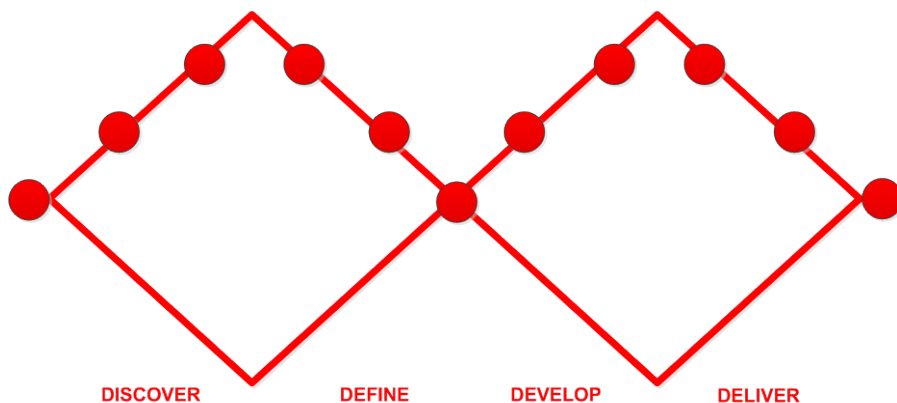

There is a wide variety of potential stakeholders for a service, i.e. **stakeholding actors**, who can bring value into the service development. In this paper, service is considered as a joint value creation process. We examine the case through the lenses of service development and service design research. We propose that it is mutually beneficiary if miscellaneous stakeholders are engaged into face-to-face, simultaneous joint activities, from various service business related organizations, in different levels of hierarchy and dissimilar positions. This in turn may increase the diversification through the broadness of the shared information and experiences, and the amount and quality of the development suggestions. Thus, this paper promotes the value of engaging all stakeholders (Prahalad and Ramaswamy, 2004b; Ramaswamy and Guillard, 2010; Prahalad and Ramaswamy, 2004a; Gummesson 2008) in developing service. It explores and discusses how to enable multiple stakeholders into co-creation and how to use this activity to develop service. The paper results a novel model and illustrates how multiple stakeholders interact in the area of idea-generation in service development.

2.1 Understanding the development through service design model

This paper suggests that the idea-generation is an important part of the service development process and benefits the value propositions. Retrospective, structural, and sequential innovation processes are common and used in service innovation (von Koskull and Strandvik 2014). Therefore, this paper takes a look into service design methodology for a different approach. Moreover, the paper explores multi-actor participation and many-to-many engagement actions in real time.

Service development and design competences are distinctive competences. They rely on service approach knowledge and practical implementation skills. (Grönroos 2009, Ojasalo and Ojasalo 2009) From our perspective, new competences and knowledge is required to support firms to engage with service design, which is a collaborative process enhancing the value of service. Business practioners seem to need information and hands on opportunities to apply moderns methods and techniques they can use in development and deployment of service.

The service logic and service design approach emphasize customer understanding, which was critical criterion in selecting the development model. The service development processes in service design field were investigated. There are several process models with various phases and suggested activities (see for example BIS Publishers/ Stickdorn and Schneider 2010; Moritz 2005, Edvardsson et al. 2002). From those, the research team selected the Double Diamond design process model (Design Council, UK, 2005), DD –model in short. The DD-model (see the following figure) is a commonly used approach in service design. The model was developed by British Design Council in 2005. The process is divided into four phases: Discover, Define, Develop and Deliver. In the first phase, the user needs are identified in order to get an initial idea or inspiration to start the project. In the second phase, “Define”, the needs are interpreted and aligned to business objectives. Thirdly, solutions are developed. This phase has a prerequisite of iteration and testing within the company and with the stakeholders. In the final phase of the design process, the developed service is finalized and launched in the market.

The Double Diamond Model, Design Council 2005

Figure 1. The Double Diamond Model (Design Council 2005).

Roughly the DD-model can be divided into two larger phases: The four phases form two separate entities for the development process (in the figure: squares) represents the designers thinking logic. Idea-generation phase and development phase. These processes can be managed differently, yet it typically is designer led and thus each phase includes typically used methods. For example the Discover and the Define phases include understanding, ideation, testing and communication activities. Previously mentioned activities in turn include various methods. The DD model is based on interaction among participants and supports continuous iteration activities. As such, it is structured and sequentially described. Yet, the iteration and dynamic properties of the model makes it usable model for real-time investigations.

The Double Diamond model provides a framework for service development. It may include various service design activities throughout the process. How participants provide their input into the process and iteration rounds is of importance. To perceive the phase dependency and iteration rounds is critical because it affects to the development process targets and outcome.

3 Stakeholder integration on idea generation phase

Research on complex socio-technical systems such as large business organizations requires novel approaches. Part of the SDL research focus on service design models, methods and tools used in order to solve the business service transformation paradigm. The service design approach is largely based on design discipline, and inherently supports the ethnographic studies. Yet, in service innovation literature, only recently, ethnographic approach is suggested as a contrast to mainstream retrospective approach (von Koskull and Strandvik 2014). Following this path, this paper explores the research project, reporting the real-time actions leading to the model. While primary method of participant observation is suggested (ibid.), this paper extends the methodological choices to cover actions during the study.

Qualitative research strategy was applied in a single case study setting in business-to-business (B2B) context in order to co-design a collaborative model. This is valid choice because researchers are unified about the central characteristics of a case study approach to be holistic and detailed in understanding (Carson, Gronhaug and Perry 2001; McKay and Marshall 2001; Gummesson, 2000, Howell 1994; Rapoport 1970). A case study may apply action research approach or vice versa (McKay and Marshall 2001). The investigated stakeholder integration project, the activities were performed and tested in real-time. As such the methodology for the study can be described as action research (AR). It is a methodological approach that embeds several streams and perspectives (Dick et al., 2009; Gustavsen, 2008; Reason and Bradbury, 2008; Coghlan and Coghlan, 2002) and as such can be described as an ethnographic method. The AR approach aims to take action and to create knowledge, and thus have both action and research outcome (Coghlan and Brannick 2014). Likewise, emphasized is the production of practical knowledge and the practical outcomes from working together with people and “ideally involving all stakeholders” (Reason and Bradbury 2008). Recently, Coughlan and Brannick (2014: glossary) defined action research as : “*A family of related approaches that integrate theory and action with the goal of addressing important organizational, community or social issues together with those who experience them*”. Here, the operating word is “together”. Thus it is a valid academic research method approach for this study.

This paper includes a case study which explores how to integrate miscellaneous stakeholders into a service development process. The context is an **industrial waste management service**. The co-designing activity was embedded in an externally funded research project, which aimed to improve strategic stakeholder integration within the case company. The authors of this paper participated to this research project (see Tossavainen 2013) and gained access on the case company, the service value proposition, processes, and stakeholders.

In the spirit of action research, the host organization and its stakeholders were involved with the study. The case company was **Lassila & Tikanoja Oyj (L&T)**. The internal stakeholder team includes the actors of the study: The members represented various units of L&T and were environmental specialists, information technology (IT) development specialists, project managers, and customer service professionals, including resources outsourced to **Elisa Ltd** and the **waste truck drivers**. The externally composed stakeholder team was formed, engaged and empowered to participate. The stakeholding organizations were **Parma Oy, Keslog Oy, Valio Oy, Puukeskus Oy, Scania Suomi Oy, Ovenia Oy, Stockmann Oyj, Caternet Finland Oy, and KONE Hissit Oy**. The individual stakeholding actors represented various functions such as environmental management, quality control, logistics, sales, key account management, development, safety, and sustainability. **Furthermore, the regulatory body responsible for the national sorting instructions, the Centre for Economic Development, Transport and the Environment (ELY)** participated the study.

The investigated activities were performed and analyzed by a research team consisting of the 3 authors of this paper. An extended research team included the case company project manager.

3.1 Many data collection methods applied

Multiple data sources including informal discussions, expert interviews, participant observation, and documents were applied. Service design methods were used in order to collect multifaceted data especially in face-to-face events.

During the period of 2012-2013, the research team of authors 1, 2, and 3 participated the study by collecting data through interviews, discussions, participant observation and participating action research activities. The research project

was executed through series of face-to-face events, which provided good opportunities to collect data, observe, and investigate activities as stakeholder integration and service development evolved and unfolded.

The service under study was firstly elaborated by informal discussions and visits to the locations. The case company was visited, observed, and series of meetings were established in order to understand the value chain, service offering, and the challenges the case company is facing. Several key stakeholders within L&T were also interviewed in order to get an extensive in-house perspective. Informal discussions and thematic interviews in the stakeholder companies with the stakeholding actors were carried out.

Documentation was produced based on the data collection and the analysis, and it included produced stakeholder maps and service blueprints. The process descriptions were investigated along with other internal documentation of L&T. Waste management reports of the stakeholder organizations were evaluated. This empirical evidence which included interview protocols, recorded interviews, and company specific documents alongside with the analysis data was stored in a separate database.

Altogether, 13 organizations and over 35 people participated to the study. Engaging stakeholding actors into simultaneous joint activities, from various organizations, different levels of hierarchy, and dissimilar positions brought broad information and experience examples during the events. The stakeholding individuals were engaged in co-creation to design and build the collaborative platform and to develop the service for the benefit of all participants. The multiple data collection resulted in rich primary data. The extended research team was able to understand the different perspectives and challenges in the current service.

3.2 Rich data analysis

Service design approach was applied to design the model through the events of participation. Through series of meetings, preparation meetings, workshops, analysis events, and seminars, the researchers gathered a wide arrange of data from recorded and transcribed interviews, to field notes, discussion notes, photos, observations, and participant observations. Relevant documentation included process and service descriptions, reports and presentation materials. The analysis of the collected data was executed by research team and at times by the research team together with the internal stakeholder team. Discussions were held on need basis to capture and clarify relevant information. Each event was planned beforehand and documented afterwards. This resulted a vast amount of plans, timetables, drafts, sketches, memorandums, reports, list of actions, and photos of the activities.

The case study focused on developing current waste management service. The design process began with the Discover phase (see Figure 1) in which the business-to-business stakeholders of the case company were interviewed. The findings from this phase were used as triggers to inspire the participants to later generate ideas for solutions. The ideas were categorized and prioritized later on with the case company. This step of the process deepened the understanding of the customer needs and their importance. In the Define phase, the design brief was modified based on the user needs identified in the interviews and the business objectives stated by the case company's contact person. A face-to-face event was organized in order to engage and motivate the stakeholders and in order to conduct multi-stakeholder activities. Several methods of service development, service design and innovation were applied in order to discover and define the service development needs. Many methods were modified and applied to fit better with simultaneous multiple stakeholder use. In this the joint development session, new methods and tools were applied to get better understanding of the chosen development target and to generate ideas to solve the identified problems or needs. Again the ideas were filtered, validated, and prioritized first with the stakeholders. This was a novel method and contradicts Ayuso et al (2011), who suggest that knowledge source from internal and external stakeholders has to be managed by the focal firm internally.

Following this activity, another event was planned, facilitated and executed. Based on the findings and analysis of the first engagement event and strong strategic guidance, the work continued. Now, the focus was shifted on another closely related service offering in order to fully use the integration of the ideas put forward by the stakeholders. There were also new stakeholding actors both external and internal brought into the event and engagement activities. The second event resulted, yet again, a good amount of validated ideas. Furthermore, the discussion among stakeholders brought new insights, suggestions, and concerns on the table. As an end result, the case company got the list of development proposals, which they can introduce to the management with the knowledge of their importance to the customers (not only one customer but several of them), the evaluation of their ability to implement the development ideas and how they were aligned to their company strategy

The original plan to develop waste management service was not prioritized by the stakeholding actors. Methods used revealed a vast amount of issues and themes that require further attention first in order to make service more customer-centric. It turned out, that ICT service around the waste management and waste sorting were more important for the participating stakeholders. The discussion on further activities continued separately in stakeholder organizations, case company and research team.

Based on the experiences, analysis, and results of the integration workshops, the research team continued further analysis with the case company team. In order to process the data collected into design drivers and further development initiatives required integrated efforts. Figure 2 depicts the essence of the collaborative idea-generation model. The stakeholders were involved in all the steps and various methods and tools were tested.

3.3 Co-designing the idea generation model

Service development is a long process and therefore this research focused on the idea generation phase. This was due to several reasons: In discussions with the case company L&T, it was important to start from the beginning of the process and to involve numerous stakeholders to broaden the needs and demands to improve the service. The strategic choice of the case company is to place the customer into the center of the development. As such, it is according to the service research fundamentals. Secondly, by starting with idea generation, the ideas and needs for change come from the customers, users and other service involved actors and not only from the internal development team. Furthermore, it allows to focus on more concrete actions and in-depth analysis on chosen ideas. This in turn may improve the outcome of the development process. The case company can then move forward with the service development process. In short, the idea generation phase sets the development phase in its validated course.

As the DD -model is very generic model for the whole service development process, the research team decided to apply it in a new way as described in the previous section. The extensive activities in format of meetings, events, and analysis sessions provided a platform to discuss, suggest, test, validate and execute developed ideas for the way of working. Co-designing collaborative idea-generation model with stakeholders was a result of all these collaborative activities, and individual efforts of each participating person. The stakeholders were invited to workshops in which several tools were used to integrate stakeholders into service development. The research team suggested the workshop idea, methods and activities to case company team. The research team was also responsible in facilitating the workshops in order to save time and efforts. Each workshop comprised sub sections with varying objectives, tasks, and tools. The storyline for the workshop was developed and operationalization of the workshop was carried out. After the workshop, memos were created and analysis was carried out.

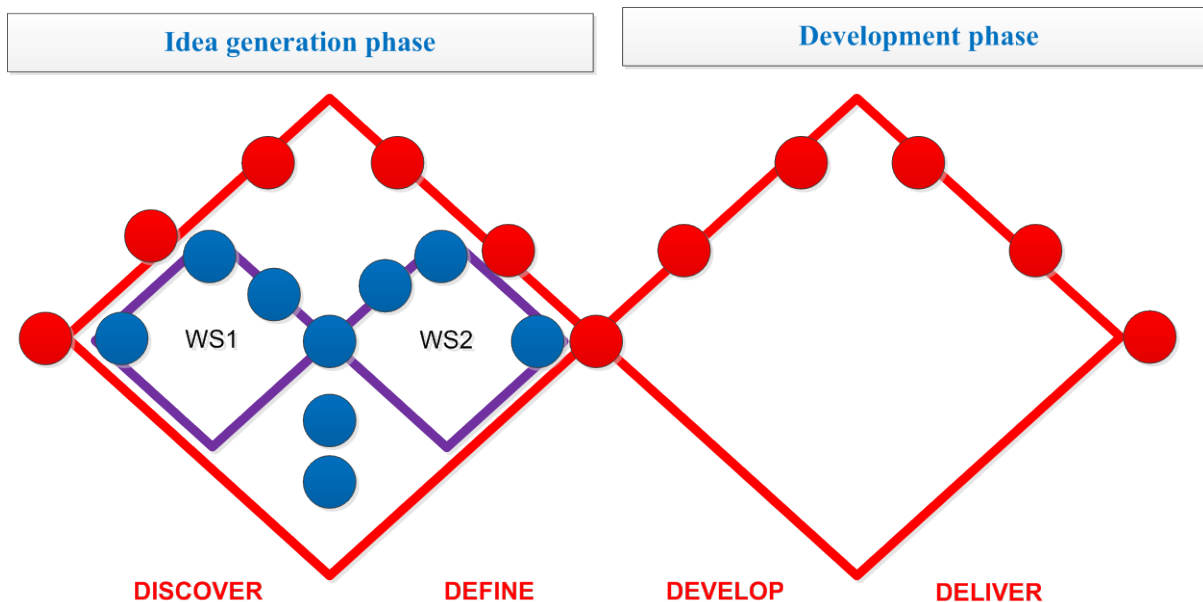

Figure 2. Modified Double Diamond model.

The figures 2 and 3 illustrate how the stakeholders were involved in each different step of the design process. The stakeholders may vary in different workshops but in every occasion they represented several organizations and functions of the stakeholder organizations. Their simultaneous participation was at most important to identify the most essential design drivers to guide the ideation phase and the design process further on. Through participating to the research project, the stakeholders learned to co-create. The stakeholders also learned service design and development process approaches, recent theoretical findings, and application of models and tools into practice.

Figure 3. Photos of the analysis session with the internal stakeholder representatives and the extended research team.

Categorization and analysis of the collected data tighter with the research team and internal stakeholder team provided another set of new knowledge and skills. In collaboration with all participants, i.e. the external business partners, case company representatives and the research team, the development activities were tested, redefined, executed and discussed. For all business practioners, the discussions and feedback sessions provided opportunities to elaborate the learnings, findings, and share knowledge. The practioners both internal and external stakeholders benefit from the research team which supported and facilitated studies, activities, and analysis processes. Yet, it provided enough examples to carry out similar tasks themselves in the future.

In the spirit of the action research the participants were actively involved in the testing and filtering of the ideas during the model development. Especially in the final definition phase the common understanding and view of the critical design drivers was collaboratively defined (see the figure 3). Separate analysis groups (working with the same data) found and categorized development initiatives first, which was then elaborated together before moving into integrating the results. Interestingly enough, the original waste management service initiative was not totally neglected, but modified with new development ideas to improve the digitalization aspect of the service.

4 Findings and expected implications

While the service business and developed service are becoming more and more complex, and may form systems of service, a more holistic view of the service is needed. Gummesson (2008) challenges the fragmentation of marketing and business functions and calls for more pragmatic and holistic approaches. Our investigation and experiences from this case study agrees with this notion. A wide array of professionals involved with the service development, their knowledge, experience, and professional skills can be harnessed into the service development and innovation.

Empirical evidence and insights from the case study suggest that a service provider (the case company) can strategically leverage simultaneously various stakeholders in service development process. This can also be an effective way to get insights not only from user or customer but a larger group of stakeholding actors both internally and externally to capture and prioritize ideas. Further, stakeholder understanding is pivotal for identifying design drivers that are used first in idea-generation phase and later applied in development activities. This paper also reveals that double-loop in idea-generation is valid due to continuation of deeper examination of the development ideas. The study suggests co-designed collaborative innovation model as a useful approach(see figure 4) to take into account service development opportunities and exploit the stakeholders' knowledge.

This novel model engages both the internal and the external stakeholders into action i.e. service development. It changes the role of a stakeholder from a passive information provider and co-producer to a truly collaborative partner. Collaborating actors from diversified fields of industry, different levels of hierarchical roles, and specialized positions, may also learn from each other. Co-designing collaborative idea-generation model with stakeholders resulted in two-way; first, the learning of joint activities, i.e. the collaboration part of the development. Second, the generated ideas are rigorously validated and prioritized for further actions.

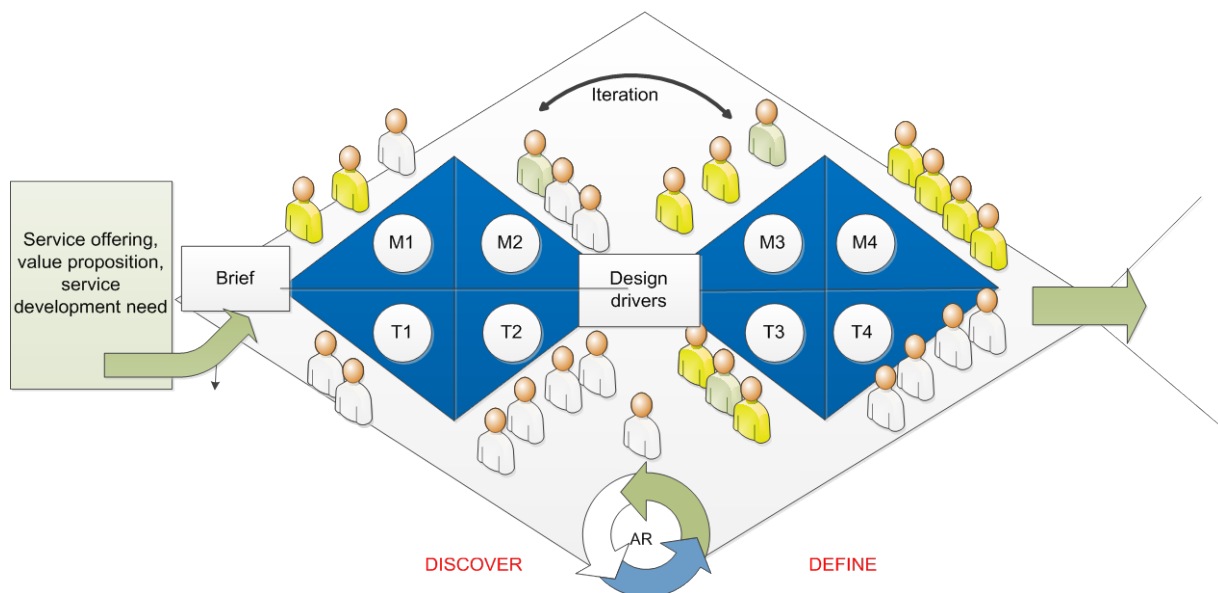

Figure 4. Collaborative idea-generation model.

As this paper focused on the process of revealing how the co-designing of the collaborative idea-generation model was created, the model is not further elaborated. Figure 4 depicts the iteration rounds and action research approach with sets of methods and tools that can be used in various phases.

The concept of balanced centrality states that all stakeholders have the right to satisfaction of needs and wants (Gummesson 2008). This research however suggests that there needs to be a place for negotiation of ideas and development initiatives beyond the individual needs and wants. This requires a platform and a model to conduct the needed activities. Facilitation is crucial for the success of the activities.

In simultaneous collaboration the stakeholders identify the biggest service development potential as suggested in the co-development model. This results in collaborative prioritization of following development activities beneficial to all parties. The empirical data discussed and the key performance indicators (see the following table) show that the model is a valid model to be conducted in service development.

The following table summarizes the main KPIs of the research project.

Table 1. Key performance indicators of the research project

145+	Ideas were generated	workshops
35+	persons involved and participated the study ranging from truck drivers to authorities	Workshops, seminars for the external stakeholders, All events and sessions with the internal stakeholders
13	Organizations participated with the partner firm; customers and authorities, outsourced, internal	Workshops and seminars
1 + 6	Partner firm participants	Continuous participation of the study; meetings, workshops, seminars; planning, analyzing, carrying out, exploring, monitoring, validating, and evaluation.
35+	Co-creation events held to design and develop the project and service	Informal discussions, interviews, in-depth analysis of the documents, meetings, workshops, seminars, actions, participant observations

4.1 Theoretical implications

This paper contributes the academic discussion in various ways. The theoretical implications of this paper validates the theoretical frameworks of balanced centrality and stakeholder-centric approach. Further, these theoretical frameworks are applied uniquely in service development context. Integration of wider variety of stakeholders into service development contributes current discussion and extends the resource integration concept towards deeper collaboration by providing a theoretically based new collaborative idea-generation model.

The empirical results contribute to resource integration discourse and stakeholder engagement. Multi-simultaneous face-to-face approach was unique because typically dyadic relations prevail. The study contributes to service research in providing the empirical evidence and strengthens the theoretical framework.

Moreover, the paper contributes the service development process discussion. In collaboration with variety of stakeholders, the DD-model was modified in several ways: The idea generation requires more time, and many methods and tools to be applied in order to capture the experiences and knowledge of the stakeholders. Iteration rounds are significant and increase the understanding of the service value-in-use.

In order to capture the essence of the balance centrality, true stakeholder integration with extended amount of resources to develop the service, more methods could be used. This would inherently also mean that those methods need to be modified for the simultaneous use of larger amount of people.

4.2 Managerial implications

The paper shows that the stakeholders are motivated and committed to the joint development and capable of working collaboratively when the face-to-face meeting is facilitated.

The stakeholders (individuals) did not know each other. All previous activities between the case company and the stakeholder company was bilateral. Thus, the understanding of the complex service system, the needs, and the requirements for it, were only partial. To build development initiative based on each bilateral interaction may be time and resource consuming. Further, it requires extensive skills in capturing the essence and convergence various issues into holistic view. By inviting, facilitating and integrating multiple stakeholding actors at the same time, in face-to-face event, into specific activities means that there is a lot more issues discussed, shared and negotiated from various perspectives at once. It brings the essence of customer understanding and reduces the time needed for converging the ideas. The converging takes place simultaneously while the stakeholders are provided means to discuss and deliberate ideas found. Through this integration of stakeholding individuals in various firms and expertise areas, and through live collaboration, the service was not only understood more extensively but also further developed.

The managerial implications of this paper suggest that facilitation is a key competence in service development. Capability to understand the context holistically and apply existing methods, techniques and tools in novel ways with stakeholders is pivotal.

5 Discussion

A generic service development model such as the Double Diamond model (Design Council 2005) fits well with B2B context and also with larger organizations. However, the study shows and results suggests that those generic models can be further developed and modified. The model developed during in an externally funded research project in collaboration with the participating stakeholders is a good example of the co-designing activities and application of the customer-centric approach and moving towards stakeholder centrality. Furthermore, the results indicate that integrating resources not only for the sake of the research project but also for the sake of business benefits is pivotal. There is no room for short cuts in getting customer understanding. Moreover, in larger organizations, it is crucial to get customer information, experiences, and professional expertise in full use by integrating those stakeholding resources available simultaneously in collaborative activities.

5.1 Conclusions

Getting the B2B customer understanding is the first priority for L&T. Leveraging knowledge from the stakeholder companies was a strategic choice. It is according to the company level strategy and according to the recent developments in service thinking. As such it was a good fit the research project objectives. Although the service paradigm was already introduced in the partner firm, service development and service design methods and tools were new to the firm. And the role of the research team was to introduce them and innovation methods to the partner firm and their customers.

As a result of the research project, the partner firm had an opportunity to try out various new methods and tools, and thus learned to use them in real-life situation. This allows those methods and tools to remain in the toolbox of the partner firm for later use. For academics, the co-designing of the project itself and also the collaborative idea-generation model with various stakeholders was a positive outcome of the project. The partner firm professionals who participated to the project got direct input and understanding from the participating stakeholders. This information created together and shared among the project participants lead to learning among the participants. New knowledge was co-created, which was a basis for new argumentation that allowed the experts of the partner firm to justify development ideas and the use of the customer-centric strategy.

5.2 Future research suggestions

This paper illustrated a study that resulted with a new collaborative idea-generation model. The proposed model warrants limitations while it was co-designed in one business-to-business setting and context. As this study focused on the idea generation phase of the DD model, it would be beneficiary to extend this approach and test this model to the latter part of the model. Furthermore, the move from customer-centricity to balanced centrality (Gummesson 2008) or stakeholder centrality requires further studies on both theoretical construct creation level as well as in practical empirical level.

As this was a single case study, the research project did not test the model in other contexts. It would be beneficiary to test the model again either in the same context or in other B2B context to validate the preliminary findings of the research. Furthermore, it would be beneficiary to study where the origin of the enthusiasm for development and for the trust for many-to-many stakeholder engagement comes from. This would be a new phase in the beginning of the model created.

Another research opportunity would be simplifying and unifying the terms in different fields and sectors of studies. The co-design seems to be a worthy theme to carry out more research, and maybe further develop the terminology and meaning of the constructs.

Ecopreneurs in Norway: A Statistical Analysis

Helge Lea Tvedt

University of Bergen, Department of Geography

This paper explores the volume of ecopreneurship in Norway. Hitherto, a few attempts to measure the “green sector” are found in Norwegian studies. These studies are often based on turnover statistics and standardized industrial classifications, and fail to incorporate the broader conceptual discussion highlighted in the research literature. The lack of conceptual awareness in the Norwegian studies creates a crude mapping of green enterprises, without going into detail on core business activities, initial business plans, objectives in product and service development and the start-up process. In terms of measuring ecopreneurship and creating a more balanced picture of green business activities in Norway, these considerations should be included. To address this issue, I use firm-level data from 437 companies to illustrate the challenges that arise in the process of operationalizing green business activities and the possibilities and limitations related to different approaches.

1 Introduction

“I believe very strongly that corporations could and should be a major force for resolving social and environmental concerns in the twenty-first century”

William Clay Ford, Jr (Executive Chairman, Ford Motor Company, 1998).

In recent years the discussions about corporate greening and environmentally sound business practices have influenced the research agenda. In relation to this debate, the *ecopreneur* has occasionally been portrayed in the academic literature (Anderson, 1998: Pastakia, 1998: Keogh & Polonsky, 1998: Isaak, 2002: Schaper, 2002: Schaltegger & Wagner, 2011). Similarly to entrepreneurs, ecopreneurs is considered agents of change (Anderson, 1998). In contrast to entrepreneurs, ecopreneurs have the ability to drive the economy towards sustainability by transcending the usual tension between business and the environment (Beveridge & Guy, 2005). However, the conception of the ecopreneur is ambiguous, leading to a multitude of definitions and understandings as well as difficulties in terms of operationalization. Sometimes, ecopreneurship is used interchangeable with green enterprises and environmental management (Schaltegger & Wagner, 2011). In other cases, ecopreneurship is simply understood as start-ups in business sectors that are entirely environmental-relevant, such as sewage and refuse disposal (OECD, 2011). Due to this ambiguity, it is difficult to establish ecopreneurship as an independent and feasible research field that can contribute with new knowledge in policy-making processes and regional development.

Based on firm-level data of 437 enterprises, this paper offers a critical discussion of the possibilities, limitations and challenges related to the different theoretical and methodological approaches involved in measuring green business activities, in particular ecopreneurship. First, the paper aims at increasing the awareness in relation to the system of concepts, as well as the approaches used to measure green business activities. Secondly, the paper calls for a more comprehensive framework that makes it possible to discriminate between ecopreneurship and other green business activities. In this relation it's important to emphasize the idiosyncrasy of ecopreneurship in order to guide researchers to conduct informative studies that can contribute in policy-making processes. Finally, theoretical and methodological discussions are combined with firm-level data from 437 enterprises in an attempt to measure the volume of ecopreneurship in the Norwegian economy.

The paper is structured as follows: Section 2 presents understandings and conceptual discussion found in the literature. In section 3, the research design and methodology is explained, before the data is presented and discussed in section 4. Section 5 focuses on the idiosyncrasy of ecopreneurship in relation to the theoretical and empirical discussions from section 2 and 4. In the final section, some concluding remarks are drawn.

2 Ecopreneurship – Sector, Firm or Technology Dependent?

Hitherto, the research on ecopreneurship has primarily focused on explaining the phenomena and creating typologies for defining ecopreneurs (Anderson, 1998: Schaper, 2002: Cohen & Winn, 2007: Schaltegger & Wagner, 2011). A literature review reveals a number of understandings and different ways to conceptualize the phenomena. Sometimes the term is used to describe the person or team who launch a green business (Cohen & Winn, 2007). In other cases ecopreneurs are used on innovative business leaders who are striving to implement technological and non-technological innovations as a strategy to become greener (Schaltegger & Wagner, 2011). Despite the conceptual ambiguities, most understandings share a common feature; *ecopreneurs are actors whom somehow combine economic and environmental performance*. However, the determinants of being an ecopreneur are not clear. Some authors focus on the environmental orientation of firms, other emphasizes the internal motivation of individuals, and yet others highlight the business sectors and technologies involved (Cohen & Winn, 2007: Schaltegger & Wagner, 2011: OECD, 2011). The remainder

of this chapter aims to clarify the concept of ecopreneurship and the different approaches used to identify and measure ecopreneurship and related concepts.

2.1 The cross-sectorial nature of green businesses

Initially, a brief discussion about business sector is necessary in order to give an account of the current academic debate. Green businesses can be found in all industries and for that reason commonly referred to as cross-sectorial (OECD, 2011). Accordingly, it is hard to identify green businesses using standardized classification systems such as NACE and ISIC, since these systems are based on value-chain logics (Menon Business Economics, 2010). The exception is business sectors that directly profit on producing goods and services that are grounded on environmental outcomes, for instance NACE (E38) *Waste collection, treatment and disposal activities* and NACE (G47.7.9) *Retail sale of second-hand goods in stores*. These sectors are usually considered environmental “core sectors” (Rogalandsforskning, 1997: OECD, 2011). To elucidate the difference between “core sectors” and “non-core sectors”, OECD (2011) distinguishes between *output* and *process* approach. According to OECD (2011) ecopreneurship can be defined in terms of the sectors firms are active in. This is called the *output approach* and corresponds with the “core sectors” in that they are restricted to parts of the economy producing specific types of output. On the other hand, *the process approach* is defined in terms of the technology used for production in any sector of the economy, referring to the act of making a business “greener” as opposed to entering the “green sector”. OECD (2011:25) interprets ecopreneurship as “entrepreneurship” in “green” sectors, exclusively focusing on the *output approach*. It is however problematic to include the *output approach* in surveys on ecopreneurship since the environmental benefits are intrinsic to the business. Put simply, the term ecopreneurship lose its significance if every business operating in environmental core sectors gain status as ecopreneurial. Ecopreneurship should include a particularity that makes it possible to distinguish it from other types of green business activities. Accordingly, focusing on the *process approach* are more suitable since the environmental benefits are extrinsic to the business and likely to differ from conventional start-ups in terms of the strategies, barriers and challenges involved. This is emphasized by Yang et al. (2012) who note that eco-innovation dynamics are different from conventional innovation processes, particularly in terms of how stakeholder groups are interacting and how environmental concerns are integrated in the process.

2.2 Environmental Technology and Turnover

Focusing on environmental goods and services and the subsequent turnover is also a common strategy used to identify green business activities. Green businesses and ecopreneurs are generally connected to environmental goods and services²⁵⁴ in one way or another, either through development or implementation. Most of the definitions referring to environmental technologies emphasize that it includes products and services that *reduce* the environmental load, i.e. is *less harmful* than current technologies (Eurostat, 2009: OECD, 2011). These definitions do however have its flaws once the temporal and geographical dimension is included. Products and services are continuously undergoing incremental and occasionally radical improvements as time goes by. Some environmental goods and services will eventually become conventional technologies, other will hardly reach the market, whereas others will sooner or later be outdated. Consequently, in terms of statistics, a technology, or a green enterprise determined on the basis of a technology can only maintain their status for a short period of time unless the data are frequently updated. In relation to this discussion, Menon Business Economics²⁵⁵ (2010) argue in their report that it’s possible to claim that virtually every company is “green” due to incremental improvements that gradually transforms the business community towards a more sustainable path.

The geographical context is also necessary to consider in this connection, as enterprises in industrialized countries are likely to have a different frame of reference than their counterparts in developing countries. Due to the relative nature of environmental technologies, it is possible that manufactures in South American countries use environmental technologies in production, while the same technology is conventional or even obsolete in the Nordic countries.

Turnover figures are often used as a quantifiable measure that makes it possible to identify enterprises based on environmental goods and services (Eurostat, 2009). Enterprises that report turnover from environmental goods and services are considered green businesses. In a report by Menon Business Economics turnover statistics is used in more satisfactory way by giving companies an “environmental weight” based on the share of turnover that is related to environmental technologies (Menon Business Economics, 2010). As a result, they are able to distinguish between enterprises with 20 per cent turnover from environmental goods and services and those whose total turnover come from environmental goods and services. A weakness by using this parameter to determine green businesses, is that turnover figures fail to include organizational changes and process innovations. Neither do the figures contain information about the content, qualities and impact of the environmental goods and services. Consequently, turnover figures per se are probably more suitable in terms of measuring fluctuations in the level of green activities in the economy, rather than as a determinant for identifying ecopreneurs or green enterprises.

²⁵⁴ Similar terms found in the literature are 1) cleantech, 2) environmental technology, 3) eco-innovations, and 4) green technologies and services.

²⁵⁵ Menon Business Economics is a consultancy firm that provides businesses, organizations, and government with industry analysis.

2.3 Environmental Performance – Trustee Duty or Core to the Business?

In the ecopreneurship literature, the environmental orientation of firms is given considerable attention. One of the most important contributions in this connection is the positioning matrix developed by Schaltegger (2002) and later extended by Schaltegger & Wagner (2011). This framework considers environmental orientation to be the main determinant for ecopreneurship. According to the positioning matrix, a company's environmental orientation is divided into low, medium and high priority. Companies who regards environmental protection as a *trustee duty* falls into a low priority category, while medium priority is given to companies who sees environmental goals as *supplementary to conventional business*. A high priority category is applied if companies integrate environmental issues in their *core business activities* (Schaltegger & Wagner, 2011). High priority is a prerequisite for ecopreneurship, and accordingly useful to distinguish ecopreneurship from other types of green business activities such as environmental management. However, as Nawrocka et al. (2009) emphasizes, having some kind of environmental strategy or eco-friendly actions is the rule rather than the exception in the prevailing business community. Accordingly, environmental orientation may be difficult to operationalize since it can materialize in many ways, including application of environmental goods and services, adoption of eco-certifications and other corporate environmental activities. The fact that environmental orientation includes a broad range of environmental activities is however advantageous in terms of measuring companies that depends their environmental performance on organizational changes, in contrast to turnover figures which only include environmental performance based on sales (section 0 & 0). The possibilities and limitations of the different measures are further discussed in the empirical section.

2.4 Business Plan and Intentions

Several authors emphasize the initial business plan and incorporate individual's ethical, social and environmental motivations in their definitions of ecopreneurs (Anderson, 1998; Isaak, 2002; Dean & McMullen, 2007). Focusing on the initial business plan is considered to capture the entrepreneurial dimension of green enterprises, and is reflected in the distinction between "*green business*" and "*green-green business*" (Isaak, 2002). According to Isaak (2002) a "*green business*" refers to companies moving towards environmental responsibility, in contrast to "*green-green businesses*" that are companies whose products and processes are designed to be green from the start. A number of researchers argue that the ideal ecopreneur launches a "*green-green business*", and are more likely to be driven by environmental and social concerns than "*green businesses*" that primarily are driven by profit (Pastakia, 1998; Isaak, 2002; Cohen et al., 2008). Similar considerations is found in Taylor & Walleys typology (2004), as the authors base the framework on internal motivations ranging from pure economic orientation in on end to sustainability orientation in the other. The focus on intentions is however criticised because the intentions of the producers is not relevant if the technical nature of their activities are inconclusive (OECD, 2011). Consequently, combining parameters may result in more accurate data in surveys on ecopreneurship and green business activities.

3 Research Methodology

The data presented in this paper were obtained during May 2014 by means of an online survey distributed to a wide range of companies located in Norway. The overall objective of the survey is to measure the volume of ecopreneurial activities in Norway using a variety measures found in the literature.

3.1 Survey design and distribution

The survey was designed to incorporate the conceptual discussion found in the research literature (section 0). Consequently, the survey takes account of several criteria that can be used to identify green businesses. This includes among other things questions concerning turnover, business plan, company profile and intentions (see Appendix 1, forthcoming). Using multiple questions to measure the same concept was a preferable strategy for two reasons. Firstly, (1) to illustrate the complexity involved in measuring ecopreneurship and green business activities, and more importantly (2) to check the consistency in the responses by comparing answers intended to measure the same concept. The latter cause is particularly useful in terms of identify and distinguish ecopreneurship from other green business activities (section 0).

The survey combines *open-ended* questions and *fixed-response* questions. The *open-ended* questions were used to obtain general information about the company, whereas the *fixed-response* questions form the basis of the analysis. The *fixed-response* questions were easy to analyse and interpret due to extensive use of Likert scales presenting a range of possible responses anchored by two opposing positions. The *fixed-response* questions were also complemented by a comment field which allowed the respondents to go into details if necessary. The survey was electronically administered through the program *SurveyXact*. Before the survey was distributed, the questionnaire was pretested on four CEOs representing companies within different business sectors. A few adjustments were made based on the pilot studies before the survey were distributed to a sample of 1154 companies representing 62% of the total population of 1860 companies. More details regarding population and sampling are given in the next section.

3.2 Population and Sampling

The total population include 1860 companies selected on the basis of business sector, start-up year, organisational form and size (Table 1). The selection process was administered through *Proff Forvalt*, a service that gives access to *Brønnøysund Register Centre*, the national register of business enterprises.

Table 1. Enterprises in the survey are based on the following criteria: business sector, start-up year, organizational form and size.

Selection criteria	1	2	3	4
Criterion	Industries according to NACE Codes (table 2)	Start-up year after 1.1.2004	Organisational form as private limited company	Number of employees between 5-99
Population	84232	13866	12415	1860

First, the companies were selected according to business sector. Enterprises that are registered in Norway will automatically be given a NACE-code when they report and register the business in the national Register of Business Enterprises. In this study, enterprises that are registered according to the NACE-codes in Table 2 are included in the population, resulting in a preliminary population of 84232 enterprises (Table 1).

Table 2. NACE-Codes that are included in the population.

Section	Subdivision	Description
B – Mining and Quarrying	6	Extraction of crude petroleum (6.1) and natural gas (6.2).
C – Manufacturing	10–11, 13–17, and 19–32.	All manufacture production and processing activities in section C, except manufacture of tobacco products (12), printing and reproduction of recorded media (18), and repair and installation of machinery and equipment (33).
M – Professional, scientific and technical activities	71, 72 and 74	Architectural and engineering activities; technical testing and analysis (71), scientific research and development (72) and other professional, scientific and technical activities (74).

The sectors included in the population represent a variety of manufacture and processing activities, professional services, engineering activities and research and development (R&D). Enterprises that are registered in “green sectors” such as *Waste collection, treatment and disposal activities (38)* and *Remediation activities and other waste management services (39)* are not included in the population. This is due to the challenges that arise if one includes the *output approach* in the mappings, instead of focusing on the *process approach* of transforming business sectors towards sustainability (section 0 & 0).

The second selection criterion is related to the start-up year. Enterprises established later than 1th of January 2004 were included in the population. Since some of the questions focus on the initial stages, a ten-year perspective was chosen to increase the validity and reliability. A longer temporal dimension will increase the probability of getting erroneous data due to changing ownership structures, unreliable sources, and difficulties in recollecting the past. Although this criterion was included in the selection process, nearly a fourth of the responding companies were originally established before the set date, but had for various reasons been assigned with a new business registration number after the set date. Accordingly, the original start-up date of these enterprises is not taken into consideration in the national register of business enterprises. Nevertheless, including this criterion in the selection process reduced the population to 13866 companies (see Table 1).

In the third case, a delimitation regarding organisational form was included in the selection process. Only private limited companies are included in the survey. Organisational forms such as one-person businesses, public corporations and limited partnerships were excluded from the population. These organisational forms were excluded for various reasons related to stock exchange listing, credibility and recognition in the market. However, the majority of the enterprises in the selected business sectors (Table 2) were private limited companies, resulting in a small reduction from 13866 to 12415 enterprises (Table 1).

Finally, number of employees was used as a selection criterion to limit the size of the enterprises. Enterprises that employ 5–99 people were included, corresponding to classifications in national statistics. Avoiding self-employed and microbusinesses at one end of the scale, and large enterprises at the other is necessary as the enterprises identified through the survey will be used in prospective qualitative case-studies. A large share of the private limited companies has less than 5 employees, reducing the preliminary population of 12415 enterprises to a final population of 1860 enterprises (Table 1).

The following stage was to obtain contact information to all the companies in the population. Contact information was obtained manually using the enterprises web pages. Of the total population of 1860 companies (N population =

1860), it was possible to obtain adequate contact information to 1154 companies (n sample = 1154), representing 62% of the total population. Due to lack or maintenance of web pages and terminations, it was not possible to obtain contact information to the remaining 38 per cent of the population. However, a subset representing 62 per cent of the population is a solid foundation and should provide a good coverage of the population. In addition, the process of manually obtaining contact information gave valuable knowledge and information about the population and the business activities involved.

The survey was distributed via e-mail to CEOs and General Managers. The survey was open for three weeks in the period 5th of May 2014 – 27th May. During this period, three reminder e-mails were sent to those who had not responded. The survey was distributed to a sample of 1153 companies, of whom 437 companies responded, equalling a response rate of 38%.

4 “Green Business” or “Greening” the Business?

A total of 437 questionnaires are analysed. The responding companies represent a variety of the Norwegian industry including manufacture and processing activities, professional services, engineering activities and research and development (R&D) (section 0). However, the population does not include enterprises in environmental core sectors that are restricted to certain parts of the economy (section 0). This is due to the difficulties of including enterprises and entrepreneurs who simply enter a “green business” as opposed to those who are making the business “greener”. Entrepreneurs who struggle to make a business “greener” are likely to face other challenges and barriers than entrepreneurs who enter “green” sectors. Consequently, in order to capture the distinctive qualities of ecopreneurship, excluding the *output approach* and consider the *process approach* is a reasonable point of departure. Finally, the national register of business enterprises is not flawless and accordingly there’s a possibility that some of the enterprises in the population is more related to the *output approach*. Figure 1 shows that the 437 enterprises are divided by 13 different business sectors. The figures are based on the enterprises report on principal activity in the survey, and not the NACE-codes found in the business register.

Figure 1. Responding enterprises according to business sector (N=437).

Enterprises doing various architectural and engineering activities (29%) are highly represented. In addition, manufacture of machinery and equipment (10%), and metal products (9%) are fairly common. Many enterprises also classify themselves in the following categories; other manufacturing n.e.c. (16%) and other professional, scientific and

technical activities n.e.c. (10%). The remaining 26 per cent are scattered across various categories, ranging from food production to medical equipment, indicating great variety in the population.

4.1 Green is the new mainstream

Initially, it's interesting to note that the responding companies represent a variety of environmental orientations. In some cases, enterprises have developed advanced environmental technologies with a clear purpose embedded in a green business model. In other cases, the environmental orientation is reflected in organisational changes such as energy efficiency, recycling and other environmental management actions. Consequently, it is problematic to operationalize terms like "ecopreneurship" and "green businesses" due to the complexity of environmental strategies involved. This is reflected in the data, as 58 per cent of the enterprises *agree* (32%) or *partly agree* (26%) that they make use of technologies and services that contribute to mitigate environmental problems (Table 3).

Table 3. Enterprises response on following state "The Company contribute to mitigate environmental problems by use of technologies and services that are less harmful than relevant alternatives (compared with current/competing technologies and services or absent alternatives, N=437)".

Response	Number of enterprises	Percent of enterprises
Agree	141	32%
Partly agree	114	26%
Neutral	133	30%
Partly disagree	22	5%
Disagree	37	8%

The high number of responding companies indicates that focusing on products, processes and services is a vulnerable strategy in terms of identifying ecopreneurship and green enterprises. As Nawrocka et al. (2009) noted its common among enterprises to address environmental issues to a greater or lesser degree (section 0). In this sense, the high percentage can best be interpreted as part of a broader environmental strategy reflected in application of environmentally sound goods and services. Additionally, as emphasized in Menon Business Economics report, the bulk of incremental improvements in products and services often include minor environmental benefits that gradually drive the economy towards sustainability. On this basis it is likely that enterprises are prone to include such improvements when they report use of technologies and services that contribute to mitigate environmental problems.

Consequently, defining enterprises based on means of production as well as the products and services they offer is a demanding task. In cases where life cycle assessments (LCA) and benchmarking studies are available it is more likely to identify ecopreneurs and green enterprises based on this parameter.

4.2 Is turnover statistics a viable parameter?

In terms of turnover, only 17 enterprises (4%) report that environmental goods and services accounts for 100 per cent of the turnover (Figure 2).

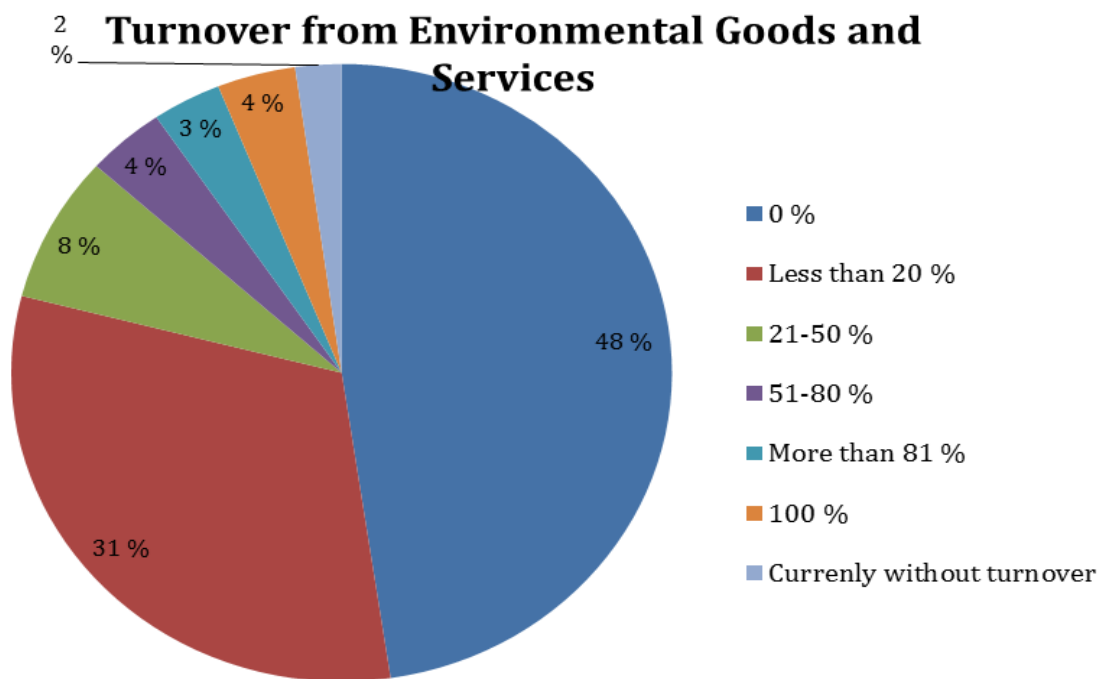

Figure 2. Turnover from environmental goods and services. The numbers in the pie chart shows the percentage of enterprises that report on turnover from environmental goods and services (N=437).

However, as Figure 2 shows, it's common that environmental goods and services accounts for a portion of the revenues, rather than the total turnover. Approximately 50 per cent of the 437 companies report turnover from environmental goods and services. This may typically be companies supplying equipment for wind farms or services related to green building projects. Many respondents emphasize that they are present in the "green economy", although it doesn't make up the principal activity of the enterprise.

"We're not a green business, but we do a lot of advisory services related to environmental planning in construction"

(Enterprise in Architectural and Engineering Activities)

"The company participate in a lot of product development, and some of the products are environmental technology"

(Enterprise in Scientific Research and Development)

Menon Business Economics include this in their mapping by giving companies an "environmental weight" based on how much of their activity that is related to environmental technology (section 0). This strategy may be useful to measure environmental activities in the economy, but it's not a suitable way to depict ecopreneurship and green enterprises, as their activities primarily are driven by clients or the project they are involved in. Put simply, the demand created by a hydro power expansion will increase the level of environmental activity in the economy, but it will not turn the contractors into "ecopreneurs" or "green enterprises". A considerable portion of the enterprises fall into this category, as 31% reports that environmental technology accounts for less than 20% of the turnover. On the other hand, enterprises with more than 50 per cent turnover from environmental goods and services indicate that the principal activity is related to environmental issues. On this basis, it is possible to argue that these enterprises can be coined "green businesses". Drawing upon this logic, figure 2 shows that 11 per cent of the enterprises report more than 51% turnover from environmental goods and services, equalling 49 of the enterprises. However, turnover statistics is a result of products and services sold to customers and do not capture internal activities such as organisational changes, process innovations and means of production. Consequently, turnover statistics are fallacious in certain cases as noted by some of the respondents.

"The company are highly focused on the environment. We exploit the whole fish, including all the by-products. In addition we have undergone several environmental measures related to energy consumption, preservation and packaging. Zero percent of the turnover comes from environmental goods and services, but the processes and organization is highly eco-friendly"

(Enterprise in Manufacture of Food Products and Beverages)

Considering this, turnover figures only include enterprises that directly profit from sales of environmental goods and services. Enterprises that increase their environmental performance by internal readjustments are likely to get ignored if turnover figures are the only parameter in the mappings.

4.3 The core of the business

In the ecopreneurship literature, environmental orientation is often given considerable attention in terms of defining enterprises as “green” or “ecopreneurial”(section 0). Enterprises that consider environmental performance as core to the business have a high environmental orientation, as opposed to low orientation in which environmental protection is regarded as a trustee duty (section 0). Table 4 shows how companies responded on environmental orientation.

Table 4. Enterprises response to following statement: “Environmental performance is core to our business”, (N=437).

Response	Number of enterprises	Percent of enterprises
Agree	40	9%
Partly agree	51	11%
Neutral	122	27%
Partly disagree	45	10%
Disagree	189	42%

The survey data shows that 9% of the enterprises *agree* and 11% *partly agree* that environmental performance is core to their business. These numbers illustrate that it’s easier for companies to identify themselves as “green” in terms of *product and service applications* and *turnover* than *environmental orientation*. In contrast to the previous parameters, environmental orientation is difficult to quantify, but still a good way to conceptualize the goals and identity of enterprises. For instance, a company supplying foundations for offshore wind parks will probably report a certain amount of turnover from environmental goods and services. However, the company are not likely to report environmental performance as core to the business, and may even regard environment as mere trustee duty. In terms of defining different green business activities, environmental orientation should be considered.

4.4 Initial Business Plan and Entrepreneurial Intentions

Integrating the entrepreneurial dimension in the mappings requires initial business plan and entrepreneurial intentions to be included. The initial business plan is used to determine whether the nascent entrepreneurs had a green business strategy ever since the beginning. The entrepreneurial intentions are related to the initial business plan, but are more focused on the entrepreneurs’ intentions in product and service development. Consequently, these criteria are used to distinguish between “*green business*” and “*green-green business*” as emphasized by Isaak (2002). Companies whose products, processes and services are designed to be green from the start are labelled “*green-green business*”, as opposed to “*green-businesses*” which gradually are moving towards environmental responsibility (section 0). Table 5 shows the enterprises response on the statement related to initial business plan.

Table 5. Enterprises response to following statement: “Environmental performance was an important part of the initial business plan” (N=437).

Response	Number of enterprises	Percent of enterprises
Agree	55	12%
Partly agree	63	14%
Neutral	116	26%
Partly disagree	42	9%
Disagree	169	38%

The numbers in table 5 are fairly similar to the figures in table 4, indicating a high degree of correspondence between the enterprises initial business plan and their core activity. Additionally, 18% report that the company/entrepreneurs had a definite goal of developing and commercializing environmental goods and services, while 19% report that their goods or services had unintended environmental benefits.

Finally, the distinction between “*green business*” and “*green-green business*” is important as the strategies, barriers and drivers involved are likely to differ (section 0). Including these considerations is therefore necessary to identify the particularity and distinctiveness of ecopreneurship.

5 The Volume of Ecopreneurship

The discussions in the preceding sections shows that green business activities is fairly common in one way or the other, and illustrate the need to differentiate between types of green business activities. Hitherto, the literature often fails to discriminate between ecopreneurship, green enterprises, environmental sectors and similar concepts. Accordingly, this

section employs the survey data and discussions in the previous sections in an attempt to identify the volume of ecopreneurship in the myriad of concepts related to the green economy. The discussions in section 0 & 0 highlights the need to consider multiple causations in determining ecopreneurship, thus the operationalization of the concept is in this connection based on a cross-checking of the different determinants considered in the paper. Focusing on single determinants face the risk of missing out important traits related to start-up, environmental orientation or internal organisation of enterprises. Consequently, it is important to isolate those enterprises that can be identified as ecopreneurial according to all the parameters discussed in section 0. Additionally, cross-checking also ensure consistency in the responses, increasing the validity as all the questions intend to measure ecopreneurship (McLafferty, 2003).

In terms of turnover, companies that report more than 51% turnover from environmental goods and services, as well as enterprises that currently are commercializing are included (section 0). Secondly, companies who report (5) *agree* or (4) *partly agree* on application of environmental goods and services are included (section 0). The third and fourth cross-checks is environmental orientation and initial business plan and is based on the same logic and terms as application of environmental goods and services (section 0 & 0). However, it is possible to discriminate between enterprises that fully agree and those who partly agree depending on the rigidity in mapping, as shown in Table 6. Finally, intentions in product development is included, however the most rigid terms only include entrepreneurs that had a definite goal of developing and commercializing environmental, in contrast to the less rigid terms that also include unintended development (section 0).

Table 6. Number of enterprises that meet all the requirements in the cross-checking's. The first row represents a less rigid requirement than the second row.

Turnover Statistics	Application of Environmental Goods and Services	Environmental Orientation	Initial Business Plan	Intentions in Technology and Service Development	Number of Enterprises
< 51% or commercializing	4 or 5	4 or 5	4 or 5	Planned, unintended or other	16
< 51% or commercializing	5	5	5	Planned	20

Table 6 shows the number of enterprises that meet all the requirements in the cross-checking. In total, 36 out of 437 enterprises are identified as ecopreneurial, equalling 8,2% of the respondents. Additionally, it is possible to subdivide the percent of ecopreneurs based on rigidity in the mapping. The most rigid mapping identifies 20 ecopreneurs, equalling 4,6 per cent. Including the less rigid mapping increase the number by additional 16 enterprises, resulting in the total number of 36 ecopreneurs.

6 Conclusion

This paper is based on a critical reflection on the system of concepts found in the ecopreneurship research and related literature. Based on a theoretical and methodological discussion of the approaches involved in measuring ecopreneurship, this paper presents empirical data to illustrate the possibilities, limitations and challenges related to the different approaches. By suggesting a more rigid approach, the paper further argues that ecopreneurship should be conceptualized as something distinct from other green business activities, or simply entrepreneurial processes within environmental sectors. Moving towards a more stringent cross-checking of variables, instead of focusing on single determinants is a possible solution to identify ecopreneurship. It is further suggested that businesses operating in "green sectors" should be excluded in favour of enterprises that are making conventional businesses "green". This approach is likely to influence the entrepreneurial process in terms of stakeholder interactions, knowledge production, identification of market opportunities and other qualitative differences.

A better understanding of the concept is necessary in order to establish ecopreneurship as a feasible research field in the future, and will eventually lead to policy implications as the field matures.

Finally, the suggested approach has certain limitations and should be considered as an initial contribution shedding light on some focal points related to measuring ecopreneurship, rather than a complete framework.

Tangibilizing the Service Concept of the Nordic Network of Applied Imaging and Analysis

Taina Vuorela¹, Helena Ahola², Juha Väänänen³, Sami Saukko⁴
^{1,2}Oulu University of Applied Sciences, ^{3,4}University of Oulu

The purpose of the paper is to gain understanding of creating and tangibilizing a networked business model of five public research laboratories. They are providing materials' imaging and analysis services as a Network to assist growth-oriented high-tech SMEs in their product development. An EU-funded project is used as a case to demonstrate the challenges and opportunities of using service design thinking tools and principles in a b2b context. These tools proved useful in tangibilizing the networked business model for the service providers. They were also useful in creating the content and structure for the Network website, where appropriate strategies tangibilize the services for customers

1 Introduction

Companies as well as research institutes and universities are becoming increasingly aware of the need and even the necessity to join forces and work collaboratively, not only with their customers but also their competitors; hence, the current UNELMA Project case and the present paper. Our purpose is to address the process of creating and tangibilizing a networked business model and a service concept by using visual tools of service design in b2b (business-to-business) service business development contexts. We will thus test how service design tools can be applied for concretizing, making sense and communicating business models of networked services. This interest arises from a need to facilitate the building of local networks. The objective of this study is to gain more theoretical understanding of networked business models in university and research institute contexts in Finland and Sweden. We are also interested in testing tangibilization strategies in this context. Kindström et al. (2012) discuss the difficulties of visualizing service marketing and the importance of this visualization in a marketing situation where the balance of firms' offerings is changing towards increased service content.

In using service design tools in this high-tech b2b context, a strong emphasis will be on value, as the theories of value creation and service experience are at the core of service business development and co-creation (Vargo; Lusch, 2004; Grönroos, 2011). The main research questions of the present paper are: 1. How to design and tangibilize (i.e. concretize) a networked business model on the basis of a joint service concept in order to provide collaboratively high-tech R&D services to b2b customers; 2. What are the main challenges and opportunities in using service design (SD) thinking and methods in such a process? The research sub-questions that will be answered by the case study are the following:

- What are the opportunities and challenges in creating a joint service concept from service providers' and customers' perspectives?
- What are the most critical phases/touchpoints in the customers' service process?
- How do SD tools help in creating a networked business model?
- How can a joint value proposition and productized service be created using SD tools?
- How can a joint service be tangibilized and visualized online?
- What kind of tangibilization strategies are the most relevant in the customer service process of the current university-based laboratories?

The present paper bases on an Interreg-funded project (2012 - 2014) as a case study that will be used to demonstrate what types of visualization strategies, narratives and metaphors are needed to tangibilize a networked service and thus complete the life cycle of a joint service creation process. This allows us to gain understanding of the critical success factors of such a process, our current focus being on its creation phase. The main aim of the UNELMA Project is to promote economic growth in the Bothnian Arc area by rendering locally available R&D services more easily accessible to SMEs' product development. The concrete aim is to develop a jointly operated materials' imaging and analysis service concept based on the micro- and nano-technological research equipment of the universities and research institutes on the coast of the Gulf of Bothnia between Finland and Sweden. The equipment is needed in the development of new materials and products (see Vuorela et al. 2013 for more information). More information about the context and data will be provided in chapter 3 below.

2 Theoretical background

As is discussed by Vuorela et al. (2013), using visual service design thinking tools in the exploration phase of a b2b service design process not only concretized complex service business-related issues, but also helped to build trust among the partners aiming to create jointly a networked service concept. In our present paper, the focus is on, not only

creating, but also tangibilizing, i.e. concretizing (see Berry; Clark, 1986), a networked business model for both the service providers and customers. We will start by reviewing of relevant theoretical issues of b2b service context and will then move on to discuss networked business models and their tangibilization.

2.1 The context of b2b (business-to-business) services

Scholars (e.g. Gummesson and Polese (2009) point out that, although the b2b context has its special features, it is not a separate 'island'. They see b2b, b2c, c2b, c2c as interdependent: the actors form networks that apply to different marketing and consumption situations (ibid). The outcome of such thinking is that services are seen through both suppliers' value propositions and customers' value actualization. This is supported by Vuorela et al. (2013), who successfully applied service design in b2b high tech contexts; service design has traditionally been used in b2b contexts more often. Yet, it is undeniable that b2b contexts are challenging; e.g. KIBS (knowledge-intensive business services) contexts have been found to require that service innovation processes are linked with the process of service delivery (Toivonen et al., 2007). When identifying the value propositions of business customers, particularly for high-tech, innovative products, scholars have found that decision-influencers value different elements during different stages of the purchasing process (Lindgreen et al., 2009). Attention should also be focused on different service- and supplier-related elements of value (ibid).

Generally, the service function should be seen as a management concept which is viewed holistically (Kowalkowski, 2011a). Within a company, the service organization may be a key entity; yet other organizational entities such as accounting and invoicing also have a role to play in the service business (ibid). When managing different customer segments with different value propositions, it is important to communicate the value propositions of a company effectively and strategically (Kowalkowski, 2011b).

2.2 Building networked business models

Generic elements of business models have been identified in the field of technology-based services by scholars (Palo; Tähtinen, 2011) who have built a framework of the elements of networked business models with a set of generic core elements, with the intention of assisting the building of such business models in practice. They emphasize the importance of three aspects of such business models, namely, the network of actors, the dynamic nature of the business model and the modularity of services (ibid). Business models have been found to be useful in multiple ways; they act as an analytical device for the actors to use in their service business activities, particularly in the case of emerging technology-based services (Palo, 2014). They can also be used as narratives and structures in order to stabilize and develop business activities (ibid).

When building networked business models, it is important to investigate the different stakeholders' expectations and the perceived value for the actors during new service development processes (Makkonen; Komulainen, 2014). Emerging needs and technologies and their matching also need to be identified; this matching process builds on the interaction between networked actors. Lucrative value propositions are more likely to arise through networked actors' individual motives to leverage value-in-context, rather than approaching future stakeholders with product- or technology-based arguments (ibid).

When outlining practical activities that can help companies reconcile different actors' perspectives, scholars have found that a fit is required regarding core content, operations and processes, customer experience and value of solutions (Hakanen; Jaakkola, 2012). The degree of competition of the suppliers and the clarity of their role division and their rapport, in general, have a bearing on the successfulness of co-creation of networked production of services (ibid). The customers' preferences for participation in the service development processes are also important (ibid).

2.3 Tangibilizing business models and services

Value is an important part of service business development, and hence requires special attention when attempting to render new service concepts more tangible for networked service providers and customer companies. Most suppliers have traditionally focused on *product-based value*, and are thus good at visualizing such value parameters as product performance, quality and price, which are typically order winners (Kindström et al., 2012) and are where many firms still tend to put heavy emphases.

Service-based value is more difficult to evaluate and quantify than product-based value. Such values are intangible and are thus harder to visualize (Grönroos, 1997). These values are often gained by customers for free; their typical parameters include operation costs, customization and performance consistency (ibid). Services can also be classified on the basis of their *relationship-based value*, that is how the supplier and customer maintain their relationship over time (ibid); ideally this collaboration enhances competitiveness (Wilson; Jantrania, 1994). Relationship-based value is difficult to tangibilize. Trust, longterm commitment and pro-activity are typical value parameters of relationship-based value (Wilson; Jantrania, 1994). Communicating the value of product offerings has been relatively easy with a fact-based documentation strategy. With companies extending their service provision, what to communicate, and how to go about it, is becoming more challenging (Kindström; Kowalkowski, 2009). Using a service offering life cycle with the following stages can be helpful: market sensing, development, sales, delivery (ibid).

Regarding further strategies suppliers can use in order to create and communicate value to customers in b2b markets, Anderson et al. (2007) propose three different strategies:

- 1/ listing all potential benefits suppliers believe their offering can deliver to customers;
- 2/ recognizing favorable points-of-difference, with suppliers acknowledging customers' alternatives and listing differentiating points between their own and competitors' offerings;
- 3/ communicating the benefits customers really appreciate and need, i.e. a resonating focus, which is difficult to manage – as it requires the most customer and competitor knowledge – but has the greatest potential (ibid). In the context of service offerings, it is important that firms align their communication with their customers' actual needs, rather than simply list all potential benefits (ibid). Orienting towards a more resonating focus in customer communication is the best option (Wilson; Jantrania, 1994).

Besides recognizing different viewpoints for value management and communication as presented above, scholars propose four (4) tangibilization strategies for concretizing and visualizing the value of services to different actors in different situations (Berry; Clark, 1986; Mittal, 1999; Hill et al., 2004; Kindström et al., 2012): 1. *envisioning*: using cues to make customers experience the service mentally, 2. *association*: linking an object, place or person with a service, 3. *documentation*: providing information about consumption, system or performance of a service; 4. *representation*: focusing on attributes of the service. Besides the service offering life cycle, the focus of visualization strategy can also be on the performance episode of the service or the service consumption episode (ibid). Kindström et al. (2012) combine the research on visualization strategies and the offering life cycle in order to show how companies can use visualization strategies; this is deemed necessary as suppliers need to find new and persuasive ways to develop unique selling points.

In an attempt to address the challenge of rendering value more tangible, attempts have been made to facilitate the meaningful participation of people without specialist business training in discussions about innovative service offering and its business viability (Mitchell; Buur, 2010; Buur; Mitchell, 2011). Business modelling can be enlivened by bringing into it three- dimensional elements. Such tangible business modeling can include not only business model canvases (Cf. Osterwalder; Pigneur, 2010), but also dynamic physical artefacts to represent components of a business and important relationships with other entities. Such interactive physical representations of the processes by which a company creates and captures value are intended to provoke discussions between people with different professions and interests (Mitchel; Buur, 2010). Bringing 3-D elements into co-creation workshops is frequent practice in service design thinking workshops, through e.g. the use of Lego blocks, but can include other 3-D elements as well when characterizing the concept of service experience.

3 Methods

The objective of the present case study is to get more understanding of the process of creating and tangibilizing a networked business model for a service concept (see Vuorela et al., 2013 on the definition of service concept) of university-based high tech laboratories using visual tools of service design. The new Nordic Network of Applied Imaging and Analysis will offer R&D services for growth-oriented SMEs in the area of the Bothnian Arc. Closer details of the methodology, data, research strategy and process will be provided below in the current chapter.

3.1 Research strategy and process

Besides reviewing relevant literature on networked business models and tangibilization, i.e. concretization, strategies for b2b services, we have used case study strategy and action research approach. Throughout the research and development process, we have applied the methods and principles of service design thinking: user-centeredness, co-creation, sequencing and a holistic view of the customers' service journey (for more information, see Stickdorn, 2011; Vuorela et al., 2013). In our research approach of action research, we are developing the R&D services of the Nordic Network in iterative phases of action and reflection. We have facilitated workshops with visual tools, such as service blueprint, idea tree, business model canvas, value proposition canvas, productization canvas and other relevant co-design tools (see Table 1 below), in order to gain understanding of the needs of relevant customers, as well as the activities of the service providers, namely research organisations.

In this paper, the main focus is on the creation phase of the process of designing a service concept prototype. We have described the exploration phase of this service design life cycle in a previous paper (Vuorela et al., 2013). In this research process, high-tech companies as customers and the network of service providers are problem owners, as they have experience-based knowledge about their actual contexts (for more information about the roles of action research participants, see Ballantyne, 2004). We have attempted to integrate customer company staff into service development throughout the process.

Diagram 1 below summarizes the empirical research process of the case study during the creation phase, as well as the theoretical aims of the study in the present paper.

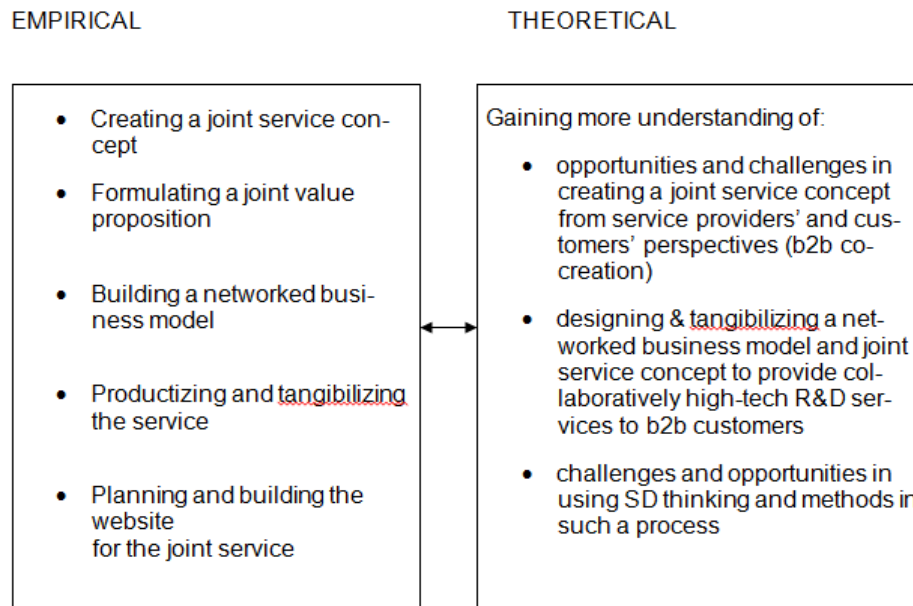

Diagram 1. The research process during the creation phase of the UNELMA Project case.

This study can be called an illustrative case study; via the case, we attempt to gain understanding which extends beyond the current UNELMA Project and its context. An illustrative case study often describes what has already been achieved in practice in (work)life; it offers insight into the nature and form of existing practices (see Eriksson; Koistinen, 2005). The objective is to reveal new and relevant cultural meanings related to the case (ibid). The aim is also to illustrate innovative practices from a b2b context.

3.2 Data description, gathering and analysis

In creating a networked business model for a joint service palette offered by the Nordic Network, efficiency and cost-effectiveness of the b2b high-tech services as well as improved customer experience are the objectives of this service development life cycle. The concrete end results of the UNELMA Project will be, in addition to the new joint service concept (UNELMA Project Plan, 2011), inter alia, improved dissemination of micro- and nano-technological research and thus activation of companies in the utilization of this information in their R&D (Vuorela et al., 2013).

The micro- and nano-technological equipment of the research laboratories of the Nordic Network is expensive. The UNELMA Project will improve the availability of the materials' imaging and analysis services by offering a combined palette of these services and the devices, facilities and staff expertise of the participating partner universities and research institutes. The services will be conceptualized so that the service providers will function as one big networked laboratory and service cluster (UNELMA Project Plan, 2011; Vuorela et al., 2013).

The workshops and meetings were the main sources of data gathering for the case study. In data gathering, we have used participative observation, which has been aided by voice-recording and photography, meeting and workshop documents, journals, diaries and notes that have been written both during and after the workshops and meetings. The data, which is available to us as researchers from the UNELMA Project is archived offline and online. The following workshops and meetings took place between September 2013 and September 2014:

- Exploration Workshop 2a with Finnish Customer
- Exploration Workshop 2b with Swedish Customer
- Creation Workshop 1: joint service
- Steering Committee (PSC) Meeting 3
- Visit to TAKOMO Enterprise Development Centre
- Creation Workshop 2: website
- Creation Meeting 1: website
- Creation Meeting 2: website
- Closing meeting: PSC & Operational Management Team (OMT)
- Visit to Luleå Science Park Business Breakfast

Systematic documentation has taken place during the different phases and the work packages of the project. The analysis of the results of the workshops and meetings has been done by the OUAS team as service development facilitators and researchers as well as all OMT meeting participants together discussing the themes arising from the material. In reporting the findings, pictures will be used to visualize and verify our actions, results and interpretations (see Tables 2-4 below in chapter 4).

The tools used in the service creation process and the motivation for why they were used in the current project (and study) will be briefly described below in Table 1.

Table 1. Tools used in the service design process of the Nordic Network of Applied Imaging and Analysis Services.

TOOL USED IN SERVICE DEVELOPMENT PROCESS	DESCRIPTION	MOTIVATION
Idea Tree: a large poster with a picture of a tree with branches spreading on both sides	Idea Tree presents the thoughts of both service providers and customers; gives a solid background to challenges at hand (Johnson; Schneiderman, 1991). One side of the tree is for the thoughts of service provider and the other for customer opinions. The branches are named with topics which encourage the representatives to think of their values, needs and challenges (Aro et al., 2012. See also Hyysalo, 2009; Hämäläinen; Vilkkä; Miettinen, 2011; Miettinen, 2011).	The main aim was to gain more customer understanding. Idea Tree is a discussion tool. Five questions were formulated on the basis of the current business relationship, to which both sides responded: 1. How do we see the future?; 2. What do we expect and hope for?; 3. What are the challenges?; 4. What is best?; How can we improve our collaboration?
Business Model Canvas (BMC)	BMC is a management tool for describing, analyzing and planning a company's business strategy (Osterwalder; Pigneur, 2010).	Understanding customers' business strategy is necessary for service providers' service business creation.
Service Blueprint	Shows physical evidence for customer interaction/action, visible employee contact/action onstage, employees' internal contact/interaction/action backstage (Zeithaml; Bitner; Gremler, 2006).	Gaining information of customers' service processes and the ways that they interlink with service providers' processes; reveals critical points in the service process.
GOP-brainstorming	A brainstorming tool adopted from ZOPP/GOPP method (http://web.mit.edu/urbanupgrading/upgrading/issues-tools/tools/ZOPP.html).	Verbalizing challenges and possibilities of current joint service creation process; created shared understanding by Network partners.
Value Proposition Canvas (VPC)	VP is a promise of value to be delivered by service provider to customer; applies to products and services. VPC describes how organisations' products and services create customer gains and benefits (Osterwalder; Pigneur, 2010).	Forming common understanding of the value of new service Network for customers
Productization Canvas (PC)	A marketing/business development tool adapted from www.hasardi.com ; was modified for current study/process.	Enabled combining essential business and marketing features of the new networked service concept.
Canvanizer of Nordic Applied Imaging Network	BMC in a digital format www.canvanizer.com	Enabled creating a shared view of new networked business model on the basis of the workshops.
Service Palette	Visualization tool of joint service; colour-coded analogy of service offering.	Created for internal and external marketing of the new networked service concept.

During the exploration phase of our research and development process, we gained understanding of the business situation and context of the Nordic Network of Applied Imaging and Analysis Services and the relevant high tech domain: customer profiles of the different partner labs and the value propositions that the labs offer to their customers (see Vuorela et al., 2013). We collaboratively drafted customer journeys and service blueprints with the partners and their customers; also the partners shared relevant information about their current service business logic (ibid).

A key achievement of the exploration phase of developing a joint service concept was the creation of trust between the partners. In this process, the co-creation workshops were an important element, as information was shared about the partners' service processes – both their challenges and success stories and the business models behind the services (ibid). Hence, when moving from the exploration phase of the service development life cycle to the creation phase, we continued using visualization tools; partly similar tools with a new angle, partly new tools (see Table 1 above) in order to tangibilize the networked business model being created for the partners taking part in the work.

As is shown in Table 1 above, in the workshops, with the help of different visualization tools, we created joint value propositions for the networked business model of the joint service concept. We also identified service provider and customer views on the challenges and opportunities of the new networked business model. Essential elements for the joint production of services were also identified. We will now turn to discussing the findings of the action research of the case study, the UNELMA Project.

4 Findings

Service design thinking as an approach to service development has been applied in the context of the UNELMA Project (for more information of the exploration phase of the service design life cycle, see Vuorela et al., 2013). This approach and its relevant visualization tools not only tangibilize the joint service concept in the making for the network of service providers, but also enabled the creation of trust between the partners, which is a prerequisite for a networked business model (see Vuorela et al., 2013; Hakanen; Jaakkola, 2012). The objective of the present case study has been to gain more understanding of the process of creating and tangibilizing a networked business model for a service concept of university-based high tech laboratories. Although the main focus in the present paper is on the creation phase, we will start by briefly outlining the final findings of the exploration phase, as they involve customer input which is crucial for the creation phase of the service design process.

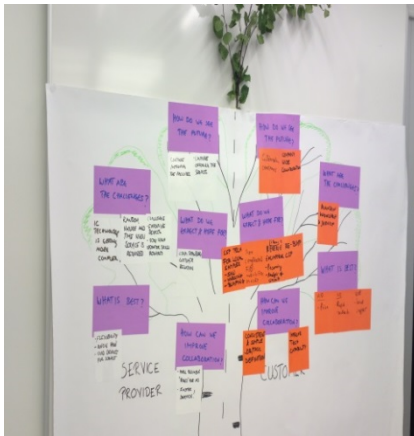

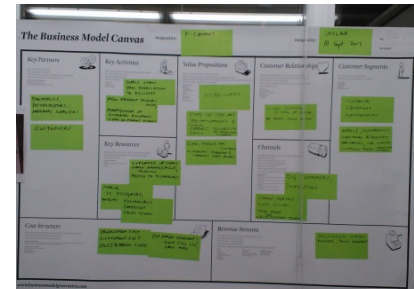

4.1 Results of customer co-creation during the exploration phase

In customer co-creation workshops, service design thinking methods were applied in order to gain more understanding of customers’ business strategies. The work was complemented by collaborative analysis by project partners, i.e. service providers, that took place in Operational Management Team (OMT) meetings of the UNELMA Project.

Idea Tree

As is described in Table 1 above, the Idea Tree is a discussion tool, and through it both the service providers and the customers were able to express their viewpoints on the current collaboration and their hopes for the future in a more interactive manner that would have been the case in an interview. For a summary of the results of the Idea Tree of a Finnish customer and service provider, see Table 2 below. There are differences in the customers and service providers’ concerns, although they both are hoping for a long-lasting business relationship. The contributions of the co-creation workshops with customers are briefed in Table 2 below.

Table 2. Extracts of results of the customer workshops and related OMT meetings of the exploration phase.

UNELMA Project Workshop TOOLS	PICTURE OF TOOL OUTCOME	CUSTOMER COMPANY VIEW	SERVICE PROVIDER VIEW
<p>Idea Tree</p>		<p><u>Best:</u> price, rapid feedback, local support <u>Future:</u> collaboration continues company-wide <u>Hope:</u> longstanding customer relationship <u>Improvements:</u> faster & more reliable service</p>	<p><u>Best:</u> flexibility, know-how, devices <u>Future:</u> continue improving facilities & offering services <u>Hope:</u> wider service offering <u>Improvements:</u> more tech capability; simple task definitions</p>
<p>Business Model Canvas</p>		<p>Customers are interested in long-standing business relationships and are interested in discussing their business model in the hope that it will improve the efficiency of service providers’ service delivery.</p>	<p>Nordic Network learned important information about customers’ gains and pains: e.g. cost structure, revenue streams, value proposition, customers, partners.</p>

UNELMA Project Workshop TOOLS	PICTURE OF TOOL OUTCOME	CUSTOMER COMPANY VIEW	SERVICE PROVIDER VIEW
Service Blueprint		Customers were able to reveal critical points in the service process to the service provider: time constraints, both points of frustration and contentedness.	Service providers gained awareness of the critical points in the process for the customer. E.g. they experience pressure at different times in the process when compared to service providers' concerns.

Customers' Business Model Canvas

The Business Model Canvas (BMC) is a strategic management tool that is designed to convey the essentials of a company's business strategy quickly and simply in a visual format. It describes the rationale of how a company creates and delivers value (Osterwalder; Pigneur, 2010). The motivation in the current study was to improve understanding of customers' business strategies prior to the creation of a networked business model for the joint service concept. Similarly to the Idea Tree, the BMC allowed discussing issues with the customer company that are delicate as often confidential. The tool allowed the customer to reveal as much information as they felt was possible without the feeling of service providers 'prying' unnecessarily (see Table 2 above for a brief of the outcome of BMC; see Table 1 for an overview of the tool).

Service Blueprints

Service Blueprinting is used for service innovation and development. The tool shows the service process within an organisation divided into different components, such as front stage with visible customer - company employee contacts and customer action, back stage with invisible employee action (Zeithaml et al., 2006). Through it, the service providers were able to establish critical points of their service for the customers (see Tables 1 and 2 above for more details).

The information gathered in customer workshops in Finland and Sweden benefitted the service creation process of the joint service concept. The Network will be able to attend to customer requirements more effectively after this collaboration, even though all customer wishes may not be within the scope of the networked offering.

4.2 Results of the creation phase

The creation phase of the service design life cycle started in the autumn of 2013 after the exploration workshops with customers had been completed. The first creation workshop amongst the project partners involved working with several visual discussion methods: GOP brainstorming, Value Proposition Canvas, Productization Canvas (see Table 1 above for details). The work was finalised through the design of a networked business model for the Nordic Network with the help of a digital BMC tool, on the basis of the results of the other visual tools of the creation phase as well as the results of the exploration phase (see Vuorela et al., 2013). The networked business model was approved by the OMT meeting and Steering Committee meeting. The results of the creation phase are discussed below and they are also briefed in Table 3 below.

Goal-oriented brainstorming

The first creation phase workshop started with a brainstorming session about the advantages and challenges of the joint one-desk service policy for the Nordic Network. The discussion method was adapted from the ZOPP/GOPP method (see Table 1 above for more details). The idea was to gain as much information as possible of project partner views through 'free-association' on the basis of a jointly formulated research question, while working with colour-coded notes that were attached to the wall; everyone could see each other's views and contribute to them with own their own hand-written notes.

The project partners identified advantages of a joint service concept for both the service providers and customers but challenges only for the service providers. Had customers taken part in the workshop, the outcome could have been slightly different. Now the project partners were putting themselves into the 'shoes' of potential customers and imagining ideal situations. Of course, they do have customer understanding due to years' of experience as well as the information that was collected in customer workshops (see Table 2 above). Naturally, the joint service concept was seen from a positive point of view: it is the main aim of the UNELMA Project. Generally, the advantages of the networked service were rapidity and reliability with an extensive offering and an efficient back-up system. The challenges involved e.g. combining competition and collaboration amongst the networked service providers (see Table 3 below for details).

Networked Value Proposition Canvas

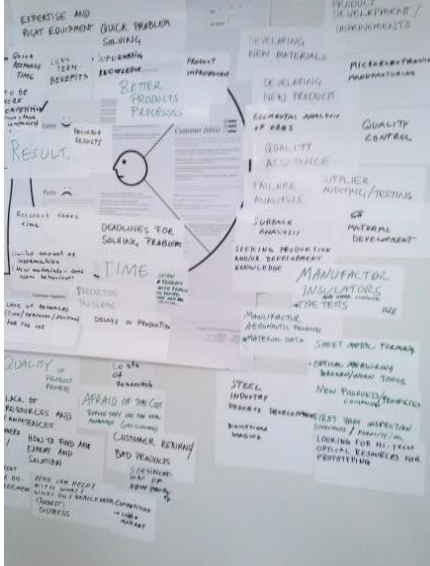

When embarking upon creating a joint value proposition for the networked service concept of applied imaging and analysis, we had the following research question in mind: How can a joint value proposition and productized service be created for the Nordic Network using service design thinking tools?

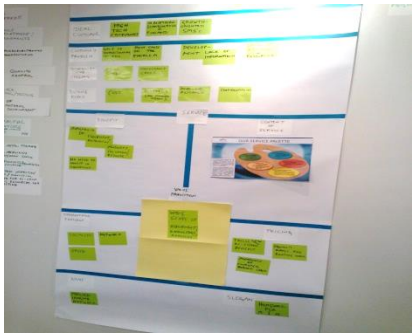

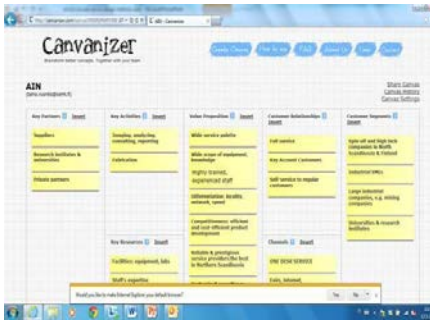

The starting point for the work on the joint value proposition was the Business Model Canvas (BMC, Osterwalder; Pigneur, 2010; see also Vuorela et al., 2012), which defines value proposition as a promise of value to be delivered to the customer company as an entire organization, or part of it. Thus, the Value Proposition Canvas (VPC) describes how a service provider’s services create customer gains and benefits (Business model generation, 2010; date of retrieval 29.7.2014; for the Value Proposition Canvas (see http://www.businessmodelgeneration.com/downloads/value_proposition_canvas.pdf)

The VPC discusses ‘customer jobs’, ‘customer pains’, ‘customer gains’ and finally ‘gain creators’ and ‘pain relievers’ (ibid). The identified issues are project partners’ opinions of what customers’ concerns are (based on their own experiences and customer co-creation workshop during the case study, see Table 2 above). E.g. *pain relievers* involve the Nordic Network Service Palette (see Table 4 below in chapter 4.3), which was decided upon prior to the current case study.

For more information on the VPC content, see Table 3 below.

Table 3. Results of the workshops and related meetings of the Creation phase.

UNELMA Project Workshop TOOLS	PICTURE OF TOOL OUTCOME	RESULTS IN BRIEF
<p>GOP-brainstorm</p>		<p>Opportunities of joint one desk policy for Customer: one contact point; fast, reliable service; back-up system; fair pricing for Service Provider: shared know-how of capability & resources of partners.</p> <p>Challenges for Service Provider: competition; admin of new customers, distribution of work, pricing, communication.</p>
<p>Value Proposition Canvas (VPC)</p>		<p>Customer Pains: e.g. time of research/analysis for critical products and processes; uncertainty of core problems with products and processes; loss of customers due to production problems.</p> <p>Customer Gains: more competitive thanks to reliable analysis results; no need for analysis equipment investments; access to expertise and ‘top- notch’ equipment.</p> <p>Gain Creators: via new networked service concept, customers develop better products with shorter time to market.</p> <p>Pain Relievers: Nordic Applied Imaging Network is a ‘public’ player: offers impartial analysis results.</p>

UNELMA Project Workshop TOOLS	PICTURE OF TOOL OUTCOME	RESULTS IN BRIEF
<p>Productization Canvas (PC)</p>		<p>The Productization Canvas crystallized the information obtained with the above VPC.</p> <p><u>Value Proposition:</u> wide scope of equipment, knowledge & services; <u>Differentiating Features:</u> locality, network, speed; <u>Ideal Customers:</u> growth-oriented high tech SMEs in Northern Scandinavia and Finland.</p>
<p>Networked Business Model Canvanizer</p>		<p>BMC for the Nordic Network of Applied Imaging and Analysis was compiled on the basis of the above tools' output and it was approved by the Project Steering Committee meeting.</p>

The VPC tool seemed slightly repetitive in the workshop and yet through it the service providers did efficient brainstorming ‘gymnastics’ about and around their future networked business model.

Productization Canvas for the Nordic Network of Applied Imaging and Analysis

The UNELMA Productization Canvas was adapted from Hasardi Productization Canvas (Lapinlahti; Vesala; Törmänen, 2013) and was used as a tool for specifying and standardizing the networked service offering of the Nordic Network. The canvas was adapted for our purposes as this helped to concretize the service offering. It crystallized the work that we had achieved through the other tools. With its help, ideal customers and their problems were defined: high tech companies in Northern Scandinavia and Finland; growth-oriented SMEs, whose activities suffer from the lack of understanding the root cause of problems in their manufacturing processes. They also lack the necessary equipment. The service providers’ opportunities for selling were also identified as well as customers’ buying risks and benefits. The core value proposition was defined as well as differentiating features. Finally, principles of pricing were discussed. Crystallizing the service content through the Productization Canvas facilitated embarking upon the tangibilization process of the joint service concept for the customers, namely the design of the website of the Nordic Network (see 4.3 and Table 4 below).

Networked Business Model for the joint service concept

Finally, on the basis of the creation workshop outcome, a networked business model for the Nordic Network was created by the OUAS facilitator team, which was then presented for the OMT meeting to be discussed and finally approved. The focus at this stage was on the customer segments, value proposition and the channels (see <http://canvanizer.com/canvas/OGUVjXNif57JN30XkFIdjZLrBNmXUJXj>), which lead us to the next stage in the tangibilization process, as already mentioned above: the website for the joint service concept.

4.3 Tangibilization strategies for the website of the Nordic Network

The Nordic Network of Applied Imaging and Analysis undertook several workshops (for their outcomes, see Tables 1-3 above) in order to develop a networked business model for the joint service efforts. In the context of the current research and development project, an effort was made to benchmark the digital marketing of several commercial competitors in the field of high-tech analytical services. It is evident, on the basis of this benchmarking, that websites are seen as an important part of the process of delivering high-tech B2B services. The benchmarked companies emphasized the following factors in their digital marketing, inter alia: their trustworthiness, independence, experience and high educational level of their workforce. This is in line with standard B2B services marketing, which relies on quality, value, skills and personal characteristics of the workforce.

The Nordic Network of Applied Imaging and Analysis website, its content and structure of navigation are the concrete outcome of the work that has been completed during the UNELMA Project case during workshops and meetings in 2012-2014. Several workshops and meetings were needed (see p. 7) when building the guidelines for the website, which is still under technical construction at

<http://webcgi oulu.fi/nano/unelma-www/>

and will be finalised in the autumn of 2014. The services of the network have been particularly challenging to describe for the website. In order to find the relevant strategies that could help to tangibilize the services of the Nordic Network for the customers, the following sub-research questions for the creation workshop and meetings on the website were drafted:

- How can a joint service be concretized, tangibilized and visualized online?
- What kind of tangibilization strategies are the most relevant in the customer service process?

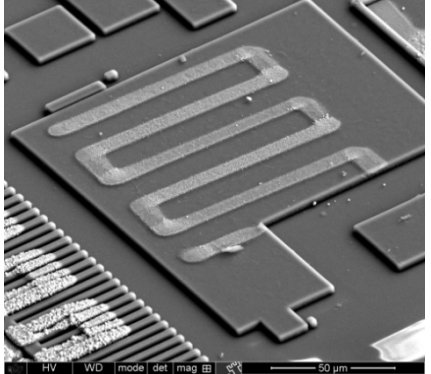

The content of the website was essentially created during the process of creating the service, and it is hence based on the workshops of both the exploration and creation phases (see Tables 1-3 above; see also Vuorela et al., 2013). In practice this means that suggestions for a narrative, metaphors, slogans and keywords were created in and around the workshops and meetings for the technical and graphical staff to be used when technically building the website.

The structure of the website was decided in workshops and meetings of the creation phase during spring 2014; e.g. a decision was made to create a static site with the following navigation bar content: Home, Services, Equipment, Partners, Success Stories, Gallery, Contact Us. The domain name for the website had been approved at the beginning of the UNELMA Project, namely appliedimagingnetwork.eu. The website still requires more material, images and text from all partners, so it is not yet complete. Hence, this online tangibilization process is ‘work in progress’, and what we are presenting are propositions for tangibilizing the services of the Nordic Network of Applied Imaging and Analysis.

As has been stated above, the co-creation work that we completed as project partners within the UNELMA Project with its visualization tools of the Business Model Canvas, Value Proposition Canvas and Productization Canvas helped to tangibilize the networked business model of the new service concept, under creation, for the service providers. The website that is currently being created for the Nordic Network will tangibilize the service concept for the customer companies and thus improve the delivery of the services. The results of the workshops and meetings of the creation phase for the Nordic Network website for joint service production are briefed in Table 4 below.

Table 4. Tangibilization strategies for the Nordic Network of Applied Imaging and Analysis website.

Network website: TANGIBILIZATION ELEMENT	PICTURE OF TANGIBILIZATION ELEMENT	DESCRIPTION	MOTIVATION FOR USE
Nordic Applied Imaging Network Logo		The logo evokes the physical properties of the micro- and nano-technological imaging processes.	Tangibilization strategy of association (see Berry; Clark, 1986; Kindström et al., 2012).
Service Palette with colour coding		Analogy of the artist’s palette demonstrates the service offering. Colours evoke the colours of the physical spectrum; the palette the wide selection of services available. The palette is an artist’s tool; the Network also provide pictures, although of a different kind.	Created for internal and external marketing. Tangibilization strategies of documentation and association (see <i>ibid</i>).

Network website: TANGIBILIZATION ELEMENT	PICTURE OF TANGIBILIZATION ELEMENT	DESCRIPTION	MOTIVATION FOR USE
Map of Gulf of Bothnia area where Network is located		The map of the area demonstrates and emphasizes the locality of the services of the Nordic Network.	Tangibilization strategy of association (see Berry; Clark, 1986; Kindström et al., 2012).
Example: Equipment of analysis		The photo depicts an expert member of staff in the process of completing an imaging / analysis process.	Tangibilization strategy of envisioning: helps the customer envisage the service mentally (see ibid).
Example: Result of imaging		Scanning Electron Microscope (SEM) image of integrated circuit surface showing a thin copper conductor line made with direct writing method.	Tangibilization strategy of envisioning: helps the customer envisage the positive outcome of the service: its quality and precision (see ibid).

When visualizing the value of their services, companies can focus on *product-based* value, *service-based* value, *relationship* value (Kindström et al., 2012). When the network partners formulated the value proposition of their joint business model, all of the above were found important: the services are performed with the help of expensive, ‘top-notch’ equipment; the services are locally available and reliable as delivered by ‘impartial’, skilled work force as they are based in universities and research institutes. Also, the network provides services collaboratively, pooling resources and know-how, which is relationship-based by definition. This is suggested through e.g. the map of the Gulf of Bothnia on the Network website, which shows the location of the Nordic Network partners (see Table 4 above).

The tangibilization strategies (Berry; Clark, 1986; Hill et al., 2004; Mittal, 1999) of *envisioning*, *association* and *documentation* (for definitions, see chapter 2.3 above) can be seen in the elements of tangibilization that have been chosen for the website of the Nordic Network. Further elements that could be included in the tangibilization elements of the website involve service consumption: depicting activities of customer companies in the service process. Facts and statistics could also be shown related to the service delivery system, at least after the networked business model has been functioning for a while. Reference cases will be an element on the website under Success Stories: some of them could include cost calculations, thus showing the advantages of the Nordic Network services for a customer company. Additionally, after the final results of a customer needs analysis of the UNELMA Project have been received and analysed, more emphasis can be placed on the resonating focus of future potential customers (Anderson et al., 2007).

During the development of the networked business model, emphasis has been put on the importance of visualizing the service offering through its entire life cycle: market sensing, development, sales and delivery as advised by scholars (see Kindström; Kowalkowski, 2009). The following elements as visualization elements should not be forgotten after the Nordic Network starts functioning: joint trade shows appearance, community activities, top management presentations, film sequences, reports, follow-up meetings, statistics, newsletters and stickers (see Kindström et al.,

2012). Additionally, the tangibilization strategy of *representation* could be emphasized, focusing on chosen attributes of the services (see Berry; Clark, 1986).

5. 5 Conclusions and discussion

In the empirical work related to the UNELMA Project, work was carried out for the project: creation of the joint service concept and building a joint networked business model on its basis. A joint value proposition was designed for the Nordic Network of Applied Imaging and Analysis and an attempt was made to productize and tangibilize the service offering. A website for the joint service concept was also planned and created.

The theoretical contributions of the study involved gaining more understanding of the opportunities and challenges in creating a joint service concept from service providers' and customers' perspectives in a b2b high tech context. Vuorela et al. (2013) discovered that a critical factor of a successful exploration phase in a service design process within b2b high tech service contexts proved to be trust. Another critical factor is finding the appropriate means that help the service providers identify the hindrances in joint service development. Joint service development requires open discussions of business models and sharing of information of business contacts and customer understanding in order to create new services together (ibid). These issues were a solid basis also for the creation phase of the service development life cycle, where we gained further understanding on creating and tangibilizing a networked business model and a joint service concept in order to provide collaboratively high-tech R&D services to b2b customers. The tools: idea trees, service blueprints and customer business model canvases (BMC) provided crucial information for the service creation: e.g. the most critical phases and touchpoints in the customers' process. When building the networked business model for the Nordic Network, the value proposition canvas and productization canvas were invaluable discussion and brainstorming tools. They were also important analytical devices for service creation in a b2b case. These tools tangibilized the service concept for the service providers. Investigating carefully the networked partners' different expectations is important in building lucrative value propositions (Makkonen; Komulainen, 2014) and helped the process of building a networked business model. It is important to bear in mind that b2b involves embeddedness of networks of stakeholders (b2b2c2b2c2c) and is rooted in systemic innovation (Gummeson; Polese, 2009). Also, different organizational entities (e.g. invoicing) should be engaged in service functions in order to improve the quality of services (Kowalkowski, 2011a): a future challenge for the current service development.

The creation of a joint website for the Nordic Network proved to be an important element for tangibilizing the new service concept and networked business model for the customers. Service design thinking was useful as an approach in this process as well: co-creation, customer focus, holistic view of the service process. When exploring the tangibilizing strategies for online service marketing purposes, the elements of *association*, *envisioning* and *documentation* proved feasible at the present stage of the Nordic Network marketing (Kindström et al., 2012). In the future, more emphasis could be placed on *representation* (ibid) and finding a clearly resonating focus towards specific focus groups of customers (Anderson et al., 2007). Focusing on the modularity of the services (see Palo; Tähtinen, 2011) may be another important focus for marketing the present networked services. Kowalkowski (2011b) emphasizes the importance of communicating a company's value propositions effectively in a new area. Tangible business modelling through 3-D elements as suggested by Mitchell and Buur (2010) seems promising for co-creation with customers. Other important future directions could involve different types of value propositions for different stakeholders (Lindgreen et al., 2009).

The reliability of the case study results has been addressed through material and researcher triangulation: both quantitative and qualitative material have been exploited and researchers have worked in multidisciplinary multi-person teams, consisting of students and research staff. Ballantyne (2004) points out that the research component in action research means research for the project, not about the project, as projects have their own action-driven research requirements; broader scholarly interests may become fulfilled later (ibid). If engaging in new joint industrial cases, in order to find synergies and new possibilities to boost local industrial companies, the partners need to engage in interactive activities to become acquainted and integrate new potential customers as well. Traditional questionnaires are a challenge in customer integration and workshop attendance requires time, which can be costly for SMEs. Relevant messages through company websites could be a fruitful direction to take in customer engagement. Building tangible websites for networked services can be challenging; the collaboration between staff members who represent different domains and speak different discourses can be time-consuming. Yet, the network partners' views, needs and roles were modified in co-creation workshops. Also, a two-year project improves the quality of the results, as matters mature over time. Interactive service design thinking approach and workshops clarified the roles of different partners in the Nordic Network and thus improved the quality of the collaboration.

The use of service design tools as ‘boundary spanning objects’ in SMEs

Juha Vänskä, Juha Arrasvuori

University of Vaasa, Department of Production, SC-Research, Finland

This explorative study was set up to shed some light on how service design tools and workshops can be utilised in practice as ‘boundary spanning objects’ while developing new, innovative services within SMEs. Although some authors have noticed and emphasises the role and importance of boundary objects in service design (e.g. Kimbell, 2011; Bjögvínsson et al., 2012), the findings and insights from the ‘boundary object’ literature appear to be largely ignored in service design literature. This paper attempts to mitigate this identified gap within the research literature. In order to provide some answer to the key question of this study, we first carried out a review of existing literature. Building on Carlile (2002; 2004), Bessant et al. (2005), Bessant and Maher (2009), and Kimbell (2011) we then developed a tentative framework to be used as a tool to analyse the empirical data collected from four new service business cases. The empirical data consists of 43 hours of audio recordings, collected during 21 service design workshops that were facilitated by the authors of this paper between December 2012 and April 2014. The main conclusion of this paper is that service design – at least when carried out with “low-tech SMEs” (den Hertog et al., 2011) like in this study – is better suited for the development of more radical innovations, that are taking place at pragmatic boundary (Carlile, 2002) and following “designing for services” approach, as suggested by Kimbell (2011).

1 Introduction

The research of service design has started to take shape (Kimbell, 2011). The literature on service design spans contributions from several research fields, such as service marketing (e.g. Shostack, 1982), new service development (e.g. Bitner et al., 2008), service operations management (e.g. Goldstein et al., 2002) and innovation management (e.g. Bessant & Maher, 2009). Ostrom et al. (2010) suggest that the design of a service may have a significant impact on any or all of the key metrics, such as costs, revenues, customer satisfaction and brand perceptions of the organization producing or delivering the service. Service design is also assumed to have a great potential to make an impact in service innovation (Tether, 2008). It has even been found hard to think about innovation without including design in the considerations (Johansson-Sköldberg et al., 2013).

In her recent study, Kimbell (2011) explored different ways of thinking and understanding service design. Drawing on the analysis of design and management literature and the results of an ethnographic case study, she proposed a new framework that makes a distinction between “*designing services*” and “*designing for services*”. The main difference between these two approaches stem from discussions whether service design is seen as a search process for problem solving that “*aims to work towards a desired state of affairs that can be determined in advance*” (Kimbell, 2011, 43), or as an exploratory enquiry in which the desired end state cannot be known due to unexpected expansions of initial concepts that are integral to a design process (Hatchuel, 2001). Following Manzini (2011), Kimbell argues that:

“...talking of designing for services rather than designing services recognizes that what is being designed is not an end result, but rather a platform for action with which diverse actors will engage over time. Designing for service, rather than designing services, points to the impossibility of being able to fully imagine, plan or define any complete design for a service since new kinds of value relation are instantiated by actors engaging within a service context. Designing for service remains always incomplete (cf. Garud et al., 2008).” (Kimbell, 2011, 45).

Kimbell’s argument seems to be well in line with discussions taking place in the field of service innovation. For instance, the service innovation model presented by den Hertog (2010, 140) consists of six dimensions: 1) new service concept, 2) new customer interaction, 3) new business partner, 4) new revenue model, 5) new delivery system (personnel, organization, culture), and 6) new technological delivery system. Due to this multi-dimensionality the determination of service innovation in advance may be problematic in practise. Moreover, it is sometimes even difficult to define exactly, when and where the innovation process starts and ends (Sundbo, 2008).

Mager (2009) argues that there are still many hurdles to be tackled until service design practices are implemented in organizational structures and roles. One of these hurdles relates on the use of service design in small and medium sized enterprises (SMEs). In their paper, Ward and Dekker (2009) refer to the results of a survey (Design Council, UK) in which 54% of small business managers believed that design would help them to improve the competitiveness of their business during the economic turndown. However, as acknowledged by Acklin (2013), SMEs tend to be reluctant to integrate design into their new product/service development practices. This is explained by noticing that SMEs tend to be risk averse on their business related decisions due to their scarce human and financial resources. It is also possible that SME managers consider the tools too academic and complicated (Sundbo, 2011). Accordingly, Löfqvist (2010) suggests that the high relative novelty (i.e. no prior knowledge or experience) of design methods and tools hampers

their utilization in small companies' design processes and practices. The high relative novelty of service design combined with an increased level of uncertainty make it easy for small business managers to abandon the idea to use design tools and to rely on their own established ways to carry out product/service development.

In this paper we suggest that the concept of 'boundary object' (Star; Griesemer, 1989; Carlile, 2002) may provide important insights to overcome some of identified challenges related on the use of service design methods and tools as a vehicle for new service development in SMEs. Although the some authors have noticed and stressed the role and importance of boundary objects in service design (e.g. Kimbell, 2011; Bjögvinsson et al., 2012), the findings and insights from boundary object literature appear to be largely ignored in service design literature. This paper attempts to mitigate this identified gap within the research literature.

Accordingly, the purpose of this explorative study is to shed some light on this issue by investigating how service design tools and workshops can be utilised in practice as 'boundary spanning objects' while developing new, innovative services within SMEs with little or no prior experience on service design. Moreover, we suggest that service design – at least when the utilization of design methods and tools is organised in SMEs following the 'workshop-approach' like in this study – is better suited for the development of more radical service innovations that often require businesses e.g. to span their innovation search space (e.g. Nicholas et al., 2013) and to manage the critical decision-making interfaces at the fuzzy front end (e.g. Reid; de Brentani, 2004)

2 Literature review

Service design literature provides a large variety of mechanisms and artefacts that can be used in different phases of service development. For instance, Blomqvist (2011) suggests that the purposes of service prototyping may be summarised as exploring (generation of new ideas and insights), evaluating (testing hypotheses to be further developed into a final suggestion or solution) and, communicating (visualization of ideas, facilitating discussion and collaboration between stakeholders). Moreover, service design is suggested to catalyse people to see issues in a fresh way and help them to achieve novel, creative solutions beyond the reach of conventional structures and methods (Meroni; Sangiorgi, 2011; Mulgan, 2014). In addition, Lin and his co-writers (2011) illustrate how service design methods, such as story-sharing, may be utilized to help practitioners not only to design better services innovations, but also to build new organizational capabilities enabling them to implement those innovations in practice. However, Manzini (2011, 4) argue that despite of all progress, service design is so far largely focused on tools and discussion concerning the question: "What do we want to do with these tools?" is still very much in its infancy.

Here, the authors of this paper want to remark that it is also important to notice that service design is not the only discipline that is facing and trying to find some plausible answers to the same (or similar) question presented by Manzini (ibid.) about the practical uses of the tools. Thus, the authors of this paper suggest that it is important to study other relevant research fields and to learn whether there are possibilities for cross-fertilization among disciplines, as suggested by Mager (2011).

For instance, the development and use of various innovation methods and tools are largely discussed within management research literature. Thomke (2006) found in his research that state-of-art development tools, especially those that exploit information technology (e.g. simulation and CAD tools) may increase developer's problem-solving capacity and enhance interaction among developer communities. In a similar way, Gray (2007) discusses how the practice of critical reflection that is facilitated through the application of reflective tools (e.g. storytelling, reflective metaphors, concept mapping) may be used as a purposeful process of exploration and discovery. In addition, Phaal et al. (2007) present a new workshop-based method that uses roadmap templates for supporting the identification and exploration of new strategic and innovation opportunities. Due to the "hands-on" nature of the development process and the extensive use of visual representations, Phaal and his co-authors demonstrate how participants even from very different backgrounds are able to communicate in a more effective way that is explained to be integral element for strategy and innovation development.

Accordingly, Kerr et al. (2013) provide a number of guiding principles (Table 1) to be adapted while organizing workshops that are targeted for developing industrially relevant strategic technology management (STM) toolkits.

Table 1. Guiding principles of STM toolkits (Kerr et al., 2013, 1068).

Human-centric	The STM tools should allow their users to participate, engage and collaborate with one another to have a strategic conversation leading to a co-created solution. The key premise of the tools is to support the social interaction and aid decision-making.
Workshop-based	The recommended mode of engagement for deploying an STM toolkit should be through workshops as they provide the platform for group interaction through structured activities centered on the application of the tools for solving strategic problems.
Neutrally facilitated	The workshops within which the STM tools are to be applied should be facilitated from a position of neutrality whereby the facilitator should be focused on the process and not contribute to the content.
Lightly processed	The process for using the STM tools within the workshops should be applied in a lightweight manner based on the premise of ‘start small and iterate fast’ and allow for a degree of flexibility by not being too prescriptive. This requires adapting the macro–micro level processes, the divergent–convergent constructs.
Modular	The STM toolkit should be built in a modular fashion with the constituent tools being readily integrated with one another.
Scalable	The tools should have the ability to be employed at the different levels both within and surrounding an organization by employing a scalable hierarchy in order to provide a wide dynamic range.
Visual	The tools should have a visual form for both their application in the workshops and their resulting output for the purposes of reporting and communicating.

The concept of ‘boundary object’ has gained a lot of interest within research community since it was first introduced by Star (1989). Whereas service design is argued to be located in the intersection of service strategy, service innovation, and service implementation (Ostrom et al., 2010), boundary objects are defined as flexible epistemic artefacts that serve as bridges between “*several intersecting social worlds and satisfy the information requirements of each of them*” (Star; Griesemer, 1989: 393). These objects that may be abstract or concrete by nature are assumed to play important role e.g. in knowledge sharing between different stakeholders and business partners (Koskinen, 2005) and in creation of common ground aimed to lead to shared understanding between occupational communities (Bechky, 2003). Spee and Jarzabkowski (2009) argue that boundary objects are relevant to strategic organizations as these tools enables strategy participants to enhance interaction and to build up bridges over the different hierarchical boundaries and strategic tasks. Furthermore, Nicolini et al. (2013) provide an illustrative example of how these objects may be used in coordination of cross-disciplinary collaboration in the “ground breaking” for developing a stem cell bioreactor. In this bioreactor project “*boundary objects included the joint papers, shared analytical methods (i.e., design of experiment method), representations of results of the experiments (e.g., in PowerPoint slides), and the bioreactor itself with its constituent elements (i.e., sensors, electronic board, connectors, computer)*” (Nicolini et al., 2012, 616).

Carlile (2002; 2004) provides a framework of boundary objects that consists of three progressively complex boundaries – a syntactic, a semantic, and a pragmatic boundary – and of three progressively complex processes, i.e. transfer, translation and transformation that comprise different approaches to sharing and assessing knowledge across boundaries. Syntactic boundaries are the simplest, assuming that differences and dependencies between actors are known and the domain specific knowledge may be sufficiently assessed and transferred *at a boundary* due to common language or syntax shared by individuals. However, when novelties arrive (e.g. in connection of changes in business environment), syntactical approach may not be sufficient anymore, and then a semantic boundary is faced. This approach is more complex than syntactic because individuals’ interpretations on the nature of novel circumstances are often different which make communication and collaboration difficult. Thus, the actors need to learn about their differences and to translate a domain-specific knowledge into a shared meaning that is adequate for the actors involved. The third approach, pragmatic boundary, is the most complex and challenging. As described by Carlile (2004), novelties may generate different interests between actors thus hampering their ability to share and assess knowledge. In order to overcome this challenge, the actors need to develop common interests that are needed in transformation of each other’s domain-specific knowledge *across boundary*. However, this often requires significant internal political effort in organizational decision-making.

Bessant and Maher (2009) provide an illustrative example in which these boundary objects and settings are analysed and discussed from the innovation management perspective. More precisely, the authors by drawing on the wider discontinuous innovation literature that has explored the new potential approaches to develop “frame breaking” service innovation by using service design tools as boundary objects within public healthcare. Findings of their study show that service design tools has the potential to provide an efficient way to engage users to act as a co-developers within the innovation process and to get an access even to those latent, “hard to articulate” user needs.

Also Kimbell, based on the findings of her ethnographic study, highlights an important role of boundary objects:

“The designers made an important part of their work the construction of artifacts to make visible and comprehensible the complexities of the service, ranging from prototypes (Case A) to sketches (Cases A and B) to

the customer journey diagrams (all three). These boundary objects (Star; Griesemer, 1989; Carlile, 2002) played an important role in all three cases as the designers tried to make the practices of service stakeholders visible to the managers to help with decision-making about the redesign of the services". (Kimbell, 2011, 48-49.)

However, Carlile (2002) also remarks that an object that is effective at one particular boundary setting may fail and even become a boundary roadblock in another setting. This seems to be well in line with discussions that have been conducted within innovation management literature. Bessant et al. (2005) suggest that under the “steady state” conditions organizations are able to follow the set of rules and systematic procedures (good practices) while scanning new innovation opportunities within known or “knowable” search space. However, when environmental complexity increases e.g. due to introduction of innovative technological solutions brought to market by new entrants, the steady state “good practices” will be challenged. Bessant and his co-authors argue that managing innovation under highly complex environment requires an organization e.g. to carry out parallel experimentation in a open and fuzzy search space by following a “probe and learn” approach instead of trying to manage all plausible risks related on innovative experiments.

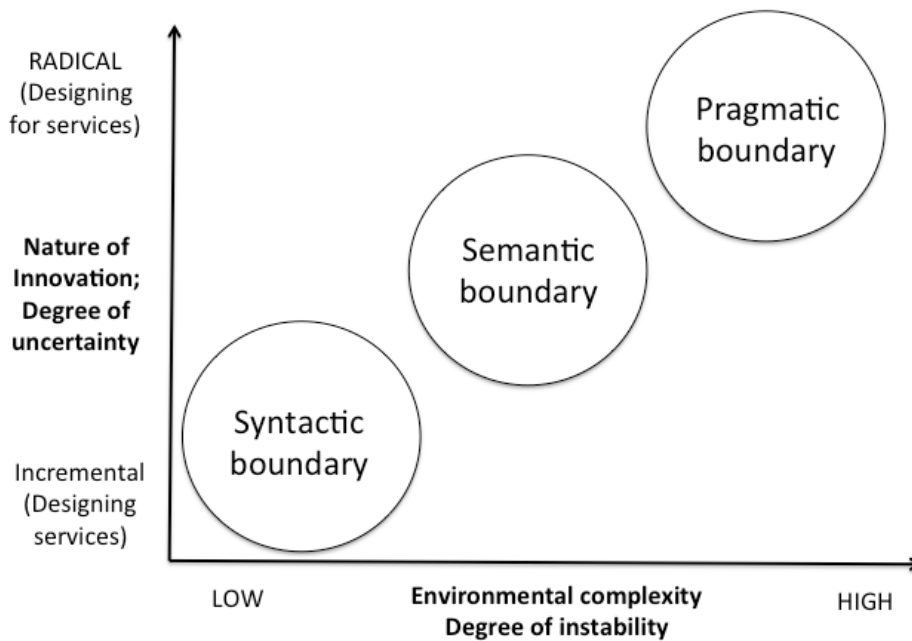

Figure 1. Tentative framework summing up the reviewed literature (adapted from Carlile (2002), Bessant et al. (2005), Bessant and Maher (2009), and Kimbell (2011)).

Figure 1 is a tentative framework sum up some of the discussion within the reviewed service design, boundary object and innovation management literature. The aim of this framework is to provide theoretical background for the analysis of findings of the empirical part of this study. As illustrated on the figure, “designing for services” (Kimbell, 2011) is considered as an example of radical (or discontinuous) innovation due to the open and uncertain nature of this design approach. Moreover, it is assumed that knowledge transfer taking place at a syntactic boundary is more related to the designing of incremental service innovations, whereas radical innovations are based on the knowledge transformation and the development of common interests across pragmatic boundaries. “Designing services” and “designing for services” (Kimbell, 2011) require businesses to span across several mental and organizational boundaries. Service design tools and workshops may assist in this. That is the reason why we chose to use the term ‘boundary *spanning* objects’ because in our mind, this term illustrates this complex and open phenomenon better than the term ‘boundary objects’.

3 Research methodology

The research was exploratory by nature. Thus, a qualitative, multiple case study approach was applied for the purpose of this study because it allows the researcher to understand the studied phenomenon and its context more deeply (Yin, 2003). Three Finnish small and medium sized service companies with little or no prior experience on service design were recruited for this study. The selection of case companies was based on their willingness to explore service design as a driver of new innovative services.

Table 2 provides an introduction to some key characteristics of selected business cases that are named in this paper as ‘SPA’, ‘SPORT’ and ‘REG’ due to confidentiality reasons. Two business cases were developed with SPORT and one each with SPA and REG.

Table 2. Key characteristics of selected companies and brief description of analysed business case(s)

	SPA	SPORT	REG
Year of establishment	1984	1950	2000
Number of employees	120	80	25
Examples of provided services	Hotel accommodation, several restaurants and cafes, spa and well-being services, conference services, guided sport and training activities, etc.	Training centre for top athletes, testing and consulting of athletes, holiday packages for families, accommodation, restaurants and cafes, well-being services, conference services, guided sport and training activities e.g. camps, etc.	Office rental services, business development services, thematic training seminars, testing services for new products, conference services, several restaurants and cafes, etc.
Prior service design experience	None	None	Some
Description of analysed business case(s)	1) Designing for "Arena Service Platform; Designing of new 'PopUp Outlet'-service concept (the first trial of a service concept new to the company)	1) Designing for "The Sport Camp 2.0"-service concept for children; (Gamification); 2) Designing a well-being service concept (incremental innovation, based on existing service modules)	1) Designing a conference service concept (incremental innovation, renewal of existing concept)
Number of workshops	9	8	4
Number of participants in workshops (excluding researchers/facilitators)	2–6	2–8	2–10
Design tools utilized in workshops	Metaphors, "Story building"	Metaphors, personas, Business Model Canvas (Osterwalder; Pigneur, 2010)	Customer survey, customer observation, customer journeys with touchpoints, Innotiimi@OPERA, mock up prototypes, story telling (pitching)

The empirical data consists of 43 hours of audio recordings, collected during 21 service design workshops that were organised at the premises of the case companies between December 2012 and April 2014. In total, 33 people from the three case companies together with their current and potential business partners participated in these workshops, which were facilitated by the authors of this paper. Most of the recorded material was transcribed for later analysis. The data was further indexed, coded and analysed in tabular displays, in which we reused constructs from earlier literature.

4 Results of empirical study

The main objective of this study was to investigate how service design tools and workshops can be utilised in practice as 'boundary spanning ob

jects' in the development of new, innovative services within SMEs. The insights from prior research literature provided a theoretical basis for the study. Moreover, both of the authors of this paper had, in addition to theoretical knowledge, prior practical experience on organizing design workshops and using service design methods and tools during these workshops. Besides, both of the researchers also had an opportunity to participate in a number of other design workshops (mainly targeted for start ups and SMEs) during the research project that were carried out by external service design professionals. All together, we had a solid starting point for our efforts to meet the objectives of this explorative study.

The empirical part of the research project started by organizing a "kick-off workshop" together with key staff members (e.g. managing director, development director) from each of the case companies. At the beginning of these workshops researchers presented the main objectives of the study and provided some illustrative examples of service design tools that may be used during the workshops. Furthermore, researchers also presented a simplified description for the multi-phased process (Figure 2) that was aimed to support the implementation of new service design in the case companies.

Figure 2. Diagram of a multi-phased design process. The diagram should not be viewed as a linear progression from Entry, through the four phases, to Exit phase with a new complete service. Rather, the multi-phased design process can be cyclical, for example, there may be several cycles between Idea generation and Prototyping phases before the service concept is mature enough for Piloting. The Evaluation phase provides main feedback to the earlier stages. However, at the end of each phase there may be reflection on what was done, and thus learning may be obtained that can be utilized during any subsequent phase.

However, most importantly, these kick-off workshops provided researchers an opportunity to learn more about the selected case companies. For this purpose researchers had prepared a list for the key questions in which we asked them e.g. to describe their typical new service development (NSD) process, what tools and methods they are using in NSD (special interest in the use of service design methods/tools), the recognized NSD related challenges/obstacles, etc. We were interested to find out if the case companies already have some on-going NSD projects that could benefit from our research based activities.

The results of the kick-off workshops showed that case companies did not have any well-structured NSD process in which different development phases are clearly defined. The most typical NSD is based on the “development projects” that respondents from case companies described to cover at least on some level all the main phases of the process presented in Figure 2. The establishment of these development projects may be based on strategic decisions (e.g. SPA had made a strategic decision to allocate resources on the development of new “family services”), but more often, NSD related decisions are made on ad-hoc basis in order to meet new customer requirements or to benefit from the identified business opportunities on the market. Respondents from case companies also pointed out that the limited amount of “spare” human and financial resources hinder the extent of NSD and make it difficult to initiate “high-risk, fuzzy” ideas for new services.

Moreover, it was also found out that the selected case companies had no prior experience on use of service design methods and tools in NSD. Or to be more precise, case company REG did have some prior service design experience – but only as an organiser of events and workshops targeted to assist regional businesses to benefit from service design. Like explained by development director of REG, “We are like the famous Cobbler whose children have no shoes”.

The “entry phase” kick-off events were followed by a varying number of “ideation phase” workshops in which the target was first to identify those service design business cases that the participating companies considered to be the most relevant. While designing the process and content for these workshops, we found it highly useful to follow the guiding principles suggested by Kerr et al. (2013). The only exception was to the “neutrally facilitated” principle pointing out that “...facilitator should be focused on process and not contribute to the content” (Kerr et al., 2013:1068). Here we found it more useful to follow Manzini (2011) who suggests that designer should not only take a role of facilitator (i.e. an actor whose task is to listen and facilitate the discussion) but also act as provoker who provides alternative, even wild and provocative proposals to stimulate discussion during the design process.

So far, we have merely discussed on NSD and service design within the case companies on a general level. However, in order to shed some light for the key question, i.e. how service design tools and workshops may be used as ‘boundary spanning objects’, it is necessary to take a closer look on the four businesses cases (see Table 2) that were analysed for this purpose. As described in Table 2, two of the selected business cases – SPORT’s ‘well-being service concept’ and REG’s “conference service concept” - were defined to follow Kimbell’s (2011) “Designing service” approach. Respectively, the two other cases, i.e. SPA’s “Arena Service Platform” and SPORT’s “The Sport Camp 2.0” were specified to follow the “Designing for Services” (Kimbell, *ibid.*) approach.

4.1 Designing new service concepts

The first two business cases, i.e. SPORT’s “well-being service concept” and REG’s “conference service concept” are examples of incremental service innovations in which the desired outcomes are defined in advance (Kimbell, 2001). During the “entry phase” discussions the representatives of both case companies found it interesting to explore what kind of new insights might be generated through service design methods. However, due to determination of desired outcomes in advance, the “search space” (Bessant et al., 2005) innovation was also significantly narrowed down.

For example, the development of SPORT's "well-being service concept" was merely based on redesigning already existing health and nutrition based services. Within the new "service concept", the main idea was to define the already existing services as "service modules". As a result of this "new to the company" service approach, it was considered easier to build up more customer- and user-friendly service packages in a flexible and cost-efficient way. The service design tools used during the workshops were "Personas" and "Business Model Canvas" (Osterwalder; Pigneur, 2010). The participants of the service design workshops consisted of the key staff members from different organizational departments who found the workshops and the use of design tools highly relevant as it enabled a more efficient communication and dialogue between different departments. No external people participated in the design workshops, even if the authors of this paper suggested that it might be beneficial in terms of outcomes of the workshops to have some customers involved. However, the development of "well-being concept" was interrupted before entering the "prototyping" and "piloting" phases. The main reason for this interruption was the lack of financial resources that were needed for furniture and other equipment investments.

In a similar way, the development of REG's "conference service concept" is an example of incremental renewal of existing services. Also here the desired outcomes were well defined from the beginning of design process – the main objective of the business case was to explore how to make conference services more "mobile" and more "visible" for participants of conferences and meetings organized at REG's facilities. During the "ideation phase", we used several service design methods and tools. The design process started with non-participatory observation of customers and a customer survey during three customer events. The findings from observation and survey were then discussed during the "customer journey" workshop that enabled e.g. to identify a number of new ideas and practical measures not only to improve the quality of service provision, but also to take one step forward on the development of a more "mobile and visible" conference service. These ideas were then developed further on the "prototyping workshop" in which we asked participants (working in small groups) to visualize their ideas by building mock-up models (using play-dough and other crafting materials) and to provide a 3-minute long pitching speech to highlight the most innovative elements of their new "mobile and visible" conference service. As REG only manages and coordinates their conference services (the actual provision of conference related services e.g. catering and technical support is outsourced to several external service providers), REG decided to invite some of their external partners to participate in the workshops. However, even though REG evaluated the service design workshops and tools to be highly valuable for them, we were not able to proceed any further on our design process due to organizational changes within REG.

4.2 Designing for new service platforms

As presented on Table 2, the other two business cases, i.e. SPORT's "The Sport Camp 2.0" and SPA's "Arena Service Platform" are examples of service innovations that are following "Designing for Services" approach suggested by Kimbell (2011). What makes these business cases highly interesting for this study, is that both of them are based on the identified business challenge that the case companies have tried to tackle over the years without any remarkable success. Thus, both companies were interested to see whether our research project was able to provide them with new insights that may help them to overcome the identified problems.

SPORT has organized sport camps for children over the 25 years. However, despite of their reputation and expertise, the number of children participating on these "traditional" sport camps has been declining especially over the last five years. This is partly explained by new entrants and increased (partly subsidised) competition that representatives of SPORT described sometimes even unfair during the "entry phase" discussions. To answer these challenges SPORT has enriched their programme by inviting magicians and famous Finnish athletes to visit the camps, but these incremental improvements have not helped SPORT to increase their attractiveness.

When the design process entered to the "ideation phase", the authors of this paper presented SPORT an initial idea that instead of trying to design a new "sport camp service concept", it could be more relevant to follow Kimbell's (2011) "Designing for Services" approach. Accordingly, we presented a provocative idea of "The Sport Camp 2.0" that was described to serve as an open platform for future children's camps. Even though representatives of SPORT described our "Sport Camp 2.0"-idea to be even too radical for them, SPORT was willing to spend time and money for our common exploratory inquiry. Before entering into the "ideation phase" the representatives of SPORT together with researchers decided on two key principles to be used as a backbone of design process. The first principle was that "Sport Camp 2.0" is going to be built on SPORT's nationally recognised reputation and expertise on sports. Secondly, the new service concepts that are designed to be introduced to the market through the "Sport Camp 2.0" platform should be "hard to duplicate" by nature. Following these two principles we first organized a workshop in which we used several pictures and photographs as metaphors in order to facilitate the generation of new ideas. This approach proved to be successful as pictures allowed participants to provide their own interpretations for the "new services concepts" more openly. Following this, some of the most promising ideas were chosen to be discussed with two focus groups in which the participants consisted of 8-13 year old children (who at the same time participated in one of the sport camps) and sport instructors (who carried out the provision of sport related services in the same camp).

At the end of "ideation phase", one of the service concepts, titled "Gamification", was selected to be discussed further. Nevertheless, it should be noticed that rest of the promising new ideas were not rejected, but merely stored in an "idea repository" to be developed further in the future. However, when process was ready to step into next phase, it became obvious the development of "Gamification" prototype is not possible by using the resources of our research

project. Therefore, SPORT decided, based on the insights and findings of the service design workshops, to build up together with external consultant and some start-ups from Finnish game industry a new “prototyping project” funding application to be submitted to the Ministry of Education and Culture who also promotes small-scaled “cross-cultural” innovation activities in Finland. In this way, SPORT also tried to efficiently diminish the risks related to the development of the first service concept to be included on “Sport Camp 2.0” platform.

Respectively, SPA was interested in to find some new insights and potential solutions on their “wicked problem”. This challenge was related on the problematic four weeks long time period in the middle of the Finnish summer holiday season when SPA’s Arena (a large indoor sports hall located next to SPA’s other buildings) did not have any proper use and thus generated only costs to be covered by incomes from other departments. As described earlier, SPA had tried to overcome this problem e.g. by developing new conference services and taking contacts to potential conference organizers, but with little success. During the “entry phase” discussions with SPA representatives it became clear that some incremental improvements do not provide a sufficient way to tackle this problem. Therefore it was decided also here to follow Kimbell’s (2011) suggestion and start a design process that was aimed to designing for new “Arena Service Platform”.

We started with SPA the “ideation phase” service design activities again by presenting pictures and photographs that were used as metaphors to facilitate discussion for new potential service concepts. However, the main service design method that we used during the “ideation phase” workshops was what we started to call “story building”. As “story telling” (e.g. Gray, 2007) and “story-sharing” (e.g. Lin et al., 2011) are described to encourage and facilitate the development of shared meanings, “story building” is an approach that facilitates shared innovation. The “story building” is based on the careful documentation of key points of discussions after each workshop into a single document. In this particular business case, these workshops were organized regularly approximately once per six weeks over the 16 months time period. Each workshop started with the review of last version of “story building” document that was then updated with new key points. Thus, no ideas were lost and the “story building” – as an iterative, reflective process – also enabled us to refresh and to take into discussions even those ideas for new services/service concepts that were earlier put “aside” for some reason. As a result of this iterative and reflective design process, we were able to generate a number of potential service concepts to be included in the “Arena Service Platform”.

In order to proceed to the next phases of design process, representatives of SPA selected one of the most promising, new to the company service concept, i.e. “PopUp Outlet” to be first prototyped and then piloted in a full scale with real business partners and customers. The basic idea was to open a PopUp retail store in the sports arena during the problematic 4-week period, and to have products from nationally recognized product brands for sale at “outlet”-prices. The intent was that the PopUp Outlet would extend the SPA’s service offering for people lodging at the spa hotel, and also invite and attract people from elsewhere to visit the PopUp and at the same time use the spa’s services. However, this posed a real learning challenge for SPA as none of staff had any prior experience on pop-up and outlet concepts. Moreover, SPA also realised that “PopUp Outlet” concept has the highly attractive to raise the interest of national product brands (the main target group) to participate and to invest their time and money for this trial. However, after intensive fieldwork, benchmarking of existing outlet concepts, several workshops and iterative rounds, the first prototype for “PopUp Outlet” was ready to be presented to the potential business partners. This was considered as a real “acid test” as especially the most important partners, i.e. national product brands do have an extensive amount of experience on outlet-sales and pop-up concepts. Thus, it was assumed that these companies would simply say no if the SPA’s “PopUp Outlet” proposal wasn’t attractive enough for them. And what happened next is highly interesting for this study. Even if some of the initially contacted national product brands did not accept the invitation to participate in SPA’s outlet concept, they actually helped SPA to develop their new service concepts by presenting a detailed list of questions to be answered by SPA. In this way these national brand owners shared some of their knowledge base with SPA. This was an important contribution that helped SPA to finalise the “PopUp Outlet” concept to be ready for full-scale piloting in co-operation with 6 national product brand owners in July 2014.

5 Conclusions

This explorative study was set up to examine and to shed some light on how service design workshops and tools can be utilised in practice as ‘boundary spanning objects’ while developing new, innovative services within SMEs. In order to provide some answer to this question we first carried out a review of existing literature. Building on Carlile (2002; 2004), Bessant et al. (2005), Bessant and Maher (2009), and Kimbell (2011) we then developed and presented a tentative framework to be used as a tool to analyse the empirical data collected from four new service business cases.

The main conclusion of this paper is that service design – at least when carried out with “low-tech SMEs” (den Hertog et al., 2011) like in this study – is better suited for the development of innovations, that are taking place at the pragmatic boundary (Carlile, 2002) and following the “designing for services” approach (Kimbell, 2001). The aim of the following discussion is to justify our conclusion.

Firstly, even if the use of different service design methods and tools proved to be an efficient way to generate a number of new ideas targeted to improve the quality of service provision and to carry out incremental renewal of service offering, the implementation of these ideas may be difficult in practice. As described on Section 4.1, the design process of promising business cases was discontinued due to different managerial reasons. SPORT’s new “well-being service concept” had problems to gather internal funding for the investments that were necessary to take new ideas to be

piloted in the real-life context. Respectively, REG's business case never entered to the "prototyping" or "piloting" phases due to organizational changes causing the loss of managerial support needed to proceed on with the service design process.

On the contrary, the two other analysed business cases described on Section 4.2 were able to avoid the above mentioned widely referred "innovation traps" (e.g. Hamel; Välikangas, 2003) – even if the innovation related risks were much higher due to novelty and complexity of the service concepts. Indeed, the representatives of both case companies were willing to accept the provocative and radical challenge once they recognized the potential benefits of open, "design for services" (Kimbell, 2011) approach. The first benefit relates on the "platform thinking" (this is the term that we used while presenting and discussing with companies during the "entry phase"). This "platform thinking" seems to enable businesses to carry out iterative experimentations with new, promising service concepts and to get some concrete results fast without loosing the business development. For example, it was already decided even before the implementation of the first full-scale trial (piloting of "PopUp Outlet" service concept) that SPA is ready to start a second round of service design process that is aimed to support the development of the "Arena Service Platform". Secondly, when the ambition level of open platform-typed service design is high enough, it seems to make possible to attract external resources to contribute the content development of new service concepts and, furthermore to share innovation related risks. This was recognized to be highly important for the participated case companies. For example, SPORT was able to apply external funding for their "Sport Camp 2.0" platform development, and national brand owners were willing to share some of their knowledge base with SPA that helped them to take their "PopUp Outlet" service concept to be piloted.

However, it should be noticed that "designing for services" and "platform thinking" requires businesses to span across several mental and organizational boundaries starting with a need to redefine what is "the service" in a particular case. That is why we chose to use the term 'boundary spanning objects' because in our mind, this term illustrates the phenomenon better than the term 'boundary objects'. When reflecting the question "what is the service" in discussions with companies during the "entry phase" (cf. Figure 2), the service was defined "something that you first develop, then you put a price tag on it and start to sell it". So, it was natural that businesses were quite confused when they heard about our suggestions to follow a platform approach. They also had to span their organizational boundaries in a completely new ways as described earlier – SPORT was looking for cooperation with game developers and SPA built up new relations with national product brand owners.

We hope that the findings of this study provided several interesting insights to be studied further in future service innovation and service design research.

Proposal of a Technology-Assisted Design Methodology for Employee-Driven Innovation

Kentaro Watanabe, Ken Fukuda, Takuichi Nishimura
National Institute of Advanced Industrial Science and Technology

The role of employees is becoming more important to manage complex service processes and varieties of customer needs in the service industry. To promote employee-driven innovation in service fields, further research on required activities of employees and the technological support for them is necessary. In this paper, the authors propose a technology-assisted design methodology to promote employee-driven innovation based on the literature study. In addition, the authors conducted a case study at an elderly-care facility for its verification.

1 Introduction

The role of employees is becoming more important to manage complex service processes and varieties of customer needs in the service industry. Employees in many of service fields are required to respond to customers and other employees flexibly and autonomously. Their skills and practical knowledge on services are highly important to innovate services.

Employee-driven innovation (EDI) (Høyrup, 2010, Kesting; Ulhøi, 2010) is expected to accelerate the improvement of productivity and quality of services. The role of employees as innovators of their services is gaining attentions not only in the management science but also in other research fields. The design research is one of the research fields which attempt to utilize the capability of employees to innovate services. The common approach of the design research is to clarify the required design activities as methodologies and to support these activities. In addition to the EDI research from the management perspective, the service design approach has a strong potential to provide a means for employees to promote EDI in the service industry. Though the relevance between EDI and service design has been discussed already (Hasu et al., 2011), few studies address the necessity of further studies on service design by employees to promote EDI. Especially, how to support the design activities of employees with information technologies has not been discussed sufficiently. Employees in service fields, especially in small- and medium-sized enterprises are in many cases too busy to reflect their services for innovating them. Their perspectives could be limited in their tasks and that makes it difficult to create affordable and effective ideas for innovation. In addition, innovative ideas tend to be localized in certain units, groups and persons and their potential has not necessarily been maximized. To tackle these issues, the utilization of recent information technologies such as human sensing, behaviour analysis and communication support in employees' design activities could be effective. However, how to integrate these technologies and design activities in an applicable form to service fields has not been established.

In this paper, the authors propose a design methodology assisted by information technologies for employee-driven innovation. The contents of this paper are as follows. In Section 2, the authors explain the result of literature study on employee-driven innovation and service design, and the potential of information technologies to promote EDI. In Section 3, the authors propose a technology-assisted design methodology including its design activities and related technologies. In Section 4, the authors explain a case study of the proposed methodology. In Section 5, the authors discuss the results of the case study, and provide conclusive remarks in Section 6.

2 Literature study

2.1 Employee-driven innovation and service design

First, the authors conducted a literature study of the existing research on employee-driven innovation and service design to clarify their relevance and the required study for service design to promote EDI.

Recently, it has been commonly noticed that the company management is not performed only with the hierarchical and top-down process. Especially for the innovation of services, the role of employees who are familiar with needs of customers and problems in work practice is important. Within this context, employee-driven innovation (Høyrup, 2010; Kesting; Ulhøi, 2010) is gaining attention in service industries. According to Kesting and Ulhøi (2010), EDI is "the generation and implementation of significant new ideas, products and processes originating from a single employee or the joint efforts of two or more employees who are not assigned to this task." Though the research on EDI is rather new, the features and requisites for EDI have been studied through various case studies of business organizations (Rocha, 2010, Teglborg-Lefèvre, 2010). In service industries, healthcare services such as hospitals are common research objects (Telljohann, 2010, Castren; Maijanen, 2013).

EDI can be discussed in relation to the existing theories and methodologies on improving, innovating and designing practices in workplaces. For example, Høyrup pointed out the relevance of EDI to organizational learning or workplace learning (Høyrup, 2010, Høyrup, 2012). Employees attempt to fit their work practices to the confronting service

situations constantly, which is considered as a fundamental learning process for EDI. This process can be considered as an opportunity to improve the employability from the employees' perspective (Høytrup, 2010) and as a source of innovation from the management's perspective. The innovation process by employees can be also explained in comparison with the existing innovation forms such as 'bricolage' that is to manage confronting problems with existing resources at hand and "ad hoc innovation" that refers to a solution to a particular problem posed by a particular client (Fuglsang, 2011, Castren; Maijanen, 2013). To promote EDI, business managers could apply structured approaches such as an incentive system for employees (Teglborg-Lefèvre, 2010) and workshops to gather innovative ideas (Telljohann, 2010). In addition to these mechanisms to promote EDI, some researchers also studied that the personal and cultural aspects of EDI such as the agency of employees toward changing their work practice affect the activities for EDI (Billett, 2012, Brandi; Hasse, 2012). These issues and discussions are closely related to the research on job design (Oldham; Hackman, 2010).

In addition to the aforementioned studies in management science, another trend to innovate services comes from the design research. Service design or the design of services was discussed in the service marketing research also (Shostack, 1984). Meanwhile, recent studies on service design are mainly from the design research. Many of service design studies take human-centered approaches (Stickdorn; Schneider, 2012). The ethnographic study is commonly conducted to understand the stakeholders of target services. As another approach to understand customers, contextual inquiry that is an interview-based field data collection technique (Beyer; Holtzblatt, 1997) is also performed for service design. The empathy for users in design thinking (Brown, 2009) is considered as an important element in service design. In addition, the recent studies on service design rely more on the active participation of employees based on approaches of participatory design (Greenbaum; Kyng, 1991) and co-design (Sanders; Stappers, 2008). Various co-design projects have been conducted especially in healthcare services (Garde; van der Voort, 2013, Sunaga et al., 2014). Furthermore, the autonomous design activities by employees are required to improve the overall productivities of the service industry (Watanabe; Nishimura, 2013).

As can be seen, the concern of service design approaches has become closer to EDI. Meanwhile, there are several differences between these two kinds of studies. Compared to the innovation research from the management perspective, the design research concerns more on its practices to create and realize new ideas from the practitioners' viewpoints. For example, design approaches are more interested in the representation of concepts and ideas. The representation forms are various such as service blueprinting (Shostack, 1984), a miniature of service environments (Garde; van der Voort, 2013) and role-plays named as acting-out (Sunaga, 2009). Through the continuous representation or prototyping, concepts of new services can be evaluated (Stickdorn; Schneider, 2012). In addition to facilitating EDI with management approaches such as incentives and rules, it would be effective to promote EDI by implementing new design activities by employees based on the service design research.

2.2 Why technology-assisted design?

While service design has become closer to the concept of EDI, most of its design activities are still driven by external designers. To make a service design approach employee-driven, its methodological process should be reconsidered.

As has been mentioned, there are two methodological features in service design. One of these features is the understanding of stakeholders and related situations realized by the external observation and analysis. This process should be internalized for an employee-driven design approach. One of the approaches which may replace the external observation is reflection. Reflection is considered as an important process in the existing studies on EDI (Høytrup, 2010, Høytrup, 2012). However, employees' thoughts tend to be limited in their roles and tasks, and it is not necessarily easy for them to understand stakeholders and related situations by reframing their mindsets compared to the design practice by external designers. Further assistance should be considered especially for busy employees.

The other methodological feature of service design is representation. Especially in service design, continuous prototyping (or representation) and evaluation by users are considered as an important process (Stickdorn; Schneider, 2012). How to externalize ideas of employees is rarely discussed in the existing studies on EDI, and this could be an important contribution of the design research to EDI. The externalized design ideas can be used to diffuse design results within the organization. Meanwhile, it is difficult to expect that employees in service fields are good in representation. It is also important how to assist representation by employees in service fields.

In this study, the authors attempt to assist employees' design activities with information technologies. In the existing study on EDI, the methods and tools are considered to take an important role to promote innovative activities by employees (Aasen et al., 2012). There have been several case studies on the application of web-based technologies to collect innovation ideas (Teglborg-Lefèvre, 2010). The research on collective intelligence and Computer-Supported Cooperative Work provides related cases also (Ackerman et al., 2013). However, there have been few studies on further technological assist for EDI except information sharing on innovative ideas. Various technologies to support service design have been developed for example in the field of Service Engineering. Especially, mobile technologies and ubiquitous technologies would be effective to support employees in an ordinary work setting in service fields. These new technologies have a strong potential to enhance the capability of EDI.

2.3 Summary

In this study, the authors suggest how to utilize these information technologies in the service design process as a technology-assisted design methodology. The authors aim at the following goals with this methodology: (1) employee-driven design activities for EDI, (2) technological assistance especially for reflection and representation.

3 Technology-assisted design methodology

3.1 Concept

In this section, the authors explain a technology-assisted design methodology for EDI. Fig. 1 shows the conceptual sketch of the proposed methodology. The authors have suggested a concept of an autonomous and continuous design approach of service processes and systems by the community of employees, named as User-driven Product/Activity Design (UPAD) (Watanabe; Nishimura, 2013). The proposed methodology intends to concretize this design concept.

In this design methodology, a community of employees performs design activities. These activities are supported by business managers and if necessary, outsources such as designers and consultants especially in its start-up process.

Figure 1. Concept sketch of the design methodology.

In this design methodology, the authors define two kinds of spaces as specific situations of employees to be supported with technologies. The first space is “work space.” The work space is an ordinary work setting for employees, and actual service processes and encounters with customers are held in this space. The second space is “design space.” The design space is any kind of situation to reflect and redesign services by employees. It includes not only workshops or formal meetings set for EDI intentionally such as (Teglborg-Lefèvre, 2010, Telljohann, 2010), but also informal meetings or even chats among employees on their specific concerns. These casual occasions in ‘in-line’ activities (Høyrup, 2012) could create new findings and sources of innovation. Design spaces could emerge anytime and anywhere, and it is important to support design activities there.

Related to these spaces, concrete design activities are defined in this methodology. They are described as a design cycle with four phases: observation, analysis, design and application. These phases are determined using the notation of the optimum design loop (AIST, 2008). The optimum design loop was developed as a theoretical process to improve service with a technological approach. The authors convert and concretize this process as a more employee-driven and autonomous design cycle.

3.2 Design phases and support technologies

In this section, the authors explain details of these design phases and required technologies to support design activities in each phase. As Fig. 1 shows, these design phases are not necessarily a one-way process but they could proceed back and forth.

3.2.1 Observation

The understanding of the current status of a service is an important step to redesign it. As has been mentioned, the observation of a service is a common practice in service design. Observation is usually conducted by a third person, but in this methodology, employees themselves mainly observe their own service activities. Therefore, the observation in this methodology means self-observation by employees and mutual observation among employees.

To observe changing situations in a work space is not easy for employees. In addition to the complexity of services, the localized concerns of employees in their own tasks make it difficult to have an overview of their own services (Kesting; Ulhøi, 2010). As technologies to support the observation phase, sensors, observation methods and information devices can be used. In the field of Service Engineering, various methods and tools have been developed to support the observation of services such as a position sensing technology (Makita et al., 2013). Usage logs of systems and tools in work spaces could be utilized also. The obtained data become a source to understand stakeholders and situations in busy daily work. The authors have summarized effective observation and analysis methods by categorizing the patterns of service processes (Watanabe et al., 2013).

Meanwhile, the subjectivity of employees such as concerns, perspectives and feelings affects the performance of services strongly. For the understanding of stakeholders including this subjectivity, the following analysis phase is important.

3.2.2 Analysis

For the deep understanding of services, reflection by employees takes an important role in the research of organizational learning and EDI. The same approach is taken in the analysis phase of the proposed methodology. Design spaces provide opportunities not only to reflect their service practices individually but also to share their perspectives and information to grasp an overview of the current services from multi-dimensional aspects.

For this purpose, the group representation of services is effective. For example, a representation tool to gather employees' perspectives on concerned issues has been proposed (Watanabe et al., 2014). In addition, the observed data could work as potential sources to understand the situations of services. By applying the analytical method to these data, a new viewpoint could be provided for employees in design spaces to indicate a new issue to be discussed. There are also several approaches to analyse and visualize data on service activities. For example, Miwa et al. proposed the statistical and time-series analysis method to visualize the characteristics of service activities (Miwa et al., 2012).

3.2.3 Design

Based on the results of the analysis phase, employees discuss how to change services. The design objects could be service processes, jobs, team arrangement and IT systems used in services. The representation of design objects by employees takes an important role in this design phase also. By representing required situations and how to realize them, employees can concretize their ideas. However, employees in service fields are not necessarily familiar with the representation methods of these design results.

The representation form of the support tool for representation should be flexible enough to represent the employees' mental models (Watanabe et al., 2014). In addition, simple and instant representation is also important for its use by busy employees. By using this kind of tool, representation of concerned issues and design results can be stored. They can be used as a stock of practical knowledge in work spaces.

3.2.4 Application

Represented design results such as new service processes, roles and rules should be disseminated to employees for the application in work spaces. This process has not been discussed sufficiently in the design research and the EDI research. Since the proposed methodology is conducted in an ordinary work setting, the application of its result should be performed with ease by a support of certain technologies.

A communication support system using for example mobile devices can be used for application support. An education system such as an e-learning system would be also a promising technology for this purpose. The applied design results are verified by using newly collected data in work spaces.

4 Case study

4.1 Method

In this paper, the authors introduce a case study related to the proposed methodology.

The field of the case study is an elderly-care facility, Wakoen. Wakoen is a health institute on long-term care for elderly people. The facility contains 3 floors (work spaces) and 150 beds, and approximately 10 employees work on each floor. The authors have been conducting a co-design project with several employees to develop a mobile communication system among employees for an elderly-care service (Watanabe; Nishimura, 2013). In this facility, various kinds of informal information for elderly-care such as requests from a residents' family used to be shared with paper notebooks. This communication system named as DANCE was designed and developed for on-time communication support to replace the notebooks, not for collecting innovative ideas. In addition, this project also aimed at realizing UPAD to promote the employee-driven design activities of service processes and systems used there (Watanabe; Nishimura, 2013). The authors started from the facilitation of a user community which consists of employees. After the continuous prototyping through their active participation, DANCE was deployed and officially used in the facility since Feb. 2014. Approximately 23 devices (iPod touch and iPad) were applied there.

There are two main functions in DANCE (Nishimura et al. 2013). The first function of DANCE is to create and share handover information about care for residents. For the handover of information, texts, photos and voice recording can be used. DANCE can recommend candidates of related message examples based on the stored messages. The name of employees who wrote recommended examples are displayed also to share expertise on communication and care skills. Users of DANCE check messages and search for the handover of a particular person with a few taps by choosing recommended keywords. After checking handover information, users can leave a message as a reply or as additional information with texts and photos. The second function is to check and edit face sheets that are sets of information on each resident. The information in face sheets includes such as dietary, required equipment and how to care for specific occasions. Users can check and modify data on items. They can check the changed history of each item also.

After the deployment of DANCE, the authors conducted the following studies concerning the proposed methodology.

(1) Analysis of the design cycle using DANCE

DANCE is a communication medium to employees and it stores messages sent by them. These messages can be used to understand service situations in the observation phase according to the proposed methodology. In addition, DANCE contains several functions for representation such as the photo function. It would be meaningful to investigate how these functions were used in design activities also.

To confirm how DANCE was used in relation to the proposed design methodology, the authors conducted the following studies. First, the authors conducted semi-structured interviews to a manager and four members who participated in the design of DANCE about the changes of service practices after the system deployment. In addition, the authors analysed how the photo function was used in the elderly-care facility. The data of DANCE used for the analysis were from May 1st to June 11th, 2014. Through these studies, the authors attempted to confirm how employees performed design activities in the design phases and how DANCE was utilized for these purposes.

(2) Workshop based on the analysis of DANCE data

DANCE does not contain the analysis method of obtained data. Therefore, it is difficult to obtain findings on the analysis phase through the aforementioned studies. To clarify the influence of analysis of observed data, the authors conducted a workshop with several employees. In this workshop, the authors showed the results of the co-occurrence network analysis. The co-occurrence network analysis is to figure out frequently used words and their relations and to represent them in a graph form. After seeing this result, the employees reflected their work based on it and redesigned it.

4.2 Result

The result of the case study is shown as follows.

(1) Analysis of the design cycle using DANCE

In the interviews, the following topics were mentioned.

- Utilization of photos for communication

One of the most significant changes after the deployment of DANCE was the utilization of photos for communication. Some of the employees used to add drawings on how to care for certain residents on the notebook. By using the photo function of DANCE, employees were able to understand the situation and to explain how to help eating and how to support the posture of a certain resident more easily.

- Timings to check handover information

The shift from a notebook to a mobile device changes the timings to check handover information. Nurses and physical therapists who work at several work spaces mentioned that it had become easier to check the situations in each work space in advance. They could not bring their devices with them during work usually because of the limited number of the devices, but in comparison to the notebooks which used to be located in each work space, employees were able to check the situations more frequently.

- Awareness of employees who have not read information

Another influence of the deployment of DANCE was that employees who have not read messages were clarified with the read/unread display in the system. How to let all of them read messages had become an issue to be solved for them.

- Sign of issues to be discussed

The interviewees cared the messages sent frequently on the similar contents or on the same resident. This could be a kind of indicator to aware an issue to be discussed in design spaces.

According to the interview results, it was clarified that the photo function was used for design and application of service activities. From the analysis of photos in DANCE, the following usages were observed.

First, it was found out that they wrote down work processes or how to care for a specific resident on paper and sent its photo to the other employees. For example, one worker sent handover information on how to take a resident to a bathroom for several occasions (daytime and night time). The other usage was to indicate important points for care by using an additional drawing function on photos such as how to set a pillow on a bed for the comfort of the resident. From these examples, the design results of service activities were effectively represented.

(2) Workshop based on the analysis of DANCE data

The authors developed co-occurrence networks of DANCE data on some residents about whom workers frequently commented. By showing these networks, several issues were suggested by participants. The authors introduce one of the networks in Fig. 2.

The participants of the workshop focused on major words in the co-occurrence network: ‘visit,’ ‘husband,’ ‘eat’ and ‘without notice.’ These keywords reminded them of messages sent frequently on this resident such as “the husband helped eating without noticing care workers.” This resident related to Fig. 2 had difficulty in swallowing and needed assistance in eating by care staff. However, her husband helped her eating without noticing care staff. This could raise the risk to cause incidents.

After the discussion among employees with different roles, they decided to allow her husband to help eating to the resident only at the dining room considering the demand of her husband. To prevent an incident, they designed their care work which was to adjust the posture of the resident before eating and to tell the husband not to bring other food like snacks. This result was sent to every employee through DANCE. After that, no more messages related to this issue had been sent.

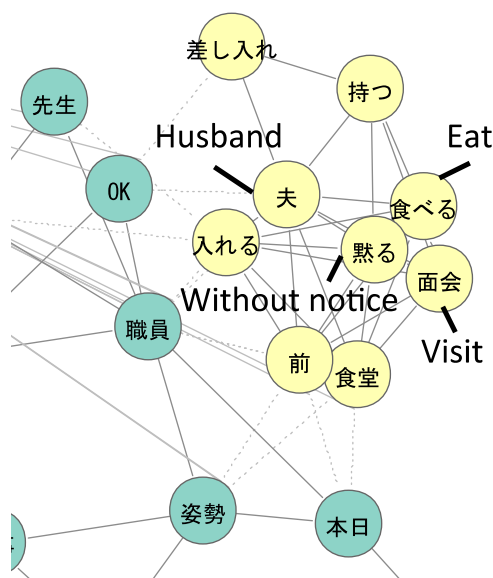

Figure 2. A part of the co-occurrence network of handover information on the resident.

5 Discussion

5.1 About the proposed methodology

According to the results of the case study, the authors discuss how the proposed methodology and the related technologies could work in service fields.

(1) Analysis of the design cycle using DANCE

According to the interviews, the handover information had become shared more fluently with DANCE according to the interview result on the easier access to the information. The visual communication using photos and drawings was used not only for communication but also for design and application of service activities such as how to set a pillow or how to take a resident to the bathroom. These activities by employees can be considered as bricolage (Fuglsang, 2011). In addition, it was clarified that using photos is effective as a means for those who are not accustomed to visual representation. By using DANCE, the representation of redesigned service activities had become easier, and more importantly, the representation result can be immediately sent to every employee though it requires more efforts to have all the employees utilize it.

These results indicate the concrete activities in three phases of the propose methodology: observation, design and application. The communication and representation functions of DANCE were able to support these activities effectively. Meanwhile, the analysis phase was not clearly explained only with the results of the interviews and the

analysis of photos. From the interview result, the frequent messages on the same issue could be the sign to notice the issues to be discussed. This point could be discussed from the workshop result as follows.

(2) Workshop based on the analysis of DANCE data

In the workshop, the co-occurrence network analysis was able to visualize the issues to be discussed, and the extracted keywords were able to remind employees the problems on services. This could be an empirical result on the effectiveness of technological analysis to reflect service practices. In this case study, the authors performed co-occurrence network analysis instead of employees, but this process could be automated by clarifying the effective conditions to visualize issues.

In addition, the effective design result for the resident, family and employees was obtained in this workshop. By discussing among different roles of employees, effective ideas were generated. Though employees have already conducted the autonomous design cycle in this facility, further studies on how to create these design spaces using support technologies are required.

5.2 Future works

In this case study, the authors used only DANCE as a data source for observation and analysis. Meanwhile, there could be various observation and analysis approaches. Further studies are required on the influence of use of other kinds of technologies like sensing devices. In this case study, the application of DANCE is the replacement of the existing media, so there were few adverse effects. But especially when the technologies to collect new data from the service field, its range of application and access to these data should be designed adequately. One of the most important points is that the application of these technologies is determined based on the autonomy of employees. Otherwise, it is difficult to make any kind of approach toward EDI success. The empirical findings from the EDI research on the influence of personalities and organizational culture would be helpful to consider how to implement design approaches for employees successfully.

In this case study, employees represented and utilized design results, but its process was not represented. This decision process in design spaces is important especially when they need to modify or repeal rules. This issue is being studied by using other representation methods such as (Watanabe et al., 2014).

For the verification of the proposed methodology, further case studies are required. The proposed methodology should be evaluated in other kind of service fields, also.

6 Conclusion

In this paper, the authors explored how EDI could be conducted and supported with the design approach. To concretize the EDI process as a design approach, the authors first conducted the literature study on EDI and service design. Based on its result, the authors proposed a technology-assisted design methodology to promote EDI. This methodology includes design activities in the four phases of the design cycle: observation, analysis, design and application, and required technologies for each phase. For the verification of the proposed methodology, the authors conducted a case study at the elderly-care facility where the authors conducted a co-design project to develop the communication system for employees named as DANCE. Through the interviews and the analysis of the data of DANCE, the authors clarified that employees actually conducted design activities in the design phases, especially observation, design and application. In addition, the communication and representation functions of DANCE applied in the service field promoted the employee-driven design activities. The authors confirmed that the analysis of obtained data in DANCE could trigger the reflection of employees in the workshop with them. In the future works, the authors would conduct more case studies with other kinds of technologies to improve the productivity of service industries.

Acknowledgement

We appreciate the sincere support for this study by Wakoen.

Building a Service Productivity Lab: Simulation-based Modelling and Analysis of Service Processes and related Performance Data

Peter Weiß^{1,2}, Andreas Zolnowski¹

¹ITMC, University of Hamburg, ²Weiss4 Business Analytics

The term “service productivity” leads more often to confusion than providing deeper meaning to business and service managers. Service productivity is often perceived as abstract concept and is not linked to resource management, service controlling or business performance management. Presented research aims at developing a SME-oriented service productivity measurement model for industrial services. Conceptual design of our solution approach is presented and relevant solutions concepts are described. The conceptualization of the PROMIDIS service productivity lab, which is currently being developed by a consortium of research partners and companies, is presented. The conceptual frame is developed and research streams are explained. The service productivity lab stimulates learning processes between industry and science. It provides insights into service-based business models operations at build time. In this way designers and practitioners can explore at build time implications on service processes and data requirements concerning supporting ICT systems and infrastructure.

1 Introduction

In manufacturing-oriented and goods-oriented industries the productivity concept is common and widely spread amongst management functions (Jones, 1988, Parasuraman, 2002, 2010). Especially the production and operation field uses productivity concepts to manage its operations (Johnston, Jones, 2004). This research intends to draw from existing research contributions and results. Available approaches are reviewed and synthesized to a software engineering-oriented (Balzert, 2008, pp. 451; Oestereich, 2008, pp. 89) solution design for given application domain. Analysis and design activities (Oestereich 2008, pp. 122 (use case, operations), pp. 134 (vocabulary), pp. 201 (define attributes (class diagrams))) presented are primarily led by software engineering techniques (e.g. object-oriented modelling through UML-models).

In focus of this research are product-related and industrial services rendered through small and medium-sized enterprises (SME). Measuring and improving service productivity in a SME environment (Gebauer et al., 2010) needs a service strategy as prerequisite. All kinds of data can be collected and measured based on existing information systems and performance measurement systems, but remains without meaning or links only in limited way to productivity of service operations. Thus managing and measuring service productivity requires the review and evaluation of existing systems. Target group of this research are SME which typically interact closely with larger corporations either as mere service suppliers (e.g. product-related services (Weiß et al., 2011, Husen, 2007, pp.21; Koch, 2010; FSO, 2011), industrial services) or provider of product-related services supporting the usage of the physical products delivered. Typically, in a product-related context besides core services, enabling and enhancing services are packaged to service offerings (Grönroos, 2007, pp. 187, pp.199). Business processes are an attractive target for productivity measures. Services are produced and consumed as processes. Hence, the process perspective can be seen as imperative because constituting a major characteristic of services (Grönroos, 2007, p. 52). From this understanding “services are processes consisting of activities or a series of activities” (Grönroos, 2007, p. 53).

The remainder of the paper is structured as follows. Firstly, service productivity is overlooked and major concepts and dimensions of a measurement model are briefly reviewed and elicited. Resulting list of design concepts provides a good check list for the later review and evaluation of existing monitoring and measurement systems. In this way gaps can be identified and recommendations for concrete measures can be made. Identified productivity concepts are then further concretized and substantiated. Especially a link to existing performance measurement systems as prevailing in industry is made. In a next step implementation steps of the conceptualized measurement system are outlined. Finally the paper summarizes yielded results and draws final conclusions as well as offering prospects about next steps to be taken and future research tasks and challenges.

2 Objectives

Subsequently, it will be argued that traditional productivity measurements are not responding to specific requirements of industrial services. Hence new ways and approaches are required which have to be based on traditional measurement systems.

Presented research aims at developing a service productivity measurement model for industrial services and elaborates especially on its strategic implications for SMEs (Gebauer et al., 2010, Kowalkowski, 2010). Conceptual design of our solution approach is presented and relevant solutions concepts are described. Today, industry still lacks appropriate systems and techniques to measure, design and manage service productivity. Most companies are lacking an appropriate service strategy which however is mandatory to decide on what should be measured. Often internal

efficiency measures (cost reduction) following traditional techniques from manufacturing and operations management dominate in a real industrial context. In consequence, industrial services are not seen as holistic strategic concept but as complementary element of a company’s offering.

Based on our use case analysis it is assumed that in reality, different maturity levels of service suppliers concerning productivity management can be determined. Some companies are still working on the level of low sophisticated approaches such as document-based procedures (based on office software such as Excel, Access, etc.). Others are operating more sophisticated software infrastructures and IT systems such as ERP, CRM, SCM, procurement systems (Weiß et al., 2011), or business intelligence (BI). Possible scenario can be simulated through modifying design parameters (such as order volumes, idle times, efforts, quality, utilization, costs, etc.). The paper argues how simulation experiments within the productivity lab can be used to gain insights about real life systems at build time. Subsequently architecture and simulation environment are presented as major deliverables including technical concepts (Coloured Petri Nets (CPN) (Jensen, Kristensen, 2009)), Business Process Modeling Notation (BPMN) (Weske, 2007), etc.). Based on conceptualization solution design is supported independently from technologies, platforms, systems or software solutions.

Finally, development of productivity cockpits are designed and developed based on gained insights from run simulation experiments. They can be either based on simple Excel sheets or on full-fledged business intelligence software packages. In the context of SME light-weight solutions and packages are preferred. Agile methods, user-centric design and applications can be seen as crucial success factor for implementing projects. Considering productivity measures and indicators at design time is challenging. The proposed productivity lab integrates referred approaches and fields. Presented dimensions span the solution space. Business process simulation (BPS) can be used to support business process benchmarking and furthermore BPS can be seen as a part of business process improvement (BPI) (Aalst, Stahl, Westergaard, 2013), (Aalst, Stahl, 2011), (Jensen, Kristensen, 2009).

3 Service Productivity

Manufacturers in many industries seek service-led growth beyond their product core. More and more capital goods manufacturing companies (Gebauer et al., 2010) and product-based companies (goods-oriented) strive “to increase their competitiveness by moving towards a service-based business model” (Kindström, 2010). Service research and studies underline that industry is undergoing a substantial change and transformation from mere “transaction-oriented” to more “relational” business interactions (e.g. Vargo and Lusch, 2004, 2011; Grönroos, 2007, pp. 30-43; pp.90-102; pp.145-164). Producer of goods will develop towards operators and solution providers facilitated through the products and services of the own enterprise or combined, joint offerings with business partners. This can be explained with a paradigm shift away from mere “seller-buyer” transactions to “co-creation” and value-in-use paradigms. Multitude of contributions exists (Grönroos, 2007, Teboul, 2006) mainly in the field of service management and marketing and an emerging contribution into the interdisciplinary research field called “service science”. Concepts often referred to in this context are “service-dominant-logic” (Vargo, Lusch, 2004, 2006; Kowalkowski, 2010), “co-creation” (Vargo and Lusch, 2006), “product-service-systems” or “value-in-use”.

3.1 Related Work

Table 1 overviews the results which yielded from our literature review. The table refers to identified approaches which are seen as most influential and appropriate for our research activities. The list is not perceived to be exclusive and listed scholars are rather chosen to represent common approaches to measure service productivity.

This section will not strive for a deeper understanding what is perceived as service businesses, but will repeat and explain some of the essence. Subsequent section aims at the further conceptualization of our measurement approach.

Table 1. Literature Review: Overview of Productivity Approaches and Models.

Author(s)	Productivity Approach and Concepts
Grönroos, Ojasalo (2004)	Service productivity as blend of functional variables: internal efficiency (cost), external efficiency (revenue) and capacity efficiency (demand). Productivity model illustrating three kind of production and consumption processes.
Johnston, Jones (2004)	System-oriented conceptualization of service productivity: Identification of three major subsystems to be looked at: customer productivity, operational productivity and interaction-induced productivity.
Grönroos (2007)	Service encounter and relationship quality, influence of interactive marketing. Service productivity model, measures and metrics. Process-related productivity measurement.

Author(s)	Productivity Approach and Concepts
Parasuraman (2002)	Conceptual framework for understanding the interplay between service quality and productivity. Service quality and boosting service productivity are in conflict. Differentiation of customer and company perspective (inputs and outputs to service process).
Jones (1988)	Model of service operations comprising three stages: productivity, capacity management, quality management. Inputs and intermediate outputs are described. Model differentiates between services and manufactured goods on the basis of time, place, and control of the production.
Vargo, Lusch (2004)	Distinguish the logic of the goods- and service centered views looking at primary unit of exchange, role of goods, role of customers, determination and meaning of value, firm-customer interaction, source of economic growth.

Service businesses (Grönroos, 2007, pp. 30; Husen, 2007, pp. 20, Koch, 2010, pp.8, FSO, 2011, Konradin, 2014, Gebauer et al., 2010) comprehend products or results no longer as mere results or output of the manufacturer’s production process but as input among others into the customer’s value generating process. Produced physical products or outputs are thus resources consumed by the customer to generate revenue or to create value for its own customers. Transforming a manufacturing business into a service business requires “servicizing” (Grönroos, 2007, pp. 444) all elements in customer relationships.

Industrial services encompass all kinds of product-related or supportive services such as industrial maintenance, repair, inspection or renewal services. Industrial services combine technical materials such spare parts, tools with immaterial elements (service-related activities). Husen (2007) sees product-related services accordingly as additional services for the primary product (tangible) and the value created through rendering these services to customers. Typically, product-related services augment the existing offering and support the usage and/or after sales phase of physical products. Examples for excellent product-related services which augment physical product offerings are rendered through Hilti (Hilti, 2014).

3.2 Service Productivity Model

The service productivity model forms one constituent element of presented solution design. Subsequently, pivotal concepts of service productivity measurement are reviewed. Productivity can be seen as an umbrella concept for various ratios such as utilization, efficiency, effectiveness, quality, etc.

Traditional manufacturing-oriented productivity concepts need to be evaluated and partially expanded to fulfil specific requirements for measuring service productivity. Understanding the essence of service operations is a prerequisite for the design of effective measurement tools and solutions. In literature various dimensions are proposed to aggregate (firm or department) or disaggregate (product, service process) service productivity into smaller building blocks and different contexts (e.g. in Jones, 1988, Parasuraman, 2002, Calabrese, 2012).

Service productivity is a complex concept (Jones, 1988, Parasuraman, 2010, Backhaus et al., 2010, Grönroos and Ojasalo, 2004, Johnston and Jones, 2004, Grönroos, 2007) and has been subject to various research initiatives and projects. Interdisciplinary research approaches are required to fully approach and understand service productivity. Many articles and contributions from various research streams have been produced during last years, so that the intention is not to be too repetitive and to discuss all relevant aspects once again. In the following it is rather aimed at summarizing the substrate of available service productivity measures and models (Table 2). It is looked at why traditional or manufacturing-oriented productivity concepts or measures typically fail or lead to unpleasant results in a services context.

Table 2. Impact of Service Productivity Measures: Measurement Concepts.

No.	Concept	Decision area
1	Profitability	Profit, costs, revenues, customer lifetime profit, retention costs, relationship costs (direct, indirect, psychological), production costs, long-term/ short-term sacrifice, customer relationship profitability, internal (cost) efficiency
2	Service quality	Service strategy fit / accuracy, service recovery process, complaints process, non-facturable services quality, customer contacts, repurchasing, cross-selling, retention, customer satisfaction, perceived service quality, value perception, SERVQUAL-determinants/indicators (tangibles, reliability, responsiveness, assurance, empathy), technical / functional quality, design quality, relationship quality

No.	Concept	Decision area
3	Customer	Customer loyalty, customer process, customer perceived value, personal experiences, segments, preferences, usage, behaviour, profile, customer lifecycle, relationship quality, complaints, order history, trust, commitment, benefits (revenue, cost), investment, customer value, volumes, profitability potential, maturity (learning / stage), external (revenue) efficiency
4	Capacity/ demand	Distribution function, arrival rates, customer share, peak times, empowerment, multi-skilling, demand forecast accuracy, customer participation rate / degree, capacity (demand) efficiency
5	Resources	Human resources / employees, physical products / resources (machines, facilities, materials, technology), systems, knowledge, internal relations, availability, service-mindedness, appearance, accessibility
6	Service process	Relationship performance (satisfaction / quality/ value / sacrifice), episode performance (satisfaction / quality / value / sacrifice), zone of tolerance, activity, idle time, resource utilization, waiting time, processing time, throughput time, arrival time, rejection rate, incidents, quality gaps, comparison standards
7	Service offering	Accessibility, interactions, communication, customer participation, core / enabling / enhancing services (and goods), perceived service value (per feature), value quantification of total service offering (total offering benefits)
8	Service encounter	Servicescape, physical dimensions, internal response, performance, spatial context, social and physical interactions, behaviour (customer, employee, systems)
9	Relationship	Customer retention rate, customer relationship quality, customer base, segments, interactions, relationship costs, sacrifice / investments
10	Image / brand	Perceived servicescape, expectations, experience, incidents (activity, episode, relationship), sign, symbols, artifacts, behaviour, social interactions, ambient conditions, brand contacts, communication messages (planned / unplanned), product / service messages, word of mouth, identity, quality gaps
11	Marketing	Promise, expectations, interactive marketing, internal marketing, customer lifecycle, external marketing (marketing P's), direct contacts / messages (initial stage, purchasing process, consumption (usage) process), external marketing fit, employee retention and satisfaction, service culture, internal behaviour, customer orientation, part-time marketers (competences / training / qualification)

In summary Figure 1 illustrates the conceptualization of the service productivity as UML class diagram. It can be as well perceived as information model. Relationships between discussed concepts have been further analysed.

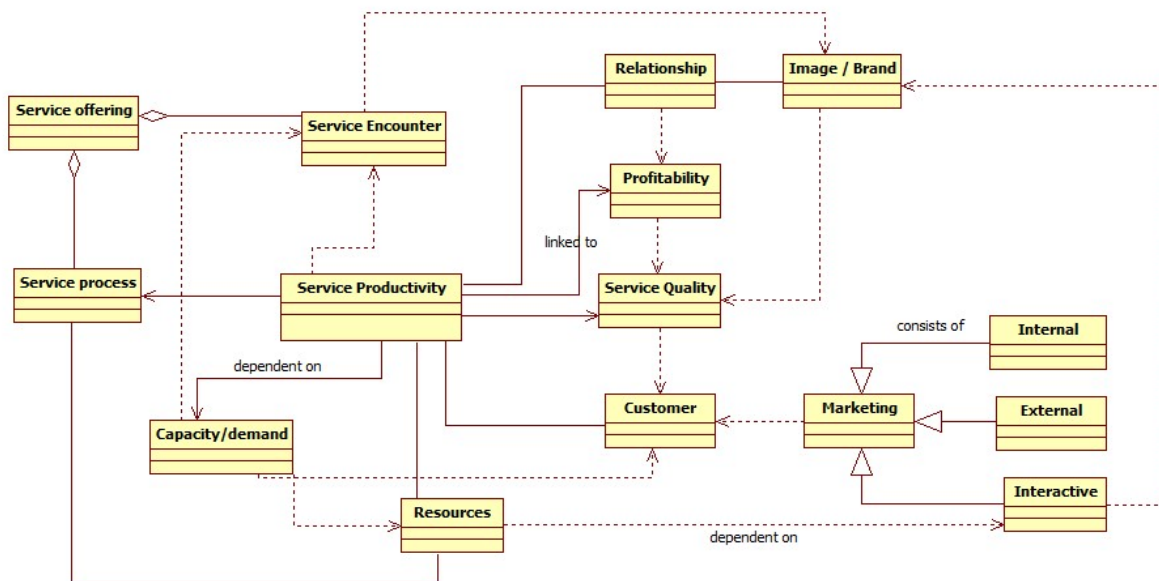

Figure 1. Service Productivity Conceptualization.

As our aim is to develop a software demonstrator software engineering (Oestereich, 2009, pp. 122, Balzert, 2008, pp. 451) techniques and processes are applied. UML (Unified Modeling Language) allows to identify information objects (Oestereich, 2009, pp. 201) which provides the basis for further steps. To give an example, shown class such as “Customer” needs to be further broken down into subclasses through applying generalization and specialization principles. In this way links between requirements (e.g. productivity model dimension) and implementable concepts can be made. Identified relationships and dependencies between the distinct system elements are represented as relationship types. Analysing dependencies and relationships between design elements provides a starting point for later cause-effect analysis and conception of productivity measurements and cockpits. Displayed productivity concepts are respectively mapped to KPI, goals and metrics of performance measurement systems.

3.3 Indicators and Metrics

As already referred to in Table 1 Grönroos and Ojasolo (2004) argue to measure service productivity as function of the variables cost efficiency (internal), revenue efficiency (external) and capacity efficiency (demand, utilization) (Grönroos, Ojasolo, 2004), (Grönroos 2007, p. 255).

As a global productivity measure service productivity measure total revenues in relation to total costs are proposed. In this proposal, “service productivity equals more or less profitability [...] or the economic result of a service operation (Grönroos, 2007, p. 255). In summary, measuring service productivity first of all requires a deeper understanding of service productivity concept and service operations (see as well Johnston and Jones, 2004).

Figure 2. Indicator Library / Catalogue: Information Model (based on Mosimann et al., 2007, further developed).

Quality, productivity and profitability are strongly intertwined and can hardly be separated (Grönroos, 2007, pp. 252, Parasuraman, 2002, Högrevé, 2011). The influence of quality and cost functions on revenue function is seen of importance and is argued to be the core of any service productivity measurement. Often, traditional manufacturing-oriented measures are applied in service operations, what leads to negative or counteracting effects.

Various different measures and indicators can be derived and applied. Effective productivity measurement has to build on both partial and total productivity measures which represent preceding views and factors related to the service productivity concept. Once the services productivity model is designed indicators can be chosen from the indicator library (Figure 2) to specify factors and variables which constitute the measurement model.

Various approaches are available in scientific literature proposing concrete dimensions on which appropriate measurements should be based. Process-based measurement relates mainly to the dimensions proposed by Johnston and Jones (2004) and Grönroos and Ojasolo (2004). The latter argues that on the highest aggregation level only financial measures, namely revenues-cost-ratio, and profitability, are to be considered. In service, productivity and profitability merge. Service productivity can be defined as function of the variables internal (cost efficiency), external (effectiveness or revenue efficiency) and capacity (demand efficiency or utilization) efficiency (Grönroos, Ojasolo, 2004):

$$f(\text{internal efficiency, external efficiency, capacity efficiency})$$

According to this perspective, productivity measurement needs to be seen as a blend of the three variables. Johnston and Jones (2004) argue to distinguish an operational and customer perspective to capture service productivity. In this way, inputs and resources brought into the transformation process through the customer are taken into account. A possible classification of service productivity measures is illustrated in Figure . Hartigh and Zegveld (2011) propose total factor productivity (TFP) as appropriate measure based on customer value (output) divided by employee and capital inputs.

Distinguishing between partial and total productivity measures appears to be most appropriate as it allows to link to respective hierarchies (modules) as applied in executable simulation and business process models.

Table 3 summarizes a proposal of Ojasalo (1999) which can be found in Grönroos (2007, p. 255) how service productivity can be approached by differentiating between physical, financial measures and/or by a combination of both.

Table 3. Service Productivity Measures (Ojasalo, 1999 in Grönroos, 2007, p.255).

	Physical measures	Financial measures	Combined measures
Partial productivity <i>(output/one input)</i>	e.g. $\frac{\text{customer served}}{\text{employee hours}}$	e.g. $\frac{\text{revenues}}{\text{labour costs}}$	e.g. $\frac{\text{revenues}}{\text{number of employees}}$
Total productivity	e.g. $\frac{\text{customer served}}{\text{total resources}}$	e.g. $\frac{\text{revenues}}{\text{cost of resources}}$	e.g. $\frac{\text{revenues}}{\text{level of resources}}$

A sound analysis of service operations necessitates selecting appropriate indicators based on partial productivity measures. Total productivity measures should address merely service quality and profitability (Grönroos and Ojasalo, 2004), (Johnston, Jones, 2004). In real practice, plenty of performance measures and indicators are available (Mosimann et al.,2007, Kimball and Ross, 2013). The prioritisation and selection of indicators and measures which show significant influence on service operations and processes can be seen as major challenge. Grönroos (2007) provides a good start and makes concrete suggestions how measures and indicators are interrelated as well how they can be prioritized in a measurement approach (Grönroos, 2007, p. 253).

The service productivity model has been already addressed extensively during previous sections. Next business process modelling will be further addressed and explained. The link and its potential contribution to service productivity measurement will be discussed. In subsequent sections performance measurement and the indicator system as core an implementation tasks are looked into. Then the interrelationships and relevance with regard to previously introduced concepts will be highlighted and explained.

3.4 Service Process Modeling

A detailed analysis of the business processes starts with reference process modeling in order to realize mayor differences and discrepancies of process instances of selected use cases. Use cases hence are an appropriate starting point of the process analysis (Oestereich, 2009, pp. 122), because complexity of analysis can be reduced through clarifying what should be regarded as part of the analysis and what can be seen as located outside the frame of analysis. In this way, partial productivity analysis can be carried out without the risk to overload the analysis activity with too many indicators and metrics.

The reference process model (Figure 3) defines typical collaborative interfaces between con-tractors and ordering parties (eBusInstand, 2011, Weiß et al., 2011). The reference process yielded from a detailed analysis of use cases. Business processes were analysed, media breaks were marked and scrutinized, redundant activities like repeated manual input of business data in company’s IT-system were identified.

Figure 3. Service Reference Process Modeling.

Next level of analysis takes focus on business documents which refers to a outcome-oriented perspective (see Figure 4). Analysis of business documents (business objects) aims at better understanding of information flows in the industrial service network. Existing interfaces yield additional information concerning the nature of interactions between customer and supplier as well between supplier and its subcontractors or partners. The interfaces are connecting the various underlying IT-systems. Hence information and data flows were analysed in depth.

Both internal and company-wide processes were assessed to measure processing time of transactions and processes, total cycle time for processing service orders and required amount of man-hours and days. Finally, the results of analysis of realized measurement leads to re-engineering of value or business processes which need to be accompanied by an appropriate change management to achieve required sustainability (Herfurth, Schuster, Weiß, 2013, Weiß et al., 2011).

Following a service strategy puts the customer process more and more in focus. Thus collaborative modelling of business processes is appealing to analyse the nature of interactions between customer and supplier. In this way, interactions are systematically understood and the supplier is able to lower costs of “being a customer”. Furthermore collaborative modelling allows studying the customer process in greater detail and reflects the need to see that what is delivered to the customer as input to the customer revenue creating processes.

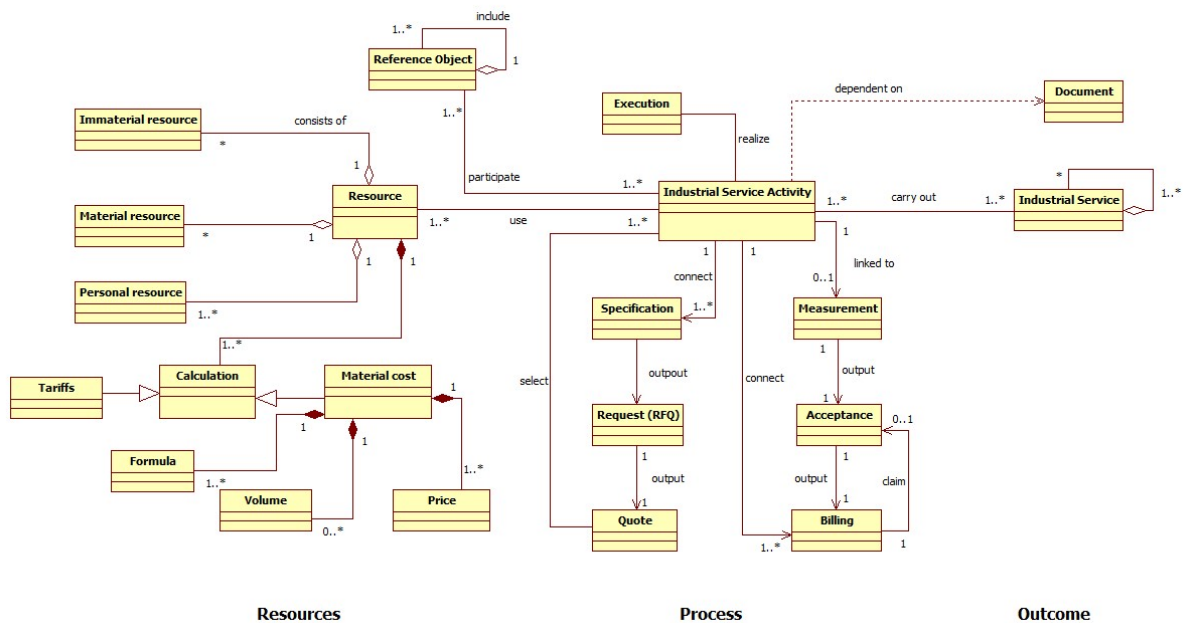

Figure 4. Industrial Service: Resource Model.

Interactions with customer yield to insights into how the value and revenue generating capabilities of a customer can be leveraged. Understanding the customer processes and what the customer intends and actually does with the offering is important.

3.5 Resource Model

Service productivity measurements relate to respective resource models. Process-based measurements describe process resources in a separate resource model (Figure 4). Resource models (see e.g. Grönroos, 2007, pp. 374, van der Aalst, van Hees, 2002, pp. 78) are the basis for capacity planning and to analyse capacity requirements of service processes.

Especially simulation-based analysis can develop a better understanding how resources are used by the various process activities. Three dimensions are distinguished: resources, process and outcome. Simulation experiments (van der Aalst et al., 2013, Jensen and Kristensen, 2009, pp. 273, van der Aalst, Stahl, 2011, pp. 287) can highlight process-based performance indicators such as average processing time, average completion time, average waiting time, throughput time, average number of cases handled, as well as providing insights concerning resulting effects of service strategies and reconfiguration of service encounters.

3.6 Simulation-based Analysis

Simulation aims at creating executable models (such as Colored Petri Nets (CPN)) (Jensen, Kristensen, 2009; Aalst, Stahl, 2011) which represent system behaviour and interactions between system elements in correspondence with systems behaviour in reality. Often modelling is used to reason or plan systems. However, simulation offers further insights and deeper understanding of systems behaviour. Experiments are run to explore and understand how the system needs to be designed to fulfil respective requirements. Our objective is to use this technique in order to design and improve service processes. Consumed and used resources by service processes are monitored. Furthermore, it is aimed at measuring service productivity which is a complex concept composed of various dimensions and variables. Subsequently, a simulation environment called simulation lab is developed. First step requires identifying constituting elements as fundamental building blocks. These concepts are transferred into implementable concepts.

The simulation approach reveals possible improvements and indicates the potential future effectiveness of service processes. Measured performance indicators (e.g. processing and throughput time) of inspected service processes support the results of our simulation-based analysis. Yielding deliverable is an indicator catalogue. While theoretical contributions concerning service productivity are manifold and exhaustive, the implementation of solutions tailored to the needs of enterprises is still challenging. Especially, small and medium-sized enterprises (SME) require solutions, which are flexible and tailored to their needs (Weiß et al., 2011). For this, the paper proposes a productivity measurement model linked with selected indicators (taken from the indicator catalogue) (Figure 2).

The challenge is to take on board individual needs and requirements while not neglecting the need to cohere to industrial standards. Simulation-based modelling and analysis supports co-creating services processes together with customers and business partners at an early stage of development. In this way, negative side effects are prevented and expectations aligned. Cost savings through less corrections thus preventing later re-engineering are argued.

The aim was to model the regarded service processes (taken from selected use cases) as close to reality as possible. In an iterative and incremental process additional information and details were added complementing the model step by step together with users. Regular process talks, workshops and consultation of users are a pivotal element of this way of analysis.

Service processes are modelled using business process representation language BPMN (Business Process Modeling Notation) (as shown in Figure 3) (Weske, 2007, pp. 205–225, Havey, 2005, pp. 143). Modeling software and tools based on BPMN are addressing simulation and typically offer rudimentary to advanced simulation capabilities. However, these tools are either expensive or are only covering some basic partly advanced functionalities (e.g. Tibco Business Suite).

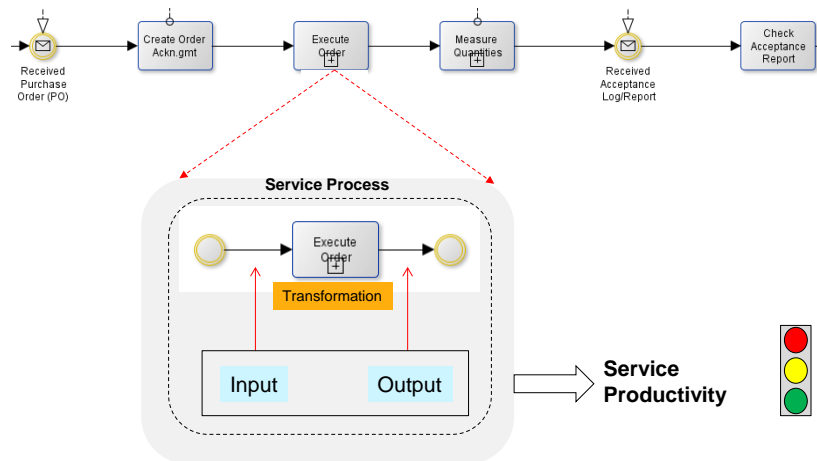

Figure 5. Process-based Productivity Measurement.

Often simulation-based modelling requires adhering to some specific modelling conventions, such as using places are not allowed or only some specific control flow nodes and patterns are supported by the simulation engine. Nevertheless, after some practicing and studying of respective modelling conventions, simulation is well supported (Jensen and Kristensen, 2009, pp. 273, van der Aalst, Stahl, 2011, pp. 293). Distribution functions determine probabilities of control nodes and number of tokens in the system. However, only standard performance indicators such as throughput time, idle time, waiting time, utilization etc. are automatically applied and displayed in standardised simulation reports. In this way, capacity efficiency can be analysed and the behaviour of the system can be studied using simple experiments.

Simulation conventions and modelling is not BPMN-specific which means that using a different software tool requires adaptations of existing models to reflect diverging modelling conventions and concepts. Hence, BPMN-based modelling software and tools try to overcome this shortcoming by translating BPMN-models into BPEL (Business Process Execution Language). BPEL is in general interpretable through workflow engines (Havey, 2005, pp. 143, pp. 103).

In summary, BPMN constitutes in an industrial context a powerful mean, as it represents a modelling language or representation which is broadly accepted and known in industrial settings. Introducing new representations and language requires efforts and it is not granted that these efforts might yield fruitful results. Based on the authors experience formal modelling techniques or unknown modelling languages to the users provoke resistance and necessitate considerable change management efforts. As a consequence communication between involved actors gets limited and distracted. Valuable information and knowledge will be hence not accessible or lost as users neglect to contribute only in a limited way if at all to respective processes and project tasks.

Another limitation refers to the fact that modelling of cases or tokens is not or only partially supported. This means that so called business objects can be modelled as data structures or models, but cannot be distinguished in the simulation models by their properties. Techniques as prioritization, time stamps, or complex token structures (such as compounds of data elements, or tuples (Cartesian products)) are not or only rudimentarily supported (van der Aalst et al., 2013).

4 Simulation-based Modelling

Colored petri nets (CPN) (Jensen, Kristensen, 2009, van der Aalst, Stahl, 2011, pp. –169–204) offer free sophisticated tools and required formal foundations to set up an simulation lab environment (van der Aalst et al., 2013). Furthermore, the organizational view supports to allocate resources and roles to single service activities. Performance indicators can be aggregated or disaggregated in relation to the hierarchical structure of the process model. Resources can be adequately described, configured and analyzed (Jensen, Kristensen, 2009, pp. 95–125, van der Aalst; Stahl, 2010, p. 281-299).

Presented approach foresees to extract business process models from selected use cases. Industrial services provide the application context. As a result business process models are modeled in BPMN notation as high level analysis (Havey, 2005, pp. 145). According to Havey (2005) BPMN develops its strength “as a graphical flowchart-like language intended for use by business analysts and developers to build business process diagrams” (Havey, 2005, p. 145). A reference business process model eases the modeling task, as it contributes the overall control flow and business logic. In this way, business vocabulary as well as a list business objects (documents) are already defined and available. Together with the industrial partners, business process models are adapted and described in further detail. For this purpose hierarchical modeling is applied.

Transforming business process models (represented in BPMN) into executable models requires first of all the mapping of modeling artefacts and concepts. As already described a top-down approach is followed. Empirical data is gathered during this phase and is used to set up simulation experiments (van der Aalst et al., 2013). For this purpose, more formalized notations (such as coloured petri net) are needed which allow to specify control flow conditions

(transition (guards) and arc inscriptions) as well as place types (business objects and data types) (van der Aalst, Stahl, 2011, pp. 171).

In first step simple simulation experiments are conducted to estimate process cost, resource utilization, idle times, processing times per task, project phase and in total. Next step in planning and preparing of simulation experiments requires constructing appropriate simulation models. Modelling formalism and tools need to support this task. Decisions have to be made concerning which simulation environment and software should be used and in best way support desired outcome. Simulation modelling encompasses analysing respective control flows and resources consumed or used by the service process. Service processes can be very complex, thus views are applied to reduce complexity by focusing on specific modelling aspects such as control flow, functions, data, process hierarchy, organisation and time, etc.

A multitude of different software and tools exists which propose various ways and approaches how business processes best can be modelled. Typically such software tools cover previously mentioned views and concepts. Typically, communities of practice have emerged and have built considerable knowledge and best practices around these modelling software and tools. In this way, plenty of design patterns and solution designs are available for most of the typically occurring problems in systems and business process modelling as well as for the development of simulation experiments. However not all software tools support the design of executable models.

Executable models require formalisms and sound mathematical foundations which often lead to kind of disconnect and distraction of users and modellers in a modelling project. Thus, formalisms are best kept in the back office and are not applied at front stage interacting with end users and stakeholders. Starting point of modelling projects are hence use cases which are best selected together with the various stakeholders and respective end users. Criteria for classifying and selecting uses cases are volume, frequency, relevance, impact, importance (strategic and operational), improvement potential, complexity, etc.

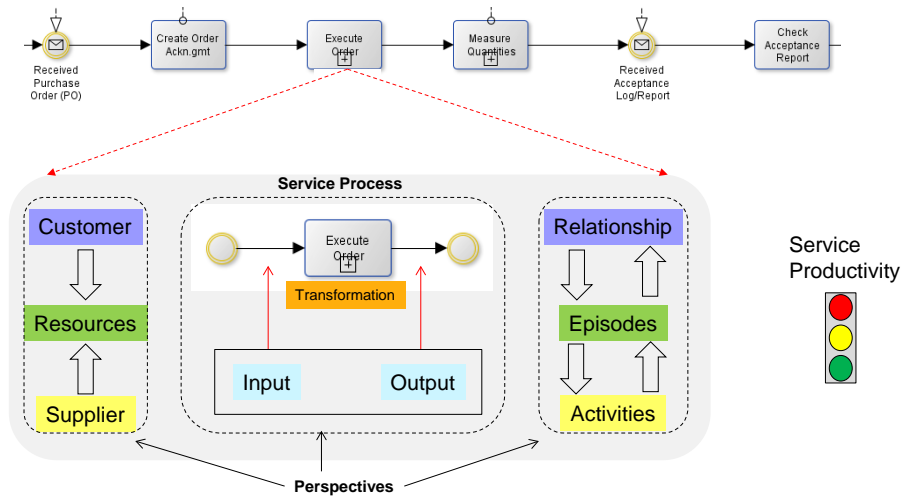

Figure 6. Service Productivity Modeling: Constructing Simulation Models.

In a first step, only standard performance indicators are used such as time, capacity (typically simple counters linked to places or transitions). One strength of CPN tools is that they can be used free of charge. Modelling conventions are as well proprietary; however, applied concepts here are CPN-specific and are generally portable and not tool-specific. This overcomes one limitation of BPMN-based tools.

Subsequently, Coloured Petri Nets (CPN) are not introduced in further detail (interested readers are referred to (Jensen and Kristensen, 2009, van der Aalst et al., 2013, van der Aalst, 2011, pp. 169–247). At this conceptual design stage it is sufficient to outline their potential contribution to create formal and expressive simulation environment. For our research on simulation models in the context of service productivity measurement, CPN offers an appropriate simulation environment. They will be used to construct simulation models and run detailed analysis on basis of this representation.

Finally, in the last section a brief overview and introduction to information and data analysis and visualization is provided. Data visualization tools serve as major user interface and support decision-making processes in real practice (design and run time).

5 Analysis and Visualisation

Controlling tools for measuring service productivity need to consider process-based and performance based indicators.

Business Intelligence (Kimball and Ross, 2013, Garcia and Harmsen, 2012) considers aspects of visualisation of service performance. Service performance will be monitored and visualised by productivity management cockpits. Business Process Management as further component considers and analysis possible service processes, management and modelling tools, which can be recommended and are applicable for a holistic service productivity model. Furthermore, Performance Measurement System as third component supports companies to select appropriate

performance indicators (van der Aalst et al., 2013, van der Aalst, Stahl, 2011, pp. 287). In this way individual solutions can be realized based on modules from a shared service productivity reference framework. Indicators are selected according to user preferences and given application scenario.

Classification of operational, financial and customer indicators supports to choose best possible indicators from the catalogue of indicators (Figure 2). The design of data visualization software needs to reflect besides the applied service productivity model concepts as well strategic elements such as addressed by Balanced Scorecard designs. It defines applied measurement logic. Basis of the Service Productivity Model are the above mentioned four components and their content. To build process-oriented service productivity models key elements and concepts such as delivered through the Balanced Scorecard have to be added and considered if relevant. BSC constitutes one interesting avenue to design and develop our controlling tools measuring and monitoring service productivity. Results of simulation experiments have to be as well integrated in our solution design. Controlling tools need to support process-related analysis and results of simulation experiments need to be visualised to the users.

The industrial service productivity model determines at that level the possible range of operational measures and requirements which are necessary to enhance service productivity. Core aspects are here an exact definition of company aims as well as the redefinition and adaption of new objectives. Second stage contains the above mentioned importance of sub classification of indicators in key performance indicators.

With the support of the indicator catalogue (Figure 2) it is now easier to determine the relevant key performance indicators and to evaluate measure and describe courses of action. Key outcomes of that stage are the differentiation and systematization of performance criteria and target fields and an identification of key performance indicators for characterizing and ascertainment of input and output effects on the different service processes. Third stage considers with support of the Balanced Scorecard significant requirements of the company strategy which can be used for a holistic management strategy to increase service productivity. Central research questions of that stage will include questions about the service productivity strategy of the company, criteria and objectives of the balanced Scorecard and direct links or related effects which can be expected between possible objectives. Visualization and data analysis can be realized based on data warehouse solutions as well as business intelligence software solutions and tools (Kimball and Ross, 2013).

Besides Open Source tools which are attractive for the targeted domain of SMEs, commercial software as Qlikview (Garcia and Harmsen, 2012) with its associative query technology offers an attractive solution concept for SMEs. Software tools implementing productivity measurement have to be created on top of existing infrastructure and software. As respective ETL-processes are flexible and data integration interfaces are adaptable, it is possible to create individual productivity measurement solutions for nearly every application domain and context.

Furthermore, concepts as the Balanced Scorecard can be used to point out relevant key performance indicators and to align operational and strategic perspectives. BSC supports in best way strategy orientated aims and to decide on appropriate measures as well as to define measurable goals and indicators to continuously monitor achievements. Solution design requires to answer questions concerning reporting and analysis. BI design typically follows a DAR approach (dashboard, analysis, reporting) which addresses all required functionality for a productivity cockpit.

6 Summary and Conclusions

Presented research aimed at developing a SME-oriented service productivity measurement model for industrial services. Conceptual design of our solution approach was presented and relevant solutions concepts were described.

Today, industry still lacks appropriate systems and techniques to measure, design and manage service productivity. Most commonly, service productivity is perceived as being complex and is not associated by service and business managers with related measurement concepts of implemented performance measurement systems. Most severely, if service productivity is measured and monitored without aligning company's strategy and marketing activities to follow the service logic, in the long term initiatives to leverage service productivity will probably fail. Often traditional techniques from manufacturing and operations management dominate available solution concepts. In consequence, deeper understanding of service operations and its imperative on company's operations and offerings need to be explored and need to be understood by decision makers.

First step of developing a service productivity model will be the identification of relevant elements or components, which are mandatory for measuring and evaluating service productivity. Given application domain is industrial services. We presented a first solution design based on a conceptual model, which includes relevant components for designing, monitoring and improving service productivity. A systematic approach is presented aiming at classifying performance indicators for service operations. Solutions concepts need to be linked to existing monitoring and controlling tools. However, redesign of measurement models might be mandatory to align company's operations and revenue generation to the service logic. Next step of our research foresees to concretize the measurement approach and to implement discussed service productivity concepts in a SME application context. Use cases will allow us to evaluate presented conceptualization of the solution approach. Design elements will flow into software demonstrators. Furthermore, simulation-based modelling and analysis will be further elaborated. Based on presented business processes executable process models will be created. Simulation experiments will be further looked into in order to demonstrate added value for SMEs to support decision making at design time.

The political embeddedness of public service innovation driven by networked ubiquitous technologies: the case of 3rd generation public bike sharing schemes in Sweden and China

Xiangxuan Xu²⁵⁶
 University of Gothenburg

One driver of the recent innovations in public services is the advancement of networked ubiquitous technologies, which significantly lowered the marginal cost of public services that previously were too costly or impossible to provide (Gardner et al.,2007). Political actors from the public sectors are usually involved during the process due to its public good character. By using the case of 3rd generation public bike sharing schemes in Sweden and China, this paper shows that political embeddedness might be one of the impact factors to diverge the business models even when the technologies are almost identical. The political embeddedness is not the only factor that has influences on the business models of public service innovation driven by networked ubiquitous technologies, but its role has been so far neglected in social innovation literatures. This paper argues that the political embeddedness perspective is an important variable to understand the holistic picture especially when it comes to the cases from a country where the market economy is not mature. The comparison between the public bike sharing schemes in Gothenburg Sweden and Hangzhou China shows that the difference in political embeddedness lies in the existence of semi-public authority and the state-owned companies as actors. And such difference has impacted the choice of the operator, the ownership structure, financing method and the policy design in the business model.

Key words: Public service innovation, social innovation, political embeddedness, networked ubiquitous technologies

Introduction

This paper discusses the influence of political embeddedness of public service on business model formation during the social innovation process driven by networked ubiquitous technologies. Social innovation in service research has gained increasing interests as many innovations in public services are providing "public goods" or semi "public goods" in the fields where one would assume innovation deficits in the pure market economy situation (Pol and Ville, 2009; Pol et al.,2007). The rise of social innovation and the adoption of new technologies are two driving forces to turn such deficits into the Promised Land for innovators.

Social innovation per se is a process of creating new solutions for the "public good" (Centre for Social Innovation, 2008), which differentiates it from the pure business innovation. Many business innovations do contribute to the society in a positive way as a result but that is not mandatory in the primary purpose. Social innovation often requires a sustainable business model that is either profit or non-profit, but to seek solutions for societal challenges are of the primary vision. The difference at the starting point might cause distinctions on its innovation process, especially in the public service domain where due to its public good character; political actors from the public sectors are more or less involved in developing these types of new services. The formation of the business model is a crucial part of diffusion and scaling up during the social innovation process. Therefore to understand the political embeddedness of developing public services is contributing to the holistic understanding of social innovation process.

The business models of social innovation vary in countless forms under different contexts. This paper is not aiming to generalize a model for all, but to raise the attention of studies on the influence of political embeddedness to the business model formation in public services by discussing a specific case, which has the technology and the political embeddedness contexts. The case shows that for implementing the same type of technology, the business model is different, and the different types of political embeddedness is one of those influencing factors.

On the technology context, one driver of the recent innovations in public services (such as eHealth and eGovernance) is the advancement of networked ubiquitous technologies, which significantly lowered the marginal cost of public services or goods that previously were too costly to provide (Gardner et al.,2007). On the other hand, networked ubiquitous technologies are driving the rise of shared economy or collaborative economy that promotes more efficient uses of resources among people; therefore many of these applications are contributing to tackle society challenges. This paper uses one of the most widely spread networked technology applications in the world - the 3rd generation public bike sharing scheme as a comparative case study.

Public bike sharing is neither a new idea, nor a new practice. Prior attempts could not sustain and scaled up as the systems were not efficient enough to balance the costs on operation in large scale. According to DeMaio's interview to

²⁵⁶ Centre for International Business Studies, School of Economics, Business and Law/Centre for European Research University of Gothenburg. P.O Box 610, Vasagatan 1, 405 30 Gothenburg, Sweden. E-mail: emily.xu@handels.gu.se

Schimmelpennick (DeMaio, 2009), the 1st generation could be traced back to the July of 1965 in Amsterdam, where ordinary bikes painted in white for public usage. People were free to borrow a bike and leave it for the next user when they reached the destination. There were no fees, no tracking of usage and no stations. The project collapsed in just a few days with many bikes ended up in canals or being stolen. Since early 1990s, the 2nd generation public bike sharing projects have emerged in Denmark, first with a small scale at Farsø, Grenå and Nakskov (26 bikes and 4 stations), and then a big installation in Copenhagen (Nielse, 1993). The 2nd generation was improved by setting up stations with a coin deposit system at the city center and specially designed bikes for intensive usage as well as advertising spaces. The system was operated by a non-profit organization. However due to the anonymity of users, it experienced thefts. The 3rd generation public bike sharing scheme is Information and Communication Technology (ICT) enabled, self-service, short-term, one-way-capable bike rental offer in public spaces, for several target groups, with network characteristics (OBIS, 2011). It is smartened with a variety of technologies such as electronically-locking racks, telecommunication systems, smartcards and mobile phone access, and on-board computers (DeMaio, 2009). All of these new features that are driven by networked technologies made it possible to operate at a large scale with a manageable cost. Velo'v in Lyon is not the first but perhaps the first one that made it noticeable. It is operated by outdoor advertising company JCDecaux with 1500 bikes. In 2007 Paris took the idea and made a huge success. The scheme is called Vélib', starting from 7000 bikes and expanded to 23,600 in central and suburbs. Since then the 3rd generation took off and disseminated rapidly around the world (Optimising Bike Sharing in European Cities, 2009). By April 2013, there were estimated 535 schemes with 517,000 bicycles worldwide, in 49 countries (Larsen, 2013).

This paper chooses two of them: The Hangzhou scheme in China and the Gothenburg Scheme in Sweden. These two schemes represent the common business models respectively in China and Sweden with different types of political embeddedness. The technologies that are adopted are almost of no fundamental difference but the business models differ.

This paper is structured as follows. After the introduction, section 1 frames the theories and concepts that are related to the empirical discussion. Section 2 discusses the methods and data collection. Section 3 describes the different business models of the 3rd generation public bike sharing schemes in Gothenburg and Hangzhou, while Section 4 discusses the influence of political embeddedness from such comparison. This paper ends with a reflective remark.

1 Theoretical framework

1.1 The social innovation process and the business model

Business model is to capture the value of innovation (Chesbrough and Rosenbloom, 2002) so that it can be diffused, scaled up and sustained. The process of social innovation often follows four stages: 1) idea generating by understanding the social needs and identifying potential solutions; 2) Prototyping and piloting ideas; 3) assessing, scaling up and diffusing good ideas; 4) learning and evolving (Mulgan, 2006). A good business model is crucial for the good ideas or good solutions to diffuse, and a sustainable business model requires continuous learning and evolving. The social innovation process is distinguished from pure business innovation process by starting with understanding the social needs and identifying solutions. As such distinction lies much on the definition and characters of social innovation, it is necessary to investigate from its definition.

There is little doubt on why the society shall not opt for social innovation, but its concept varies at the meanings and in practice. However it is not impossible to find some common ground. In general it can be understood as new solutions to meet social goals (Mulgan, 2006; Mulgan et al., 2007). The Young Foundation defined it as "*innovation activities and services that are motivated by the goal of meeting a social need and that are predominantly developed and diffused through organizations whose primary purpose is social.*" In this more narrowed version, the character of "social purpose" is emphasized. European Commission launched a guide book for social innovation in 2013, which raised the attention on its systematic character as social innovation creates "new social relationships or collaboration" (European Commission, 2013:6). Pol and Ville (2009) reviewed its concepts from various sources and organizations and categorized those into 4 groups. One is as mentioned earlier that is related to social purposes that is linked to improve the quality of life. The second has an emphasis on the "public good" that is related to system-changing. The third one attempts to draw a line between social innovation and business innovation, which defines social innovation as needs ignored on the market (Forum on Social Innovation, 2000). The other concept is proposed by Heiscale (2007) which links to institutional change in cultural, normative and regulative structures. Pol and Ville (2009) argued that the importance of the "practice" character of social innovation by concluding that "the term social innovation is of great importance when its empirical meaning is distilled". Moreover they also argued that government has a role to play in a subset of social innovation (they defined it as pure social innovation) because "the free market economy will not produce the socially optimal amount of pure social innovations".

Therefore the concept of social innovation in public services is often characterized by some sort of social purposes, with a systematic and practices in its nature and with the involvement of the government. These three characters indicate that the business model of such practice is: 1) led by a certain social purpose as the primary driving force; 2) context-specific due to the systematic and practice nature; 3) involved with multiple actors from public and private sectors. For public service innovation where public goods or semi-public goods are supposed to deliver, there is a role

of the government to play when the market itself will not produce the socially optimal amount of pure social innovations.

1.2 The political embeddedness of social innovation in public services

The public-private partnership is perhaps common to use in public service research. However in this case, the scheme from China involves state-owned companies and semi-public authorities, where the boundaries of the public and private isn't that clear as the Chinese economy is undergoing the transformation from a former communist planning economy to a market economy. Therefore the political embeddedness perspective suits better to discuss the case.

The term political embeddedness is used in international business research and management research, which means "a specific form of social embeddedness characterized by a mix of formal and informal ties with political agents" (Granovetter, 1985; Grabher and Stark, 1997 in Krug, 2012). It often refers the connections to the government or state-owned resources, as well as the influence on policies (Okhmatovskiy, 2010). In the contemporary Chinese context, empirical studies show the general pattern of close relationships between firms and the state, where political embeddedness "turns local government agencies into market players, as they are directly involved in market transactions instead of being the representatives and executors of formal institutions" (Krug, 2012). Not only in the Chinese market, the involvement of the government and public authorities in developing public services is self-evident due to its public goods character. There might be different types of how it is involved in the roles and responsibilities, ownership structures, financing methods, contracting, policy making and many other related aspects which are influencing the formation of business models for social innovation in public services. The influences are not necessarily always positive, and the political embeddedness perspective provides a way to look at both sides.

In this paper, the political embeddedness is reflected in the actors who are public authorities, state-owned companies or semi-public authorities, and their roles and responsibilities in implementing the 3rd generation public bike sharing schemes.

1.3 The business model of 3rd generation public bike sharing scheme as social innovation

The 3rd generation public bike sharing scheme can be understood as a semi-public services social innovation driven by networked ubiquitous technologies, which is provided by the collaboration of the public and private actors, or actors who are semi-public.

The 3rd generation public bike sharing scheme in Gothenburg-- Styr&Ställ was initiated by the municipality and is the second largest bike sharing scheme in Sweden. First inception in Aug.2010, it has gained increasing popularity among the users during the last three years. In 2011 it generated 180,500 trips, and the number has been more than doubled in year 2013 with a total rental of 420,500 times and 24,640 seasonal registered users (Trafikkontoret Göteborgs Stad, 2013:5). So far, the system has total 1000 bikes and 60 stations that are distributed in the city center. According to the operation manager Stefan Lind, the number of daily rental in 2013 is 2,500 times and the daily rental per bike is 2.5 times.

The city of Hangzhou runs the country's first 3rd generation public bike sharing scheme and is also the second largest one. Influenced by the successful story of bike sharing scheme in Lyon and Paris, the municipal government of Hangzhou decided to introduce the 3rd generation bike sharing scheme to its citizens in 2008. The same year in May the first pilot of 61 stations with 2,800 bikes were launched and got immediate positive response from the citizens and tourists. By June 2013 the system has expanded to 69,700 bikes and 3000 stations, covering the major districts of city centre and tourist destinations within; the average daily rental reached 257,600 and number of daily rental per bike was 3.7 times (Hangzhou Bike Sharing, 2012). The aim is to expand further to 800,000 bikes (Liu, 2014).

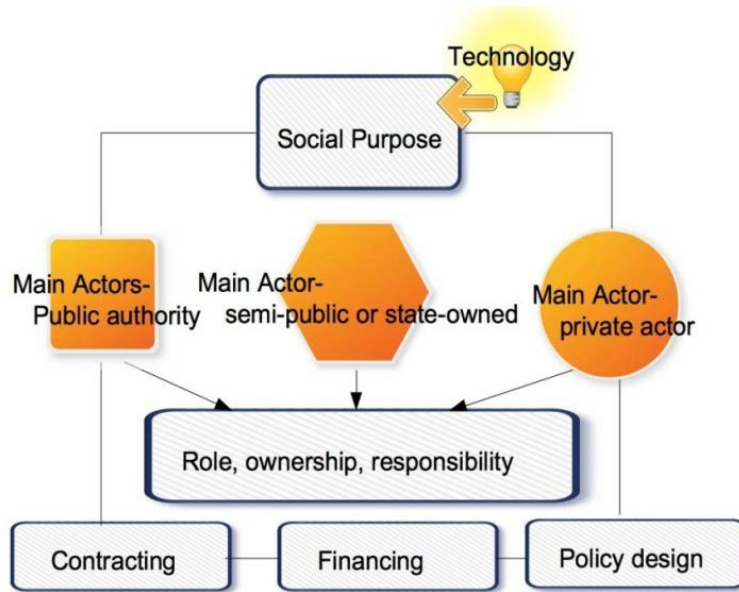

Figure 1. the analytical framework of business model for 3rd generation public bike sharing schemes.

A business model usually consists of actors and their roles and responsibilities, their relations to each other (in this case it is the operation and contract), ownership and financing. Due to the characters of social innovation, the social purpose shall be included in the business model. Another aspect to add is the policy perspective. Therefore the analytical framework of the business model of the 3rd generation public bike sharing scheme is defined as in 5 parts: the social purpose, the main actors and their ownership responsibilities, financing, contracting, as well as the policy design.

2 Data collection and method

This paper uses qualitative case studies as the method. The first hand data is collected mainly from interviews and field trips. The interview questions are designed in to semi-structured in order to gather more inputs from the interviewees. The second hand data are from related documents, media clips and leaflets.

Field trips and interviews have been done during March and April 2014 in Hangzhou China and Gothenburg Sweden. The details are summarized in Table 1. Interviews were 45 minutes to 1 hour in length. The design of interview questions adopts the scheme framework provided by *Optimising Bike Sharing in European Cities A Handbook* (OBIS, 2011). The interview questions were structured in 4 parts: 1) the aims and objectives of the scheme. 2) The physical and technology of the scheme. 3) The business model of the scheme (who are involved, what are the roles and responsibilities of each actor and how each actor works with each other). 4) The policy designs (if any on the city, regional and national level) for the scheme. Discussions from Parts 1, 3, 4 are analyzed in the next section, while the information on the physical design and technology (part 2) is operated as a control factor (confirm that the technology parts are of no fundamental differences).

Table 1. Interviews (face to face interviews).

Name	Title	Organization	Org. Type	Time
Chaoyong Liu	Deputy general manager	Hangzhou Bike Sharing, China	State-owned	14-03-04
Yuhang Cao	Deputy general manager	Bicycle service Jiaxing, China	State-owned	14-03-07
Liqiang Zhang	General manager	GST (green smart traffic) tech, China	Joint-stock	14-03-10
Lei Shi	Executive vice president	WASU Group, China	State-owned	14-03-14
Stefan Lind	Operational manager	Jedecaux, Sweden	Private company	14-04-10
Jonas Åker	Project manager	Urban Transport Administration, Gothenburg Sweden	Public Authority	14-04-16

3 Empirical discussions of the business models

3.1 The social purpose of the 3rd generation public bike sharing scheme

Generally speaking all 3rd generation public bike sharing schemes are contributing to the environmental sustainability as it promotes the usage of riding bikes (Åker, 2014; Liu, 2014). And as a semi-public goods type of services with very

low rental fees, it contributes to the overall welfare of the citizens and users. Despite these two social purposes, two cities do have differences on the more specific social purpose from the public authorities' point of view.

In the city of Gothenburg, it is to enhance the picture of the city as a bike friendly city. Gothenburg has a well-established bike culture, and so far the scheme is not aimed to replace the private bikes, nor to compete with other public transportation methods such as buses, trams, boats, trains or car polls, but as a complementary choice to enhance the popularity of the public transportation system as a whole and to make it more sustainable (Åker, 2014).

In Hangzhou the scheme is positioned (and it is similar in other cities of China) as a “min shen gong chen” meaning projects designed to improve the lives of citizens (Liu, 2014; Cao, 2014; Zhang, 2014; Shi, 2014). One way to explain this position is due to China's Confucius cultural and conventions, the government considered itself to have a “parental” role to take care of its people; therefore the public bike sharing scheme is one of these projects that making such efforts visible. Consequently it is legitimized to subsidize the project without any referendum among citizens.

Other benefits are ranging from increasing the cycling modal share, as an additional mobility option, to increase attractiveness for tourists, to make the cycling more visible and positive city image to when the whole public transportation system becomes more popular, it might reduce the usage of passenger cars, and hence reduce the carbon emissions (Åker, 2014; Liu, 2014; Zhang, 2014; Cao, 2014). However, the urban area in the city of Hangzhou is much bigger than that in the city of Gothenburg (16.5 times bigger), and the public transportation facilities and density in central city areas are less developed than Gothenburg, therefore to manage public transport demand is an important motive for Hangzhou (such as congestion avoidance and last/first mile problem) but not for Gothenburg. But these differences are not caused by political embeddedness.

3.2 Actors, Ownership, responsibility

Gothenburg

In Gothenburg case, the Municipal government (Public Authority) is the initiator and host, Urban Transport Administration (Public Authority) is executing the project, while the installation, operation and maintenance are by the private outdoor advertising company Jcdecaux. The whole system including physical infrastructures and all data gathered from the docks and users' accounts are owned by Jcdecaux; Municipality owns the brand name “Styr & Ställ” (Åker, 2014; Lind, 2014).

The Urban Transport Administration monitors and evaluates the services, jointly with other public departments to plan the land use of stations. The operator is responsible to build, operate and maintain the system and all services (Åker, 2014).

Hangzhou

The Municipal government (Public Authority) is the initiator and host; Hangzhou public transport group (solely state-owned liability limited company, a semi-public authority) is executing the project. Hangzhou public transport group set up solely-owned subsidiary HangZhou bike sharing (State-owned company) to operate (Liu, 2014); to make the business sustainable, it then set up joint-stock company GST Tech (joint-state-owned) to export the system to other cities in China as an extra source of income (Zhang, 2014). During the contracting period, the operator is the owner of the whole system including the physical infrastructures and all data gathered from the docks and users' accounts (Liu, 2014).

Public authority plans, monitors, evaluates and contract. The operator is responsible to build, operate and maintain the system and all services (Liu, 2014).

3.3 Financing

Gothenburg

The municipality uses advertising spaces as an exchange for the services so it does not directly subsidize it. The operator balances the account by incomes from the advertising and a small part from bike users' payments (Åker, 2014; Lind, 2014).

Hangzhou

The initial investment (infrastructure and all the physical investment) is from government subsidies, and the aim is to maintain the business self-sufficient for long run. Apart from the direct subsidies, the operator balances the finance from advertising, by users' payment, and by exporting the system to other cities (Liu, 2014).

3.4 Contract

Gothenburg

Beroud and Anaya (2012) defined this type of institutional arrangement as private intervention of public services. The whole system is installed, operated and maintained by private multinational outdoor advertising company Jcdecaux according to tjänste concession (service concession, Procurement Directive 2004²⁵⁷). According to the statistics of a summary of 51 schemes in Europe, outdoor advertising companies Jcdecaux and ClearChannel are the top two operators (OBIS, 2011:26).

The municipality offers outdoor advertising spaces to Jcdecaux as an exchange for construction, operation, maintenance and services of the scheme during the contract period (with possibility to extend, Åker, 2014).

Hangzhou

The whole project is constructed, operated and maintained by Hangzhou Bike Sharing, which was founded in 2008 to implement the city's public bike sharing scheme by state-owned company Hangzhou transportation group, as a solely-owned subsidiary. To make the business sustainable, the group then set up joint-stock company GST Tech to export the system to other cities in China as an extra source of income (Liu, 2014; Zhang, 2014).

Explicitly, general rules of national public procurement regulation are applied but the municipal government has more flexibility on how to implement it. Some provincial or city authority publishes directive documents to regulate and guide the implementation of the public biking sharing schemes. Hangzhou municipal government has such guidance (Liu, 2014).

Implicitly, the common method is mainly called Zhengfu goumai fuwu, which means government buys services (Liu, 2014; Zhang, 2014). Literally the translation doesn't help to understand what it means. The meaning of it can be reflected better in its principle "shi chang hua yun zuo, gong yi xing fu wu" (market operation for non-profit, welfare public services). Therefore the author concludes such method as "Commercial operation of public welfare services".

3.5 Policy design

In both China and Sweden, there is no national level policy concerning public bike sharing scheme, but on the municipality level, both have defined the primary objective and benefits, both have evaluations, and both have regular meetings in the beginning to coordinate the planning and construction of the stations. On municipality level, both DON'T have regular communication platform for all stakeholders (Liu, 2014; Åker, 2014).

The difference on policy design is mainly on municipality level. Hangzhou has launched its own policy to regulate the implementation of the scheme, which integrated the public bike sharing scheme into the municipal public transportation system.

4 A summary of the business models and its relation to political embeddedness

Table 2 summaries the major findings in the business models of 3rd generation public bike sharing schemes in Gothenburg (the private intervention of public services) and Hangzhou (the commercial operation of public welfare services).

²⁵⁷ Service concession is the supplier provides services of general economic interest e.g. energy, water and waste disposal. Article 17 of the Procurement Directive, refers to the definition of service concession in Article 1(4): 'Service concession' is a contract of the same type as a public service contract except for the fact that the consideration for the provision of services consists either solely in the right to exploit the service or in this right together with payment (Directive 2004/18/EC).

Table 2. A summary of the business models.

	Gothenburg: private intervention of public services	Hangzhou: Commercial operation of public welfare services
Social Purposes	Sustainability and welfare	Sustainability and welfare
Actor-Initiator and host	Municipal government	Municipal government
Actor- Execution	Urban Transport Administration (Public Authority)	Hangzhou public transport group (solely state-owned liability limited company-semi-public authority)
Actor- Operator	By outdoor advertising company Jcdecaux (private actor).	Hangzhou public transport group set up solely-owned subsidiary HZ bike sharing company to operate the project; to make the business sustainable, it then set up joint-stock company GST Tech to export the system to other cities in China as an extra source of income
Contract	The municipality offers outdoor advertising spaces to Jcdecaux as an exchange for construction, operation, maintenance and services of the scheme during the contract period (with possibility to extend).	Zhengfu goumai fuwu
Ownership of the facility and data	Jcdecaux owns all except the brand name (The municipality owns the name)	HZ bike sharing company during the contracting period, but as it is also state-owned, theoretically all citizens have the ownership
Responsibilities	Public authority- plan, monitor and evaluate and contract; Jcdecaux- to build and operate and maintain	Public authority- finance, plan, guide and evaluate and to create the operator; Operator- to build and operate and maintain
Financing	Advertising, by users' payment	Government Subsidies, Advertising, by users' payment, exporting the system to other cities
Policy design	No specific policies	launched its own policy to regulate the implementation of the scheme, which integrated the public bike sharing scheme into the municipal public transportation system

The difference in political embeddedness of this comparison lies in the existence of semi-public authority actors and the state-owned companies as actors in the Hangzhou case. And such difference has impacted the choice of the operator, the ownership structure, financing method and the policy design. Hangzhou public transport group is a state-owned enterprise and a semi-public authority, and this special in-between role enables it to create its own operator, yet another state-owned company: the Hangzhou bike sharing company. Under such structure, the public authority has more control over the operators not only by contracting power but the hierarchy power. While in the Gothenburg case, the public authority only has the contracting power, which leads to less control over the operator. Secondly it made possible for the creation of a semi- state owned company GST Tech to export the system to other cities in China as an extra source of income, which adds on the innovation in the business model and increases the diffusion of innovation. While in the Gothenburg case, such role is carried by the private actor. Thirdly the Hangzhou Public Transport Group is responsible for the planning and management of the city's public transportation system, it made less barrier to incorporate the bike scheme to the entire public transportation system. While in the Gothenburg case, such integration has been difficult (for instance the bike scheme has not yet been able to integrate to the planning of Västtrafik's public transportation system). As different city may have different operators, it could be a barrier for future integration of public bike sharing schemes on a regional level. The involvement of the semi-public or semi-market actors on the other hand creates confusions. The definition of responsibility, power and ownership is not very clear among involved companies in the Hangzhou case. Gothenburg one has a more clear contract to regulate the power and responsibilities of the host government and the operators.

The strong involvement of the semi-public authority and state-owned actors is a result of the country's transformation from centralized planning economy toward a market economy. The business model "Commercial operation of public welfare services" indicates the path of such transformation. Beyond that, the paternalistic Confucius values approach and the authoritarian convention are facilitating the strong role of the government in economic activities. As a result, this makes it easier to finance the public bike sharing scheme in China especially in the initial

phase and for large size of schemes by government subsidies. In the Gothenburg case, there is no investment from the tax money. The negative side is of course the Hangzhou government thus shares more financial risks.

5 Reflective remarks

The political embeddedness is not the only factor that has influences on the business models of public service innovation driven by networked ubiquitous technologies, but its role has been so far neglected in social innovation literatures. The case studies of the 3rd generation public bike sharing schemes in Hangzhou and Gothenburg illustrates the influence of different types of political embeddedness on the business model formation of public service during the social innovation process for implementing the same type of technology. In this case, it impacts the choice of operator, sources of financing, ownership and policy design of the scheme. Although the findings are limited as case specific, it shed lights on raising the attention of studies on the influence of political embeddedness to the business model formation in social innovation process, especially when one intends to analyze cases from a country where the market economy is not mature. The other aspect is related to the networked ubiquitous technologies and the ownership of data generated from its applications. As shown from the cases, the ownership theoretically belongs to the operator, but there is a lack of further clarification on its usage and in both cases there are lack of specific regulations and rules for the operators and other actors to follow. This issue might not be case specific but a general one for most of the public service innovations driven by networked ubiquitous technologies, and it requires further study.
